1 Introduction

On June 21, 2004, the Federal Energy Regulatory Commission (FERC) approved an Anadromous Fish Agreement and Habitat Conservation Plan (HCP) for the Rock Island Hydroelectric Project (Rock Island – FERC License No. 943) on the Columbia River in Washington State, operated by Public Utility District No. 1 of Chelan County (Chelan PUD). The HCP provides a comprehensive and long-term adaptive management plan for meeting a No Net Impact (NNI) goal for species addressed in the plan (Plan Species) and their habitats. This document fulfills Article 413(a) of the FERC Project license issued on January 1, 1989[1], and Section 4.8 of the HCP, which requires annual reporting of progress toward achieving the NNI goal. Responsibilities toward achieving the NNI goal are described in Section 3 of the HCP and in a 10-year Comprehensive Report assessing overall status of NNI, as well as successive 10-year intervals, in common understandings based upon completed studies, including those conducted as research and development for NNI progress or those not considered valid due to extenuating circumstances (Section 5.2.3 of the HCP).

The signatories of the Mid-Columbia HCPs (HCPs of the Wells, Rocky Reach, and Rock Island hydroelectric projects) meet as combined Coordinating Committees, Hatchery Committees, and Tributary Committees to expedite the process of overseeing and guiding HCP implementation. Minutes from the 2017 monthly meetings are compiled in Appendix A (HCP Coordinating Committees), Appendix B (HCP Hatchery Committees), and Appendix C (HCP Tributary Committees). The HCP Policy Committees provide a forum for resolution of disputes that are either elevated to or arise in the HCP Coordinating Committees and remain unresolved. The HCP Policy Committees did not meet in 2017 because no issues were discussed requiring dispute resolution. Therefore, there are no HCP Policy Committees meeting minutes to append to this annual report. Appendix D lists members of the Rock Island HCP Committees. The Rock Island HCP Coordinating Committee oversaw the preparation of this 14th Annual Report, which covers the period from January 1 to December 31, 2017. (The 1st through 13th Annual Reports covered the periods January 1 to December 31, 2004, through 2016, respectively.)

[1] 46 FERC, paragraph 61,033 (1989)

2 Progress Toward Meeting No Net Impact

The Rock Island HCP requires preparation of an Annual Report that describes progress toward achieving the performance standard of NNI for each Plan Species. The NNI standard consists of two components: 1) 91% combined adult and juvenile project survival, as achieved by project improvement measures implemented within the geographic area of the project; and 2) up to 9% compensation for unavoidable project mortality provided through hatchery and tributary programs, with up to 7% compensation provided through hatchery programs and 2% through tributary programs (Section 3.1 of the HCP).

In 2017, Chelan PUD has met or exceeded all requirements for NNI under the Rock Island HCP for spring migrant HCP Plan Species (spring Chinook salmon [*Oncorhynchus tshawytscha*], steelhead [*O. mykiss*], and sockeye salmon [*O. nerka*]). Since 2010, and including 2017, project survival standards have been exceeded for steelhead, yearling Chinook salmon, and sockeye salmon; all of which are currently designated Phase III (Standards Achieved). As of 2017, coho salmon (*O. kisutch*) are also now classified as Phase III (Standards Achieved) under the Rock Island HCP (see Section 2.1.1). Discussions about hatchery compensation needed to meet Chelan PUD's NNI mitigation requirement for coho salmon began within the HCP Hatchery Committees in 2017, and is expected to be finalized in 2018 (see Section 2.2.2.15). For subyearling summer/fall Chinook salmon (a summer migrant and non-Endangered Species Act [ESA]-listed Plan Species), considerable life-history variability and limited technology constrain the ability to estimate project survival (see Section 2.1.1). As a result, subyearling summer Chinook salmon are designated as Phase III (Additional Juvenile Studies[2]) and will continue to be compensated through the Tributary Conservation and Hatchery Compensation Plans at levels consistent with the HCP. As established in Section 3.1 of the HCP, the inability to estimate survival due to limitations of technology shall not be construed as a success or a failure to achieve NNI.

Recalculated NNI production levels for all Plan Species were agreed upon in 2011 within the HCP Hatchery Committees, and implementation began with the 2014 release year and will continue for the next 10 years (release years 2014 through 2023). Chelan PUD funded the Tributary Conservation Plan at the level established in the HCP ($485,200 in 1998 dollars) and will continue to do so for the duration of the HCP (see Section 2.3; Table 1 [below]).

[2] The current phase designation will be re-evaluated in 2019.

Table 1
Rock Island Habitat Conservation Plan No Net Impact Progress for Plan Species (2017)

HCP Plan Species (ESA Status)	Survival Standard Met	Hatchery Compensation Provided	Tributary Conservation Plan Funded	NNI
Spring Chinook Salmon Yearlings (ESA-listed)	Yes – Combined Adult and Juvenile	Yes	Yes	Yes
Steelhead (ESA-listed)	Yes – Combined Adult and Juvenile	Yes	Yes	Yes
Sockeye Salmon (Not Listed)	Yes – Combined Adult and Juvenile	Yes	Yes	Yes
Summer/Fall Chinook Salmon (Not Listed)	Phase III (Additional Studies)	Yes	Yes	Yes – NNI compensation provided, but additional studies required
Coho Salmon (Not Listed)	Phase III (Standards Achieved)	Yes	Yes	Yes

Throughout 2017, the HCP Coordinating, Hatchery, and Tributary Committees reached agreement on numerous issues during meetings in support of achieving the NNI goals, all of which were documented in the meeting minutes or were described in stand-alone statements of agreement (SOAs). These agreements, along with approvals for funding of habitat projects by the Rock Island HCP Tributary Committee, are summarized in Table 2 and discussed in the remainder of this report.

Table 2
Summary of 2017 Decisions for Rock Island Habitat Conservation Plan

Date	Agreement	HCP Committee	Reference
January 24, 2017	Agreed to a 10-day review period (initiated when the revised SOA is distributed) and a vote via email on the revised draft SOA titled, Acknowledgement of Rock Island Powerhouse 1 Units B1-B4 Consultation	Coordinating	Appendix A
January 24, 2017	Agreed Chelan PUD does not need to provide an annual fish passage plan for HCP Coordinating Committees review (the plan will be removed from the annual Rock Island and Rocky Reach HCP Action Plan)	Coordinating	Appendix A

Date	Agreement	HCP Committee	Reference
January 27, 2017	Approved a Douglas PUD, Chelan PUD, and WDFW request for gametes from four female and four male Twisp River hatchery-origin steelhead that WDFW will collect at the Twisp Weir in 2017 for use in pilot studies on egg-to-fry survival, as follows: Douglas PUD, Chelan PUD, WDFW, USFWS, the YN, and the CCT approved on January 18; and NMFS approved via email on January 27, 2017	Hatchery	Appendix B
February 3, 2017	Approved via email the Chelan PUD SOA titled, Acknowledgement of Rock Island Powerhouse 1 Units B1-B4 Consultation, as follows: Chelan PUD approved on January 24; the CCT approved on January 25; NMFS and USFWS approved on January 26; WDFW approved on February 1; and the YN approved on February 3, 2017	Coordinating	Appendix A and Appendix E
February 15, 2017	Approved the hatchery portion of the 2017 Rock Island and Rocky Reach HCP Action Plan	Hatchery	Appendix B
February 22, 2017	Approved the 2016 Rock Island Smolt Monitoring Program and Gas Bubble Trauma Report, after no disapprovals were received prior to the 30-day review deadline on February 22, 2017	Coordinating	Appendix A and Appendix G
February 22, 2017	Approved the 2016 Rock Island and Rocky Reach Pikeminnow Control Program Summary Report, after no disapprovals were received prior to the 30-day review deadline on February 22, 2017	Coordinating	Appendix A and Appendix H
February 22, 2017	Approved the 2017 Rock Island Bypass Monitoring Plan, after no disapprovals were received prior to the 30-day review deadline on February 22, 2017	Coordinating	Appendix A and Appendix I
March 9, 2017	Approved a time extension request from Trout Unlimited on the Methow Valley Irrigation District Instream Flow Improvement Project, to extend the period of their contract from September 30, 2016 to November 30, 2017	Tributary	Appendix C
March 9, 2017	Approved a budget amendment request from Trout Unlimited on the Beaver Fever: Restoring Ecosystem Function Project, to move $1,997.00 from "Administration/Overhead" to "Salaries and Benefits," $2,294.94 from "Administration/Overhead" to "Professional Services," and $7,028.75 from "Administration/Overhead" to "Project Materials"	Tributary	Appendix C
March 9, 2017	Approved the tributary portion of the 2017 Rock Island and Rocky Reach HCP Action Plan	Tributary	Appendix C
March 13, 2017	Approved the Chelan PUD SOA titled, M&E Reporting Schedule for the Douglas PUD, Grant PUD, and Chelan PUD Hatchery Programs	Hatchery	Appendix B and Appendix F
March 13, 2017	Agreed Chelan PUD and USFWS may perform maturation sampling on 300 Chiwawa spring Chinook salmon	Hatchery	Appendix B

Date	Agreement	HCP Committee	Reference
March 16, 2017	Approved the 2016 Rock Island HCP Annual Report after no disapprovals were received prior to the 30-day review deadline on March 16, 2017	Coordinating	Appendix A
March 16, 2017	Approved the Chelan PUD 2017 Steelhead Release Plan, as follows: Chelan PUD approved on March 13; and USFWS, WDFW, NMFS, the YN, and the CCT approved via email on March 16, 2017	Hatchery	Appendix B and Appendix J
March 24, 2017	Approved the 2017 Rock Island and Rocky Reach Fish Spill Plan, as revised, after no disapprovals were received prior to the 30-day review deadline on March 24, 2017	Coordinating	Appendix A and Appendix K
March 28, 2017	Approved adding Catherine Willard (Chelan PUD) to the HCP Coordinating Committees email distribution list	Coordinating	Appendix A
March 28, 2017	Agreed to vote via email on the Revised Draft 2017 Rock Island and Rocky Reach HCP Action Plan	Coordinating	Appendix A
March 30, 2017	Approved the Rock Island and Rocky Reach Coho Phase Designation SOA, as revised *(Note: Carmen Andonaegui provided WDFW approval of the SOA via email on March 30, 2017)*	Coordinating	Appendix A and Appendix E
April 5, 2017	Approved via email the 2017 Rock Island and Rocky Reach HCP Action Plan, as revised, as follows: Chelan PUD and USFWS approved on March 30; NMFS approved on April 4; and WDFW, the CCT, and the YN approved on April 5, 2017	Coordinating	Appendix A and Appendix L
April 7, 2017	Approved via email the 2017 Broodstock Collection Protocols	Hatchery	Appendix B and Appendix M
April 13, 2017	Approved a time extension request from CCFEG on the White River Floodplain Connection (RM 3.4) Project, to extend the period of the contract from September 30 to December 30, 2017	Tributary	Appendix C
April 13, 2017	Approved a request for funding from CCFEG on the Debry Creek Fish Passage – Collins Project, contributing $65,000 to the project	Tributary	Appendix C
April 19, 2017	Agreed via email to add Alf Haukenes (WDFW Hatchery/Wildlife Interactions Unit leader) to select HCP Hatchery Committees email distribution lists, per a request by Mike Tonseth (WDFW HCP Hatchery Committees Representative), as follows: WDFW, Douglas PUD, NMFS, and USFWS approved on April 17; Chelan PUD and the YN approved on April 18; and the CCT approved on April 19, 2017	Coordinating	Appendix A
April 19, 2017	Approved the Outplanting Adults Plan for Spring Chinook Salmon in the Chewuch River	Hatchery	Appendix B

Date	Agreement	HCP Committee	Reference
June 8, 2017	Approved a budget amendment request from CCFEG on the Permitting Nutrient Enhancement in the Chiwawa River Basin Project, to move $1,028 from "Professional Services" and "Indirect/Admin/Overhead" to "Sponsor Salaries and Benefits"	Tributary	Appendix C
June 8, 2017	Approved via email a time extension request from Trout Unlimited on the Barkley Irrigation Project, to extend the project from May 31, 2017 to December 31, 2018	Tributary	Appendix C
June 27, 2017	Agreed to add Chad Jackson (WDFW) and Mike Tonseth (WDFW) to the HCP Coordinating Committees email distribution lists and provide them both with access to the HCP Coordinating Committees extranet site because Jackson will potentially become the WDFW HCP Coordinating Committees Representative and Tonseth will likely be a new WDFW HCP Coordinating Committees Alternate *(Note: on August 14, 2017, Jackson became the representative and Patrick Verhey remained the alternate; however, Tonseth remained on the email lists and retained extranet access, per a request from WDFW)*	Coordinating	Appendix A
July 13, 2017	Approved a budget amendment request from CCFEG on the White River Floodplain Connection (RM 3.4) Project, to move all available funds in "Excavation and Heavy Equipment" ($5,000) and "Project Materials and Equipment" ($500) to "Salaries and Benefits," "Overhead and Administration," and "Permit Fees"	Tributary	Appendix C
July 13, 2017	Approved a time extension request from CCFEG on the Permitting Nutrient Enhancement in the Chiwawa, to extend the period of the contract from June 30, 2017 to June 30, 2018	Tributary	Appendix C
July 13, 2017	Approved a Small Projects Program application from Chelan County Natural Resources Department titled, Poison Canyon Restoration	Tributary	Appendix C
August 18, 2017	Approved the Chelan PUD 2018 Hatchery M&E Implementation Plan, as follows: Chelan PUD, WDFW, USFWS, the YN, and NMFS approved on August 16; and the CCT approved on August 18, 2017	Hatchery	Appendix B and Appendix N
October 24, 2017	Approved the 2017 Rock Island and Rocky Reach Fish Spill Program Report, with the CCT abstaining	Coordinating	Appendix A and Appendix O
November 15, 2017	Approved the M&E Plan for PUD Hatchery Programs (2017 Update)	Hatchery	Appendix B and Appendix P
November 15, 2017	Approved the Final Chelan PUD SOA, Regarding District's Coho Obligation, as followed: CCT approved on November 14, and Chelan PUD, WDFW, USFWS, the YN, and NMFS approved on November 15, 2017.	Hatchery	Appendix B and Appendix F

The following sections summarize the achievements, actions, and activities taken in 2017 specific to project survival and dam operations, hatchery compensation, and funding of tributary habitat protection and restoration projects.

2.1 Project Survival and Dam Operations

2.1.1 Status of Phase Designations for Current Plan Species

A major feature of the Rock Island HCP is what is termed a "phased implementation plan" to achieve the survival standards. This approach includes three phases (Phase I, II, and III), and consists of conducting survival studies over multiple years and evaluating the achievement of survival standards, which is needed to proceed to the next phase. Progress through each phase has been described at length in previous HCP Annual Reports submitted to FERC.

Section 5.2 of the Rock Island HCP states that a combined adult and juvenile project survival of 91% shall be achieved and maintained. In October 2006, following 3 years of valid juvenile survival studies and completion of 3 years of adult passage survival estimates, the Rock Island Project proceeded to Phase III (Standards Achieved), meaning the Rock Island Project had achieved a combined adult and juvenile survival of 91%. This standard is in place for steelhead, spring Chinook salmon, and sockeye salmon.

Section 5.3.3 of the Rock Island HCP allows for reduced spill if survival standards for juvenile migration have been exceeded and an additional 1 to 3 years of testing confirm achievement of the survival standards under the new spill operations. Beginning in 2007 and continuing through 2010, Chelan PUD tested juvenile survival at Rock Island Dam under a 10% spill condition during the spring juvenile migration period. The current phase designations for all Rock Island Plan Species under conditions of 10% spill are summarized in Table 3.

Table 3
Phase Designations for Rock Island Habitat Conservation Plan Under Conditions of 10% Spill

Plan Species	Project Survival (%)	Phase Designation	SOA Date
Okanogan and Wenatchee Rivers Sockeye Salmon	91.75[1]	Phase III (Standards Achieved)	January 25, 2013
UCR Steelhead	96.08[1]	Phase III (Standards Achieved)	January 25, 2013
UCR Yearling Chinook Salmon	93.65[1]	Phase III (Standards Achieved)	January 25, 2013
UCR Subyearling Summer/ Fall Chinook Salmon	To Be Determined	Phase III (Additional Juvenile Studies)	September 29, 2016
Coho Salmon	93.98[2]	Phase III (Standards Achieved)	March 30, 2017

Note:
1. Combined adult and juvenile project survival achieved (standard is 91%)
2. Juvenile project survival achieved (see below)

In 2013, information was reviewed on the status of tag technology and life-history attributes of subyearling summer Chinook salmon in the Mid-Columbia. Based on this information and review, the Rock Island HCP Coordinating Committee agreed that empirical estimates of juvenile project survival were not feasible. As a result, on June 25, 2013, the Rock Island HCP Coordinating Committee approved an SOA maintaining subyearling summer Chinook salmon in Phase III (Additional Juvenile Studies) for 3 years (through June 2016). In June 2016, the Rock Island HCP Coordinating Committee re-evaluated the ability to conduct survival studies on subyearling Chinook salmon. Once again, available data indicated conducting survival studies on subyearling Chinook salmon is not feasible at this time. On September 29, 2016, the Rock Island HCP Coordinating Committee approved an SOA maintaining subyearling summer Chinook salmon in Phase III (Additional Juvenile Studies) for another 3 years (through September 2019) and stipulating that it will continue to evaluate or monitor study design, tag technology, and life-history information to better understand future survival study feasibility by 2019.

In 2016, coho salmon were classified as Phase III (Standards Achieved – Interim Value), and were due to be re-evaluated in 2017. In September 2016, Chelan PUD began discussing estimates of juvenile coho salmon survival through the Rock Island and Rocky Reach projects with the Rock Island HCP Coordinating Committee. In January 2017, Chelan PUD presented results from an analysis conducted by Drs. John Skalski and Richard Townsend (Columbia Basin Research), based on passive integrated transponder (PIT)-tag data from 2010 to 2016, which indicated that projected coho salmon survival through the Rock Island Project is 93.98% with a standard error of 0.0233, and through the Rocky Reach Project is 92.94% with a standard error of 0.0081. Chelan PUD drafted an SOA indicating these data demonstrate that yearling Chinook salmon are a good surrogate for juvenile coho salmon, with 93% survival at both Rock Island and Rocky Reach projects. The draft SOA designated juvenile coho salmon as being in Phase III (Standard Achieved) at both the Rock Island and Rocky Reach projects. Concern was expressed about combining survival through the Rock Island and Rocky Reach projects and setting a precedent for accepting lower standards than is stated in the HCPs[3] (the projected survival for coho salmon through the Rock Island Project was slightly less than 93%). The Rock Island and Rocky Reach HCP Coordinating Committees discussed how Drs. Skalski's and Townsend's initial analysis used only 2 years of acoustic and PIT-tag data (2010 and 2011) for the Rocky Reach Project that resulted in an average survival of 95.15% for the 2-year period, which meant that a survival level of only 88.71% would be needed during the third year of study to achieve Phase III (Standards Achieved). Chelan PUD chose not to accept these data in the interest of using all data available for a more robust dataset. Governing documents were reviewed, including past SOAs containing variability in the data and based on less years of data, where the HCP Coordinating Committees were satisfied with making a decision based on the available data. After 3 months of discussion, the Rock

[3] Section 5.2.2 of the Rocky Reach HCP states, "If Juvenile Project Survival for each Plan Species is measured to be greater than or equal to 93%, then the District will proceed to Phase III (Standard Achieved)."

Island and Rocky Reach HCP Coordinating Committees agreed there is a high level of confidence that the projected coho salmon survival through the Rocky Reach Project is sufficient to meet or exceed the standard. On March 30, 2017, the Rock Island and Rocky Reach HCP Coordinating Committees approved the Rock Island and Rocky Reach Coho Phase Designation SOA, as revised (Appendix E), designating juvenile coho salmon in Phase III (Standard Achieved) at both Rock Island and Rocky Reach projects. The Rock Island and Rocky Reach HCP Coordinating Committees notified their respective HCP Hatchery Committees of approval of this SOA, to initiate moving forward with hatchery compensation planning (see Section 2.2.2.15).

2.1.2 Assessment of Project Survival

The Rock Island HCP requires that Chelan PUD shall work toward a 91% combined adult and juvenile project survival at Rock Island Dam, which is achieved by project-improvement measures implemented within the geographic area of the project. Progress toward this objective is described in the following section.

2.1.2.1 Adult Passage Monitoring

When the Rock Island HCP was signed in 2002, it was acknowledged there was no scientifically rigorous method for the Rock Island HCP Coordinating Committee to assess adult project passage survival for Plan Species. Existing methods did not differentiate between mortality caused by the project and other sources of mortality (e.g., delayed mortality from injuries resulting from passage at downstream projects, injuries sustained by marine mammals, or harvest activities). Section 5.2 of the Rock Island HCP states, that given the inability to differentiate between the sources of adult mortality, initial compliance with the combined adult and juvenile survival standard would be based on the measurement of 93% juvenile project survival or 95% juvenile dam passage survival and an adult survival estimate of 98 to 100%.

Beginning in December 2012, Chelan PUD was able to evaluate adult passage survival through the Rock Island Project (dam and reservoir) for spring Chinook salmon, steelhead, and sockeye salmon, even though unknown harvest mortality remained in the survival estimates for steelhead and sockeye salmon. PIT-tag detections from the PIT Tag Information System database were used to evaluate adult fish migrating upstream in 2010, 2011, and 2012 to estimate project conversion rates. For spring Chinook salmon and steelhead, adults destined for the Methow and Okanogan river systems were used for the survival evaluation. For sockeye salmon, adults originating from the Wenatchee and Okanogan river systems were evaluated. The 3-year arithmetic mean survival rates at Rock Island Project for adult spring Chinook salmon, steelhead, and sockeye salmon were 99.89%, 99.31%, and 98.37%, respectively (Table 4.) Chelan PUD will re-evaluate adult passage survival at Rock Island in 10-year intervals, as required per the HCP.

Juvenile, adult, and combined (juvenile and adult) survival rates at the Rock Island and Rocky Reach projects are presented in Table 4. Adult conversion rates were calculated from adult passage data for the years 2010 through 2012.[4]

Table 4
Habitat Conservation Plan Juvenile, Adult, and Combined Survival Rates at Rock Island and Rocky Reach

Project	Species	Juvenile Survival	Adult Survival	Combined[5]
Rock Island	Steelhead	96.75%	99.31%[2]	96.08%
	Spring Chinook Salmon	93.75%[1]	99.89%[3]	93.65%
	Sockeye Salmon	93.27%	98.37%[2]	91.75%
Rocky Reach	Steelhead	95.79%	98.93%[2]	94.77%
	Spring Chinook Salmon	92.37%[1]	99.90%[3]	92.28%
	Sockeye Salmon	93.59%	98.92%[4]	92.58%

Notes:
1. Includes spring-migrating yearling Chinook salmon.
2. Estimate does not account for fish losses due to recreational harvest in any years.
3. No recreational harvest occurred.
4. Estimate adjusted for fish losses from recreational harvest in 2010 and 2011, but not for harvest losses in 2012.
5. Combined survival is the product of juvenile and adult survival estimates (e.g., 98% × 93% = 91%).

The HCP combined adult and juvenile project survival standard is 91%. The HCP combined adult and juvenile project survival estimates apply to fish actively migrating through the Rock Island and Rocky Reach projects in the mainstem Columbia River and do not include mortality occurring in other locations (i.e., they do not include ocean or tributary mortality).

2.1.2.2 Valid Study Flow Duration Curve Update

Section 13.24 of the Rock Island HCP requires that as part of the 2013 comprehensive review, and every 10 years thereafter, the Rock Island Coordinating Committee shall update the spring and summer period Flow Duration Curves used to define valid survival studies. The updated Flow Duration Curves must reflect "Representative Flow Conditions," meaning river flows between the 10th and 90th percentiles on the Flow Duration Curve, as calculated from the Grand Coulee Dam daily average outflow. In 2013, efforts began to update the Flow Duration Curve. The HCP Coordinating Committees agreed to develop the updated Flow Duration Curve with the historical 1929 to 1978 and 1983 to 2001 datasets used previously, to which the new 2002 to 2012 dataset was added. For comparison, Flow Duration Curves were also constructed using only the 1983 to 2012 dataset. The HCP Coordinating Committees also agreed to revise the definition of the

[4] Buchanan R. A. and J. R. Skalski, 2012. *Estimation of the Adult Salmon and Steelhead Conversion Rates through Rock Island and Rocky Reach Projects, 2010-2012*. Prepared for Public Utility District No. 1 of Chelan County. December 2012.

summer period to comprise June 1 through August 15, compared to the former July 1 through August 15 period. Updated Flow Duration Curves were expected to become final in early 2014; however, in February 2014, a fracture discovered in Wanapum Dam postponed a number of efforts, including updating the curves, until time allows. The final updated Flow Duration Curves are projected to be completed in 2018.

2.1.2.3 2017 Survival Studies

No yearling or subyearling Chinook salmon survival studies were conducted in 2017 at the Rock Island Project.

There are no planned Rock Island juvenile salmonid project survival studies for 2018. However, in 2017, the Rock Island HCP Coordinating Committee continued briefly discussing the upcoming HCP 10-year check-in survival study for Rock Island Dam in 2020, in terms of completing ongoing improvements and maintenance (see Section 2.1.3.2).

2.1.3 Project Operations and Improvements

This section summarizes project operations and progress toward maintaining the juvenile project survival standards at Rock Island Dam in 2017. Actions in 2017 were guided by the 2017 Rocky Reach and Rock Island HCP Action Plans (Appendix L), as approved by the Rocky Reach and Rock Island HCP Coordinating Committees on April 5, 2017 (Appendix A).

2.1.3.1 Operations

2.1.3.1.1 Juvenile Bypass System and Fish Spill Operations

At Rock Island Dam, juvenile fish spill operations are guided by two documents. The Rock Island and Rocky Reach HCP Coordinating Committees approved the 2017 Rock Island Bypass Monitoring Plan (Appendix I) and the 2017 Rocky Reach and Rock Island Fish Spill Plan (Appendix K) on February 22 and March 24, 2017, respectively, after no disapprovals were received prior to the 30-day review deadlines. The Rock Island bypass system operated from April 1 through August 31, 2017, which covered the normal bypass operating period for the outmigration of juvenile salmon and steelhead at Rock Island Dam.

Spring fish spill at Rock Island Dam for yearling Chinook salmon, steelhead, and sockeye salmon began on April 16, 2017, at 0001 hours and continued uninterrupted for 40 days through 2400 hours on May 25, 2017. The target spill level for the duration of the spring spill period in 2017, was 10% of the estimated daily average river flow, as specified and approved in the Rock Island Fish Spill Plan (Appendix K). Actual spill for this 40-day period averaged 35.22% of the total river flow, and comprised 9.69% fish spill and an additional 25.53% unavoidable hydraulic spill. The Columbia River average flow through Rock Island Dam during the spill period was 227,790 cubic feet per second (cfs), and the daily average spill was 80,222 cfs. Following completion of spring spill on May 25, 2017, spill at Rock Island Dam was provided for 99.8% of the steelhead outmigration, 97.0% of the sockeye salmon outmigration, and 98.4% of the yearling Chinook salmon outmigration passing Rock Island Dam.

Summer fish spill at Rock Island Dam for subyearling Chinook salmon began at 20% of daily average flow on May 26, 2017, at 0001 hours, immediately following completion of spring spill at 10%. Spill continued uninterrupted for 85 days at a spill target of 20% of the estimated daily average river flow. Spill ended on August 18, 2017, at 2400 hours. Actual spill for the 85-day period averaged 29.47% of the total river flow, and comprised 19.89% fish spill and an additional 9.58% unavoidable hydraulic spill. The Columbia River average flow rate past Rock Island Dam during the spill period was 162,085 cfs, and the daily average spill rate was 47,774 cfs. Following completion of the bypass operations on August 31, 2017, it was estimated that summer spill at Rock Island Dam was provided for 97.5% of the subyearling Chinook salmon outmigration passing Rock Island Dam.

Complete Rock Island Dam 2017 fish spill operations results are summarized in the 2017 Rocky Reach and Rock Island Fish Spill Report (Appendix O), which was approved by the Rocky Reach and Rock Island HCP Coordinating Committees, with the Colville Confederated Tribes (CCT) abstaining, on October 24, 2017.

2.1.3.1.2 Juvenile Sampling Facility

Each year, Chelan PUD operates the Rock Island Dam Juvenile Sampling Facility (RIJSF) from April 1 to August 31. The RIJSF is used to examine outmigrating juvenile salmonids for species composition and fish condition, including gas bubble trauma. Data collected provide information for in-season management decisions regarding juvenile anadromous fish passage.

The 2016 Rock Island Smolt Monitoring Program and Gas Bubble Trauma Report (Appendix G), which summarizes activities at the RIJSF in 2016, was approved by the Rock Island HCP Coordinating Committees after no disapprovals were received prior to the 30-day review deadline on February 22, 2017. A complete report summarizing 2017 activities at the RIJSF is expected in 2018.

2.1.3.1.3 Pikeminnow Predator Control

Chelan PUD has implemented a northern pikeminnow (*Ptychocheilus oregonensis*) predator-control program in the Rock Island Project since 1995. Since 1996, Chelan PUD has contracted annually with the U.S. Department of Agriculture (USDA) to carry out this program. Chelan PUD also provides funding for the annual Pikeminnow Derby sponsored by the East Wenatchee Rotary Club.

Complete results from the 2016 removal effort were summarized in the 2016 Rock Island HCP Annual Report, and are described in the 2016 Rock Island and Rocky Reach Pikeminnow Control Program Summary Report (Appendix H), which was approved by the Rock Island and Rocky Reach HCP

Coordinating Committees after no disapprovals were received prior to the 30-day review deadline on February 22, 2017.

In 2017, Chelan PUD continued implementing the northern pikeminnow removal program with Columbia Research long-line angling during the pre-migration period to target large pikeminnow that stage in deep reservoir areas and are difficult to capture with other gear types. The 2017 USDA hook-and-line angling program commenced during the peak of the juvenile salmonid migration. The total combined harvest of pikeminnow in 2017 from Rocky Reach and Rock Island reservoirs was 91,147 fish. Harvest numbers from the various control efforts in 2017 were as follows: USDA hook-and-line angling – 62,387 fish; Columbia Research long-line angling – 24,981 fish; East Wenatchee Rotary Club Pikeminnow Derby – 2,628 fish; and removal by Chelan PUD Fish and Wildlife personnel – 1,151 fish. A report summarizing results of the 2017 removal effort is expected sometime in early 2018.

2.1.3.1.4 Rock Island Dam Powerhouse 1 Turbine Units B1 to B4

In October 2015, Rock Island Dam Powerhouse 1 Turbine Units B1, B2, B3, and B4, were removed from service due to cracks discovered in the turbine unit blades (see Section 2.1.3.2). The unit capacity of Units B1 to B4 is 6.75 thousand cubic feet per second (kcfs) each (27 kcfs total). With Units B1 to B4 out of service, generation at Rock Island Dam is reduced from the usual 216 kcfs to 189 kcfs. Maintenance is planned for the units with a target completion date of April 2020. In 2017, a finite analysis identified several more parts in need of repair (see Section 2.1.3.2); however, because the failing parts were caught early enough, the repairs should not impact the maintenance schedule for Turbine Units B1 to B4.

2.1.3.1.5 Pacific Lamprey Passage at Tumwater Dam

In March 2016, the U.S. Fish and Wildlife Service (USFWS) raised a question regarding how to properly address Pacific lamprey passage at Tumwater Dam as it relates to HCP Plan Species broodstock collection. Per the Rock Island and Rocky Reach HCPs, the HCP Hatchery Committees have oversight regarding trapping for broodstock, and the HCP Coordinating Committees have oversight regarding fish passage. After internal discussion, Chelan PUD agreed this same demarcation applies to Pacific lamprey at Tumwater Dam when either collection of broodstock or adult passage of HCP Plan Species is of concern. Therefore, any future discussions of Pacific lamprey passage at Tumwater Dam will likely be presented to the HCP Coordinating and Hatchery Committees, because the issue involves activities overseen by both committees.

In 2017, Chelan PUD voluntarily drafted an engineering feasibility report to determine how lamprey passage could be improved at Tumwater Fishway, should the need arise. Progress updates on the status of the feasibility report were provided to the HCP Coordinating Committees and HCP Hatchery Committees.

2.1.3.1.6 Federal Columbia River Power System National Environmental Policy Act Scoping Process

In January 2017, Chelan PUD notified the HCP Coordinating Committees that the District planned to submit comments on the Federal Columbia River Power System National Environmental Policy Act Scoping Process documents. Comments were regarding maintaining the integrity of the HCPs and acknowledging the PUDs have certain protections under the HCPs. The comments focused on: 1) analyzing the potential effects of predation, specifically in the estuary; 2) acknowledging scientific uncertainties associated with Upper Columbia River (UCR) spring-run Chinook salmon; and 3) climate change (as it relates to how to replace clean renewable energy sources if hydroelectric dams are removed). The comments were submitted to the U.S. Army Corps of Engineers on February 7, 2017.

2.1.3.1.7 Rock Island Dam Powerhouse 2 Rehabilitation

In October 2017, Chelan PUD notified the HCP Coordinating Committees that the Board of Commissioners is beginning to engage in planning for the rehabilitation of Powerhouse 2 at Rock Island Dam. An economic analysis recommended a rehabilitation, versus a full overhaul, to extend the lifespan of the system by an additional 40 years. In-depth analyses will be regularly conducted throughout the duration of the rehabilitation, parts will be refurbished and sandblasted to ensure they are structurally sound, and machine tolerances will be returned to their original specifications. The turbine runners will stay the same, and there will be no changes to the name plate discharge or horsepower ratings of the turbine units. Rehabilitation is tentatively scheduled to begin by the third quarter of 2021 (following the HCP 10-year check-in survival study for Rock Island Dam that will conducted in 2020), and all eight turbine units are scheduled to be complete by the first quarter of 2029 (before the HCP 10-year check-in survival study for Rock Island Dam in 2030). This rehabilitation is not expected to affect the relicensing of Rock Island Dam in 2028.

2.1.3.1.8 Spill Gate Change

On May 18, 2017, Rock Island Dam lost the capability of operating automated spill gate 7, resulting in a total of three spill gates being out of service during the spill and fish migration season (spill gates 7, 17, and 25). Due to the record-high river flow past Rock Island Dam and snowpack estimates that at the time were exceeding 100% in basins above Rock Island Dam, Rock Island Dam engineers converted two notch gates back to full gate operation to address concerns about overall spillway capacity and dam safety. Chelan PUD internally discussed at length which notch gates to convert back to full gate operation and decided to convert notched spill gates 18 and 26. This was based on the following: 1) conversion of these gates to full gate operation was not expected to have negative impacts to juvenile fish passage; 2) gates 18 and 26 are located away from the left powerhouse entrance of the right bank adult fish ladder and would have no impact on adult fish passage; and 3) both of these gates are shallow spill gates so additional total dissolved gas from the gate conversions would be negligible. This conversion was temporary until July 21, 2017, when gates 18 and 26 were converted back to their notched gate configuration (see Section 2.1.3.2).

2.1.3.1.9 Application for Non-Capacity Amendment

In 2017, Chelan PUD filed with FERC an Application for Non-Capacity Amendment to modify the former Olds Bridge recreation site in the existing Recreation Plan. Prior to filing with FERC, Chelan PUD must conduct stakeholder consultation to ensure the proposed amendment is consistent with current Rock Island Project operations and implementing existing license management plans. As requested, the Rock Island HCP Coordinating Committee representatives submitted edits and comments, or an indication of no comments, on the application by the review deadline.

2.1.3.2 Improvements and Maintenance

Facility improvements and maintenance at the Rock Island Project in 2017 that had the potential to affect Plan Species are described in this section.

2.1.3.2.1 Rock Island Dam Powerhouse 1 Turbine Units B1 to B4

In October 2015, surface cracks were discovered on the turbine unit blades of Rock Island Dam Powerhouse 1 Unit B2. Based on surveys conducted, the cracks were attributed to corrosion fatigue. Units B1, B2, B3, and B4 are all similar, and initial analyses of the turbine blades on Units B1, B3, and B4 showed the same signs of metal fatigue that were identified on Unit B2; therefore, all four units were removed from service (see Section 2.1.3.1). In July 2016, following several months of blade repairs and continued cracking, Chelan PUD presented to the Rock Island HCP Coordinating Committee maintenance plans for Units B1 to B4. These plans were designed to optimize flow, increase unit efficiency, and benefit fish passage survival. In February 2017, to demonstrate clear support for the rehabilitation, the Rock Island HCP Coordinating Committee approved the SOA, "Acknowledgement of Rock Island Powerhouse 1 Units B1-B4 Consultation" (Appendix A and E). In August 2017, results from a finite metal analysis identified additional parts in need of repair, including: 1) rotor poles; 2) generator shaft; and 3) wicket gate body and stems. These repairs should not impact the target completion date of April 2020, which is in time for Chelan PUD to conduct the HCP 10-year check-in survival study for Rock Island Dam (see Section 2.1.2.3).

2.1.3.2.2 2016/2017 Rock Island Dam Adult Fish Ladder Winter Maintenance

The middle ladder at Rock Island Dam was taken offline for annual winter maintenance on December 6, 2016, and returned to service on January 6, 2017. Activities beyond general maintenance included: 1) replacing lower valves (gear stems wore out); 2) conducting grating inspection; and 3) evaluating concrete integrity.

The left ladder at Rock Island Dam was taken offline for annual winter maintenance on December 21, 2016, and returned to service on February 27, 2017. Activities beyond general maintenance included maintenance on the gates and valves.

The right ladder at Rock Island Dam was taken offline for annual winter maintenance on January 9, 2017, and returned to service on February 2, 2017. Activities conducted included general maintenance.

2.1.3.2.3 Automated Spill Gates 7, 17, and 25

In May 2017, Chelan PUD notified the HCP Coordinating Committees that three spill gates were currently out of service (spill gates 7, 17, and 25; see Section 2.1.3.1). An explanation of the equipment failures and timeline for repairing the gates is as follows:

- Spill Gate 7 – one of the suspension cables on spill gate 7 became unattached, damaging the gate and guiderails, and jamming the gate in place.
- Spill Gate 17 – during operation, the gear shaft twisted in half in the gear box, damaging the gate and gear box, and jamming the gate in place.
- Spill Gate 25 – after the spill gate 17 failure, mechanics observed the same cracks in the gear shaft on spill gate 25 and removed the gate from service.

Spill gate 7 will require that divers be deployed to complete the repairs and spill gates 17 and 25 need new gear boxes. The spill gates are targeted to be back in service by spring 2018.

2.1.3.2.4 2017/2018 Rock Island Dam Adult Fish Ladder Winter Maintenance

The right and left ladders at Rock Island Dam were taken offline for annual winter maintenance on December 4 and December 18, 2017, respectfully. The middle ladder at Rock Island Dam will be taken offline for annual winter maintenance when the right and left fish ladders are returned to service. All fishways at Rock Island Dam should be back to service by mid-February 2018.

2.2 Hatchery Compensation

Section 8.1 of the Rock Island HCP describes a Hatchery Compensation Plan with two primary objectives: 1) to provide compensation for Plan Species; and 2) to implement specific elements of the hatchery program consistent with the overall objectives of rebuilding natural populations and achieving NNI. In 2017, Chelan PUD continued providing funding and capacity for hatchery production consistent with meeting NNI. Recalculated hatchery production values required to meet NNI through 2023 were approved by the Rock Island HCP Hatchery Committee on December 14, 2011, and represented in *Chelan PUD's No Net Impact and Inundation Obligations for Release Years 2014-2023*. Hatchery compensation for the Rock Island Project in 2017 included the release of 2,525,168 juvenile salmonids (combined Rock Island and Rocky Reach hatchery compensation; Table 5).

To improve coordination, a representative from Grant PUD is invited to the monthly HCP Hatchery Committees meetings. The Grant PUD representative and the Priest Rapids Coordinating Committee (PRCC) Hatchery Sub-Committee facilitator also receive meeting announcements, final agendas, and meeting minutes. Furthermore, in June 2015, the HCP Hatchery Committees agreed to convene joint sessions of the HCP Hatchery Committees and PRCC Hatchery Sub-Committee when discussing agenda items applicable to and requiring participation from both committees. This practice benefits the HCP Hatchery Committees through increased coordination and sharing of expertise. The Grant PUD representative has no voting authority under the HCPs; however, because these joint discussions influence similar and sometimes overlapping hatchery programs, those discussions are documented and included here, accordingly. The HCP Hatchery Committees and PRCC Hatchery Sub-Committee continued holding joint sections of meetings in 2017 when agenda items pertain to both sets of committees. This coordination and joint process is planned to continue in 2018.

2.2.1 Hatchery Production Summary

Table 5 summarizes and compares HCP hatchery production objectives and actual 2017 smolt releases.

Table 5
2017 Production Level Objectives and Smolt Releases for Rock Island Habitat Conservation Plan Hatchery Programs

Species[a]	Program	Final Rearing Site	Rock Island Production Level Objectives (2014 to 2023)[b]	Total Releases for Rock Island in 2017 (Number of Fish)
Spring Chinook Salmon	Chiwawa (Wenatchee)	Chiwawa	144,026	163,411 smolts
Summer/Fall Chinook Salmon	Wenatchee	Dryden Pond	318,000	334,133 smolts
Steelhead	Wenatchee	Chiwawa Hatchery[c]	247,300[d]	251,692 smolts
Sockeye Salmon	Okanogan	kł cp̓əlk̓ stim̓ Hatchery	591,050[e] (34% of kł cp̓əlk̓ stim̓ Hatchery production)	1,526,600 fry
Spring Chinook Salmon	Okanogan	Chief Joseph Hatchery	115,000 (12.81% of Chief Joseph Hatchery production)	121,159 smolts
Summer Chinook Salmon	Okanogan	Chief Joseph Hatchery /Omak Pond	94,570 (13.51% of Chief Joseph Hatchery production	54,395 subyearlings
Summer Chinook Salmon	Okanogan	Similkameen	166,569 (12.81% of Chief Joseph Hatchery production)	73,778 yearlings

Notes:

a. Coho salmon mitigation met by the funding agreement with the YN.
b. As specified in the Rocky Reach and Rock Island HCP Hatchery Committees SOA Chelan PUD Hatchery Compensation, Release Years 2014 to 2023, approved December 14, 2011.
c. Includes releases from Blackbird Island Pond.
d. Steelhead production at Chiwawa Acclimation Facility includes Rock Island and Rocky Reach obligations.
e. Combined with the Rocky Reach HCP, the Okanogan sockeye salmon production requirement totals 591,050 smolts (production is allocated between the two HCPs); the table includes the number of fry released. By agreement of the HCP Hatchery Committees, this production requirement is satisfied for Okanogan sockeye salmon by funding of the Okanagan Skaha Lake sockeye salmon reintroduction program until otherwise determined by the HCP Hatchery Committees.

2.2.2 Hatchery Planning and Implementation

This section details the actions taken in 2017 that are relevant to planning for hatchery operations supporting the HCP.

2.2.2.1 2017 Broodstock Collection Protocols

In March 2017, the HCP Hatchery Committees began their review of the draft 2017 Broodstock Collection Protocols for Chinook salmon and steelhead. The revised draft protocols were approved, via email, as follows: Washington Department of Fish and Wildlife (WDFW), Chelan PUD, Douglas PUD, National Marine Fisheries Service (NMFS), USFWS, the CCT, and the Yakama Nation (YN) approved on April 7, 2017. The 2017 Broodstock Collection Protocols (Appendix M) were distributed to the HCP Hatchery Committees on April 14, 2017, and implemented at program hatcheries throughout 2017. In-season revisions were made as needed in coordination with the HCP Hatchery Committees. As in previous years, the 2017 Broodstock Collection Protocols were intended to guide the collection of salmon and steelhead broodstock in the Methow River, Wenatchee River, and Columbia River basins. The protocols are consistent with previously defined program objectives such as program operational intent (i.e., conservation and/or harvest augmentation) and mitigation production levels (i.e., HCPs), and they comply with ESA permit provisions.

2.2.2.1.1 Chiwawa Spring Chinook Salmon Broodstock Collection

In August 2017, WDFW presented provisional data to the HCP Hatchery Committees regarding Wenatchee spring Chinook salmon broodstock collection. The program collected enough broodstock to meet production obligations, but was four females short of its natural-origin target due to three factors: 1) adult natural-origin fish were limited and hard to acquire; 2) the collection weir was not operational as early in the season as intended because of high flows; and 3) mechanical issues took the weir out of operation for 1 week at a critical point, and the weir was lowered towards the end of the collection season to avoid impinging fish.

2.2.2.1.2 Brood Year 2017 Wenatchee Steelhead Release Plan

In March 2017, Chelan PUD and WDFW presented to the HCP Hatchery Committees a Draft 2017 Wenatchee Steelhead Release Plan and also presented preliminary results from the 2016 Wenatchee steelhead release (Appendix B). Chelan PUD summarized preliminary results for survival to McNary Dam for screened versus non-screened fish, brood origin, and release locations, and the HCP Hatchery Committees discussed the results. Release strategy objectives for 2017 were the same as in 2016 and included evaluating best management practices for hatchery releases to optimize homing fidelity, minimize residualism, maximize out-migration survival, and minimize negative ecological interactions. The plan initially implemented a paired release design by vessel type, brood origin, and release sites, and also a detailed monitoring and evaluation (M&E) plan. In 2017, the plan stipulates performing screened (volitional) releases, plus more intensive length-weight sampling and

PIT-tagging a group of non-moving fish to assess behavior. The 2017 Wenatchee Steelhead Release Plan (Appendix J) was approved by the Rock Island and Rocky Reach HCP Hatchery Committees on March 16, 2017, and was implemented in April and May 2017.

2.2.2.2 Hatchery Monitoring and Evaluation Plan Implementation

2.2.2.2.1 Hatchery Monitoring and Evaluation Plan – 2017 Update

Since 2013, Chelan PUD hatchery M&E programs have been operated in accordance with the *Monitoring and Evaluation Plan for PUD Programs 2013 Update*. The plan was updated in 2017, titled *Monitoring and Evaluation Plan for PUD Hatchery Programs – 2017 Update (Appendix P)*, as described below.

In May 2017, Chelan PUD and the HCP Hatchery Committees began reviewing the objectives in the *Monitoring and Evaluation Plan for PUD Hatchery Programs – 2013 Update* in order to update the plan in 2017. The review began with Table 1, which includes program objectives, indicators, and goals for conservation hatchery programs including productivity and monitoring indicators. Regarding the second objective, "determine if the proportion of hatchery fish affects freshwater productivity," the HCP Hatchery Committees noted improvements to methodologies for estimating freshwater productivity are underway, and the objective should be revisited once more accurate estimates for Methow Basin data are available. Regarding the fourth objective, "determine if the program has affected genetic diversity and population structure," the HCP Hatchery Committees reviewed further information from WDFW about genetic monitoring, as discussed in Section 2.2.2.3 though no substantial edits were made in 2017 to genetic monitoring objectives due to pending updates.

Chelan PUD and the HCP Hatchery Committees frequently discussed brood year (BY) stray rates, specifically Question 6.1.1 of the M&E Plan, in 2017. Discussions centered around the initial selection of the 5% maximum threshold for BY stray rates, how empirical information should factor into thresholds, recent scientific literature on the topic, the purpose of the thresholds, hatchery versus wild strays, and potential changes to the thresholds. Further discussions included setting a quantitative versus qualitative threshold, removing the threshold altogether, and how the metric is related to other metrics with which it is evaluated. Section 4.4 and Question 6.1.1 of the plan were revised and reviewed, and currently the section and question focus on determining what the BY stray rate is, and putting the rate into context with respect to other stray rates, and management concerns.

In addition to stray rates, Chelan PUD and the HCP Hatchery Committees revised language for statistical analyses associated with Objective 5, added fish-per-pound targets and release numbers to Appendix 5, updated Table 3, revised non-target taxa of concern language in Section 7.2, and added to Section 8 (Adaptive Management). To complete analyses specified in Section 8, the HCP Hatchery Committees determined they need to identify major program changes in fish culture or M&E for each program and began drafting program timelines as described below. Tracy Hillman, Chair of the

Rock Island, Rocky Reach, and Wells HCP Hatchery Committees, also finalized Appendix 1, Carrying Capacity, as described in Section 2.2.2.4. Lastly, edits were made throughout the document for clarification and ease of cross-referencing appendices. The HCP Hatchery Committees approved the final plan, *Monitoring and Evaluation Plan for PUD Hatchery Programs – 2017 Update,* in November 2017 (Appendix P).

2.2.2.2.2 Hatchery Monitoring and Evaluation Implementation Plan

The Chelan *County* PUD Hatchery *Monitoring and Evaluation Implementation* Plan, is prepared annually to describe the M&E activities for the next calendar year. The Rock Island and Rocky Reach HCP Hatchery Committees approved the Chelan PUD 2018 Hatchery M&E Implementation Plan (Appendix N) on August 18, 2017, following a 30-day HCP Hatchery Committees review period.

2.2.2.2.3 Genetic Analyses for Habitat Conservation Plan Program Species

The M&E Plan specifies genetic analyses, which should occur at 10-year intervals in order to examine the potential for changes in genetic diversity of natural populations as a result of hatchery programs. In 2016, the HCP Hatchery Committees recognized the need to reconsider the genetic sampling intervals and scheduling for HCP program species.

WDFW worked on this task throughout 2016 and 2017. They conducted a literature review and made a list of relevant reports. They developed a draft timeline for sample collection, analyses, and reporting to meet all monitoring objectives, and they investigated potential analyses with geneticists to inform updated sampling intervals. This material was shared with the HCP Hatchery Committees in January 2017, then revised and shared again in April 2017. The timeline includes analysis needs, the projected year of the analysis, and the requirements for M&E reporting. The HCP Hatchery Committees discussed whether analysis intervals should be based on listing status or other factors, and whether to synchronize analysis years for the same species across basins, or by each basin. A power analysis was proposed as a way to determine how large of a genetic change could be detected in a population and how rapid it may occur (which would inform the analysis interval). The HCP Hatchery Committees also recognized that a baseline genetic period for each program needs to be determined, because hatchery programs change over time, especially in regard to broodstock. It was determined that the WDFW genetics lab should work on a power analysis to determine recommended analysis frequency, and the HCP Hatchery Committees should determine baseline periods for each program.

2.2.2.2.4 Timelines for Habitat Conservation Plan Programs

To complete analyses specified in Section 8 of the M&E Plan, Chelan PUD and the HCP Hatchery Committees determined they need to identify major program changes in fish culture or M&E for each program, and began drafting program timelines in October 2017. The timelines will be used to determine breaks for statistical analysis and will help complete the 5-year statistical and 10-year comprehensive reports.

Tracy Hillman drafted the timeline for spring Chinook salmon, which the HCP Hatchery Committees reviewed in October 2017. Timelines for steelhead, summer Chinook salmon, sockeye, and Entiat programs are also being drafted and will be discussed in 2018.

2.2.2.2.5 Expanded Sampling at the Off-Ladder Adult Fish Trap

In February 2017, WDFW introduced the idea of expanding sampling at the off-ladder adult fish trap (OLAFT) at Priest Rapids Dam as an approach for monitoring spring Chinook salmon. The HCP Hatchery Committees discussed how sampling could inform unbiased estimates for prespawn mortality, and provide data for managing Percent Hatchery Origin Spawners (pHOS) and Proportionate Natural Influence (PNI) objectives. Sampling at Wells and Tumwater dams for spring Chinook salmon could be decreased if a sampling scheme for the OLAFT is developed. WDFW indicated they would develop an overview of the expanded sampling strategy. Because the strategy has not been developed yet, expanded sampling at the OLAFT will likely be discussed in 2018, but not implemented in 2018.

2.2.2.2.6 Hatchery Monitoring and Evaluation Plan Reporting

In September 2017, the Chelan PUD 2016 Hatchery M&E Plan Report, titled *Monitoring and Evaluation of the Chelan and Grant County PUDs Hatchery Programs 2016 Annual Report,* which documented M&E activities in 2016 (Appendix Q) was finalized following a 30-day HCP Hatchery Committees review period. In addition, Chelan PUD began working with the HCP Hatchery Committees in 2016 to develop a long-term scheduling plan to logically orchestrate HCP requirements and M&E reporting, including annual and 5-year interval reports, and the 10-year Program Review (Rock Island HCP: Section 8.7).

From January to March 2017, Chelan PUD and the HCP Hatchery Committees discussed the purpose and contents of the annual, 5-year, and 10-year reports and drafted a schedule. The 10-year Program Review is an HCP requirement, the 5-year Statistical Report is an M&E Plan requirement, and the M&E Plan is a requirement of permitting, so Chelan PUD coordinated with Douglas PUD and Grant PUD to develop reporting timelines, and a Rock Island and Rocky Reach HCP Hatchery Committees SOA describing the background and purpose of the timeline. The *Final M&E Reporting Schedule for the PUD Hatchery Programs,* finalized in March 2017, describes the content and function of each report and development and due dates through 2052 (Appendix F). The Rock Island and Rocky Reach HCP Hatchery Committees approved the SOA, M&E Reporting Schedule for the Chelan PUD, Douglas PUD, and Grant PUD Hatchery Programs, in March 2017 (Appendix F).

2.2.2.3 Hatchery Monitoring and Evaluation Plan Appendices

In January 2015, while discussing where to append the memorandum clarifying standardized methods for Hatchery M&E Plan Objective 8.3, Fecundity at Size, the HCP Hatchery Committees recognized that the Hatchery M&E Plan Appendices had not yet been finalized. In March 2015, the

HCP Hatchery Committees agreed to reconvene the Hatchery Evaluation Technical Team (HETT) to finalize the appendices. The HETT first reconvened in April 2015, and discussed a plan for completing the appendices, which are living documents, subject to change as more data become available. Appendices were split up among HETT members to complete by varying dates, and work continued in 2016 to finalize the Hatchery M&E Plan Appendices. HETT members distributed drafts of Appendices 2, 4, 5, and 6 in February and March 2016. In March 2016, the HCP Hatchery Committees discussed how carrying capacity estimates should be calculated for Appendix 1 and provided feedback to Tracy Hillman on material that should be included in Appendix 1. Hillman presented carrying capacity estimates for Chiwawa River spring Chinook salmon to the HCP Hatchery Committees in April 2016, and the HCP Hatchery Committees suggested Hillman focus on methodology for calculating carry capacity estimates when drafting Appendix 1, with some populations included as examples. In May 2016, Appendix 3 was distributed for review. In June 2016, the HCP Hatchery Committees discussed and revised draft Appendices 2 through 6. The HCP Hatchery Committees approved Appendices 2 (Hatchery Replacement Rate Targets), 4 (Spatial Distribution of Spawners), and 6 (Rearing Targets) in June 2016. Appendix 6 was later revised, and a final revised version was approved in August 2016. Appendix 3, PNI and pHOS Targets and Sliding Scales, was revised and later approved in August 2016. Appendix 5, Stray Rate Objectives, was further revised and discussed in August, September, and October 2016. In October 2016, the HCP Hatchery Committees discussed that material in Appendix 5 is redundant with the Hatchery M&E Plan, and decided to delete Appendix 5. Appendices 2, 3, 4, and 6 were renumbered and appended to the Hatchery M&E Plan in 2017. In October 2017, Hillman presented Appendix 1, Estimation of Carrying Capacity, to the HCP Hatchery Committees, which included an example of how carrying capacity is estimated for spring Chinook salmon in the Chiwawa River watershed and the entire Wenatchee River Basin. The HCP Hatchery Committees concluded their review of the Hatchery M&E Plan Appendices when Appendix 1 was finalized along with the *Monitoring and Evaluation Plan for PUD Hatchery Programs – 2017 Update* in November 2017.

2.2.2.4 Okanogan Sockeye Salmon Mitigation

In 2017, Chelan PUD provided a twelfth year of funding for a portion of the Okanagan Nation Alliance (ONA)'s 12-year Skaha Lake Sockeye Salmon Reintroduction Program (the current hatchery production obligation for Okanogan sockeye salmon mitigation is a combined 591,050 smolts for Rocky Reach and Rock Island HCPs). Chelan PUD funding contributed to the construction of the new kł cp̓əlk̓ stim̓ Sockeye Salmon Hatchery in Penticton, British Columbia, which was completed in September 2014; currently Chelan PUD funding contributes to operation and maintenance of the hatchery and to the M&E program. In June 2015, the hatchery held its first official fish release of roughly 1.7 million fry, mostly in Shingle Creek, and some in Okanagan Lake as part of a ceremonial ONA release. The hatchery was designed to support up to an 8-million-egg program; however, the plumbing system initially installed supports a production capacity of 5 million eggs. The egg-take goal of 5 million eggs was achieved for the first time in 2016. In spring 2017, the hatchery released roughly 4,449,000 fry (Chelan PUD's proportion was 1,526,600) into Skaha Lake.

2.2.2.5 Hatchery and Genetic Management Plans

Efforts continue to complete the consultation process, including coordination in prior years among Chelan PUD, NMFS, USFWS, the YN, WDFW, the CCT, and Grant and Douglas PUDs.

2.2.2.5.1 Chiwawa Spring Chinook Salmon

On July 3, 2013, NMFS issued a new Permit No. 18121 jointly to WDFW, Chelan PUD, and the YN (as an authorized agent of Chelan PUD) for operation of the Chiwawa spring Chinook salmon hatchery program. An amended permit was issued on May 29, 2015. This program was still awaiting consultation by the USFWS which was completed in 2017.

2.2.2.5.2 Wenatchee Steelhead

On June 30, 2014, after more than 4 years of consultation, the initial draft Wenatchee Steelhead Biological Opinion (BiOp) was completed by NMFS. The BiOp was revised several times in 2014 and 2015, and a final BiOp was issued on July 20, 2016. Section 7(a)(2) consultation with USFWS was completed in 2017 and the Section 10 (a)(1)(A) permit (NMFS No. 18583) was issued on December 31, 2017.

2.2.2.5.3 Wenatchee Summer Chinook Salmon

In May 2013, NMFS requested that Chelan PUD and other Permit No. 1347 permit holders submit letter applications for extension of Permit No. 1347. NMFS indicated that an extension of the existing Permit No. 1347 was feasible. Chelan PUD submitted an extension request letter on August 27, 2013. Subsequently, on September 20, 2013, Chelan PUD received a letter from NMFS indicating that the existing ESA permits would be extended until new consultations are completed and new permits issued. In 2014, NMFS indicated that, due to higher priority permitting of programs rearing ESA-listed species, permitting of summer and fall Chinook salmon programs would not be addressed until spring 2015. In 2015, permitting of summer and fall Chinook salmon programs was postponed again because parties agreed that these programs are the lowest priority for completing consultation.

In May 2017, NMFS indicated they were drafting the proposed action for the batch of unlisted Chinook salmon programs in the UCR (Wenatchee summer Chinook, Chelan Falls summer Chinook, Wells summer Chinook, Priest Rapids fall Chinook, Methow summer Chinook, and Ringold upriver bright fall Chinook) and would be coordinating with parties to gain needed information. In June 2017, the HCP Hatchery Committees discussed possible consultation pathways for the unlisted programs. In September 2017, NMFS indicated that the BiOp for the Columbia River unlisted summer Chinook salmon programs was being drafted. The applicants officially initiated consultation with request letters in November 2017, and NMFS responded with letters of sufficiency to the applicants on

November 25, 2017. The draft BiOp was available for the applicants and HCP Hatchery Committees to review in November to December 2017. The BiOp was finalized on December 25, 2017, and Section 10 permits are expected to be issued in 2018.

2.2.2.5.4 Biological Opinion for Chiwawa Spring Chinook Salmon, Wenatchee Steelhead, and Wenatchee Summer Chinook Salmon Programs

On November 28, 2012, NMFS requested formal consultation with USFWS under Section 7(a)(2) of the ESA on the proposed permitting of the following five hatchery programs that operate in the Wenatchee subbasin: Chiwawa River spring Chinook salmon, Nason Creek spring Chinook salmon, White River spring Chinook salmon, Wenatchee River summer steelhead, and Wenatchee River summer Chinook salmon. A partial draft BiOp was distributed by USFWS on December 23, 2014. Another draft was submitted for review on September 8, 2016. A completed BiOp was issued by USFWS on November 27, 2017.

2.2.2.6 Wenatchee Steelhead Relative Reproductive Success Study

The Rock Island HCP, Section 8.5.3, requires that Chelan PUD fund and implement a steelhead relative reproductive success (RRS) study. The Wenatchee Steelhead RRS Study began in 2008 and incorporated data from each subsequent BY, to 2011. The study objective was to measure the RRS of hatchery-origin steelhead in the natural environment and determine the degree to which any differences in reproductive success between hatchery- and natural-origin steelhead can be explained by measurable biological characteristics.

In September 2015, WDFW and NMFS presented to the HCP Hatchery Committees the results of the Wenatchee Steelhead RRS Study. In summary, many differences in life-history traits were detected between hatchery and natural fish; however, there were no apparent differences in spawn timing. Additionally, spawning distribution was similar. Hatchery-by-hatchery (HxH) broodstock male and female fish had the lowest RRS. Hatchery-by-wild (HxW) broodstock male and female fish had a RRS between those of HxH broodstock and wild-by-wild (WxW) broodstock. WxW male and female fish had almost indistinguishable RRS from wild fish, though the RRS had greater variance between years. Size and season also contributed to variation in RRS among individuals. A final report documenting the study results will be distributed in 2018.

2.2.2.7 Dryden Overwintering Feasibility Study/Wenatchee River Total Maximum Daily Load

In 2011, Chelan PUD agreed to assess the feasibility of modifying the Dryden Acclimation Facility to accommodate overwinter rearing, as memorialized in the SOA titled *Chelan PUD Hatchery Compensation, Release Years 2014-2023*, approved by the Rocky Reach and Rock Island HCP Hatchery Committees on December 14, 2011. Concurrent with this effort, Chelan PUD is evaluating ways to meet the Washington State Department of Ecology's addendum to the Wenatchee Total

Maximum Daily Load (TMDL) establishing modified phosphorus targets for discharge into the Wenatchee River, effective in 2019.

In July 2012, Chelan PUD committed to conduct specific actions toward assessing the feasibility of converting the Dryden Acclimation Facility to an overwinter facility in conjunction with determining how best to meet TMDL requirements for phosphorous discharge by 2018. Based on the proposed schedule for implementing these actions, Chelan PUD expected to have all the information needed to make a decision by 2015.

In March 2015, the HCP Hatchery Committees agreed for Chelan PUD to continue their Wenatchee and Chelan Falls Summer Chinook Size Target Study for 1 additional year in order to obtain additional data to better inform a long-term decision. This study was intended to contribute information about the performance of hatchery fish released at a smaller size, which may help Chelan PUD meet the phosphorus TMDL targets at the facility (described below). Adding an additional year of testing, however, postponed making a final decision for another year.

In January 2016, Chelan PUD presented the results of their feasibility analysis to the HCP Hatchery Committees and concluded that the most effective and risk-minimizing approach to meeting phosphorous discharge limits is to rear Wenatchee summer Chinook salmon to a smaller size (anticipated to be 18 fish per pound). This would be accomplished by constructing a new, chilled, partial-water reuse system at Eastbank Fish Hatchery using circular ponds as a successfully demonstrated rearing practice, prior to transfer to the Dryden Acclimation Pond for final spring acclimation. Chelan PUD proposed to proceed with a feasibility study for design of a chilled, partial-water reuse aquaculture system at Eastbank Fish Hatchery for Wenatchee summer Chinook salmon, to enable Chelan PUD to meet phosphorus discharge limits under the Wenatchee River TMDL for dissolved oxygen and pH levels. On February 17, 2016, the Rock Island and Rocky Reach HCP Hatchery Committees approved the Improvement Feasibility at Eastbank Hatchery for Wenatchee summer Chinook salmon SOA. The next steps in the feasibility study, should the improvements be warranted, may include a complete design and construction in 2018, and first fish ponded in summer 2019.

2.2.2.7.1 Dryden Water Quality Monitoring

In 2017, Chelan PUD implemented the sixth year of water quality monitoring at the Dryden Acclimation Facility to help inform the ongoing evaluation of the feasibility for meeting phosphorus TMDL requirements. Water quality monitoring at the Dryden Acclimation Facility will continue in 2018.

2.2.2.7.2 Summer Chinook Salmon Size Target Study

In 2015, Chelan PUD conducted the second and final year of the Wenatchee and Chelan Falls Summer Chinook Size Targets Study with the National Oceanic and Atmospheric Administration's Northwest Fisheries Science Center to help inform the feasibility of converting the Dryden Acclimation Facility to an overwinter facility in conjunction with determining how best to meet TMDL requirements. During the first year of this study (BY 2012), there were challenges reaching the specific size targets. During the second year of this study (BY 2013), size targets were generally met, and preliminary results showed differences as a result of rearing vessel and/or release size in juvenile performance for Wenatchee summer Chinook salmon and no difference in juvenile performance between the four size-at-release targets. In 2015, the HCP Hatchery Committees agreed for Chelan PUD to conduct a third year of the study (BY 2014) to attempt to replicate success from the BY 2013 study. Results from the BY 2014 study will be available in 2018.

2.2.2.8 Supplemental Radio-Tagging of Summer Steelhead

In November 2015, the HCP Hatchery Committees received a proposal from WDFW and the University of Idaho to PIT-tag and radio-tag summer steelhead collected at Tumwater Dam and the Twisp Weir. WDFW and University of Idaho were trying to tag up to 500 summer steelhead at Priest Rapids Dam; however, due to lower than expected return rates in 2015, only 400 summer steelhead were tagged. There were 100 tags left, and WDFW and University of Idaho suggested tagging at Tumwater Dam and the Twisp Weir could provide additional information on parameters such as estimating stray rates and estimating overwinter survival, among other things. The HCP Hatchery Committees approved the proposal, which was also conducted during the spring of 2016 and 2017.

2.2.2.9 Releasing PIT-Tagged Pacific Lamprey in the Tumwater Dam Fishway

In April 2016, YN presented a Scope of Work (SOW) to the HCP Hatchery Committees titled *SOW for Releasing Adult Pacific Lamprey within Tumwater Dam Fish Ladder*. The YN agreed to monitor Pacific lamprey passage through the ladder throughout Plan Species broodstock collection, and report back to the Hatchery Committees should any effects be identified. PIT-tagged Pacific lamprey were released in the Tumwater fishway in 2016.

Pacific lamprey were released into several locations in the Wenatchee River again in 2017. In 2017, 14 Pacific lamprey were counted at the Tumwater Dam observation window during non-trapping periods indicating complete ascension of the Tumwater fishway. Additionally, one Pacific lamprey was observed ascending the denil to the trap hopper while trapping was actively occurring.

2.2.2.10 Steelhead Gamete Request

In January 2017, Chelan PUD, Douglas PUD, and the HCP Hatchery Committees discussed Douglas PUD's planned pilot study for estimating steelhead egg-to-fry survival in the Twisp River in 2017 (Attachment B). Douglas PUD requested gametes from three female and three male Twisp hatchery-origin steelhead, surplus to broodstock and escapement needs, that WDFW would collect at the Twisp Weir in spring 2017 for use in the egg-to-fry survival study. WDFW and Chelan PUD indicated interest in also using gametes from surplus steelhead, and the request was modified to four female and four male steelhead to accommodate the Chelan PUD egg to emergence study to be conducted in the Chelan River. The HCP Hatchery Committees approved the request. In February 2017, however, Douglas PUD indicated intent to perform an egg-to-fry survival study with spring Chinook salmon instead of steelhead in 2017. The purpose of this study is to get better estimates of spring Chinook salmon egg-to-fry survival than previously attained in other studies. Douglas PUD communicated that they would still work with Chelan PUD to acquire the surplus steelhead gametes needed from the Twisp River for the Chelan PUD study, and would provide an update to the HCP Hatchery Committees when the spring Chinook salmon study plan is developed.

2.2.2.11 Maturation Sampling for Chiwawa Spring Chinook Salmon

In March 2017, Chelan PUD proposed performing maturation sampling on 300 spring Chinook salmon from the 2017 release group for the third year in a row, in partnership with the USFWS and WDFW. The Rock Island HCP Hatchery Committee agreed to this request on March 13, 2017.

2.2.2.12 Coho Salmon Recalculation Agreements

In March 2017, the Rocky Reach and Rock Island HCP Coordinating Committees approved the Designation of Juvenile Coho Salmon in Phase III (Standard Achieved) at the Rock Island and Rocky Reach Projects SOA (Appendix E), as described in Section 2.1.1. Approval of this SOA initiated the hatchery compensation planning process, because survival estimates inform mitigation calculations. Chelan PUD and YN worked together to calculate mitigation numbers based on methods used during the 2013 NNI Recalculation for other species.

In May 2017, Chelan PUD reviewed the 2013 NNI Recalculation approach for determining mitigation. In August 2017, Chelan PUD presented a draft SOA for review, regarding District's Coho Obligation (Appendix B). The mitigation proposed in the SOA included a 7% compensation rate at both Rocky Reach and Rock Island as agreed to by the Rocky Reach and Rock Island HCP Coordinating Committees for BYs 2017 to 2021. The SOA is an agreement about the methodology used to calculate hatchery compensation levels, and is an agreement that Chelan PUD will meet its obligation through funding and/or facility use to support a coho salmon reintroduction project. While reviewing the draft SOA, CCT requested more time to coordinate revisions with YN, and due to ongoing coordination, the SOA was separated into two SOAs, with the first one focusing on just the methodology for meeting Chelan PUD's coho salmon obligation without the funding arrangement discussed. The Rocky Reach and Rock Island HCP Hatchery Committees approved the SOA Regarding District's Coho Obligation on November 15, 2017 (Appendix F). A second SOA regarding the funding arrangement is expected in early 2018.

2.2.2.13 Lifecycle Modeling for Wenatchee Spring Chinook Salmon

In September 2017, the HCP Hatchery Committees invited Jeff Jorgensen (Ocean Associates, Inc.) to discuss his work on lifecycle modeling for Wenatchee spring Chinook salmon (Appendix B). Jorgensen leads a lifecycle modeling team whose work is mostly directed to inform biological opinions and recovery planning. The Wenatchee lifecycle model is a population dynamics model that addresses how the population changes relative to natural factors or demographic rates, and has its roots in a matrix-type model. Jorgensen described how to run the model and use its modules, and the model's different scenarios and outputs. There are different scenarios for evaluating hatchery management in which the HCP Hatchery Committees expressed interest. Broodstock collection levels, smolt releases, and domestication are all factors that can change, affecting the number of hatchery-origin spawners in the wild, for example. Future collaborations between the HCP Hatchery Committees and Jorgensen may involve running certain hatchery module scenarios in the Wenatchee Basin.

2.2.2.14 Brood Year 2016 Nason Creek Spring Chinook Salmon Surplus

In September 2017, the HCP Hatchery Committees discussed a surplus identified in the Chelan PUD and Grant PUD Hatchery Programs M&E Progress Report – August 2017 (Appendix B). There was an over-production of both WxW and HxH spring Chinook salmon for the Nason Creek brood. As a result, a surplus of 41,263 HxH spring Chinook salmon were released into Banks Lake. WDFW indicated that capacity issues at the hatchery influenced the decision to release the fish, and an overage outside of the 110% acceptable limit was not expected based on estimates of fish on hand during the eyed-egg stage and during tagging. The HCP Hatchery Committees discussed policy for moving and tagging fish outside of what is described in broodstock collection protocols, and expressed concerns about marking WxW fish with adipose-clips and coded-wire tags. The HCP Hatchery Committees discussed adding as many management options and caveats in the broodstock collection protocols as feasible each year to reduce in-season decision-making.

2.2.3 Maintenance and Improvements

2.2.3.1 Chelan Fish Hatchery Rehabilitation Design

In 2015, a rehabilitation feasibility study began for the Chelan Fish Hatchery Building, which is more than 60 years old. Rehabilitation is planned for the existing hatchery building, including the offices, incubation, early rearing, and ancillary functions. No program changes are proposed at this time. The feasibility study continued in 2016 and will be finalized in 2018.

2.3 Tributary Committees and Plan Species Accounts

As outlined in the Rock Island HCP, the signatory parties each designated one member to serve on the Tributary Committee. The Rock Island, Rocky Reach, and Wells HCP Tributary Committees meet on a regularly scheduled basis as a collective group to enhance coordination and minimize meeting dates and schedules. Subject items requiring decisions are voted on in accordance with the terms outlined in the specific HCPs. During 2017, the Rock Island HCP Tributary Committee met on six occasions and held one conference call.

An initial task of the HCP Tributary Committees in 2017 was to review and update their operating procedures that provide a mechanism for decision making. These were initially developed in 2005 and were included in that year's annual report (Anchor 2005)[5]. The HCP Tributary Committees also developed Policies and Procedures for soliciting, reviewing, and approving project proposals (Anchor 2005). The Policies and Procedures provide formal guidance to project sponsors on submission of proposals for projects to protect and restore habitat of Plan Species within the geographic scope of the HCP. The HCP Tributary Committees established two complementary funding programs, the General Salmon Habitat Program (GSHP) and the Small Projects Program.

In 2017, the HCP Tributary Committees reviewed their Policy and Procedures document and agreed to add the following language to the beginning of Section 6.3 (Timelines and Extensions):

> Project Sponsors must have a signed contract with the Committees within one (1) year from the date when the Committees approved the project. In the event the Project Sponsor does not have a signed contract because of a lack of additional funds (cost share), a lack of landowner support, or any other reason, the Committees may cancel funding for the project. After the one-year period, the Project Sponsor may need to resubmit a new proposal seeking funding for a canceled project.

They also reviewed their Operating Procedures and agreed to remove the following statement from Section IX (Plan Species Account):

> The Committees will provide financial reports to the District no less than on a quarterly basis.

The Committees provide annual reports and believe there is no need to provide quarterly reports.

2.3.1 Regional Coordination

Similar to the HCP Hatchery Committees and to improve coordination, a representative from Grant PUD and the facilitator of the PRCC Habitat Sub-Committee were invited to the HCP Tributary Committees monthly meetings. In addition, these representatives received meeting announcements, draft agendas, and meeting minutes. This benefits the HCP Tributary Committees through increased coordination and the sharing of expertise. The Grant PUD representative and PRCC Habitat Sub-Committee facilitator have no voting authority.

The HCP Tributary Committees also coordinate with the Upper Columbia Salmon Recovery Board (UCSRB). Coordination is typically between the chairperson of the HCP Tributary Committees and the

---

[5] Anchor Environmental, L.L.C. 2005. *Annual Report, Calendar Year 2005, of Activities under the Anadromous Fish Agreement and Habitat Conservation Plan.* Rock Island Hydroelectric Project, FERC license no. 943. Prepared for FERC by Anchor Environmental L.L.C. and Public Utility District No. 1 of Chelan County.

Executive Director or the Natural Resource Program Manager of the UCSRB. In addition, some members of the HCP Tributary Committees typically attend UCSRB meetings to foster coordination in developing and selecting projects for funding. Some members of the HCP Tributary Committees are also members of the UCSRB's Regional Technical Team, which increases coordination in selecting projects for funding. Many of the Policies and Procedures of the Salmon Recovery Funding Board (SRFB) and HCP Tributary Committees are complementary, and annual funding rounds by these funding entities have been coordinated during the last several years.

In addition to coordinating with the SRFB process and the PRCC Habitat Sub-Committee, the Rock Island HCP Tributary Committee coordinates funding of GSHP proposals with Bonneville Power Administration and the U.S. Bureau of Reclamation. The purpose of this coordination, according to Section 2 of the Tributary Fund Policies and Procedures for Funding Projects, is to collaborate with regional, local, state, tribal, and national organizations that fund salmon habitat projects. The efforts resulted in identification of possible cost-shares for suitable habitat restoration projects.

2.3.2 Fiscal Management of Plan Species Accounts

The HCP Tributary Committees set up methods for the long-term management of the Plan Species accounts for each HCP. The Rock Island HCP Tributary Committee appointed the accounting firm Clifton Larson Allen to perform the necessary tasks for fiscal management of the Rock Island Plan Species Account. These tasks include the following: 1) develop a long-term approach to maintain the funds and to carry out tax calculations and reporting; 2) conduct the daily management of activities (such as processing of invoices); and 3) provide technical expertise on financial matters to the committees. The beginning balance of the Rock Island Plan Species Account on January 1, 2017, was $5,897,144.62. Chelan PUD's annual Rock Island contribution was $737,452.00. Interest received during 2017 was $31,692.34. Funds disbursed for projects in 2017 totaled $100,663.45. In addition, $3,545.04 was paid to Clifton Larson Allen and Chelan PUD for account administration, $1,000.00 was paid to the UCSRB for sponsorship in the 2018 Upper Columbia Science Conference, and $50.90 was paid in bank fees. The ending balance on December 31, 2017, was $6,561,029.57. The 2017 Annual Financial Report for this Plan Species Account is provided in Appendix R.

The Rock Island HCP Tributary Committee delegated signatory authority to the Chairperson for processing of payments for invoices approved by the Committee, with the HCP Coordinating Committees Chairperson serving as the alternate. Chelan PUD recognizes the uniqueness of the Rock Island HCP Tributary Committee decision-making process and delegation of signatory authority to the Chairperson, and the Chelan PUD subsequently has provided funding necessary to assign reasonable liability insurance to the Tributary Chairperson.

2.3.3 General Salmon Habitat Program

The HCP Tributary Committees established the GSHP as the principle mechanism for funding projects. The goal of the program is to fund projects for the protection and restoration of Plan Species habitat. An important aspect of this program is to assist project sponsors in developing practical and effective applications for relatively large projects. Many habitat projects are increasingly complex in nature and require extensive design, permitting, and public participation to be feasible. Often, a reach-level project involves many authorities and addresses more than one habitat factor. Because of this trend, the GSHP was designed to fund relatively long-term projects. There is no maximum financial request in the GSHP; the minimum request is $100,000, although the HCP Tributary Committees may approve lesser amounts during a phased project.

In 2014 the HCP Tributary Committees announced that they would accept GSHP applications at any time during the year. They also announced that they would continue to accept SRFB applications for projects where Plan Species Account Funds are included as cost-shares in SRFB Proposals.

In an effort to coordinate with ongoing funding and implementation programs within the region, the HCP Tributary Committees used the previously established technical framework and review process for this geographic area and worked with the other funding programs to identify cost-sharing procedures (see Section 2.3.1).

2.3.3.1 2016 General Salmon Habitat Projects

The SRFB announced its 2017 funding cycle in March, with draft proposals due on April 14, 2017, and final proposals due on June 30, 2017. The HCP Tributary Committees received and reviewed nine draft proposals. The HCP Tributary Committees identified four projects that they believed warranted full proposals and dismissed five projects because they were inconsistent with the intent of the Tributary Fund, did not have strong technical merit, or had low benefits per cost.

In July, the HCP Tributary Committees received four full SRFB proposals to the GSHP. All were cost-shares with the SRFB or other funding entities. The HCP Tributary Committees approved funding for three projects. In addition, the HCP Tributary Committees received one full proposal to the GSHP that was outside the SRFB process. The Rock Island Tributary Committee approved funding for that project. Table 6 identifies the projects, sponsors, total cost of each project, amount requested from Tributary Funds, and, if funded, which Plan Species Account supported the project.

Table 6
General Salmon Habitat Program Projects Reviewed by the Habitat Conservation Plan Tributary Committees in 2017

Project Name	Sponsor	Total Cost	Request from Tributary Committee	Plan Species Account
Salmon Recovery Funding Board Applications				
M2 WDFW Flow Connection Project	MSRF	$78,828	$11,824	W: $11,824
M2 Mid-Sugar Acquisition Project	MSRF	$291,268	$43,690	W: $43,690
Piscine Passage Design (Brush and Minnow Creeks)	CCFEG	$162,500	$52,500	Not funded
Methow Basin Barrier and Diversion Assessment	CCFEG	$206,650	$40,000	W: $40,000
General Salmon Habitat Program Applications				
Derby Creek Fish Passage – Collins Project	CCFEG	$155,000	$65,000	RI: $65,000

In 2017, the Rock Island HCP Tributary Committee agreed to fund the following GSHP project:

- **Derby Creek Fish Passage – Collins Project for the amount of $65,000 (with cost share the total cost of the project was $155,000) –** This project will remove the lowermost fish passage barrier culvert (river mile [RM] 0.3) on Derby Creek, a tributary to the Wenatchee River. Removal of the lowermost barrier will open about 10 miles of habitat for steelhead spawning and rearing.

2.3.3.2 Modifications to General Salmon Habitat Program Contracts

In 2017, the Rock Island HCP Tributary Committee received the following requests from sponsors asking for modifications to GSHP projects funded by the Committee:

- In April, Trout Unlimited – Washington Water Project (TU-WWP) asked the Rock Island HCP Tributary Committee for a time extension on the *Methow Valley Irrigation District Instream Flow Improvement Project* from September 30, 2016 to November 30, 2017. The extra time is needed to complete tasks associated with the project. The Rock Island HCP Tributary Committee approved the time extension.
- In April, TU-WWP asked the Rock Island HCP Tributary Committee for a budget amendment on the *Beaver Fever: Restoring Ecosystem Function Project*. TU-WWP asked the Committee to move $1,997.00 from “Administration/Overhead” to “Salaries and Benefits,” $2,294.94 from “Administration/Overhead” to “Professional Services,” and $7,028.75 from “Administration/Overhead” to “Project Materials.” The Rock Island HCP Tributary Committee approved the budget amendment.
- In May, TU-WWP asked the Rock Island HCP Tributary Committee for a time extension on the *Barkley Irrigation Project* from May 31, 2017 to December 31, 2018. Extra time was needed

because of a delay in construction. The Rock Island HCP Tributary Committee approved the time extension.

- In July, TU-WWP asked the Rock Island HCP Tributary Committee for a budget amendment on the *Beaver Fever: Restoring Ecosystem Function Project*. TU-WWP asked the Committee if they could use $10,000 under Construction and Permitting to purchase a hydraulic post driver. The driver would be used to install beaver dam analogues. This would eliminate the need to rent the equipment and could be used on other projects. The Rock Island HCP Tributary Committee denied the request, because equipment purchased with Plan Species Account Funds becomes the property of the Committee and the Committee is not set up to deal with equipment storage, maintenance, management, and liability, and they do not want to be in a position of lending expensive equipment to project sponsors.

2.3.4 Small Projects Program

The Small Projects Program has an application and review process that increases the likelihood of participation by private stakeholders that typically do not have the resources or expertise to go through an extensive application process. The HCP Tributary Committees encourage small-scale projects by community groups, in cooperation with landowners, to support Plan Species recovery on private property. Project sponsors may apply for funding at any time, and in most cases, will receive a funding decision within three months. The maximum contract allowed under the Small Projects Program is $100,000.

2.3.4.1 2016 Small Projects

In 2017, the HCP Tributary Committees received four requests for funding under the Small Projects Program. Table 7 identifies the project, sponsor, total cost of the project, amount requested from Tributary Funds, and which Plan Species Account supported the projects.

Table 7
Projects Reviewed by the Habitat Conservation Plan Tributary Committees under the Small Projects Program in 2017

Project Name	Sponsor	Total Cost	Request from Tributary Committee	Plan Species Account
Poison Canyon Restoration Project	CCNRD	$37,918	$21,600	RI: $21,600
Cottonwood Bridge Removal Project	CDLT	$95,000	$21,000	RR: $21,000
Frazer Creek – Lazy K Property Appraisal	MSRF	$1,421.40	$1,421.40	Not funded
Upper Beaver Creek – Anderson Property Appraisal	MSRF	$1,421.40	$1,421.40	Not funded

In 2017, the Rock Island HCP Tributary Committee agreed to fund the following Small Project:

- **Poison Canyon Restoration Project for the amount of $21,600 (with cost share the total cost of the project was $37,918) –** This project will install 20 wood jams using on-site wood and hand tools to aggrade incised reaches within Poison Canyon, a tributary to Sand Creek, which is a tributary to Mission Creek. Aggrading the channel should improve instream flows and water quality in Mission Creek.

2.3.4.2 Modifications to Small Project Contracts

In 2017, the Rock Island HCP Tributary Committee received the following requests from sponsors asking for modifications to Small Projects funded by the Committee.

- In April, Cascade Columbia Fisheries Enhancement Group (CCFEG) asked the Rock Island HCP Tributary Committee for a time extension on the *White River Floodplain Connection (RM 3.4) Project*. CCFEG asked the Committee to extend the period of the contract from September 30, 2017 to December 30, 2017. The Rock Island HCP Tributary Committee approved the time extension.
- In June, CCFEG asked the Rock Island HCP Tributary Committee for a budget amendment on the *Permitting Nutrient Enhancement in the Chiwawa River Basin Project*. CCFEG asked the Committee to move $1,028 from "Professional Services" and "Indirect/Admin/Overhead" to "Sponsor Salaries and Benefits." The total budget amount did not change because of this amendment. The Rock Island HCP Tributary Committee approved the budget amendment.
- In June, CCFEG asked the Rock Island HCP Tributary Committee for a budget amendment on the *White River Floodplain Connection (RM 3.4) Project*. CCFEG asked the Committee to take all the available funds in "Excavation and Heavy Equipment" ($5,000) and "Project Materials and Equipment" ($500) and move those into "Salaries and Benefits," "Overhead and Administration," and "Permit Fees." The total budget amount did not change because of this amendment. The Rock Island HCP Tributary Committee approved the budget amendment.
- In July, CCFEG asked the Rock Island HCP Tributary Committee for a time extension on the *Permitting Nutrient Enhancement in the Chiwawa River Basin Project*. Because of ongoing discussions with the U.S. Forest Service, USFWS, and Washington State Department of Ecology, CCFEG asked to extend the period of the contract from June 30, 2017 to June 30, 2018. The Rock Island HCP Tributary Committee approved the time extension.

2.3.5 Tributary Assessment Program

The Rock Island HCP established the Tributary Assessment Program (separate from the Rock Island Plan Species Account) intended to fund monitoring and evaluation of the relative performance of projects funded by the initial contribution to the Plan Species Account. The Tributary Assessment program comprised a fixed contribution of $200,000, not subject to inflation adjustment. To date, Chelan PUD has not spent any of the original $200,000.00 total for the Rock Island HCP Tributary Assessment Program.

3 Habitat Conservation Plan Administration

This section lists events of note that occurred in 2017 related to the administration of the HCPs and provides a list of reports published in 2017 that relate to the HCPs.

3.1 Mid-Columbia Habitat Conservation Plan Forums

In 2005 and 2006, Mid-Columbia Forums were held as a means of communicating and coordinating with the non-signatories and other interested parties regarding the implementation of the HCPs. Non-signatory parties at the time of the 2006 meeting included the Confederated Tribes of the Umatilla Indian Reservation and American Rivers. As in 2006 through 2016, these parties were invited by letter in 2017 to participate in a meeting with members of the HCP Coordinating, Hatchery, and Tributary Committees, in conformity with the 2005 FERC Order on Rehearing 109 FERC 61208 and in accordance with the offer to non-signatory parties of non-voting membership in HCP Hatchery and Tributary Committees processes. The non-signatory parties again indicated no interest in attending a meeting with the HCP Committees in 2017.

3.2 Habitat Conservation Plan Related Reports and Miscellaneous Documents Published in Calendar Year 2017

The following is a list of reports released in 2017 that are related to the implementation of the Rock Island HCP:

- Anchor QEA and Chelan PUD (Public Utility District No. 1 of Chelan County), 2017. Annual Report Calendar Year 2016 of Activities Under the Anadromous Fish Agreement and Habitat Conservation Plan Rock Island Hydroelectric Project FERC License No. 943. Prepared for FERC. April 2017.
- Chelan PUD, 2017. Chelan PUD Rocky Reach and Rock Island HCPs Final 2017 Fish Spill Report. September 2017.
- Chelan PUD, 2017. Final 2017 Rocky Reach and Rock Island HCP Action Plans. April 2017.
- Hillman, T., M. Miller, M. Johnson, C. Moran, J. Williams, M. Tonseth, C. Willard, S. Hopkins, B. Ishida, C. Kamphaus, T. Pearsons, and P. Graf, 2017. *Monitoring and Evaluation of the Chelan and Grant County PUDs Hatchery Programs: 2016 Annual Report*. Report to the HCP and PRCC Hatchery Committees. September 15, 2017.
- Hillman, T., T. Kahler, G. Mackey, Andrew Murdoch, K. Murdoch, T. Pearsons, M. Tonseth, and C. Willard, 2017. Monitoring and evaluation plan for PUD hatchery programs: 2017 update. Report to the HCP and PRCC Hatchery Committees. November 16, 2017.
- Hopkins, S., and L. Keller, 2016. *2016 Rock Island Dam Smolt Monitoring Program and Gas Bubble Trauma Evaluation Final Report.* Prepared for Public Utility District No. 1 of Chelan County. December 2016.

- Hopkins, S., 2016. *Northern Pikeminnow Predator Control Program Rocky Reach and Rock Island Hydroelectric Projects Final Summary Report 2016*. Prepared for Public Utility District No. 1 of Chelan County. December 2016.
- Keller, L., and S, Hopkins, 2017. *Rock Island Dam Smolt Monitoring and Gas Bubble Trauma Evaluation Plan 2017*. Prepared for Public Utility District No. 1 of Chelan County. January 2017.
- Mosey, T., 2017. *2017 Fish Spill Plan Rock Island and Rocky Reach Dams*. Prepared for Public Utility District No. 1 of Chelan County. March 2017.

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Coordinating Committees

Date: February 28, 2017

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the January 24, 2017, HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Coordinating Committees met at the Grant PUD Office in Wenatchee, Washington, on Tuesday January 24, 2017, from 10:00 a.m. to 12:45 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Alene Underwood (Chelan PUD Fish and Wildlife Program Manager) will provide Chelan PUD's comments on the Federal Columbia River Power System (FCRPS) National Environmental Policy Act (NEPA) Scoping Process to Kristi Geris for distribution to the Coordinating Committees (Item II-B).
- Lance Keller will revise the draft Statement of Agreement (SOA), "Acknowledgement of Rock Island Powerhouse 1 Units B1-B4 Consultation," as discussed, and will provide the revised draft SOA to Kristi Geris for distribution to the Coordinating Committees (Item II-C). *(Note: the revised draft SOA was distributed following the meeting on January 24, 2017, and is available for a 10-day review with vote via email due to Keller by Friday, February 3, 2017.)*
- Lance Keller will revise the Draft 2017 Rock Island and Rocky Reach HCP Action Plan, as discussed, and will provide the revised draft plan to Kristi Geris for distribution to the Coordinating Committees (Item II-D). *(Note: the revised draft plan was distributed following the meeting on January 24, 2017, and is available for review with edits and comments due to Keller by Wednesday, February 22, 2017.)*
- Lance Keller will provide fish rescue numbers from the 2016/2017 Rock Island and Rocky Reach dams adult fish ladder maintenance periods to Kristi Geris for distribution to the Coordinating Committees (Item II-E). *(Note: Keller provided fish rescue numbers [Attachment B] to Geris on February 16, 2017, which Geris distributed to the Coordinating Committees on February 17, 2017.)*
- Lance Keller will notify the Rocky Reach HCP Coordinating Committee when the Rocky Reach Dam adult fish ladder is brought back online from the 2016/2017 Rocky Reach Dam adult fish ladder maintenance period (Item II-E). *(Note: Keller provided notification that the Rocky Reach Dam adult fishway was returned to service on February 14, 2017, which was distributed to the Coordinating Committees by Kristi Geris that same day.)*

- Tom Kahler will provide fish passage count data for winter months at Wells Dam for review regarding timing of winter maintenance at Wells Dam to Kristi Geris for distribution to the Coordinating Committees (Item III-A).
- Tom Kahler will notify the Wells HCP Coordinating Committee when the Wells Dam west fishway is brought back online from the 2016/2017 Wells Dam fishway maintenance period (Item III-A). *(Note: Kahler provided this notification to Kristi Geris on February 21, 2017, which Geris distributed to the Coordinating Committees that same day.)*
- Tracy Hillman (HCP Tributary Committees Chairman) will provide U.S. Fish and Wildlife Service's (USFWS's) presentation on the Silver Side-Channel Rehabilitation Project to Kristi Geris for distribution to the Coordinating Committees (Item IV-A). *(Note: the presentation was posted to the Coordinating Committees HCP Extranet Site [file was too large to email], and the Coordinating Committees were notified by Geris following the meeting on January 24, 2017.)*
- John Ferguson will follow up with Michelle Rub (National Marine Fisheries Service [NMFS]) regarding possibly presenting an update on her presentation, "Estimation of Survival and Run Timing of Adult Spring/Summer Chinook from the Columbia River Estuary to Bonneville Dam," to the Coordinating Committees during a future meeting (Item V-E).
- **The Coordinating Committees meeting on February 28, 2017, will be held in-person at the Grant PUD office in Wenatchee, Washington (Item V-E).**

Decision Summary

- Rock Island HCP Coordinating Committee representatives approved the SOA, "Acknowledgement of Rock Island Powerhouse 1 Units B1-B4 Consultation," via email as follows: Chelan PUD approved on January 24, 2017; the Colville Confederated Tribes (CCT) approved on January 25, 2017; NMFS and USFWS approved on January 26, 2017; Washington Department of Fish and Wildlife (WDFW) approved on February 1, 2017; and the Yakama Nation (YN) approved on February 3, 2017 (Item II-C).
- Wells HCP Coordinating Committee representatives approved the 2017 Wells Dam Gas Abatement Plan and Bypass Operating Plan (GAP and BOP), as revised, via email as follows: Douglas PUD approved on February 7, 2017; NMFS approved on February 8, 2017; USFWS approved on February 10, 2017; and WDFW, CCT, and the YN approved on February 14, 2017 (Item III-B).

Agreements

- Rock Island HCP Coordinating Committee representatives present agreed to a 10-day review period (initiated when the revised SOA is distributed) and a vote via email on the revised draft SOA, "Acknowledgement of Rock Island Powerhouse 1 Units B1-B4 Consultation," (Item II-C).

- Rock Island and Rocky Reach HCP Coordinating Committees representatives present agreed Chelan PUD does not need to provide an annual fish passage plan for Coordinating Committees review. The plan will be removed from the annual Rock Island and Rocky Reach HCP Action Plan (Item II-D).

Review Items

- Kristi Geris sent an email to the Coordinating Committees on December 15, 2016, notifying them the Draft 2015 Douglas PUD Pikeminnow Program Annual Report is available for a 60-day review period, with edits and comments due to Tom Kahler by Monday, February 13, 2017.
- Kristi Geris sent an email to the Coordinating Committees on January 5, 2017, notifying them the Draft 2017 Wells Dam GAP and BOP is available for a 30-day review period, with edits and comments due to Tom Kahler by Monday, February 6, 2017 (Item III-B). *(Note: USFWS provided comments on the draft plan on February 2, 2017, which Douglas PUD incorporated into the plan, and a Revised Draft 2017 Wells Dam GAP and BOP was distributed to the Coordinating Committees by Geris on February 7, 2017, with a vote via email due by Tuesday, February 14, 2017; see Decision Summary.)*
- Kristi Geris sent an email to the Coordinating Committees on January 23, 2017, notifying them that six Chelan PUD documents are available for a 30-day review, including: the Draft 2016 Rock Island Smolt Monitoring Program and Gas Bubble Trauma (SMP and GBT) Report; the Draft 2016 Rocky Reach Juvenile Fish Bypass System (RRJFBS) Report; the Draft 2016 Rock Island and Rocky Reach Pikeminnow Control Program Summary Report; the Draft 2017 Rock Island Bypass Monitoring Plan; the Draft 2017 Rock Island and Rocky Reach HCP Action Plan; and the Draft 2017 Rocky Reach Juvenile Sampling Facility (RRJSF) Protocol. Edits and comments on these documents are due to Lance Keller by Wednesday, February 22, 2017 (Item II-D). *(Note: a Revised Draft 2017 Rock Island and Rocky Reach HCP Action Plan was distributed for review on January 24, 2017. The Draft 2017 RRJFBS Operations Plan was distributed for a 30-day review period on February 17, 2017 [comments due Monday, March 20, 2017], replacing the Draft 2017 RRJSF Protocol, which was mistakenly distributed instead of the RRJFBS Operations Plan.)*
- Kristi Geris sent an email to the Coordinating Committees on January 24, 2017, notifying them the revised draft SOA, "Acknowledgement of Rock Island Powerhouse 1 Units B1-B4 Consultation," is available for a 10-day review with votes via email due to Lance Keller by Friday, February 3, 2017 (Item II-C).
- Kristi Geris sent an email to the Coordinating Committees on February 8, 2017, notifying them the Draft 2016 Wells HCP Annual Report is available for a 30-day review with edits and comments due to Geris by Friday, March 10, 2017 (Item V-D).

- Kristi Geris sent an email to the Coordinating Committees on February 16, 2017, notifying them the Draft 2016 Rock Island and Rocky Reach HCP Annual Reports are available for a 30-day review with edits and comments due to Geris by Monday, March 20, 2017 (Item V-D).
- Kristi Geris sent an email to the Coordinating Committees on February 22, 2017, notifying them the Draft 2017 Rock Island and Rocky Reach Fish Spill Plan is available for a 30-day review with edits and comments due to Lance Keller by Friday, March 24, 2017.
- Kristi Geris sent an email to the Coordinating Committees on February 23, 2017, notifying them the Draft 2017 Wells HCP Action Plan is available for review. Douglas PUD will request approval of the plan during the Coordinating Committees meeting on March 28, 2017 (Item III-C).

Finalized Documents

- The final SOA, "Acknowledgement of Rock Island Powerhouse 1 Units B1-B4 Consultation," was distributed to the Coordinating Committees by Kristi Geris on February 13, 2017 (Item II-C).
- The Final 2017 Wells Dam GAP and BOP was filed with FERC on February 27, 2017, and was distributed to the Coordinating Committees by Kristi Geris that same day (Item III-B).

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda, and the following revisions were requested:

- Lance Keller and Alene Underwood added a notification of Chelan PUD's intent to comment on the FCRPS NEPA Scoping Process.
- Ferguson added two updates under HCP Administration: 1) Coordinating Committees email distribution; and 2) Draft 2017 HCP Annual Reports.

B. Meeting Minutes Approval (John Ferguson)

The Coordinating Committees reviewed the revised draft November 15, 2016, meeting minutes. Kristi Geris noted that the Draft 2017 Wells Dam GAP and BOP and Douglas PUD's Draft 2015 Douglas PUD Pikeminnow Program Annual Report were added under the review items. She said those documents are available for review, with edits and comments due to Tom Kahler by February 6 and February 13, 2017, respectively. Geris also said the Final Wells Post-Season Bypass Report and Passage-Dates Analysis was added under the finalized documents. She said the report was finalized following a 60-day review period, which ended on December 5, 2016, and was distributed to the Coordinating Committees on December 28, 2016. She said, as noted in the email, the edits discussed and requested by the Coordinating Committees were incorporated into the final passage-dates analysis, and the post-season bypass report was updated accordingly. Geris said all other comments and revisions received from members of the Committees were incorporated into the revised minutes. Coordinating Committees members present approved the November 15, 2016, meeting minutes, as revised. The CCT abstained, because a CCT representative was not present during the November 15, 2016, meeting.

C. Last Meeting Action Items (John Ferguson)

Action items from the Coordinating Committees meeting on November 15, 2016, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the meeting on November 15, 2016):*

- *Lance Keller will confirm the appropriate title for Alene Underwood (Chelan PUD), for the administrative record, regarding her participation in the Coordinating Committees meeting on October 25, 2016 (Item I-B).*
  Keller confirmed Underwood's title, Chelan PUD Fish and Wildlife Program Manager, on November 18, 2016.
- *Bob Rose will provide a list of Yakama Nation (YN) concerns regarding datasets used for estimating coho salmon survival, which will be used in future discussions of the Rock Island and Rocky Reach Coho Salmon Phase Designation, prior to the Coordinating Committees meeting on December 13, 2016 (Item III-A).*
  This will be discussed during today's meeting.
- *Chelan PUD and the YN will convene to discuss concerns regarding datasets used for estimating coho salmon survival, prior to the Coordinating Committees meeting on December 13, 2016 (Item III-A).*
  Chelan PUD and the YN plan to meet after the meeting today.
- *Rock Island and Rocky Reach Coho Salmon Phase Designation will be discussed during the Coordinating Committees meeting on December 13, 2016 (Item III-A).*
  This will be discussed during today's meeting.
- *Chelan PUD will provide a Rock Island Powerhouse 1 Maintenance Update during the Coordinating Committees meeting on December 13, 2016, including discussing the Draft Federal Energy Regulatory Commission (FERC) Notification Letter for Rock Island B1-B4 Maintenance (Item III-B).*
  This will be discussed during today's meeting.
- *John Ferguson will coordinate with Denny Rohr (Priest Rapids Coordinating Committee [PRCC] Facilitator) regarding scheduling a joint HCP/PRCC meeting soon to discuss estimating the survival of subyearling Chinook salmon passing Mid-Columbia dams (Item V-A).*

Ferguson recalled that the Coordinating Committees agreed to convene quarterly, joint HCP/PRCC sessions to continue discussions regarding subyearling Chinook salmon passage studies; however, the joint meetings have not occurred to date. Ferguson said he spoke with Rohr who indicated the PRCC still intends to convene joint HCP/PRCC sessions; however, the PRCC is discussing this topic and several other issues and is not ready for joint sessions at this time.

II. Chelan PUD

A. Rock Island and Rocky Reach Coho Salmon Phase Designation (Steve Hemstrom, Lance Keller, Alene Underwood, and Catherine Willard)

Steve Hemstrom recalled the SOA, "Regarding District's Coho Obligation" (approved by the Rock Island and Rocky Reach HCP Coordinating Committees on June 26, 2007), which designated coho salmon in the Rock Island and Rocky Reach reservoirs as in Phase III Additional Juvenile Studies. Hemstrom recalled the 2007 SOA assumed an interim juvenile dam-passage survival value of 93%, unless compelling evidence indicated otherwise, in which survival studies would be conducted. Hemstrom said in 2010, installation of the Rocky Reach Dam juvenile salmon bypass passive integrated transponder (PIT)-tag detector provided key infrastructure needed to estimate survival rates of PIT-tagged juvenile coho salmon, yearling spring Chinook salmon, and steelhead released in the Methow River basin. He said new data are now available, and Chelan PUD is reassessing coho salmon survival.

Hemstrom said Chelan PUD asked John Skalski (Skalski Statistical Services) and Rich Townsend (Columbia Basin Research) to complete an analysis of hydrosystem survival estimates for PIT-tagged juvenile coho salmon, yearling spring Chinook salmon, and steelhead released from the Methow River basin through two reaches: 1) from Rocky Reach Dam to McNary Dam; and 2) from McNary Dam to John Day Dam. Hemstrom said the most recent analysis also includes statistical analyses based on PIT tags detected at the corner collector located at Bonneville Dam, as well as an additional year of data for all analyses (distributed September 22, 2016). He said there are now PIT-tag data from 2010 to 2016, providing a robust dataset. He said these data indicate coho salmon and yearling spring Chinook salmon survive most similarly from Rocky Reach Dam to McNary Dam and McNary Dam to John Day Dam. He added that the difference in estimated survival between the two species is not statistically significant.

Casey Baldwin asked about the standard errors on the estimates. Hemstrom said the reach survival estimates based on PIT tags had standard errors of approximately 8% for coho and Chinook salmon, whereas the standard errors associated with the dam-passage survival estimates based on acoustic tags were less than 2.5% (which meets the HCP requirements for standard error). Hemstrom added that it is important to remember this analysis is using a comparison. John Ferguson asked if the passage timing is similar, and Catherine Willard (Chelan PUD HCP Hatchery Committees Alternate) said passage timing of coho and Chinook salmon occurs within approximately 1 or 2 weeks of each other. Hemstrom also noted that the analysis uses the harmonic mean for travel times. Ferguson asked when an updated report from Skalski and Townsend will be available for review, and Alene Underwood replied, likely within the next couple of weeks. Hemstrom added that Chelan PUD also plans to distribute an SOA for discussion at the next Coordinating Committees meeting on February 28, 2017.

Hemstrom said the ultimate goal is to estimate coho salmon survival through the Rock Island and Rocky Reach reservoirs based on comparisons of the species's hydrosystem survival. He explained this calculation as being in the form of the following ratio:

$$\frac{Coho\ \ salmon\ survival\ from\ Rocky\ Reach\ Dam\ to\ McNary\ Dam}{Yearling\ Chinook\ salmon\ survival\ from\ Rocky\ Reach\ Dam\ to\ McNary\ Dam} = Survival\ ratio$$

He added, for example, that if coho salmon were to survive twice as well as yearling Chinook salmon the survival ratio would be 2, and if half as well it would be 0.5. Ferguson asked about the range of calculated survival ratios among the years, and Hemstrom said they ranged from less than 1.0 to about 1.3 to 1.4. Hemstrom added that the average ratio is 1.0024 based on PIT-tag data. Baldwin noted that a mean and the standard error associated with the mean are important information to have when interpreting significance, and when the mean is converted to a ratio, the variance is lost. Hemstrom said a standard error on the ratio was calculated, as well and is in the report. He explained when the individual survival of two species is compared, both species include a standard error; therefore, variance is already captured in the individual survival. He added that the ratios would be used to adjust the available dam-passage survival estimates for each project and species, based on the more precise acoustic telemetry data. He also said the exact values are in the report and recalled that adjusting the dam-passage estimates by the ratios resulted in estimates of 92.94% and 93.98% survival for coho salmon passing Rocky Reach Dam and Rock Island Dam, respectively.

Baldwin asked about fish-size comparisons between hatchery and wild coho salmon (i.e., how well are hatchery coho salmon surrogates for wild coho salmon). Willard said, overall, the two are similar with little variation. She added that occasionally, hatchery coho salmon are released a little earlier than the wild coho salmon outmigration. Lance Keller agreed he does not recall a significant discrepancy. Underwood said hatchery coho salmon are typically released when fish size is about 14.8 to 20 fish per pound. Jim Craig noted that hatchery fish are often times larger than wild fish; however, data on wild coho salmon are not substantial enough to confirm such a comparison.

Hemstrom said analyzing the survival ratios of 7 years of PIT-tag data, including a range of river environments and water years, incorporates all available data into the analysis, providing the most robust dataset available to date. He said Chelan PUD would like to achieve Phase III (Standard Achieved) for juvenile coho salmon through this analysis. Underwood also reiterated that the 2007 SOA stipulates:

> *"Juvenile coho [salmon] survival studies will not be performed unless there is compelling[1] information that demonstrates hydro project operations have an impact of greater than 7% mortality on coho [salmon]."*

She said, additionally, a survival study does not seem feasible at this time, based on fish counts in the river and juvenile collector at Rocky Reach Dam. Hemstrom noted that upward of 1,000 acoustically-tagged fish would be needed to obtain a standard error of 2.5%. Underwood said Chelan PUD intends to request (Standard Achieved) for juvenile coho salmon for the life of the license. She said a re-evaluation will coincide with the 10-year check-in. Baldwin asked how re-evaluation works, and Keller read from the Rock Island and Rocky Reach HCPs:

> *"…the District shall re-evaluate survival under the applicable standard every 10 years. Representative species shall be picked by the Coordinating Committee. This re-evaluation will occur over one year and be included in the pertinent average for that particular species. If the survival standard is met, then Phase III (Standard Achieved) status will remain. If the survival standard is not met, then an additional year of testing will occur. If the survival standard remains unmet over three years of re-evaluation, then Phase II designation will take affect for the representative species, and the Coordinating Committee shall re-evaluate the survival of other Plan Species, as appropriate."—Rock Island HCP (page 12); Rocky Reach HCP (page 13)*

Ferguson asked about timing of the next 10-year check-in. Keller said the next check-in is scheduled for 2020 for the Rock Island HCP and 2021 for the Rocky Reach HCP.

---

[1] "Compelling" evidence could relate to information collected as part of the hatchery monitoring and evaluation program. For example, smolt-to-adult survivals for coho [salmon] that are significantly lower than other species in the same geographical area may be compelling evidence that coho [salmon] are experiencing differential mortality rates at project passage. In all cases the evidence should be empirical and related to Project survival.

B. Chelan PUD Intent to Comment on FCRPS NEPA Scoping Process (Alene Underwood)

Alene Underwood notified the Coordinating Committees that Chelan PUD is preparing comments on the FCRPS NEPA Scoping Process documents, and plans to submit them by February 7, 2017. She said the comments are regarding maintaining the integrity of the HCPs and acknowledging the PUDs have certain protections under the HCPs. She said the comments focus on: 1) analyzing the potential effects of predation, specifically in the estuary; 2) acknowledging scientific uncertainties associated with Upper Columbia River spring-run Chinook salmon; and 3) climate change (as it relates to how to replace clean renewable energy sources if dams are removed). Underwood said she will provide Chelan PUD's comments on the FCRPS NEPA Scoping Process to Kristi Geris for distribution to the Coordinating Committees.

C. Rock Island Powerhouse 1 Maintenance Update (Lance Keller)

Lance Keller distributed hard copies of the draft SOA, "Acknowledgement of Rock Island Powerhouse 1 Units B1-B4 Consultation," which was distributed electronically to the Coordinating Committees by Kristi Geris on January 23, 2017. Keller recalled Rock Island Powerhouse 1 Units B1 to B4 were taken out of service for periodic maintenance, at which time staff noticed cracks in the turbine blades. He said, when cracks were discovered, the cracked areas were fixed, the blades were determined to be crack-free, and the units were put back into service. However, during follow-up inspections, staff discovered that additional cracks had formed. Keller said pieces of the blades were sent out for metallurgic analysis and results indicated the blades were at the end of their lifespan. He noted that these units are the original units installed at Rock Island Dam in 1933. He said Chelan PUD decided to perform maintenance on all four units. He said rehabilitation plans were reviewed at length with the Coordinating Committees, a draft notification letter to FERC about the proposed maintenance was provided to the Coordinating Committees for a 30-day review period, and no comments were received on the plans or letter. Keller said, because no comments were received, FERC has requested additional assurances the Rock Island HCP Coordinating Committee is indeed supportive of the proposed rehabilitation; therefore, Chelan PUD drafted this SOA.

Keller said Chelan PUD requested and received bids for the rehabilitation work in December 2016, including bids for repairing one unit at a time or two at a time. He said a company named Andritz Hydro (based in Austria, with a location in the United States) provided a bid for repairing three units all at once. Keller recalled the old maintenance schedule included the last unit returning to service in March 2020, which was an aggressive schedule that also had no room for slippage ahead of the 2020 10-year check-in scheduled for Rock Island Dam. He said, with the proposal from Andritz Hydro, the new schedule includes dewatering Unit B4 in June 2018, and Units B2 to B3 in July 2018 (three units at once). He said those units will be back online by the first quarter of 2019, and then Unit B1 will be dewatered and recommissioned by about November 2019. Keller said Chelan PUD held a Board of

Commissioners meeting on December 30, 2016, to accept the bid. Alene Underwood said Andritz Hydro will be handling the entire rehabilitation, and Chelan PUD is confident all units will be back to service in 2019.

Keller reiterated this SOA is simply a formal document FERC requested to demonstrate a clear paper trail that the Rock Island HCP Coordinating Committee supports this rehabilitation. Underwood said Chelan PUD hopes to keep this process moving and requested a vote take place today, via email, or during the next Coordinating Committees meeting on February 28, 2017. Keller also noted that he will revise the minor typos in the draft SOA and will provide a revised draft SOA to Geris for distribution to the Coordinating Committees.

Bob Rose asked if Chelan PUD knows, or rather anticipates, whether the proposed design changes will benefit fish. He recalled similar claims from Grant PUD during an overhaul of turbines at Priest Rapids Dam; however, the designs had errors. Rose asked if the language in the SOA background can be changed to reflect this uncertainty. Keller said Chelan PUD can state with a high level of confidence these design upgrades will benefit fish passage; however, he also agreed to modify the background language, as requested. Jim Craig requested a 10-day review and vote via email after the revised draft SOA is distributed.

Coordinating Committees representatives present agreed to a 10-day review period (initiated when the revised SOA is distributed) and vote via email on the revised draft SOA, "Acknowledgement of Rock Island Powerhouse 1 Units B1-B4 Consultation." *(Note: the revised draft SOA was distributed following the meeting on January 24, 2017, and is available for a 10-day review with vote via email due to Keller by Friday, February 3, 2017.)*

Rock Island HCP Coordinating Committee representatives approved the SOA, "Acknowledgement of Rock Island Powerhouse 1 Units B1-B4 Consultation," via email as follows: Chelan PUD approved on January 24, 2017; the CCT approved on January 25, 2017; NMFS and USFWS approved on January 26, 2017; WDFW approved on February 1, 2017; and the YN approved on February 3, 2017. The final SOA was distributed to the Coordinating Committees by Geris on February 13, 2017.

D. Draft 2017 Rock Island and Rocky Reach HCP Action Plan (Lance Keller)

Lance Keller distributed hard copies of the Draft 2017 Rock Island and Rocky Reach HCP Action Plan, which was distributed electronically to the Coordinating Committees by Kristi Geris on January 23, 2017. He said the draft plan was presented to the HCP Hatchery Committees during their meeting on January 18, 2017, and will be presented to the HCP Tributary Committees during their meeting on March 9, 2017. He said, once those committees approve their respective portions of the action plan, Chelan PUD will request Rock Island and Rocky Reach HCP Coordinating Committees approval of the entire plan.

Keller said the first four documents listed in the action plan (the Draft 2016 Rock Island SMP and GBT Report; the Draft 2016 RRJFBS Report; the Draft 2017 Rock Island Bypass Monitoring Plan; and the Draft 2017 RRJSF Protocol), as well as the Draft 2016 Rock Island and Rocky Reach Pikeminnow Control Program Summary Report, were distributed to the Coordinating Committees by Geris on January 23, 2017. These five documents and the draft action plan are available for a 30-day review, with edits and comments due to Keller by Wednesday, February 22, 2017. *(Note: the Draft 2017 RRJFBS Operations Plan was distributed for a 30-day review period on February 17, 2017 [comments due Friday, March 17, 2017], replacing the Draft 2017 RRJSF Protocol, which was mistakenly distributed instead of the RRJFBS Operations Plan.)*

Keller said the 2017 action plan is business as usual except for the coho salmon survival standards SOA. He said he also wanted to discuss the 2017 Rock Island and Rocky Reach Fish Passage Plan. He said this plan has been included in the Rock Island and Rocky Reach Action Plan for years; however, Chelan PUD has not distributed the plan to the Coordinating Committees since 2013, and he cannot recall why. He explained the fish passage plan document summarizes bypass operations, adult passage, and fish spill operations, all of which are already covered under other documents that the Coordinating Committees review. He said the fish passage plan is essentially a summary of other documents, and asked if the Coordinating Committees want to receive this plan in 2017. Rock Island and Rocky Reach HCP Coordinating Committees representatives present agreed Chelan PUD does not need to provide an annual fish passage plan for Coordinating Committees review. The plan will be removed from the annual Rock Island and Rocky Reach HCP Action Plan.

Keller also noted that pikeminnow trapping activities will be removed from the action plan and will be added again if the activities are actually planned. Keller said he will revise the Draft 2017 Rock Island and Rocky Reach HCP Action Plan, as discussed, and will provide the revised draft plan to Geris for distribution to the Coordinating Committees. *(Note: the revised draft plan was distributed following the meeting on January 24, 2017, and is available for review with edits and comments due to Keller by Wednesday, February 22, 2017.)*

E. Rock Island and Rocky Reach Adult Fish Ladder Maintenance Update (Lance Keller)

Lance Keller reviewed maintenance updates at Rock Island Dam and Rocky Reach Dam, as follows:

<u>Rock Island Dam</u>

Keller recalled that at Rock Island Dam, one ladder remains operational for fish passage at all times, and up to two ladders can be offline for maintenance.

Middle Ladder

Keller said the middle ladder at Rock Island Dam was taken offline for annual winter maintenance on December 6, 2016. He said a fish rescue was conducted, and he reviewed the numbers. He added that he will provide fish rescue numbers from the 2016/2017 Rock Island and Rocky Reach dams adult fish ladder maintenance period, to Kristi Geris for distribution to the Coordinating Committees. *(Note: Keller provided fish rescue numbers [Attachment B] to Geris on February 16, 2017, which Geris distributed to the Coordinating Committees on February 17, 2017.)*

Keller said extensive (beyond general) maintenance activities conducted included: 1) replaced lower valves (gear stems wore out); 2) conducted grating inspection; and 3) evaluated concrete integrity. Keller said the middle ladder was returned to service on January 6, 2017.

Left Ladder

Keller said the left ladder at Rock Island Dam was taken offline for annual winter maintenance on December 21, 2016. He said a fish rescue was conducted, and he reviewed the numbers (Attachment B). He said extensive maintenance activities conducted included maintenance on the gates and valves. He said Chelan PUD contracts a consultant to clean the windows in the fish ladders, which still needs to be done. Keller said the left ladder is expected to return to service by the first week in February 2017.

Right Ladder

Keller said the right ladder at Rock Island Dam was taken offline for annual winter maintenance on January 9, 2017. He said a fish rescue was conducted on January 9 and 13, 2017, and he reviewed the numbers (Attachment B). John Ferguson asked if Pacific lamprey slipped through the grating this year as they have done in the past. Keller said yes, that 93 of 100 Pacific lamprey rescued came from the auxiliary water system (AWS) side of the diffuser grating, and 7 of 100 were rescued from the fish ladder side of the grating. He said the diffuser grating has 1-inch spacing and recalled having past issues with bowed veins. He said, Chelan PUD now conducts a “ping” test each year to determine the veins’ integrity. He said veins that are bowing are repaired. He said, unfortunately, the grating cannot be replaced with smaller spaced grating as was done at Rocky Reach Dam because this would restrict flow too much. He further explained that the picket barrier is a wall several feet tall and wide, and reducing the spacing between the gratings will create hydraulic issues. He said this may still be something Chelan PUD further investigates in the future.

Keller said maintenance activities conducted on the right ladder were minimal, and the ladder is expected to return to service by the end of January 2017.

Rocky Reach Dam

Keller recalled that the Rocky Reach HCP Coordinating Committee agreed to Chelan PUD's request to begin the 2016/2017 Rocky Reach Dam adult fish ladder maintenance period 3 weeks early to allow more time to complete needed work on the AWS pumps. He said as agreed, the adult fish ladder at Rocky Reach Dam was taken offline for annual winter maintenance on December 12, 2016. He said a fish rescue was conducted in the upper ladder on December 12, 2016, while the lower ladder remained watered with entrances open. He said the lower ladder was then dewatered on December 23, 2016, and a fish rescue was conducted that same day.

Keller reviewed the fish rescue numbers (Attachment B), and noted that all mortalities were juveniles. He explained that when the upper ladder is dewatered, water can only get out through the orifice of the weir. He said, once the water reaches a certain level, a gate is dropped closing the orifice. He said, this year, when the gate was dropped, a carabiner prevented the gate from completely closing, and a few smaller fish exited through the orifice and slipped through the floor gratings. He said when the fish were discovered, they had already expired.

Keller also noted 169 adult Pacific lamprey were rescued. He recalled replacing the upper ladder 1-inch floor grating with 3/4-inch grating in the lower weir section of the adult ladder, and said the rescued Pacific lamprey did not descend until they reached the remaining 1-inch grating. He said Chelan PUD plans to replace this remaining 1-inch grating in the lower weir section of the adult ladder in 2017. He also noted the one rescued bull trout, which was found holding in the middle of the 169 adult Pacific lamprey.

Keller said all rescued fish were released in the Rocky Reach Dam forebay. Casey Baldwin asked why the Pacific lamprey were not released farther upstream to avoid potential fallback. Keller said the Pacific lamprey were released at the landing near the bypass, per usual. He said the river is fairly calm there and suitable habitat is nearby. Jim Craig agreed this is a safe release location for Pacific lamprey.

Keller recalled that Chelan PUD requested approval from the Rocky Reach HCP Coordinating Committee for an early outage of the ladder to rehabilitate the AWS pumps and, specifically, to refurbish the seal on one of the butterfly valves. He said, by the time Chelan PUD received the estimate from the contractor, there was not enough time to complete the repairs within the allotted maintenance work window. Keller apologized for the disorganization that resulted in not completing the intended repairs after the Rocky Reach HCP Coordinating Committee approved the extended outage. He said the fish ladder will be returned to service as soon as possible, which is expected by the week of February 20, 2017, and he added that he will notify the Rocky Reach HCP Coordinating Committee when this occurs. *(Note: Keller provided notification that the Rocky Reach Dam adult* *fishway was returned to service on February 14, 2017, which was distributed to the Coordinating Committees by Geris that same day.)*

Keller said, regarding rehabilitating the AWS pumps, Chelan PUD investigated replacing the butterfly valves rather than repairing them, which turned out to be more cost-effective. He said Chelan PUD now plans to purchase the parts for all three pumps and replace the valves in each pump at a rate of one pump per year starting in 2017 (i.e., the 2017/2018 winter maintenance period). He added that by having the new parts onsite, this prevents the need to ship the valves offsite and will not require an early winter maintenance outage.

III.Douglas PUD

A. Wells Dam Fishway Maintenance Update (Tom Kahler)

Tom Kahler reviewed maintenance updates at Wells Dam, as follows:

East Fishway

Kahler said the east fishway at Wells Dam was taken offline for annual winter maintenance on December 7, 2016. He said a fish rescue was conducted, and a fish-salvage memorandum for the east fishway (Attachment C) was distributed to the Coordinating Committees by Kristi Geris on December 8, 2016. Kahler said routine maintenance was conducted, as well as maintenance on the fish pump (which was already completed in the west fishway). He said the east fishway was returned to service on January 9, 2017.

West Fishway

Kahler said the west fishway at Wells Dam was taken offline for annual winter maintenance on January 16, 2017. He said the upper ladder was dewatered on January 16, 2017, and a fish rescue was conducted that same day. He said the dewatering process in the lower ladder began on January 17, 2017; however, the gate motor that operates the leaf gates of the fishway collection gallery froze, and staff had to manually crank the gates closed. He said dewatering of the collection gallery was completed on January 19, 2017, and a fish rescue was conducted that same day. He said a fish-salvage memorandum for the west fishway (Attachment D) was distributed to the Coordinating Committees by Geris on January 19, 2017. Kahler said the west fishway is expected to return to service by the end of January 2017, and he added that he will notify the Wells HCP Coordinating Committee when this occurs. *(Note: Kahler provided this notification to Geris on February 21, 2017, which Geris distributed to the Coordinating Committees that same day.)*

Winter Maintenance Timing

Kahler said the Wells HCP contains no specific requirement for timing of winter maintenance; however, Douglas PUD has historically targeted December 1 to February 28 for completing necessary work. Kahler said the Mechanic Foreman at Wells Dam inquired about starting annual winter maintenance earlier, possibly by mid-November, in an effort to complete work before the coldest part of winter and freezing temperatures, which complicate maintenance activities. Kahler said, with this earlier schedule, maintenance could be completed as early as the end of December.

Kahler said he reviewed count data at Wells Dam and discovered there is more steelhead movement in February than December. He said fish counts are recorded via video during the winter months (offseason), and when fish counters return, the count video is immediately reviewed. The Wells HCP Coordinating Committee agreed to consider this further, and Kahler said he will provide fish passage count data for winter months at Wells Dam, to Geris for distribution to the Coordinating Committees for review.

B. Draft 2017 Wells Dam Gas Abatement Plan and Bypass Operating Plan (Tom Kahler)

Tom Kahler said Kristi Geris sent an email to the Coordinating Committees on January 5, 2017, notifying them the Draft 2017 Wells Dam GAP and BOP was available for a 30-day review period, with edits and comments due to Kahler by Monday, February 6, 2017. Kahler explained that Douglas PUD's FERC license, issued in 2012, required combining the GAP and BOP into one document (the BOP is now an appendix in the GAP). He said, per the license, Douglas PUD must provide the Wells HCP Coordinating Committee the opportunity to consult on both plans, but only requires Wells HCP Coordinating Committee approval of the BOP. He said the full document (2017 Wells Dam GAP and BOP) must ultimately be approved by the Washington State Department of Ecology and the Aquatic Settlement Work Group, prior to submitting the final document to FERC by February 28, 2017. *(Note: USFWS provided comments on the draft plan on February 2, 2017, which Douglas PUD incorporated into the plan, and a Revised Draft 2017 Wells Dam GAP and BOP was distributed to the Coordinating Committees by Geris on February 7, 2017, with a vote via email due by Tuesday, February 14, 2017.)*

Wells HCP Coordinating Committee representatives approved the 2017 Wells Dam GAP and BOP via email as follows: Douglas PUD approved on February 7, 2017; NMFS approved on February 8, 2017; USFWS approved on February 10, 2017; and WDFW, CCT, and the YN approved on February 14, 2017. The Final 2017 Wells Dam GAP and BOP was filed with FERC on February 27, 2017, and was distributed to the Coordinating Committees by Geris that same day.

C. Draft 2017 Wells HCP Action Plan (Tom Kahler)

Tom Kahler said the Draft 2017 Wells HCP Action Plan is not yet ready for distribution.

Kristi Geris sent an email to the Coordinating Committees on February 23, 2017, notifying them the Draft 2017 Wells HCP Action Plan is available for review. Douglas PUD will request approval of the plan during the Coordinating Committees meeting on March 28, 2017.

IV. HCP Tributary and Hatchery Committees Update

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman updated the Coordinating Committees on the following actions and discussions that occurred during the HCP Tributary Committees meeting on January 12, 2017:

- *ORRI Phase II Side Channel Reconnection Project*: The Okanagan Nation Alliance (ONA) recently contacted the HCP Tributary Committees requesting feedback on the Okanagan River Restoration Initiative (ORRI) Phase II Side Channel Reconnection Project. The project (implemented in 2013) reconnected a side channel to the mainstem Okanagan River, with the goal of maintaining side channel connectivity at all flows. Monitoring indicates there is a blockage issue, and river flow through the side channel is too low (to provide rearing habitat for native fish) during low flow conditions. ONA asked the HCP Tributary Committees to provide feedback about what can be done to preserve the reconnected channel as a permanent channel. The HCP Tributary Committees believed the channel could remain permanent by: 1) adding another riffle or expanding the existing riffle in the main channel; 2) excavating to design grade; 3) widening the approach channel; and 4) adding a high-flow return to the approach channel.
- *Beaver Fever Project Presentation*: Trout Unlimited and USFWS provided an update on the Beaver Fever: Restoring Ecosystem Function Project. The purpose of the project is to re-establish beavers and install beaver-dam analogs (BDAs) in tributaries of the Wenatchee and/or Entiat river basins. The Rock Island HCP Tributary Committee agreed to fund the installation of BDAs, but not the reintroduction of beavers. The sponsor used the Beaver Restoration Assessment Tool model and conducted site visits to help identify suitable locations for installing BDAs. So far, 10 different drainages have been evaluated, and potential areas have been identified for implementation. Trout Unlimited asked if BDAs should be concentrated within a single watershed or spread across several watersheds, and what information should be collected once the BDAs are installed. Trout Unlimited also asked whether they should explore partnerships with other entities (to help monitor the structures). The HCP Tributary Committees suggested focusing on one watershed (e.g., in Mission, Peshastin, or Roaring creeks). The HCP Tributary Committees would like to know the effects of

BDAs on water temperatures, stream flows, and salmonid abundance. The HCP Tributary Committees also suggested exploring additional relationships. Hillman recalled Jeff Korth discussing results from beaver reintroduction efforts in the Methow River Basin, specifically that there were difficulties getting beavers to colonize, resulting in not being able to collect certain data. Hillman said this is why the HCP Tributary Committees requested specific data to help inform actions in the future.

- *Nason Creek River Mile 4.6 Channel Reconnection Project*: In 2013, the Rock Island HCP Tributary Committee agreed to partially fund this project. The goal of this project is to provide high-flow refugia and rearing habitat for adult and juvenile salmonids in Nason Creek by reconnecting a 4.6-acre, high-flow channel to the mainstem near river mile 4.6. Because Chelan County was unable to secure a cost share, the proposal will be resubmitted. In 2013, the project cost was about $525,000, and the Rock Island HCP Tributary Committee agreed to fund $88,000 at that time. Chelan County met with the U.S. Forest Service (USFS), and USFS is unwilling to approve reconnecting the upper end of the side channel because water will be on both sides of the road, which will increase the likelihood of eroding the road prism. Chelan County spoke with the Washington State Department of Transportation (WSDOT), and WSDOT did not have the same concern; however, USFS indicated support for a downstream-only connection. The Rock Island HCP Tributary Committee said this is now a vastly different project, and requested that Chelan County resubmit a new proposal. The Rock Island HCP Tributary Committee recommended that Chelan County continue seeking approval from USFS to reconnect the upstream end. If USFS approves, funds from the Rock Island Plan Species Account can be used for the upstream connection. Hillman said he believes the sponsor will ask the Bonneville Power Administration to fund the downstream connection; however, Chelan County does not want to push the upstream connection with USFS at this time.
  Casey Baldwin said it seems the Rock Island HCP Tributary Committee put up 15% for the Salmon Recovery Funding Board (SRFB) to match, and he asked why the remainder did not get funded. Hillman explained that higher priority projects received the available SRFB funds in 2013.
- *Silver Side-Channel Rehabilitation Project Presentation*: A couple years ago, the Rocky Reach HCP Tributary Committee approved funding for the design of enhancement work implemented in the lower portion of the Silver Side Channel in the Methow River basin. The purpose of the project is to increase habitat quality and quantity for salmonids within the side channel and floodplain corridor. USFWS provided a lengthy presentation, including before and after photographs of the construction process, evidence of improved channel complexity, improved fish passage, and restored riparian and floodplain habitat, among other things. Hillman said he believes USFWS or WDFW will also conduct fish monitoring in the future. He said the presentation was quite interesting and suggested contacting Robes Parrish (USFWS)

about providing the presentation to the Coordinating Committees. Hillman said he will provide Parrish's presentation to Kristi Geris for distribution to the Coordinating Committees. *(Note: the presentation was posted to the Coordinating Committees HCP Extranet Site [file was too large to email], and the Coordinating Committees were notified by Geris following the meeting on January 24, 2017.)*

- *Meeting Schedule*: The HCP Tributary Committees will continue to meet on the second Thursday of each month.
- *Next Steps*: The next meeting of the HCP Tributary Committees will be on March 9, 2017.

Hillman updated the Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on January 18, 2017:

- *Representative Changes and Distribution Lists*: Casey Baldwin is now the CCT HCP Hatchery Committees Alternate. Brett Farman has been designated the new NMFS HCP Hatchery Committees Representative, and Charlene Hurst has also been designated the new NMFS HCP Hatchery Committees Alternate.
- *DECISION: Twisp Hatchery-origin Steelhead Gametes*: Douglas PUD indicated that WDFW and Cramer Fish Sciences are proposing to conduct a steelhead egg-to-fry survival study in the Twisp River. The purpose of the study is to provide estimates of egg-to-fry survival within the Twisp River to support estimates of survival throughout the range of steelhead spawning, and also to examine survival across different habitat conditions. The proposed approach involves burying 100 fertilized eggs in substrate in 12 different locations within the Twisp River. To conduct the study, WDFW and Cramer Fish Sciences requested fertilized eggs from three female and three male Twisp River hatchery steelhead from the Methow Fish Hatchery. Hillman said the HCP Hatchery Committees approved this request, except for NMFS, who are still discussing the request internally. Hillman noted that this work has already been performed in other places, and the proposed study is just filling a data gap in the Methow River Basin. *(Note: NMFS approved the study proposal via email on January 27, 2017.)*
- *Twisp Steelhead Program Broodstock Issues*: WDFW expressed concern that operation of the Twisp River Steelhead Program may pose long-term genetic risks to the Twisp River steelhead population. Corrective actions discussed could potentially create programmatic issues with regard to Section 10 permitting and may create further genetic issues. WDFW suggested further discussing this topic with the Joint Fisheries Parties and during future HCP Hatchery Committees meetings.
- *Chelan Falls Broodstock Collection Canal Trap Pilot Study Results*: Chelan PUD implemented a pilot study to trap summer Chinook salmon in an effort to determine an easier method for collecting summer broodstock for the Chelan Falls program. The pilot study was conducted in 2016 and was successful in collecting 100 summer Chinook salmon, including 51 males and

49 females. Because the warm water temperatures of the Chelan River have the potential to affect gamete quality of fish collected at the Chelan Falls Canal Trap, Chelan PUD evaluated the potential effects of high water temperature on gamete quality compared to fish collected in other locations. Results indicated that fish collected at the Chelan Falls canal trap had a slightly higher eye-up rate compared to fish collected at the Eastbank Outfall and Entiat National Fish Hatchery (93% compared to 91%). Chelan PUD will repeat the study in 2017.

- *Draft 2017 Rock Island and Rocky Reach HCP Action Plan*: The Rock Island and Rocky Reach HCP Hatchery Committees will review the draft plan, provide comments, and likely approve the hatchery portion during the next HCP Hatchery Committees meeting on February 15, 2017. Douglas PUD will likely present the Draft 2017 Wells HCP Action Plan at that time.
- *Genetic Analysis for HCP Program Species:* The HCP Hatchery Committees continued discussing timing of genetic sampling for all stocks in the Mid-Columbia River Basin. The HCP Hatchery Committees are coordinating with WDFW to determine whether sampling needs to occur every 5 years or some other frequency. The HCP Hatchery Committees are awaiting feedback from a geneticist.
- *Monitoring and Evaluation (M&E) Report Scheduling*: The HCP Hatchery Committees are discussing timing of hatchery M&E reporting. The HCP Hatchery Committees are still proposing completing an annual report, with no changes. However, the HCP Hatchery Committees want to add a statistical report, generated every 5 years, to analyze all data using statistics identified in the Hatchery M&E Plan, which can be used to determine whether the Hatchery M&E Plan needs adjusting. The statistical report will not include recommendations. Recommendations will be included in the comprehensive report, which will be drafted every 10 years. This reporting schedule is consistent with the respective HCPs; it will just align better with other HCP processes and there will be more information developed along the way to help inform HCP actions. The PUDs are preparing an SOA for consideration during the next HCP Hatchery Committees meeting on February 15, 2017. Ferguson asked who will conduct the statistical analyses. Hillman said this was not discussed; however, this task will likely fall under the same groups who draft the reports (i.e., WDFW, BioAnalysts, etc.).
- *Stray Rate Targets*: During the last HCP Hatchery Committees meeting on October 19, 2016, Grant PUD discussed stray rate targets and the possible need to revise the brood year stray rate target. During the January meeting, Grant PUD provided a presentation on stray rate targets for within population, among population, and brood year. The HCP Hatchery Committees do not wish to change the within or among population stray rate targets because they are based on extinction risk and are included in the Recovery Plan. On the other hand, the Hatchery M&E Plan does allow brood year stray rate targets to change if the best available information suggests it is appropriate to do so. The HCP Hatchery Committees

discussed a recently published paper (Ford et al. 2015)[2] showing stray rates in natural-origin spring Chinook salmon in the Wenatchee River basin. The paper indicates that stray rates can range from 1 to 100% depending on what spawning aggregate is considered. Hillman said Grant PUD plans to present a short white paper on brood year stray rates and the Committees will evaluate and determine if the brood year stray rate target needs adjusting. The current brood year stray rate target is 5%.

- *Next Steps*: The next meeting of the HCP Hatchery Committees will be on February 15, 2017.

V. HCP Administration

A. CCT HCP Alternate Representation (John Ferguson)

John Ferguson said a letter requesting Casey Baldwin be designated the CCT Alternate Representative for the HCP Hatchery Committees and Coordinating Committees was distributed to the Coordinating Committees by Kristi Geris on January 6, 2017. Ferguson clarified there is no approval process on designation of representatives; therefore, the letter serves as notification of the designation. *(Note: Baldwin has been added to the appropriate email distribution lists, has been given member access to the HCP Hatchery Committees and Coordinating Committees HCP Extranet Sites, and given visitor access to the HCP Tributary Extranet Site.)*

B. NMFS HCP-HC Representation (John Ferguson)

John Ferguson said a letter designating Brett Farman as the NMFS HCP Hatchery Committees Representative and Charlene Hurst as the NMFS HCP Hatchery Committees Alternate was distributed to the Coordinating Committees by Sarah Montgomery (HCP Hatchery Committees Support Staff) on December 23, 2016. Ferguson said the representation transition does not officially take effect until February 1, 2017. *(Note: Justin Yeager and Craig Busack [current NMFS HCP Hatchery Committees Representative and Alternate, respectively] will be removed from the HCP Hatchery Committees email distribution lists and have HCP Hatchery Committees HCP Extranet Site access deactivated on February 1, 2017.)*

---

[2] Ford, M.J., A. Murdoch, and M. Hughes, 2015. Using parentage analysis to estimate rates of straying and homing in Chinook salmon (*Oncorhynchus tshawytscha*). *Molecular Ecology* 24:1109-1121. Doi: 10.1111/mec.13091

C. Coordinating Committees Email Distribution – Sarah Montgomery (John Ferguson)

John Ferguson said Sarah Montgomery was added to the "final CC agenda only," "draft CC minutes only," and "final CC minutes only" email distribution lists (same as Tracy Hillman), to help with administration and support of the HCPs.

D. Draft 2016 HCP Annual Reports (John Ferguson)

John Ferguson recalled that the HCP annual reports summarize activities performed under each HCP during a given year. He said the Draft 2016 Wells HCP Annual Report will be distributed to the Coordinating Committees by Kristi Geris for a 30-day review by the Coordinating Committees on Wednesday, February 8, 2017. He said the Draft 2016 Rock Island and Rocky Reach HCP Annual Reports will be distributed for a 30-day review by the Coordinating Committees on Thursday, February 16, 2017. *(Note: please coordinate review of the reports with respective HCP Tributary and Hatchery Committees representatives, as needed.)*

Geris sent an email to the Coordinating Committees on February 8, 2017, notifying them the Draft 2016 Wells HCP Annual Report is available for a 30-day review with edits and comments due to Geris by Wednesday, March 8, 2017. Geris sent an email to the Coordinating Committees on February 16, 2017, notifying them the Draft 2016 Rock Island and Rocky Reach HCP Annual Reports are available for a 30-day review with edits and comments due to Geris by Thursday, March 16, 2017.

E. Next Meetings

John Ferguson said, in October 2016, Bob Rose began discussing with Brian Burke (NMFS) about possibly presenting to the Coordinating Committees an update on his "Blob" presentation (last presented to the Coordinating Committees in October 2015). Ferguson recalled the last correspondence suggested providing the presentation to the PRCC and Coordinating Committees in February 2017. Ferguson said he also contacted Michelle Rub about possibly presenting an update on her presentation about pinniped predation in the Columbia River Estuary (last presented to the Coordinating Committees in June 2015). Scott Carlon said Rub is providing a presentation during the PRCC meeting tomorrow, January 25, 2017. Carlon said he believes the presentation is regarding requesting No Net Impact funds to conduct research on trap designs to further study pinniped predation. He said this presentation may be separate from the one Rub last provided to the Coordinating Committees. Ferguson said Burke indicated he is available to present during the Coordinating Committees meeting on February 28, 2017, but Ferguson has not yet received a response from Rub. Ferguson said he will follow-up with Rub regarding possibly presenting during a future meeting.

The February 28, 2017, meeting will be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington. The March 28, 2017, and April 25, 2017, meetings will be held by conference call or in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington, as is yet to be determined.

Subject: Summary CPUD Adult Ladder Fish Rescue Numbers

Results From Rock Island Right Adult Ladder Fish Rescue

Species	Alive	Mortalities
Wild Rainbow Trout/Steelhead	23	0
Hatchery Rainbow Trout/Steelhead	8	0
Northern Pikeminnow	2	0
Wild Summer Chinook Smolt	6	0
Smallmouth Bass	2	0
Sucker	7	0
Adult Lamprey	100	0
Chiselmouth	1	0
Red Sided Shiner	40	0
Three-Spined Stickleback	12	0

Results From Rock Island Center Adult Ladder Fish Rescue

Species	Alive	Mortalities
Wild Rainbow Trout/Steelhead	4	0
Northern Pikeminnow	1	0
Sculpin	1	0

Results From Rock Island Left Adult Ladder Fish Rescue

Species	Alive	Mortalities
Wild Rainbow Trout/Steelhead	11	0
Hatchery Rainbow Trout/Steelhead	2	0

Results From Rocky Reach Adult Ladder Fish Rescue

Species	Alive	Mortalities
Wild Rainbow Trout/Steelhead	24	1
Hatchery Rainbow Trout/Steelhead	49	5

Mountain Whitefish	101	15
Adult Lamprey	169	0
Sucker	2	0
Shiner	2	0
Sculpin	1	0
Sandroller	1	0
Wild Adult Steelhead	1	0
Wild Cutthroat Trout	1	0
Wild Chinook Smolt	1	0
Bull Trout	1	0

Memorandum

TO: Scott Carlon, NOAA National Marine Fisheries Service
FROM: Tom Kahler, Douglas PUD
SUBJECT: Fish Salvage During Annual Maintenance Outage of Wells Dam East Fishway
DATE: December 9, 2016

The Wells Dam east fishway was taken out of service for annual maintenance on the morning of December 7, 2016. At 8:30 AM, we closed the ladder exits, and at 9:30 AM commenced operations to salvage fish remaining in the ladder, and completing those operations shortly after 11:30 AM. We released salvaged fish to the Columbia River above the dam (Wells Project boat launch on the east embankment).

We completed the dewatering of the east fishway by draining the collection gallery on December 8, 2016, commencing fish-salvage operations around 1:50 PM when water depth receded to a level that allowed entry by the salvage crew, and completing those operations around 2:45 PM. We released salvaged fish to the Columbia River above the dam (Wells Project boat launch on the east embankment).

The following tables summarize the fish salvaged from both the ladder and collection gallery.

Actual number of fishes salvaged from the east ladder at Wells Dam on December 7, 2016

Species	Live	Dead
Whitefish	98	0
Chiselmouth	4	0
Oncorhynchus mykiss	13	0
O. tshawytscha (parr)	1	0

Estimated numbers of fish salvaged from the east-fishway collection gallery at Wells Dam on December 8, 2016

Species	Live	Dead
O. mykiss	8	0
O. tshawytscha (parr)	1	0
Northern Pikeminnow	13	0
Sculpin sp	2	1
Whitefish spp	28	0
Sticklebacks	18	2

Memorandum

TO: Scott Carlon, NOAA National Marine Fisheries Service
FROM: Tom Kahler, Douglas PUD
SUBJECT: Fish Salvage During Annual Maintenance Outage of Wells Dam West Fishway
DATE: January 19, 2017

The Wells Dam west fishway was taken out of service for annual maintenance on the morning of January 16, 2017. At 9:00 AM, we closed the ladder exits, and at 10:30 AM commenced operations to salvage fish remaining in the ladder, and completed those operations shortly after 12:00 PM. We released salvaged fish to the Columbia River at the Wells Project boat launch near the Wells Hatchery outfall.

A failed gate motor on the fishway entrance prevented the completion of the dewatering of the collection gallery on January 17 as scheduled, and necessitated the rescheduling of salvage activities for January 19. We completed the dewatering of the west fishway by draining the collection gallery on January 19, 2017, commencing fish-salvage operations around 10:40 AM when water depth receded to a level that allowed entry by the salvage crew, and completed those operations around 11:25 AM. We released salvaged fish to the Columbia River at the Wells Project boat launch near the Wells Hatchery outfall.

The following tables summarize the fish salvaged from both the ladder and collection gallery.

Actual number of fishes salvaged from the west ladder at Wells Dam on January 16, 2017

Species	Live	Dead
Whitefish spp (Mountain and Lake)	43	0
Oncorhynchus mykiss	10	3*
O. tshawytscha (parr)	1	0

*The three mortalities were residual hatchery steelhead

Estimated numbers of fish salvaged from the west-fishway collection gallery at Wells Dam on January 19, 2017

Species	Live	Dead
O. mykiss	12	0
Burbot (with prey fish protruding from mouth)	1	0
Northern Pikeminnow	7	1
Sculpin spp	4	0
Suckers	9	1
Whitefish	20	0
Peamouth Chub	15	0
Sticklebacks	20	1

Burbot (*Lota lota*), with prey, captured in the Wells Dam west-fishway collection gallery on January 19, 2017.

Re: Final Minutes of the February 28, 2017, HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Coordinating Committees met at the Grant PUD Office in Wenatchee, Washington, on Tuesday February 28, 2017, from 10:00 a.m. to 1:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Alene Underwood (Chelan PUD Fish and Wildlife Program Manager) will provide Chelan PUD's comments on the Federal Columbia River Power System (FCRPS) National Environmental Policy Act (NEPA) Scoping Process to Kristi Geris for distribution to the Coordinating Committees (Item I-C).
- Tom Kahler will provide fish passage count data for winter months at Wells Dam for review regarding timing of winter maintenance at Wells Dam to Kristi Geris for distribution to the Coordinating Committees (Item I-C).
- John Ferguson will request from Michelle Rub (National Marine Fisheries Service [NMFS]) an estimation of survival of adult spring/summer Chinook salmon from the Columbia River estuary to Bonneville Dam in 2016 (Item I-C). *(Note: Rub indicated she does not yet have a final estimate for 2016, as distributed to the Coordinating Committees by Kristi Geris on March 13, 2017.)*
- Lance Keller will discuss internally proposals regarding the Rock Island and Rocky Reach Coho Salmon Phase Designation and report back to the Coordinating Committees with a recommended path forward that will be discussed during the meeting on March 28, 2017 (Item III-A).
- Lance Keller will inquire internally about the basis for the fish spill patterns implemented at Rock Island and Rocky Reach dams, as well as how these patterns are evaluated for efficacy (Item III-C).
- Tom Kahler will finalize the 2015 Douglas PUD Pikeminnow Program Annual Report and provide the final report to Kristi Geris for distribution to the Coordinating Committees (Item IV-A). *(Note: Kahler provided the final report to Geris prior to the meeting on March 28, 2017, which Geris distributed to the Coordinating Committees that same day.)*

- **The Coordinating Committees meeting on March 28, 2017, will be held in-person at the Grant PUD office in Wenatchee, Washington (Item V-A).**

Decision Summary

- The Wells HCP Coordinating Committee approved the 2016 Wells HCP Annual Report after no disapprovals were received prior to the 30-day review deadline.

Agreements

- There were no HCP Agreements discussed during today's meeting.

Review Items

- Kristi Geris sent an email to the Coordinating Committees on February 8, 2017, notifying them the Draft 2016 Wells HCP Annual Report is available for a 30-day review with edits and comments due to Geris by Friday, March 10, 2017.
- Kristi Geris sent an email to the Coordinating Committees on February 16, 2017, notifying them the Draft 2016 Rock Island and Rocky Reach HCP Annual Reports are available for a 30-day review with edits and comments due to Geris by Monday, March 20, 2017.
- Kristi Geris sent an email to the Coordinating Committees on February 17, 2017, notifying them the Draft 2016 Rocky Reach Juvenile Fish Bypass System (RRJFBS) Report is available for a 30-day review, with edits and comments due to Lance Keller by Monday, March 20, 2017.
- Kristi Geris sent an email to the Coordinating Committees on February 22, 2017, notifying them the Draft 2017 Rock Island and Rocky Reach Fish Spill Plan is available for a 30-day review with edits and comments due to Lance Keller by Friday, March 24, 2017 (Item III-C).
- Kristi Geris sent an email to the Coordinating Committees on February 23, 2017, notifying them the Draft 2017 Wells HCP Action Plan is available for review. Douglas PUD will request approval of the plan during the Coordinating Committees meeting on March 28, 2017.
- Kristi Geris sent an email to the Coordinating Committees on March 1, 2017, notifying them the Draft Rocky Reach Total Dissolved Gas Alternative Analysis Report is available for review with edits and comments due to Marcie Clement (Chelan PUD) by April 1, 2017.
- Kristi Geris sent an email to the Coordinating Committees on March 3, 2017, notifying them the Draft 2017 Broodstock Collection Protocols are available for an expedited review. Douglas PUD will request approval of the protocols during the Coordinating Committees meeting on March 28, 2017.

Finalized Documents

- Kristi Geris sent an email to the Coordinating Committees on March 24, 2017, notifying them that the 2016 Wells HCP Annual Report was finalized following a 30-day review period, which ended on March 10, 2017. Comments received on the draft report were incorporated into the final report.
- The Final 2015 Douglas PUD Pikeminnow Program Annual Report was distributed to the Coordinating Committees by Kristi Geris on March 28, 2017.

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. Tom Kahler added an update on the 2015 Douglas PUD Pikeminnow Program Annual Report.

B. Meeting Minutes Approval (John Ferguson)

The Coordinating Committees reviewed the revised draft January 24, 2017, meeting minutes. Kristi Geris said a second revised draft was distributed to the Coordinating Committees on February 22, 2017, which included corrections to document and review item dates. Geris said she also added the Draft 2017 Wells HCP Action Plan under the review items, which will be a decision item for Douglas PUD during the Coordinating Committees meeting on March 28, 2017. Geris said all comments and revisions received from members of the Committees were incorporated into the revised minutes. Coordinating Committees members present approved the January 24, 2017, meeting minutes, as revised. The Washington Department of Wildlife (WDFW) abstained, because a WDFW representative was not present during the January 24, 2017, meeting.

C. Last Meeting Action Items (John Ferguson)

Action items from the Coordinating Committees meeting on January 24, 2017, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the meeting on January 24, 2017):*

- *Alene Underwood will provide Chelan PUD's comments on the FCRPS NEPA Scoping Process to Kristi Geris for distribution to the Coordinating Committees (Item II-B).*
  This action item will be carried forward.
- *Lance Keller will revise the draft Statement of Agreement (SOA), "Acknowledgement of Rock Island Powerhouse 1 Units B1-B4 Consultation," as discussed, and will provide the revised draft SOA to Kristi Geris for distribution to the Coordinating Committees (Item II-C).*

The revised draft SOA was distributed following the meeting on January 24, 2017, and was available for a 10-day review with vote via email due to Keller by Friday, February 3, 2017 (the SOA was approved, as reflected in the Coordinating Committees meeting minutes from January 24, 2017).

- *Lance Keller will revise the Draft 2017 Rock Island and Rocky Reach HCP Action Plan, as discussed, and will provide the revised draft plan to Kristi Geris for distribution to the Coordinating Committees (Item II-D).*

  The revised draft plan was distributed following the meeting on January 24, 2017, and is available for review with edits and comments due to Keller by Wednesday, February 22, 2017.
- *Lance Keller will provide fish rescue numbers from the 2016/2017 Rock Island and Rocky Reach dams adult fish ladder maintenance periods to Kristi Geris for distribution to the Coordinating Committees (Item II-E).*

  Keller provided fish rescue numbers to Geris on February 16, 2017, which Geris distributed to the Coordinating Committees on February 17, 2017.
- *Lance Keller will notify the Rocky Reach HCP Coordinating Committee when the Rocky Reach Dam adult fish ladder is brought back online from the 2016/2017 Rocky Reach Dam adult fish ladder maintenance period (Item II-E).*

  Keller provided notification that the Rocky Reach Dam adult fishway was returned to service on February 14, 2017, which was distributed to the Coordinating Committees by Kristi Geris that same day.
- *Tom Kahler will provide fish passage count data for winter months at Wells Dam for review regarding timing of winter maintenance at Wells Dam to Kristi Geris for distribution to the Coordinating Committees (Item III-A).*

  This action item will be carried forward.
- *Tom Kahler will notify the Wells HCP Coordinating Committee when the Wells Dam west fishway is brought back online from the 2016/2017 Wells Dam fishway maintenance period (Item III-A).*

  Kahler provided this notification to Kristi Geris on February 21, 2017, which Geris distributed to the Coordinating Committees that same day.
- *Tracy Hillman (HCP Tributary Committees Chairman) will provide U.S. Fish and Wildlife Service's (USFWS's) presentation on the Silver Side-Channel Rehabilitation Project to Kristi Geris for distribution to the Coordinating Committees (Item IV-A).*

  The presentation was posted to the Coordinating Committees HCP Extranet Site (file was too large to email), and the Coordinating Committees were notified by Geris following the meeting on January 24, 2017.
- *John Ferguson will follow up with Michelle Rub regarding possibly presenting an update on her presentation, "Estimation of Survival and Run Timing of Adult Spring/Summer Chinook from the*

Columbia River Estuary to Bonneville Dam," to the Coordinating Committees during a future meeting (Item V-E).

Ferguson said he contacted Rub and she indicated she recently provided a comprehensive presentation on her work to the Priest Rapids Coordinating Committee (PRCC) and suggested providing another presentation after more data are collected in 2017. Tom Kahler noted that he and Lance Keller did not attend the presentation to the PRCC and would be interested in obtaining the 2016 estimation of survival of adult spring/summer Chinook salmon from the Columbia River estuary to Bonneville Dam. Ferguson said he will request this from Rub. *(Note: Rub indicated she does not yet have a final estimate for 2016, as distributed to the Coordinating Committees by Kristi Geris on March 13, 2017.)*

II. HCP Tributary and Hatchery Committees Update

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman reported that the HCP Tributary Committees did not meet in February 2017 and plan to meet next on March 9, 2017.

Hillman updated the Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on February 15, 2017:

- *DECISION: Draft 2017 Rock Island and Rocky Reach HCP Action Plan*: The HCP Hatchery Committees received the Draft 2017 Rock Island and Rocky Reach HCP Action Plan in January 2017 and in February 2017, the Rock Island and Rocky Reach HCP Hatchery Committees approved the hatchery portion of the plan. The HCP Tributary Committees will review the tributary portion in March 2017. Hillman added that the HCP Tributary Committees will also review the tributary portion of the Draft 2017 Wells HCP Action Plan in March 2017.
- *Egg-to-Fry Survival Study in the Twisp River*: In January 2017, the HCP Hatchery Committees approved the use of surplus Twisp River steelhead for a pilot study on egg-to-fry survival. Douglas PUD in consultation with the lead on the study, Phil Roni (Cramer Fish Sciences), has now decided to switch the focus of the study to spring Chinook salmon (instead of steelhead). Jeff Korth asked what the driver was to change the study. Tom Kahler explained that in the Upper Columbia River basin, spring Chinook salmon are the only endangered species. He said with regard to lifecycle, Douglas PUD has data for spring Chinook salmon at all life stages but egg-to-fry and fry-to-parr. He said, therefore, obtaining a complete dataset for spring Chinook salmon is more urgent than for steelhead.
- *USFWS Bull Trout Consultation Update*: USFWS is in the process of finalizing the draft Biological Opinion covering hatchery programs in the Wenatchee basin. However, the process is on hold because Chelan PUD and WDFW have not yet provided comments.

- *NMFS Consultation Update*: NMFS has signed the permits for Methow spring Chinook salmon, which will then be sent to the permittees for signature. Kahler said Douglas PUD received and signed the permits. Korth said WDFW received the permits, which are now in Olympia, Washington, for signature. Hillman said comments were also received on the Colville Confederated Tribes (CCT) Tribal Resources Management Plan (TRMP). Casey Baldwin said the CCT received the comments and are incorporating some edits into the TRMP. He said the CCT are expecting authorization within days.
- *Draft 2017 Broodstock Collection Protocols:* Typically, in February of each year, WDFW provides draft broodstock collection protocols to the HCP Hatchery Committees for review and approval (per the SOA, *Annual Broodstock Collection Protocols*, approved by the HCP Hatchery and Coordinating Committees on September 17 and October 28, 2014, respectively). This year, however, WDFW did not yet have the spring Chinook salmon forecast and could not finish the draft protocols for review during the month of February. WDFW has the forecast now, and the protocols will be provided to the HCP Hatchery Committees before the HCP Hatchery Committees meeting on March 13, 2017. The protocols will also require review and approval by the Wells HCP Coordinating Committee.
- *Spring Chinook Salmon Outplanting in the Chewuch River*: The HCP Hatchery Committees developed a draft plan for outplanting surplus MetComp fish in the Chewuch River, with the goal of determining whether these fish stay in the Chewuch River. The fish will be planted at two locations, including near the Chewuch campground (upstream from the uppermost Chewuch River passive integrated transponder [PIT] array), and then downstream by the Memorial Bridge (upstream from the lower Chewuch River PIT array). The fish will be monitored for movement and will be evaluated for potential spawning success (female carcasses will be examined for egg retention). A final plan is expected to be approved during the HCP Hatchery Committees meeting on March 13, 2017.
- *Hatchery Monitoring and Evaluation Report Scheduling*: The HCP Hatchery Committees have been discussing the timing of hatchery monitoring and evaluation (M&E) reporting in the future (including annual reporting), creating an updated 5-year statistical report (to replace the 5-year report currently specified in the Hatchery M&E Plan), and continuing the 10-year program review report. The HCP Hatchery Committees discussed including more statistics in the annual report to help inform development of the Hatchery M&E Plan, and then the 5-year statistical report can be more about comparing supplemented and un-supplemented populations. The HCP Hatchery Committees also discussed synchronizing the 5-year statistical report with the 10-year program review report. Currently, the 5-year statistical report is scheduled to be completed in 2018, and the 10-year program review report is scheduled for 2020 (2-year gap). The HCP Hatchery Committees decided to align the two reports to avoid the need of developing additional statistical analyses. A final reporting schedule is expected to

be approved during the HCP Hatchery Committees meeting on March 13, 2017. Kahler asked if a 5-year statistical report and 10-year program review report will be prepared when the deadlines align. Hillman said the 10-year program review report includes the information in the 5-year statistical report; therefore, only the 10-year program review report will be written in overlapping years.

- *Expanded Sampling at the Off-ladder Fish Trap*: The HCP Hatchery Committees discussed a proposal by WDFW to expand sampling at the off-ladder fish trap (OLAFT) with the purpose of increasing monitoring to include evaluation of spring Chinook salmon. The proposal includes PIT-tagging spring Chinook salmon and operating the OLAFT earlier (instead of trapping from July to mid-November, start trapping in mid-April through November). This schedule captures the spring Chinook salmon run-at-large, which improves estimates of abundance and escapement, and informs proportion of hatchery-origin spawners and proportionate natural influence. WDFW wants to verify the HCP Hatchery Committees support for this proposal before moving forward. If approved, this plan may result in less trapping at Tumwater and Wells dams. The HCP Hatchery Committees requested WDFW prepare a white paper outlining the proposal. Kahler asked when WDFW would like to implement this plan, and Korth said this spring 2017. Hillman added that the 2017 Broodstock Collection Protocols were drafted to include flexibly in case the plan with the OLAFT is approved.
- *Stray Rate Targets*: Todd Pearsons (Grant PUD) provided a presentation on stray rates to the HCP Hatchery Committees in January 2017, and the HCP Hatchery Committees requested Pearson provide a white paper. The HCP Hatchery Committees reviewed and discussed the white paper; however, the Committees were unable to reach resolution on stray rate targets. Three stray rate targets were discussed. Two targets are related to the recipient stock, which are linked to extinction risk and are included in the Recovery Plan; therefore, the HCP Hatchery Committees will not change those. The other target stipulates a 5% brood-year stray rate (i.e., among the brood year released, 95% need to return to the natal stream). There seems to be no scientific justification for the 5% value. The Hatchery M&E Plan indicates if empirical data suggest a different stray rate, then the target can be re-evaluated. Ford et al. (2015)[1] addressed this and indicated that stray rates can range from 1 to 100% depending on what spawning aggregate is considered. The HCP Hatchery Committees are now considering setting a management goal for a brood-year stray rate.

[1] Ford, M.J., A. Murdoch, and M. Hughes, 2015. Using parentage analysis to estimate rates of straying and homing in Chinook salmon (*Oncorhynchus tshawytscha*). *Molecular Ecology* 24:1109-1121. Doi: 10.1111/mec.13091.

- *Next Steps*: The next meeting of the HCP Hatchery Committees will be on Monday, March 13, 2017.

III.Chelan PUD

A. DECISION: Rock Island and Rocky Reach Coho Salmon Phase Designation (Lance Keller, Steve Hemstrom, and Catherine Willard)

Lance Keller said the draft SOA, "Designation of Rock Island and Rocky Reach Juvenile Coho in Phase III (Standard Achieved)," (Attachment B), and the report by John Skalski (Skalski Statistical Services) and Rich Townsend (Columbia Basin Research), "Comparison of Juvenile Survival of Chinook Salmon, Sockeye Salmon, Steelhead, and Coho Salmon through the Chelan PUD Projects, 2010–2016," (Attachment C), were distributed to the Coordinating Committees by Kristi Geris on February 15, 2017. Keller said Skalski's and Townsend's report (Attachment C) summarizes those data included in the draft SOA (Attachment B). Keller said the draft SOA background section reviews the history of previous SOAs and summarizes a comparison of data illustrating that juvenile spring Chinook and coho salmon survive similarly through the hydrosystem, which translates into a ratio that is applied to Rock Island and Rocky Reach juvenile spring Chinook salmon survival rates to generate values for juvenile coho salmon. He said the last page of the draft SOA includes the math of the conversion (or adjustment) for the Rock Island and Rocky Reach Projects. He read the draft SOA agreement statement and noted the last sentence is key; the data presented indicate yearling Chinook salmon are a good surrogate for juvenile coho salmon, resulting in 93% survival for coho salmon at Rock Island and Rocky Reach projects.

John Ferguson said projected coho salmon survival through the Rocky Reach Project was calculated to be 92.94% with a standard error of 0.0081, and the Rock Island Project was calculated to be 93.98% with a standard error of 0.0233. Keller said that is correct. Jeff Korth asked if 93% is the standard, and Keller said yes, it is. Keller told Korth (who was unable to attend the last meeting), that during the last Coordinating Committees meeting on January 24, 2017, Steve Hemstrom thoroughly explained the analyses included in the draft SOA. Keller said these analyses are similar to the Grant PUD data, i.e., same approach and utilizing PIT-tag data. Korth asked how this designation aligns with the next 10-year check-in. Keller said this would put coho salmon on the same track as the other Plan species, with a check-in for the Rock Island HCP in 2020 and for the Rocky Reach HCP in 2021.

Bob Rose said the Yakama Nation (YN) are uncomfortable with the way the draft SOA is stated. Casey Baldwin said after Hemstrom's presentation last month, the CCT are comfortable with the draft SOA. Jim Craig said USFWS is also comfortable with the draft SOA. He added that this SOA has been discussed for several months now. Ferguson agreed with Craig, noting the several iterations of reports Skalski and Townsend updated.

Keller said approving this SOA in the Coordinating Committees allows Chelan PUD to move forward with developing a hatchery compensation plan with the HCP Hatchery Committees, given the 93% value. Rose said he understands the application of this SOA with regard to moving forward with developing a hatchery compensation plan. He said he believes the data included in the SOA can still be used for that purpose; however, using these data for re-designation is the issue. He said 92.94% is not 93%. He said the way the SOA is stated sets an element of permanency. Ferguson said he is not certain phase designation can be separated from the hatchery compensation process. Keller said Chelan PUD understands that mean coho salmon survival at the Rocky Reach Project is below 93% by 0.06%; however, the mean at the Rock Island Project is almost a full percentage point above 93%. He recalled that the SOA, "Regarding District's Coho Obligation" (approved by the Rock Island and Rocky Reach HCP Coordinating Committees on June 26, 2007), states:

> "Juvenile coho [salmon] survival studies will not be performed unless there is compelling[2] information that demonstrates hydro project operations have an impact of greater than 7% mortality on coho [salmon]."

Keller said Chelan PUD believes these data can be used to provide comfort that this is not the case. He said compelling evidence is not leaning toward a large effect on juvenile coho salmon. Ferguson also noted there are multiple years of data behind these values. Korth said he typically does not view the mean to be the most important factor; rather, he becomes concerned when the standard errors are out of bounds. Ferguson agreed.

Rose said he believes the Coordinating Committees can disassociate the phase designation aspect of this SOA from what the HCP Hatchery Committees need to move forward with developing a hatchery compensation plan. He added that he does not want to hold up the HCP Hatchery Committees; however, the YN wants to further discuss the phase designation. Ferguson asked what this changes. Keller said he views the designation, Phase III (Standard Achieved), as tied to the 93% value. He said, if the Coordinating Committees provide the HCP Hatchery Committees with 92.94% survival for juvenile coho salmon, this is not really Phase III (Standard Achieved). He said, however, using the

---

[2] "Compelling" evidence could relate to information collected as part of the hatchery monitoring and evaluation program. For example, smolt-to-adult survivals for coho [salmon] that are significantly lower than other species in the same geographical area may be compelling evidence that coho [salmon] are experiencing differential mortality rates at project passage. In all cases, the evidence should be empirical and related to Project survival.

values from the analysis and considering the standard errors better demonstrates how 93% survival for coho salmon at Rock Island and Rocky Reach projects is reasonable. He added that the analyses show how close to 93% the Rocky Reach Project is, and there is room to spare in the Rock Island Project.

Rose said Keller is making a fundamental assumption that survival through the Rock Island and Rocky Reach projects can be combined. Rose said with the way the HCPs are written, he does not believe Chelan PUD has the ability to do this. Keller asked if Rose is suggesting separate SOAs for each Project. Rose said he is noting that the Rocky Reach and Rock Island projects are different Projects, and it seems Chelan PUD is proposing a relationship similar to the Grant PUD Priest Rapids and Wanapum projects, under the Grant PUD Salmon and Steelhead Settlement Agreement. Keller said Chelan PUD understands Rock Island and Rocky Reach are two different HCPs, and the reason Chelan PUD is proposing one SOA is consistent with the 2007 SOA. Keller said he understands Rose's point, and Keller said his intention is simply to look at the picture as a whole. Rose said he is struggling with that notion, and setting these precedents is bothersome.

Baldwin asked about the downside of continuing in Phase III (Standard Achieved – Interim Value) for juvenile coho salmon for the Rocky Reach Project. Keller said the goal of the Rocky Reach HCP is to achieve Phase III (Standard Achieved). He said Chelan PUD would like to use Skalski's and Townsend's analyses to show the goal has been achieved. He said data were reviewed for the natural juvenile coho salmon run through the Juvenile Bypass System at the Rocky Reach Project, and most likely, a study would not be feasible due to low sample size. He said Skalski's and Townsend's analyses are the best-available data for moving forward. He said achieving Phase III (Standard Achieved) would align coho salmon with the other Plan species with regard to the 10-year check-in.

Rose said there is a difference between best-available data and sufficient data. He said just because these are the data in-hand, does not mean it is enough. Ferguson said Chelan PUD is just saying this is a good dataset. He said 93% at both Projects falls well within the confidence intervals. He reiterated that it is not the mean that counts, it is how tight the dataset is. He said, in this case, the dataset is awfully tight.

Hemstrom said Chelan PUD would approach coho salmon in the same manner as the other Plan species if there was the ability to; however, there is not. He said the Projects could be split into two SOAs; however, the data would be the same as presented in the single SOA. He said Chelan PUD strives to meet the goals established in the HCPs and is attempting to do so with the data that are available. He asked Rose if he had suggestions about what to do alternatively.

Rose said he is interested in being explicit to the HCPs. He said, in this case, there probably should be two SOAs, which is more appropriate with regard to the separate HCPs. He said Section 5.2.2 of the Rocky Reach HCP states:

> "If Juvenile Project Survival for each Plan Species is measured to be greater than or equal to 93%, then the District will proceed to Phase III (Standard Achieved)."

Rose said the HCP does not say 92%, plus or minus some value. He said he wants to avoid setting this precedence, which could turn into a slippery slope. He said there is no clear rationale to do something different than what was agreed to in the HCPs. Korth said he understands Rose's point; however, he noted that this circumstance is not nearly as egregious as what has occurred in other committees. Ferguson noted that the HCP also does not specify mean, average, or otherwise, and he would hope that the HCP Coordinating Committees would not be affected by the actions of other committees. He said 93% could be an absolute level or fall within the 95% confidence interval. He said the Coordinating Committees could interpret this in several ways. Baldwin added that the HCP could be interpreted as both the mean and standard error need to be above 93%, which may never be achieved. He said he is not proposing this; however, if the HCP does not say 'mean,' it could be interpreted this way. Ferguson said, if Chelan PUD writes an SOA that states the Rock Island Project meets the standard, but the Rocky Reach Project does not, given the data, it seems the error is larger around 93.98%, which means there is more uncertainty around the Rock Island Project than the Rocky Reach Project. Rose said this is the problem; twisting the language around. He said he disagrees with these interpretations. He said, if these details were intended when writing the HCPs, they would have been written this way. He said he does not believe the Coordinating Committees have this leeway to go with these interpretations.

Rose said the YN are not yet ready to vote on this draft SOA. He suggested instead, two SOAs, providing the HCP Hatchery Committees with 92.94% to move forward with hatchery compensation planning and continuing to discuss coho salmon phase designation for the Rocky Reach Project during the Coordinating Committees meeting on March 28, 2017. Ferguson asked if the proposed Rock Island Project SOA would indicate Phase III (Standard Achieved), and Rose said this is correct. Rose added, he is only uncomfortable with the proposed Phase III (Standard Achieved) designation for the Rocky Reach Project. Keller questioned if Chelan PUD writes two different SOAs, should the Rock Island Project SOA indicate 93.98% instead of only 93%. Craig asked if this would reduce the coho salmon compensation for that Project, and Keller said yes, it would. Keller also questioned, if discussions are coming down to these numbers (small percentages), should Chelan PUD include the numbers from Skalski's and Townsend's report.

Scott Carlon said he is comfortable with Chelan PUD producing two SOAs. Rose asked Carlon what he thinks about only one SOA. Carlon replied that two SOAs is the cleanest approach for purposes of explaining this in layman terms.

Korth said, next year, 2017 data can be added and the analyses can be recalculated. Keller questioned then, what the duration of the Rocky Reach Project SOA would be. He said Chelan PUD is essentially building a hatchery compensation program based on the SOA and its duration. He asked if the analyses are recalculated, is the hatchery compensation only good for 1 year. Korth asked what does the HCP state regarding adding other data. Tom Kahler said the Wells HCP stipulates anytime a survival study is conducted, that value is included in a multi-year-average value and hatchery compensation is based on that new value for subsequent brood years. Keller said he believes the Rocky Reach and Rock Island HCPs stipulate the same.

Keller said one option would be to draft a 10-year SOA using the interim value stated in the 2007 SOA, and have the HCP Hatchery Committees develop a hatchery program based on that value. Ferguson said this option would avoid a hatchery compensation that fluctuates up and down. Keller agreed, noting that a fluctuating compensation would affect a lot of moving parts, including planning and permitting.

Ferguson asked how much work is involved to operate under an annual number if mitigation for the Rocky Reach Project is adjusted each year with new PIT-tag data. Catherine Willard (Chelan PUD HCP Hatchery Committees Alternate Representative) said this is something that would be applied to future years. She said whatever is determined for 2017 would be applied to brood year 2019. She said there is no way to adapt the program that quickly. She said, in terms of percentages, 93% versus 93.98%, converted to number of smolts, for mitigation the difference is not very large. Korth added that the hatchery permits incorporate a level of flexibility that would accommodate the types of adjustments being discussed.

Hemstrom said the Rock Island and Rocky Reach projects have operated under the 2007 SOA, which assumed 93% survival and compensated 7% for coho salmon for both Projects. He said if Chelan PUD drafts two separate SOAs, with Rock Island establishing Phase III (Standard Achieved) and Rocky Reach not quite at 93%, he asked if compensation would continue at 7% for the Rocky Reach Project. Willard said this is correct. Ferguson asked about the duration of the SOA for the Rocky Reach Project. Korth suggested assigning an appropriate duration that avoids an annual check-in. Ferguson suggested drafting a 5-year SOA. He added that if Chelan PUD continues recalculating the data each year and the Rocky Reach Project achieves 93% survival for coho salmon, Chelan PUD can draft a new SOA. Rose said he does not recall the Coordinating Committees ever discussing this topic in the past because there was no need to. He said, however, he is also uncomfortable with the notion of just considering the average each year, and when the average finally reaches 93%, this is considered acceptable. He suggested instead establishing a block of time. He said he does not believe phase designation should be considered on an annual basis. Korth asked Rose what block of time would he be comfortable with. Rose said 5 years may be sufficient. He also suggested aligning the SOA with the next check-in for the Rocky Reach Project (2021).

Keller said because this draft SOA has evolved into something completely different, he will want to discuss internally the proposals regarding the Rock Island and Rocky Reach Coho Salmon Phase Designation and report back to the Coordinating Committees with a recommended path forward that will be discussed during the meeting on March 28, 2017.

Ferguson recalled the driver behind finalizing these decisions is that the hatchery compensation for the Rock Island and Rocky Reach projects is expiring soon, and Keller said this is correct.

Hemstrom noted there was a lot of discussion about what dataset to use. He said, initially, Skalski was not planning to use all the years included in the final analysis. Hemstrom said Chelan PUD asked Skalski to use them all in order to achieve the best-possible dataset. He questioned what data to use now. He asked if the analyses should continue to incorporate all years to represent multiple hydrosystem passage years. He said whatever is decided will make a difference in the results. He said Skalski initially suggested using only 2 years of data in which acoustic tag survival studies occurred (2010 and 2011). Hemstrom said had Chelan PUD agreed to this, the standards would have been met for both Projects a while ago. He said, however, Chelan PUD wanted to take a closer look and use all the available information. Baldwin said this is important to know. He said the more years added to the analyses, the more certainty. He said this brings up another point. He said although there are tight standard errors on the acoustic data, the standard errors are not as tight for PIT-tag estimates. He said the data appear tight; however, in reality, there is more uncertainty with PIT-tag data. He said he appreciates Chelan PUD using the full dataset.

B. Rock Island and Rocky Reach Adult Ladder Maintenance Update (Lance Keller)

Lance Keller said the right bank adult fishway at Rock Island Dam was returned to service on February 2, 2017, and the adult fishway at Rocky Reach Dam was watered up and back in operation on February 14, 2017, which was distributed to the Coordinating Committees by Kristi Geris that same day. He said, as of February 27, 2017, the left bank adult fishway at Rock Island Dam was back in operation. He summarized that all fishways at Rock Island and Rocky Reach dams are now operational.

C. Draft 2017 Fish Spill Plan (Lance Keller)

Lance Keller said Kristi Geris sent an email to the Coordinating Committees on February 22, 2017, notifying them the Draft 2017 Rock Island and Rocky Reach Fish Spill Plan is available for a 30-day review with edits and comments due to Keller by Friday, March 24, 2017.

Keller said he received a question from Bob Rose regarding the shape of spill at the Projects and how these came to be. Rose said he also does not recall if monitoring is conducted to verify the spill shapes are still relevant. Keller said he spoke with Steve Hemstrom who said the spill shapes are based on historical hydroacoustic data and there is no real method available for doublechecking those data, outside of conducting another hydroacoustic study.

Keller said, at Rock Island Dam, a diel shape is implemented for summer and spring spill, as outlined in the fish spill plan. He said, at Rocky Reach Dam, summer spill shifts from a 9% spill during the first hour, to 6%, back to 9%, then to 12%, and back to 9% (daily shape), and, in total, spill averages out to be 9%. He said the volume spilled varies based on the flow estimate for each day, and the shape is applied to that (also outlined in the fish spill plan).

Rose asked if the spill pattern is germane throughout the course of a season, or from 1 year to the next. He asked if there is a way to monitor that the best spill pattern is being implemented for smolts. He said the fish spill plan states:

> Spill-shaping attempts to optimize spill water volume to maximize spill passage effectiveness for smolts.

Rose asked how to verify this is occurring. Keller said he will ask Thad Mosey (Chelan PUD Fish Biologist and Spill Coordinator) about the basis for the fish spill patterns implemented at Rock Island and Rocky Reach dams, as well as how these patterns are evaluated for efficacy.

D. Chelan PUD Documents for Review (Lance Keller)

Lance Keller said Kristi Geris sent an email to the Coordinating Committees on January 23, 2017, notifying them the Draft 2016 Rock Island Smolt Monitoring Program and Gas Bubble Trauma Report was available for a 30-day review, with edits and comments due to Keller by Wednesday, February 22, 2017. Geris also sent an email to the Coordinating Committees on February 17, 2017, notifying them the Draft 2016 RRJFBS Report is available for a 30-day review, with edits and comments due to Keller by Monday, March 20, 2017.

Keller said USFWS provided comments on the Draft 2016 Rock Island Smolt Monitoring Program and Gas Bubble Trauma Report on February 14, 2017, and on the Draft 2016 RRJFBS Report on February 21, 2017, as distributed to the Coordinating Committees those same days. Keller said some comments were regarding number discrepancies, which he explained was due to version-control issues. He said another comment was regarding the 53% mortality rate documented for juvenile salmonids on April 1, 2016, at Rock Island Dam. He explained that the new RO4 gate was set open too far, which resulted in a number of deaths due to impingement at the traveling water screens. He also noted that the mortalities on April 1, 2016, accounted for 20% of the observed mortalities for the year. He said the gate was adjusted that same day, and fishway attendants now regularly monitor the settings on the gate to avoid the same issue in the future. Keller said USFWS also provided comments regarding differences in species compositions at both dams, which Keller explained is due to different sampling methodologies (active sampling versus 24 hour gatewell collections). Keller said analyses conducted by Scott Hopkins (Chelan PUD) also indicate that in 2015 at the Rocky Reach Juvenile Sampling Facility there were zero collections under 1 minute, whereas, in 2016, there were 24 collections under 1 minute. He said if there were not so many sockeye salmon causing short index collections, other species may have been collected. He said, during spring 2015, there were also more sample minutes. He said, lastly, the Rock Island Dam gatewell collection system has an unknown collection efficiency, versus collection efficiency being very good at Rocky Reach Dam, confirmed by acoustic survival studies.

Keller said the CCT also provided comments on both draft reports on February 15, 2017, as distributed to the Coordinating Committees that same day. Keller said, in the Draft 2016 RRJFBS Report, there was confusion about condition sampling. He said as formerly written, it appeared only the first 100 fish were sampled for condition; however, the language was revised to clarify that condition sampling was performed on all fish sampled.

IV. Douglas PUD

A. 2015 Douglas PUD Pikeminnow Program Annual Report (Tom Kahler)

Tom Kahler said Kristi Geris sent an email to the Coordinating Committees on December 15, 2016, notifying them the Draft 2015 Douglas PUD Pikeminnow Program Annual Report is available for a 60-day review period, with edits and comments due to Kahler by Monday, February 13, 2017. Kahler said comments were received from USFWS, which will be incorporated into the final draft. Kahler said he will have the 2015 Douglas PUD Pikeminnow Program Annual Report finalized and provide the final report to Geris for distribution to the Coordinating Committees.

V. HCP Administration

A. Next Meetings

The next scheduled Coordinating Committees meeting is on March 28, 2017, to be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington.

The April 25 and May 23, 2017, meetings will be held by conference call or in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington, as is yet to be determined.

VI. NMFS

A. PRESENTATION: The "Blob" (Brian Burke)

Brian Burke (NMFS) shared a presentation titled, "Recent Oceanographic and Biological Observations" (Attachment D), which was distributed to the Coordinating Committees by Kristi Geris on March 1, 2017. This presentation is an update on Burke's "Blob" presentation, which was presented to the Coordinating Committees in October 2015.

This presentation provided an overview of recent oceanographic and biological observations including, supporting field sampling and data sources, large-scale oceanographic patterns (the "Blob" and El Niño), the resulting ecology, and models. NMFS scientists annually collect migration data for juvenile salmon. The data indicate that outmigration timing for juvenile salmon affects survival. In 2016, yearling Chinook, sockeye, and coho salmon, and steelhead outmigrated earlier than typical, which can affect adult return rates. Also, in recent years, the abundance of sea lions below Bonneville Dam and in the lower Columbia River is also peaking earlier, which can affect predation levels on spring migrating adults returning to the Columbia River, and especially the early migrating stocks from the Upper Columbia River and Snake River. In 2013, a warming of sea surface temperatures in the offshore northern Pacific Ocean, or the "Blob," was observed. The primary driver of the "Blob" is related to a ridge of high pressure forming, which happens periodically; however, what typically occurs is nowhere near the magnitude that was recently experienced. This is because of the simultaneous occurrence of warm water in the Gulf of Alaska and along the coast (the "Blob") and warm water coming up onto the shelf from the south as a result of an El Niño event. Certain biological responses to this warming are becoming evident, such as the sudden radical shift in jellyfish and copepod species composition and total krill abundance along the offshore eastern Pacific Ocean. In 2015 and 2016, shifts in ichthyoplankton composition were also observed. Anchovies and sardines were found in the northern transect more than usual, which was also an indication that they spawned earlier. The basin-scale and regional physical indices and regional biological indices suggest mostly poor conditions for salmon occurred in 2015 and 2016. Although data suggest bad conditions for salmon, these new food sources (sardines and anchovies) may be helpful. Overall, Burke indicated modeling based on the biological and physical metrics sampled suggests there will be a substantial decrease in spring and fall Chinook salmon returns to the Columbia River in 2017.

DRAFT

Rocky Reach and Rock Island Habitat Conservation Plans Coordinating Committees

Statement of Agreement

Designation of Rock Island and Rocky Reach Juvenile Coho in Phase III (Standard Achieved)

(February 28, 2017)

Agreement Statement

The Rock Island and Rocky Reach HCP Coordinating Committees (CC) have reviewed PIT-tag based estimates of juvenile coho passage survival compared with PIT-tag based yearling spring Chinook passage survival in the Columbia River hydropower system, prepared by J. Skalski and R. Townsend (2017). The CC agrees that comparison of PIT-tag based juvenile coho survival and yearling spring Chinook survival using juveniles released in the Methow sub-basin upstream of the Rocky Reach Project over seven consecutive migration years (2010-2016) demonstrates that juvenile coho survive hydropower system passage similar to yearling spring Chinook. Because juvenile coho and yearling spring Chinook passage survival is comparably similar, and because Chelan PUD has measured direct passage survival of yearling spring Chinook through Rocky Reach ($\hat{S}$ = 92.72) and Rock Island ($\hat{S}$ = 93.75) in HCP acoustic tag survival studies, the CC also agrees that juvenile coho survival can be estimated using Chelan PUD's yearling Chinook acoustic tag survival estimates and coho PIT-tag based survival estimates. Yearling spring Chinook are in Phase III (Standard Achieved) at both Rock Island and Rocky Reach. The CC acknowledges that based on the estimated juvenile coho survival of 93.98% at Rock Island and 92.94% at Rocky Reach (Skalski and Townsend 2017), the CC agrees to move juvenile coho at both Projects from Phase III Standard Achieved Interim-Value to designation of Phase III Standard Achieved, with 93% survival at both Projects.

Background

The Rocky Reach and Rock Island HCP Coordinating Committees reviewed and approved an SOA on June 26, 2007 and agreed that (1) an interim coho juvenile survival value of 93% would be assumed and (2) juvenile coho survival studies would not be performed unless there was compelling information that demonstrated hydro project operations were having an impact greater than seven percent mortality on coho. As approved, juvenile coho were designated as Phase III (Standard Achieved – Interim Value) for the Rocky Reach and Rock Island Projects.

Comparison of Juvenile Coho and Yearling Spring Chinook PIT-tag Survival Estimates Through the Mid-Columbia

PIT-tag based estimates of survival for hatchery released juvenile coho and hatchery released yearling spring Chinook through the Mid-Columbia can be used to evaluate how juvenile coho survive relative to yearling spring Chinook. Skalski and Townsend (2017) analyzed PIT-tagged juvenile coho and PIT-tagged yearling spring Chinook released from Winthrop National Fish Hatchery, Methow Hatchery and all Methow Sub-basin acclimation sites to estimate juvenile passage survival from Rocky Reach tailrace to McNary tailrace, and survival from McNary to John Day tailrace, 2010 through 2016 (Table 1) .

Table 1. Cormack-Jolly-Seber PIT tag survival estimates of juvenile coho salmon and yearling spring Chinook salmon from Rocky Reach (RRH) to McNary (MCN) and McNary to John Day (JD) for pooled releases from the Winthrop National Fish Hatchery, Methow Hatchery, and Methow sub-basin final acclimation sites.

Year	Release Sizes Coho/Chinook	PIT Survival Coho/Chinook RRH to MCN	$\hat{S}$ SE Coho/Chinook	PIT Survival Coho/Chinook MCN to JD	$\hat{S}$ SE Coho/Chinook
2010	11,859 / 25,806	88.15% / 76.17%	(0.0915)/ (0.0421)	96.73%/ 100.1%	(0.1570)/ (0.1228)
2011	20,873 / 28,117	66.55% / 62.65%	(0.0411)/ (0.0314)	120.3%/ 97.11%	(0.1778)/ (0.1022)
2012	17,891 / 29,569	67.78% / 72.07%	(0.0362)/ (0.0336)	84.39%/ 78.38%	(0.0742)/ (0.0549)
2013	23,851 / 35,498	83.34%/ 82.15%	(0.0547)/ (0.0423)	83.26%/ 91.25%	(0.0931)/ (0.0916)
2014	23,489 / 22,475	72.60%/ 75.39%	(0.0436)/ (0.0565)	87.25%/ 93.0%	(0.0822)/ (0.1255)
2015	24,233 / 31,913	75.18%/ 71.08%	(0.0863)/ (0.0422)	91.69%/ 80.44%	(0.2036)/ (0.0837)
2016	17,885 / 31,884	67.73% / 76.09%	(0.0223)/ (0.0252)	98.66%/79.70%	(0.0828)/ (0.0502)

(Source: Skalski and Townsend 2017)

The PIT-tag survival estimates for juvenile coho and yearling spring Chinook were generated for fish migrating in the same river reaches in the same years, Rocky Reach to McNary and McNary to John Day, 2010 to 2016 (Skalski and Townsend 2017). Comparison of Rocky Reach to McNary reach survival estimates suggest juvenile coho salmon and yearling spring Chinook have the most comparable survivals with a survival ratio near 1.0000. In six of seven years of comparison, reach survival ratios for juvenile coho to yearling spring Chinook were not significantly different between the two species and the seven year weighted mean reach survival ratio was not significantly different (weighted mean=0.9549; SE=0.0307; P=0.1921) (Table 2).

Table 2. Ratios of multiple-project (hydro system) reach survivals for the above Rocky Reach release groups of juvenile coho and yearling spring Chinook salmon, (2010–2016). Numbers in bold indicate survival ratios that are significantly different from 1 ($P < 0.05$).

Species Ratio	Year	Rocky Reach to McNary	P (≠ 1)	McNary to John Day	P (≠ 1)
Coho/Spr Chinook	2010	1.1573 (0.1361)	0.2478	0.9602 (0.1949)	0.8382
	2011	1.0623 (0.0845)	0.4612	1.2392 (0.2248)	0.2873
	2012	0.9405 (0.0667)	0.3720	1.0767 (0.1210)	0.5264
	2013	1.0145 (0.0846)	0.8641	0.9124 (0.1371)	0.5231
	2014	0.9630 (0.0925)	0.6890	0.9382 (0.1544)	0.6888
	2015	1.0577 (0.1367)	0.6730	1.1399 (0.2795)	0.6168
	2016	0.8901 (0.0416)	**0.0082**	1.2379 (0.1299)	0.0670

<u>Projection of Coho Salmon Project Survival Using Acoustic Tag/PIT Tag Survival Estimates</u>

A ratio estimator was used to project coho salmon acoustic-tag passage survival based on PIT-tag data on juvenile coho salmon, and PIT-tag and acoustic-tag data on yearling Chinook salmon. Using PIT-tag releases, reach survivals from Rocky Reach tailrace (detections in the Rocky Reach bypass) to McNary tailrace were estimated for coho and spring Chinook salmon for the years 2010–2016 (Table 1). In addition, acoustic-tag investigations were performed on spring Chinook salmon at Rocky Reach (i.e., 2010, 2011) and Rock Island (i.e., 2007, 2008, and 2010) as part of the HCPs' survival compliance testing. Assuming the PIT-tag studies and acoustic-tag studies are each reliably estimating the same quantities, ratios of reach survivals for juvenile coho and yearling Chinook salmon should be the same whether they were estimated using acoustic or PIT tags.

Table 3: PIT-tag reach survival estimates from Rocky Reach tailrace to McNary tailrace $\left(\hat{S}_{\mathrm{RR-MCN}}^{\mathrm{PIT}}\right)$, ¼-root survival $\left(\hat{S}^{1/4}\right)$, and coho-to-Chinook-salmon survival ratios through the four Mid-Columbia projects $\left(\hat{R}\right)$. Standard error in parentheses.

	$\hat{S}_{\mathrm{RR-MCN}}^{\mathrm{PIT}}$		$\hat{S}^{1/4}$		
Year	Coho	Chinook	Coho	Chinook	$\hat{\bar{R}}_{\mathrm{Coho/Chin}}^{\mathrm{PIT}}$
2010	0.8815	0.7615	0.9690	0.9342	1.037
2011	0.6655	0.6265	0.9032	0.8897	1.015
2012	0.6778	0.7207	0.9074	0.9214	0.985
2013	0.8334	0.8215	0.9554	0.9520	1.004
2014	0.7260	0.7539	0.9231	0.9318	0.991
2015	0.7518	0.7108	0.9312	0.9182	1.014
2016	0.6773	0.7609	0.9072	0.9340	0.971
				Average	**1.0024** (0.0084)

(Source: Skalski and Townsend 2017)

The value of $\hat{\hat{R}}$ = **1.0024** in Table 3 above was used to project average direct-measured yearling Chinook salmon acoustic tag passage survival at the Rocky Reach Project of $\hat{S}_{\mathrm{Chin}_{\mathrm{ACO}}}$ = 0.9272 into a coho salmon project passage survival estimate, where

$$\begin{aligned}\hat{S}_{\mathrm{Coho}_{\mathrm{ACO}}} &= \hat{\hat{R}}^{\mathrm{PIT}}_{\mathrm{Coho/Chin}} \cdot \hat{\hat{S}}_{\mathrm{Chin}_{\mathrm{ACO}}} \\ &= 1.0024(0.9272) \\ &= \mathbf{0.9294}\ \left(\widehat{\mathrm{SE}} = 0.0081\right).\end{aligned}$$

The same coho-to-Chinook-salmon survival ratio of $\hat{\hat{R}}$ = **1.0024** was used to project average direct-measured yearling acoustic tag passage survival at the Rock Island Project of $\hat{S}_{\mathrm{Chin}_{\mathrm{ACO}}}$ = 0.9375 into a coho salmon project passage survival estimate, where

$$\hat{S}_{\mathrm{Coho}_{\mathrm{ACO}}} = \hat{\hat{R}}^{\mathrm{PIT}}_{\mathrm{Coho/Chin}} \cdot \hat{\hat{S}}_{\mathrm{Chin}_{\mathrm{ACO}}}$$

$$= 1.0024(0.9375)$$

$$= \mathbf{0.9398}\ \left(\widehat{\mathrm{SE}} = 0.0233\right).$$

1.0 Introduction

Juvenile coho salmon survival has not been directly estimated through Rocky Reach and Rock Island projects. However, there are PIT-tag estimates of survival through the Mid-Columbia that can be used to evaluate how coho salmon survivals would rank against that of spring Chinook salmon, steelhead, and sockeye salmon, and whether any of these other species could be used as a surrogate for coho salmon. As such, PIT-tag releases from Winthrop and Methow fish hatcheries and Osoyoos Lake were used to estimate smolt survival from Rock Reach tailrace to McNary tailrace, 2010 to 2016. The year 2010 marked the year when the new PIT-tag detection system went into operation at Rocky Reach Dam.

In addition, a ratio estimator was developed for coho salmon based on a combination of PIT-tag and acoustic-tag data to estimate project passage survival at either Rocky Reach or Rock Island dams. The ratio estimator was available from 2010–2011 when concurrent PIT-tag and acoustic-tag releases were occurring as part of the survival compliance trials at the two projects. The ratio estimator was used to project coho salmon survival on a per-project basis at the two sites.

2.0 Comparison of PIT-tag Survival Estimates through the Mid-Columbia

2.1 Methods

Two sets of PIT-tag survival analyses were performed. The first set was based on coho salmon, spring Chinook salmon, and steelhead hatchery releases above Rocky Reach Dam from the Winthrop and Methow hatcheries, and sockeye salmon releases from Osoyoos Lake. For these four release groups, survival was estimated from Rocky Reach tailrace to McNary tailrace and from McNary tailrace to John Day tailrace. The second set was based on PIT-tag releases from Rock Island Dam of coho, sockeye, spring Chinook salmon, and steelhead. Release sizes were an order of magnitude smaller in this second set of survival analyses. Smolt survival was estimated from Rock Island tailrace to McNary tailrace, and from McNary tailrace to John Day tailrace in the second set of analyses.

2.2 Results

2.2.1 Winthrop, Methow, and Osoyoos Releases

Reach survival estimates from Rocky Reach tailrace to McNary tailrace are summarized in Table 1, associated detection probabilities in Table 2, and harmonic mean travel times in Table 3. Comparison of Rocky Reach to McNary reach survival estimates suggests coho salmon and spring Chinook salmon had the most comparable values (Table 4) with a mean ratio of 0.95 ($\widehat{\text{SE}}$ = 0.03). In 6 of 7 years of comparison, reach survival was not significantly different between the two species. Survival between both coho and spring Chinook salmon were also comparable within the McNary tailrace to the John Day tailrace reach with a mean ratio of 1.06 ($\widehat{\text{SE}}$ = 0.05) (Table 4). The survival of spring Chinook and coho salmon was not significantly correlated between Rocky Reach and McNary tailraces (r = 0.61, P = 0.14) nor between McNary and John Day tailraces (r = 0.39, P = 0.38) (Table 5). The survival of steelhead and coho salmon was not significantly correlated between Rocky Reach and McNary tailraces (r = 0.41, P = 0.36), but was between McNary and John Day tailraces (r = 0.80, P = 0.03) (Table 5).

2.2.2 Rock Island Dam Releases

Reach survival estimates from Rock Island tailrace to McNary tailrace are summarized in Table 6, associated detection probabilities in Table 7, and harmonic mean travel times in Table 8. None of the comparisons between coho salmon and the other salmonids were significantly different for the years 2013–2016, with the exception of the McNary to John Day reach in 2016 (Table 9), in which coho had a dramatically lower estimated survival rate than historically observed. The small sample sizes and large standard errors contributed to the lack of significant differences. Survival estimates between coho and the other salmonids were generally uncorrelated (Table 10), again because of small sample sizes and large standard errors. The exception was the correlation in survival of spring Chinook and coho salmon between the McNary and John Day tailraces (r = 0.95, P = 0.0520).

Table 1: Cormack–Jolly–Seber (CJS) survival estimates for pooled releases of coho salmon, spring Chinook salmon, and steelhead from Winthrop and Methow hatcheries (2010–2016) and sockeye salmon releases in Osoyoos Lake (2013–2016).

Release Year and Species	Release Size	Probability of Survival: Rocky Reach to McNary	Probability of Survival: McNary to John Day

3.0 Comparison of Acoustic-tag and PIT-tag Project Survival Estimates

During the three years, 2002-2004, head-to-head comparisons of project passage survival at Rock Island Dam were performed using yearling Chinook salmon. Fish source, handling and release procedures were all comparable to permit direct comparison of project survival using the two tagging methods.

In two of the three years, acoustic-tag and PIT-tag survival estimates for yearling Chinook salmon were within 0.01 of each other. The third year, the difference was 0.028 (Table 11). In no year were the two estimates of project passage survival significantly different ($P > 0.10$). The 3-year average for acoustic-tag studies was $\hat{\bar{S}} = 0.9442$, and for PIT-tag studies, $\hat{\bar{\ }} = 0.9344$ (Table 11). These studies strongly suggest PIT-tag and acoustic-tag studies are estimating comparable values.

Table 11: Comparison of acoustic-tag and PIT-tag paired-release estimates of Rock Island project passage survival for yearling Chinook salmon, 2002-2004. Sample sizes are the combined upstream and downstream (i.e., $R_1 + R_2$) releases in the paired-release design. Statistical error in parentheses.

	Pit-tag		Acoustic-tag	
Year	$R_1 + R_2$	$\hat{S}$	$R_1 + R_2$	$\hat{S}$
2002	90,002	0.9555 (0.0249)	798	0.9520 (0.0263)
2003	103,730	0.9339 (0.0115)	999	0.9387 (0.0157)
2004	99,999	0.9139 (0.0227)	1,001	0.9419 (0.0118)
Average		0.9344		0.9442

4.0 Projection of Coho Salmon Acoustic-tag Estimates of Project Survival

A ratio estimator was used to project coho salmon acoustic-tag project passage survival based on PIT-tag data on coho salmon and PIT-tag and acoustic-tag data on Chinook salmon. Using PIT-tag releases, reach survivals from Rocky Reach tailrace to McNary tailrace were estimated for coho and spring Chinook salmon for the years 2010–2016 (see Section 2.0). In addition, acoustic-tag investigations were performed on spring Chinook salmon at Rocky Reach (i.e., 2010, 2011) and Rock Island (i.e., 2007, 2008, 2010) as part of the survival compliance testing. Assuming the PIT-tag and acoustic-tag studies are each reliably estimating the same quantities, ratios of reach survivals for coho and Chinook salmon should be the same whether they were estimated using acoustic or PIT tags. Hence, the identity of the form

$$\frac{\left(\hat{S}_{\mathrm{Coho}_{\mathrm{PIT}}}\right)^{\frac{1}{4}}}{\left(\hat{S}_{\mathrm{Chin}_{\mathrm{PIT}}}\right)^{\frac{1}{4}}} = \frac{\hat{S}_{\mathrm{Coho}_{\mathrm{ACO}}}}{\hat{S}_{\mathrm{Chin}_{\mathrm{ACO}}}}$$

suggests a ratio estimator

$$\hat{S}_{\mathrm{Coho}_{\mathrm{ACO}}} = \frac{\left(\hat{S}_{\mathrm{Coho}_{\mathrm{PIT}}}\right)^{\frac{1}{4}}}{\left(\hat{S}_{\mathrm{Chin}_{\mathrm{PIT}}}\right)^{\frac{1}{4}}} \cdot \hat{S}_{\mathrm{Chin}_{\mathrm{ACO}}},$$

or more simply,

$$\hat{S}_{\mathrm{Coho}_{\mathrm{ACO}}} = \hat{R}^{\mathrm{PIT}}_{\mathrm{Coho/Chin}} \cdot \hat{S}_{\mathrm{Chin}_{\mathrm{ACO}}}, \tag{1}$$

and where

$\hat{S}_{\mathrm{Coho}_{\mathrm{PIT}}}$ = estimated survival from Rocky Reach tailrace to McNary tailrace using PIT-tag data for coho salmon,

$\hat{S}_{\mathrm{Chin}_{\mathrm{PIT}}}$ = estimated survival from Rocky Reach tailrace to McNary tailrace using PIT-tag data for Chinook salmon,

$\hat{S}_{\mathrm{Chin}_{\mathrm{ACO}}}$ = estimated project survival (either Rocky Reach or Rock Island) using acoustic-tag data for Chinook salmon,

$\hat{R}^{\mathrm{PIT}}_{\mathrm{Coho/Chin}}$ = ratio of coho to Chinook salmon project passage survival based on PIT-tag data.

The 0.25-root of the PIT-tag estimate of survival from Rocky Reach tailrace to McNary tailrace (i.e., four projects) was used to express PIT-tag survival on a per-project basis consistent with the acoustic-tag estimates of survival. The ratio $\hat{R}^{\mathrm{PIT}}_{\mathrm{Coho/Chin}}$ estimates the relative survival of coho compared to Chinook salmon smolts through a Mid-Columbia River project.

The variance of $\hat{S}_{\mathrm{Coho}_{\mathrm{ACO}}}$ was estimated by

$$\begin{aligned}\widehat{\mathrm{Var}}\left(\hat{S}_{\mathrm{Coho}_{\mathrm{ACO}}}\right) = {} & \widehat{\mathrm{Var}}\left(\hat{\hat{R}}^{\mathrm{PIT}}_{\mathrm{Coho/Chin}}\right)\hat{\hat{S}}^{2}_{\mathrm{Chin}_{\mathrm{ACO}}} \\ & +\widehat{\mathrm{Var}}\left(\hat{\hat{S}}_{\mathrm{Chin}_{\mathrm{ACO}}}\right)\left(\hat{\hat{R}}^{\mathrm{PIT}}_{\mathrm{Coho/Chin}}\right)^{2} \\ & -\widehat{\mathrm{Var}}\left(\hat{\hat{R}}^{\mathrm{PIT}}_{\mathrm{Coho/Chin}}\right)\cdot\widehat{\mathrm{Var}}\left(\hat{\hat{S}}_{\mathrm{Chin}_{\mathrm{ACO}}}\right),\end{aligned}$$

based on Goodman (1960). The variance estimates for $\hat{\hat{R}}$ and $\hat{\hat{S}}$ were based on the empirical variance for sample means.

In order to use the maximum amount of tag information available, the average coho-to-Chinook-salmon survival ratio $\hat{\hat{R}}^{\text{PIT}}_{\text{Coho/Chin}}$ was calculated over the years 2010–2016 (Note: 2010 was the first year the PIT-tag detector was operational at the Rocky Reach juvenile bypass). The average ratio over the seven-year period was $\hat{\hat{R}}$ = 1.0024 ($\widehat{\text{SE}}$ = 0.0084) (Table 12). An R-value of 1.0024 suggests coho salmon survival is ever so slightly higher than Chinook salmon through a Mid-Columbia project. The value of $\hat{\hat{R}}$ = 1.0024 was then used to calibrate average observed Chinook salmon project passage survival at the Rocky Reach Project (Table 13) of $\hat{S}_{\text{Chin}_{\text{ACO}}}$ = 0.9272 into coho salmon project passage survival, where

$$\hat{S} \qquad \hat{\hat{R}} \quad {}_{\text{o/Chin}} \; \hat{\hat{S}}$$

$$0024(0\ 9272)$$

$$\left(\widehat{\text{SE}} \qquad 0081\right).$$

Hence, Rocky Reach project passage survival for coho salmon is projected to be 0.9294 ($\widehat{\text{SE}}$ = 0.0081).

Similarly, the average estimate of Chinook salmon project passage survival for the three years of acoustic-tag study—2007, 2008, and 2010—at Rock Island was $\hat{S}_{\text{Chin}_{\text{ACO}}}$ = 0.9375 ($\widehat{\text{SE}}$ = 0219)(Table 13). Using the same coho-to-Chinook-salmon survival ratio (i.e., 1.0024), the coho salmon project passage survival at Rock Island was projected to be

$$\hat{S} \qquad \hat{\hat{R}} \quad {}_{\text{o/Chin}} \; \hat{\hat{S}}$$

$$4(0\ 9375)$$

$$\left(\widehat{\text{SE}} \qquad 0233\right).$$

Consequently, Rock Island project passage survival for coho salmon is projected to be 0.9398 ($\widehat{\text{SE}}$ = 0.0233).

Table 12: PIT-tag reach survival estimates from Rocky Reach tailrace to McNary tailrace $(\hat{S}\quad)$, ¼-root survival $(\hat{S}^{1/4})$, and coho-to-Chinook-salmon survival ratios through Mid-Columbia projects $(\hat{R})$. Standard error in parentheses.

Average	0.9272 (0.0022)	0.9375 (0.0219)

5.0 Discussion

Given the small sample sizes of the Rock Island Dam releases, comparison between coho and other salmonids is best performed using the upstream releases above Rocky Reach Dam. Spring Chinook appear to be most comparable to coho salmon, with a strong positive correlation and a survival ratio near 1 between Rocky Reach and McNary tailraces and between McNary and John Day tailraces (Tables 4 and 5). From these perspectives, one might expect coho salmon survival through the Mid-Columbia hydroprojects to be similar to that seen for spring Chinook salmon.

Using that positive correlation between coho and spring Chinook salmon PIT-tag survival estimates, a ratio estimator (1) was used to produce project-specific estimates of coho salmon survival at Rocky Reach or Rock Island Dam. Projected coho salmon survival through the Rocky Reach Project was calculated to be $\hat{S}$ = 0.9294 ($\widehat{\mathrm{SE}}$ = 0.0081). For Rock Island, coho salmon project passage survival was estimated to be $\hat{S}$ = 0.9398 ($\widehat{\mathrm{SE}}$ = 0.0233).

Appendix A

The appendix lists tag files used in the above Rocky Reach analysis. The criteria used in the selection of release groups were: releases in the general area above Rkm 843.080 during the April to May period; consisted primarily of Winthrop or Methow stock or raised by Winthrop or Methow hatcheries; and had an individual release size, or could be reasonably pooled into a group (i.e., a close succession of smaller releases at the same site), that was greater than 500 fish. Sockeye salmon were released in Osoyoos Lake (OSOYOL) or at Osoyoos Lake Narrows Hwy 3 Bridge (OSOYBR).

Rock Island virtual releases were based on yearly pooled releases of spring Chinook salmon, and sockeye salmon, or steelhead tagged at the Rock Island bypass trap, or coho salmon detected as a recapture at Rock Island Dam.

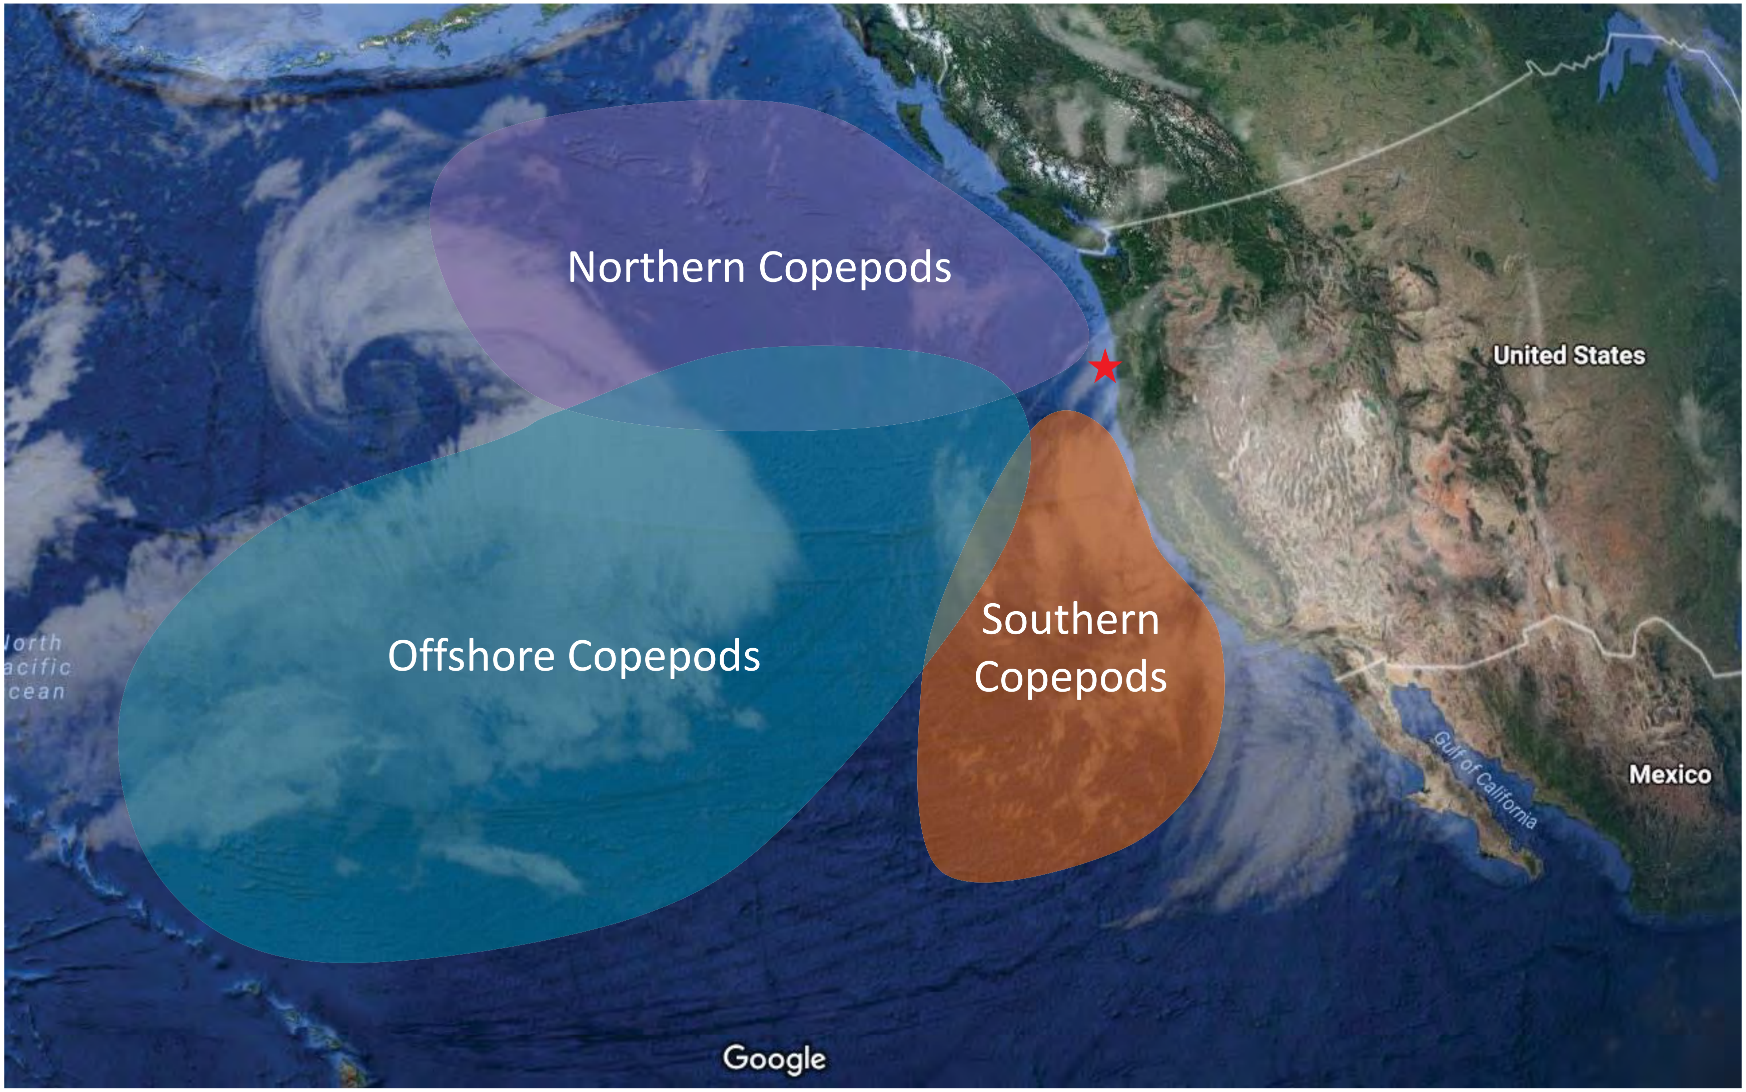
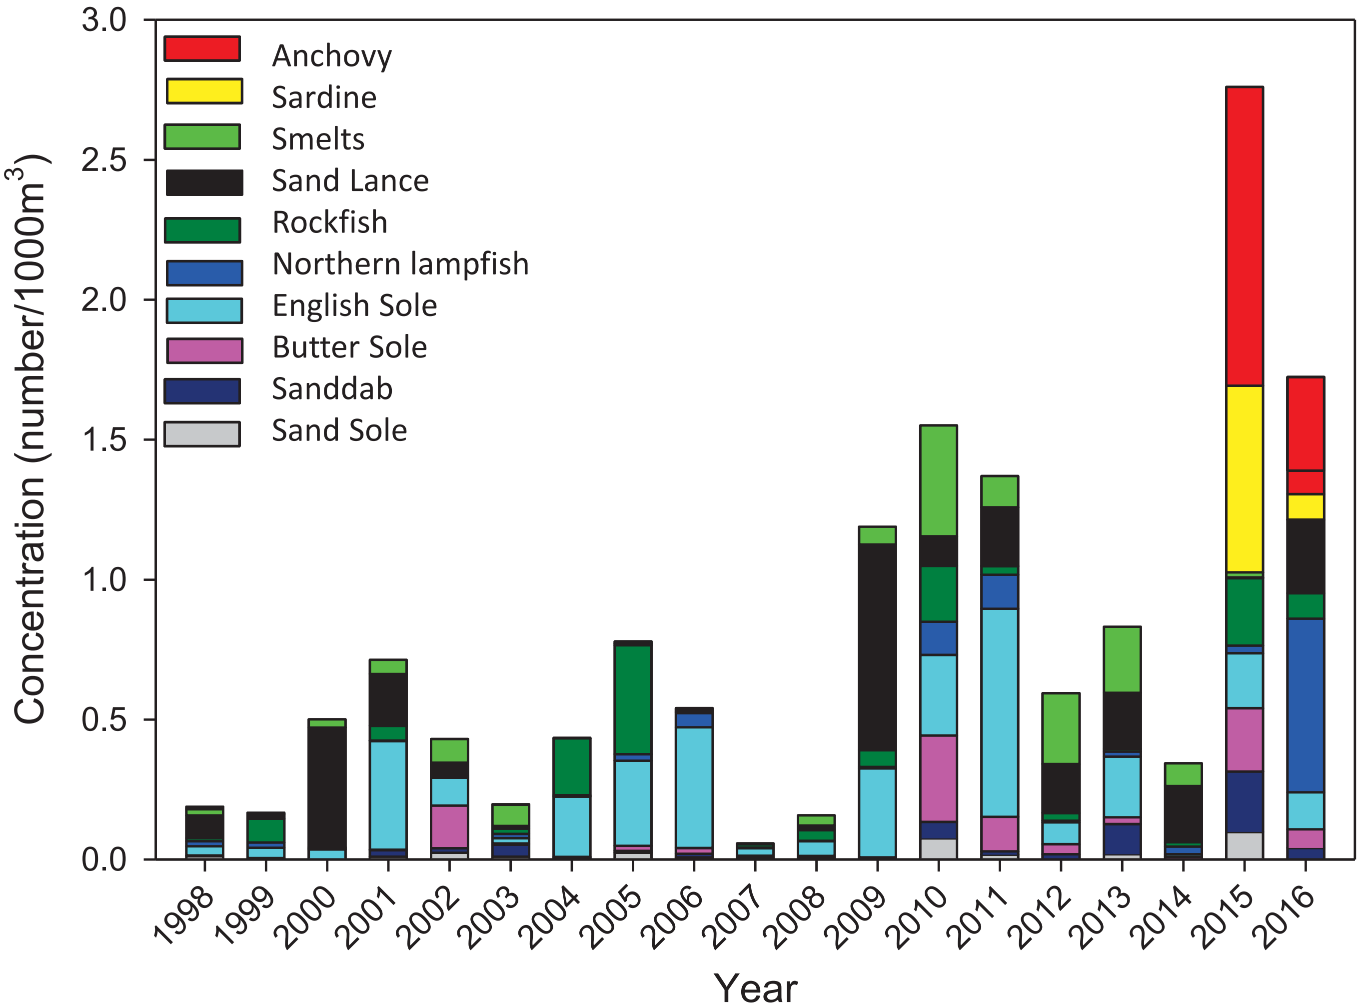
Copepod Species Indicate Source Waters for Transport



Winter (Jan – March) Ichthyoplankton



- Earliest (by three months) and most widespread spawning of anchovies and sardines in NCC
- Also found Pacific hake and jack mackerel eggs and larvae off Newport
- Both years had a diversity of larvae represented in the winter samples

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: May 15, 2017

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Revised Minutes of the March 28, 2017, HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met at the Grant PUD Office in Wenatchee, Washington, on Tuesday March 28, 2017, from 10:00 a.m. to 12:40 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Alene Underwood (Chelan PUD Fish and Wildlife Program Manager) will provide Chelan PUD's comments on the Federal Columbia River Power System (FCRPS) National Environmental Policy Act (NEPA) Scoping Process to Kristi Geris for distribution to the HCP Coordinating Committees (Item I-C). *(Note: Underwood provided these comments to Geris following the meeting on March 28, 2017, which Geris distributed to the HCP Coordinating Committees on March 29, 2017.)*
- Tom Kahler will provide fish passage count data for winter months at Wells Dam for review regarding timing of winter maintenance at Wells Dam to Kristi Geris for distribution to the HCP Coordinating Committees (Item I-C).
- John Ferguson will coordinate with Tracy Hillman (HCP Hatchery Committees Chairman) to obtain HCP Hatchery Committees and Wells HCP Coordinating Committee approval of the 2017 Broodstock Collection Protocols prior to the April 15, 2017 deadline to the National Marine Fisheries Service (NMFS; Item II-A). *(Note: Ferguson discussed the timeline with Hillman following the meeting on March 28, 2017, who coordinated with the HCP Hatchery Committees to deliver the protocols by approximately April 7, 2017.)*
- Douglas PUD will provide the Draft 2016 Douglas PUD Pikeminnow Removal Program Annual Report for review to Kristi Geris for distribution to the HCP Coordinating Committees (Item III-A). *(Note: Tom Kahler provided the draft report for review to Geris following the meeting on March 28, 2017, which Geris distributed to the HCP Coordinating Committees on March 29, 2017.)*
- Douglas PUD will provide an electronic copy of the 2017 Trapping Activities at Wells Dam Gantt Chart to Kristi Geris for distribution to the HCP Coordinating Committees (Item III-E). *(Note: Tom Kahler provided the chart to Geris following the meeting on March 28, 2017, which Geris distributed to the HCP Coordinating Committees on March 29, 2017.)*

- Chelan PUD will complete edits to the Revised Draft Rock Island and Rocky Reach Coho Phase Designation Statement of Agreement (SOA), as discussed, and will provide a final SOA to Kristi Geris for distribution to the HCP Coordinating Committees (Item IV-A). *(Note: Lance Keller provided the final SOA to Geris on March 29, 2017, which Geris distributed to the HCP Coordinating Committees that same day.)*
- Anchor QEA, LLC, will communicate to Washington Department of Fish and Wildlife (WDFW) what discussions took place during today's HCP Coordinating Committees meeting regarding the Revised Draft Rock Island and Rocky Reach Coho Phase Designation SOA, and will request that WDFW submit a vote via email by close of business Thursday, March 30, 2017 (Item IV-A). *(Note: Kristi Geris coordinated with WDFW, as discussed, and WDFW submitted their approval of the SOA on March 30, 2017.)*
- Anchor QEA will notify the HCP Hatchery Committees that the HCP Coordinating Committees approved the Rock Island and Rocky Reach Coho Phase Designation SOA, so the HCP Hatchery Committees may move forward with hatchery compensation planning (Item IV-A). *(Note: Kristi Geris notified Sarah Montgomery [HCP Hatchery Committees Support Staff] about the approval, as discussed, on March 30, 2017.)*
- Chelan PUD will incorporate gate sequence details into the 2017 Rock Island and Rocky Reach Fish Spill Plan and will provide the final plan to Kristi Geris for distribution to the HCP Coordinating Committees (Item IV-B).
- The Yakama Nation (YN) will provide the report, "Translocation of Adult Pacific Lamprey within the Wenatchee Subbasin (2015-2016 Broodstock)," to Kristi Geris for distribution to the HCP Coordinating Committees (Item IV-C). *(Note: Bob Rose provided the report to Geris during the meeting on March 28, 2017, which Geris distributed to the HCP Coordinating Committees on March 29, 2017.)*
- Kristi Geris will add Catherine Willard (Chelan PUD HCP Hatchery Committees Alternate) to the HCP Coordinating Committees email distribution list, as approved by the HCP Coordinating Committees (Item IV-F). *(Note: Geris added Willard to the list on March 29, 2017.)*
- Chelan PUD will provide the Revised Draft 2017 Rock Island and Rocky Reach HCP Action Plan for vote via email to Kristi Geris for distribution to the HCP Coordinating Committees (Item IV-G). *(Note: Lance Keller provided the revised plan to Geris on March 29, 2017, which Geris distributed to the HCP Coordinating Committees on March 30, 2017.)*
- Chelan PUD will address comments received on the Draft 2016 Rock Island and Rocky Reach HCP Annual Reports and will provide the revised reports to Kristi Geris for final production (Item VI-H). *(Note: Lance Keller provided the revised reports to Geris on March 29, 2017.)*
- Chelan PUD will provide the Final 2016 Rocky Reach Juvenile Fish Bypass System Report to Kristi Geris for distribution to the HCP Coordinating Committees (Item IV-I).

- **The HCP Coordinating Committees meeting on April 25, 2017, will be held in-person at the Grant PUD office in Wenatchee, Washington (Item V-A).**

Decision Summary

- The Wells HCP Coordinating Committee representatives present approved the 2017 Wells HCP Action Plan (Item III-C). *(Note: Carmen Andonaegui provided the Washington Department of Fish and Wildlife's [WDFW's] approval of the plan via email prior to the meeting on March 28, 2017.)*
- The Rock Island and Rocky Reach HCP Coordinating Committees representatives present approved the Rock Island and Rocky Reach Coho Phase Designation SOA, as revised (Item IV-A). *(Note: Carmen Andonaegui provided WDFW's approval of the SOA via email on March 30, 2017.)*
- The HCP Coordinating Committees representatives present approved adding Catherine Willard to the HCP Coordinating Committees email distribution list (Item IV-F).
- The Rock Island and Rocky Reach HCP Coordinating Committees representatives approved the 2017 Rock Island and Rocky Reach HCP Action Plan, as revised, via email as follows: Chelan PUD and U.S. Fish and Wildlife Service (USFWS) approved on March 30, 2017; NMFS approved on April 4, 2017; and WDFW, the Colville Confederated Tribes (CCT) and the YN approved on April 5, 2017 (Item IV-G).
- The Wells HCP Coordinating Committee approved the 2017 Broodstock Collection Protocols, as revised, via email as follows: Douglas PUD approved on April 10, 2017; and NMFS, USFWS, WDFW, the CCT, and the YN approved on April 11, 2017.

Agreements

- The HCP Coordinating Committees representatives present agreed to vote via email on the Revised Draft 2017 Rock Island and Rocky Reach HCP Action Plan (Item IV-G).
- HCP Coordinating Committees representatives agreed via email to add Alf Haukenes (WDFW Hatchery/Wildlife Interactions Unit leader) to select HCP Hatchery Committees email distribution lists, per a request by Mike Tonseth (WDFW HCP Hatchery Committees Representative), as follows: WDFW, Douglas PUD, NMFS, and USFWS approved on April 17, 2017; Chelan PUD and the YN approved on April 18, 2017; and the CCT approved on April 19, 2017.

Review Items

- Kristi Geris sent an email to the HCP Coordinating Committees on March 1, 2017, notifying them the Draft Rocky Reach Total Dissolved Gas Alternative Analysis Report is available for review with edits and comments due to Marcie Clement (Chelan PUD) by Friday, March 31, 2017 (Item IV-D).

- Kristi Geris sent an email to the HCP Coordinating Committees on March 29, 2017, notifying them the Draft 2016 Douglas PUD Pikeminnow Removal Program Annual Report is available for a 60-day review period, with edits and comments due to Tom Kahler by Monday, May 29, 2017 (Item III-A).
- Kristi Geris sent an email to the HCP Coordinating Committees on March 30, 2017, notifying them the Revised Draft 2017 Rock Island and Rocky Reach HCP Action Plan is available for review with votes via email due to Lance Keller (with Geris copied) by Wednesday, April 5, 2017 (Item IV-G). *(Note: votes were submitted, and the plan was approved as described under the Decision Summary.)*
- Kristi Geris sent an email to the HCP Coordinating Committees on April 17, 2017, notifying them a Wells Project Land-use Permit Application (Small Block LLC) was available for a 60-day review period, with edits and comments due to Tom Kahler by Friday, June 16, 2017.
- Kristi Geris sent an email to the HCP Coordinating Committees on April 27, 2017, notifying them a Wells Project Land-use Permit Application (City of Pateros) was available for a 60-day review period, with edits and comments due to Tom Kahler by Monday, June 26, 2017.

Finalized Documents

- The Final 2017 Wells HCP Action Plan was distributed to the HCP Coordinating Committees by Kristi Geris on March 29, 2017 (Item III-C).
- The Final 2016 Rock Island and Rocky Reach HCP Annual Reports were distributed to the HCP Coordinating Committees by Kristi Geris on April 6, 2017 (Item IV-H).

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. The following revisions were requested:

- Lance Keller added: 1) Draft Rocky Reach Total Dissolved Gas Alternative Analysis Report; 2) Rocky Reach Juvenile Fish Bypass System (RRJFBS) marked fish release; 3) request to add Catherine Willard to the HCP Coordinating Committees email distribution list; 4) Draft 2017 Rock Island and Rocky Reach HCP Action Plan; 5) Draft 2016 Rock Island and Rocky Reach HCP Annual Reports; and 6) Draft 2016 Rocky Reach Juvenile Fish Bypass System Report.
- Tom Kahler removed the 2017 Broodstock Collection Protocols, and added: 1) Draft 2016 Douglas PUD Pikeminnow Removal Program Annual Report; and 2) Twisp Pond update.

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft February 28, 2017, meeting minutes. Kristi Geris said she added under the Decision Summary that the Wells HCP Coordinating Committee approved the 2016 Wells HCP Annual Report after no disapprovals were received prior to the 30-day review period deadline. She said she also noted distribution of the Final 2016 Wells HCP Annual Report and Final 2015 Douglas PUD Pikeminnow Program Annual Report under the Finalized Documents. She said all comments and revisions received from members of the Committees were incorporated into the revised minutes. HCP Coordinating Committees members present approved the February 28, 2017, meeting minutes, as revised.

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on February 28, 2017, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the meeting on February 28, 2017):*

- *Alene Underwood (Chelan PUD Fish and Wildlife Program Manager) will provide Chelan PUD's comments on the FCRPS NEPA Scoping Process to Kristi Geris for distribution to the HCP Coordinating Committees (Item I-C).*
  This action item will be carried forward.
- *Tom Kahler will provide fish passage count data for winter months at Wells Dam for review regarding timing of winter maintenance at Wells Dam to Kristi Geris for distribution to the HCP Coordinating Committees (Item I-C).*
  This action item will be carried forward.
- *John Ferguson will request from Michelle Rub (National Marine Fisheries Service [NMFS]) an estimation of survival of adult spring/summer Chinook salmon from the Columbia River estuary to Bonneville Dam in 2016 (Item I-C).*
  Rub indicated via email she does not yet have a final estimate for 2016, as distributed to the HCP Coordinating Committees by Kristi Geris on March 13, 2017.
- *Lance Keller will discuss internally proposals regarding the Rock Island and Rocky Reach Coho Salmon Phase Designation and report back to the HCP Coordinating Committees with a recommended path forward that will be discussed during the meeting on March 28, 2017 (Item III-A).*
  This will be discussed during today's meeting.
- *Lance Keller will inquire internally about the basis for the fish spill patterns implemented at Rock Island and Rocky Reach dams, as well as how these patterns are evaluated for efficacy (Item III-C).*
  This will be discussed during today's meeting.

- *Tom Kahler will finalize the 2015 Douglas PUD Pikeminnow Program Annual Report and provide the final report to Kristi Geris for distribution to the HCP Coordinating Committees (Item IV-A).*
  Kahler provided the final report to Geris prior to the meeting on March 28, 2017, which Geris distributed to the HCP Coordinating Committees that same day.

II. HCP Tributary and Hatchery Committees Update

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Tributary Committees meeting on March 9, 2017:

- *Methow Valley Irrigation District Instream Flow Improvement Project*: Trout Unlimited submitted a time extension request on the Methow Valley Irrigation District (MVID) Instream Flow Improvement Project, requesting to extend the period of their contracts from March to November 2017. The HCP Tributary Committees approved this request.
- *Entiat Stillwaters Gray Reach Acquisition*: The Chelan-Douglas Land Trust (CDLT) submitted a time extension and amendment request on the Entiat Stillwaters Gray Reach Acquisition Project, requesting to extend the period of the contract and to use part of the remaining balance of this project to help cover expenses associated with lot sales and the purchase of additional properties, which were not part of the original proposal. Because the amendment represented a significant departure in the scope of the original project, the Rocky Reach HCP Tributary Committee denied the amendment and time extension, and indicated if CDLT wants to use funding for additional properties they will need to submit a new proposal. This project will be terminated at the end of March 2017.
- *Similkameen River Mile 3.8 Rehabilitation Project*: The Okanogan Conservation District submitted a budget amendment request on the Similkameen River Mile (RM) 3.8 Rehabilitation Project, requesting an additional $24,851 to be added to their budget resulting in an increase from $67,370 to $92,221. The Rocky Reach HCP Tributary Committee approved the budget amendment.
- *Beaver Fever: Restoring Ecosystem Function Project*: Trout Unlimited submitted a budget amendment request on the Beaver Fever: Restoring Ecosystem Function Project, requesting to shift funds among different budget line items. The Rock Island HCP Tributary Committee approved the budget amendment. The total budget will not change as a result of this amendment.
- *General Salmon Habitat Program Proposal*: Cascade Columbia Fisheries Enhancement Group (CCFEG) submitted a General Salmon Habitat Program Proposal titled, Derby Creek Fish Passage – Collins Project. The purpose of the project is to remove the lowermost fish passage

barrier culvert on Derby Creek, to provide access to spawning and rearing habitat for steelhead. CCFEG requested $90,000 from HCP Tributary Funds; however, the HCP Tributary Committees were unable to make a funding decision because they need more information on the passability of a possible barrier farther downstream of the barrier proposed for removal. The HCP Tributary Committees requested additional information.

- *Draft HCP Tributary Committees Action Plans*: The Wells, Rock Island, and Rock Reach HCP Tributary Committees reviewed their respective draft action plans for 2017 and approved the tributary sections of their respective draft action plans.
- *Review of Tributary Committees' Policies and Procedures*: The HCP Tributary Committees rearranged certain sections of the Tributary Committees' Policies and Procedures document to highlight the importance of allowing public access on properties acquired with Plan Species Account funds and also to reflect a more logical order. The HCP Tributary Committees are also drafting language to add to the document regarding limiting the amount of time between when a project is approved for funding and when the sponsor signs a contract. Hillman said, for example, one project still has no signed contract 5 years after it was approved for funding.
- *Contributions to Plan Species Accounts*: The PUDs deposited funds into each of the Plan Species Accounts at the end of January 2017. Chelan PUD deposited $737,452 into the Rock Island Account and $349,271 into the Rocky Reach Account. Douglas PUD deposited $267,771 into the Wells Account. As of March 2017, the unallocated balances within each account were $5,559,653 in the Rock Island Account, $2,378,263 in the Rocky Reach Account, and $1,331,318 in the Wells Account. This totals about $8,269,234 for restoration/protection efforts.
- *Middle Entiat Restoration Project Presentation*: The Bureau of Reclamation (Reclamation) provided a status update on the Middle Entiat Restoration Project to the HCP Tributary Committees and the Priest Rapids Coordinating Committee (PRCC) Habitat Subcommittee. Hillman recalled this is the restoration project in the Middle Entiat Basin the Bonneville Power Administration (BPA) was going to fund, but were unable to reach agreement with CDLT regarding liability. Ultimately, Reclamation will be able to fund much of the project, and the status update included an overview of the scope of the project and the current landowner-project sponsor relationship. Chelan County was able to reach an agreement with CDLT on liability. Chelan County will assume responsibility for projects above the ordinary high-water mark, and Washington Department of Natural Resources will be responsible for projects below the ordinary high-water mark. In terms of funding, Reclamation will fall short by about $1 to 1.5 million to complete the project. Reclamation asked the HCP Tributary Committees and the PRCC Habitat Subcommittee about their interest in funding specific components of the restoration project. The HCP Tributary Committees will review this request during the HCP

Tributary Committees meeting on April 13, 2017. Jim Craig asked, considering that the liability issue has been resolved, will Reclamation ask BPA to cover the shortfall. Hillman said no, BPA has made it clear they no longer will be involved with this project. John Ferguson asked if there has been any indication why BPA is not willing to come back to the project. Hillman said he is not certain, but it is likely because BPA has reallocated their funds to other projects in the Methow and Wenatchee basins. Craig questioned if this has implications regarding funding of intensively monitored watershed evaluations being conducted in the basin. Hillman said he heard BPA is still considering this, but has not yet made a decision.

- *Next Steps*: The next meeting of the HCP Tributary Committees will be on Thursday, April 13, 2017.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on March 13, 2017:

- *DECISION: Wells HCP 2017 Action Plan*: The Wells HCP Hatchery Committee approved the hatchery section of the Wells HCP 2017 Action Plan.
- *DECISION: Hatchery Monitoring and Evaluation Reporting Schedule*: Douglas PUD presented an SOA memorializing the hatchery monitoring and evaluation (M&E) reporting schedule, as discussed in previous HCP Hatchery Committees meetings. The Wells HCP Hatchery Committee approved the SOA.
- *Methow Fish Hatchery Pond 13*: Douglas PUD noted a high level of bird predation in Pond 13 at the Methow Fish Hatchery (FH) last winter. In summer 2016, about 80,000 spring Chinook salmon were stocked in outdoor Pond 13 at Methow FH. Despite installing wiring and conducting bird hazing efforts, more than 40,000 spring Chinook salmon were removed by mergansers, cormorants, herons, and other avian predators. Douglas PUD speculated this is likely because Pond 13 at Methow FH was the only waterbody that did not freeze over last winter. Fish managers estimated approximately 35,000 spring Chinook salmon remain in the pond. Despite this large loss, there will be no impact on the release goal for the program. Douglas PUD plans to install additional fencing. Craig asked if installing bird netting is not possible because of snow load, and Tom Kahler said he believes that is the reason.
- *DECISION: Hatchery Monitoring and Evaluation Reporting Schedule*: Chelan PUD presented an SOA memorializing the hatchery M&E reporting schedule, as discussed in previous HCP Hatchery Committees meetings. The Rock Island and Rocky Reach HCP Hatchery Committees approved the SOA.
- *DECISION: Draft 2017 Steelhead Release Plan*: Chelan PUD presented the Draft 2017 Steelhead Release Plan. In short, the plan is similar to the 2016 Steelhead Release Plan, and the Rock Island and Rocky Reach HCP Hatchery Committees approved the plan.

- *USFWS Bull Trout Consultation Update*: USFWS is moving forward with finalizing the draft Biological Opinion (BiOp) covering hatchery programs in the Wenatchee basin. Comments are due Friday, March 31, 2017. USFWS will address comments received and plans to complete the BiOp by mid-May 2017. Next, USFWS will work on either the Methow steelhead BiOp or the Columbia River mainstem unlisted programs, pending a decision on a path forward by NMFS.
- *NMFS Consultation Update*: The signed permits for Methow spring Chinook salmon are with the applicants. NMFS is now working on the Methow steelhead consultation, with no known completion date. Kahler said he spoke with Charlene Hurst (NMFS HCP Hatchery Committees Alternate) who indicated she does not believe the permit for Methow steelhead will be ready in 2017.
- *Draft 2017 Broodstock Collection Protocols:* WDFW presented the draft protocols and reviewed the new items. The HCP Hatchery Committees reviewed the protocols and provided comments to WDFW by March 16, 2017. Hillman said he understands Mike Tonseth (WDFW HCP Hatchery Committees Representative) is currently addressing the comments and will revise the protocols or will schedule a conference call to discuss difficult comments, as needed. Hillman said he believes Tonseth will request a vote via email this week or in early April 2017. Bob Rose asked if the technical issues were resolved with fish health, regarding transferring steelhead to Wells FH due to live spawning. Hillman said he will discuss this under the next topic. Ferguson asked how HCP Hatchery Committees and Wells HCP Coordinating Committee approval of the protocols will be coordinated. Hillman said the HCP Hatchery Committees are aware the protocols need to be approved by the HCP Hatchery Committees and then by the Wells HCP Coordinating Committee before submitting to NMFS on April 15, 2017. He said he has not heard from Tonseth, so he hopes this means a conference call will not be needed. Ferguson said he will coordinate with Hillman to obtain HCP Hatchery Committees and Wells HCP Coordinating Committee approval of the 2017 Broodstock Collection Protocols prior to the April 15, 2017 deadline to NMFS. Kahler said Douglas PUD provided Tonseth with extensive comments on the steelhead program, and Kahler believes Douglas PUD and Tonseth will convene a call today. *(Note: Ferguson discussed the timeline with Hillman following the meeting on March 28, 2017, who coordinated with the HCP Hatchery Committees to deliver the protocols by approximately April 7, 2017.)*
- *Brood Year 2017 Twisp River Steelhead*: WDFW discussed two recommended revisions to brood year (BY) 2017 Twisp River Steelhead in the 2017 Broodstock Collection Protocols. First, rather than acclimating and releasing BY 2017 smolts (S1s) at the Twisp Acclimation Pond, WDFW recommended releasing the 48,000 S1s at Buttermilk Bridge, to encourage the juveniles to return farther upstream into the Twisp River, resulting in better distribution. The Wells HCP Hatchery Committee representatives present agreed to this revision. Second,

WDFW proposed collecting BY 2017 steelhead at the Twisp Weir in the spring and then transferring them to Winthrop National Fish Hatchery (NFH) to be spawned as part of the aggregate composite population. The eggs or fry would then be transferred to Wells FH to be reared as S1s. The Wells HCP Hatchery Committee is still considering this request with regard to aspects such as fish health, live-spawning, sampling schemes, tagging, and hatchery space, among other things. Hillman said he believes a vote via email will be requested by the end of March 2017. Kahler said he believes the YN are interested in this because of the kelt reconditioning issue. He explained that the YN had been conducting live spawning of the Twisp portion of Methow basin releases and holding progeny at Methow FH; however, since those fish were live-spawned, organ and tissue samples could not be collected to examine for viruses. Kahler said to deal with this lack of parental screening, the WDFW fish health protocols developed by Bob Rogers (WDFW), required the sampling of progeny of the live-spawned females prior to their transfer from Methow FH to Wells FH, and this protocol differs from that implemented for the Winthrop NFH steelhead program. Kahler said there were some questions about what would become of that WDFW protocol. He said if all adults are transferred to Winthrop NFH for spawning, there were questions about whether the WDFW disease-screening protocol would be implemented prior to transferring the fish to Wells FH, or whether WDFW would accept the USFWS protocol as adequate screening. Regardless, this issue will not affect the kelt program because the females from the programs would be live-spawned in any case; but spawning all the fish at WNFH and following the USFWS screening protocols would simplify everything, including the kelt-reconditioning program. Bob Rose noted that Keely Murdoch (YN HCP Hatchery Committees Alternate) was not expressing concern; rather, this was a technical discussion she brought up that WDFW is working on.

- *Spring Chinook Salmon Outplanting in the Chewuch River*: Recall the HCP Hatchery Committees developed a draft plan for outplanting surplus, passive integrated transponder (PIT)-tagged MetComp fish in the Chewuch River, with the goal of monitoring movement and spawning. Chelan PUD revised the draft plan and following discussions, a few more edits were identified. Chelan PUD will address those comments and will redistribute a second revised draft plan for approval.
- *Brood Year Stray Rate Targets*: The HCP Hatchery Committees continued discussing BY stray rate targets for their programs and requested Hillman write up a suggestion he discussed during the meeting. Hillman explained the idea is to keep stray rate targets for recipient populations and spawning aggregates because those are linked directly with extinction risk. He said a BY stray rate target, on the other hand, is not linked directly to extinction risk and it is not easily justified biologically. He said if the HCP Hatchery Committees agree that a BY stray target is necessary, the HCP Hatchery Committees will need to identify targets for each program, which will be a difficult task. Rose asked what the need is to establish a target, and

asked if stray rates are alarmingly high. Hillman said there is a need to have targets for recipient populations and spawning aggregates because those are biologically justified (i.e., they are linked with extinction risk). In contrast, according to Todd Pearson's (Grant PUD) research, a BY stray rate target is not well founded biologically and no other hatchery program has a BY stray rate target. Hillman said it is important to measure it, because it informs the other stray rate metrics (i.e., recipient stray rate metrics), but assigning a target to BY stray rate may be less important. Hillman added that yes, in some years, BY stray rates are high, but when BY stray rates are high, recipient population or spawning aggregate rates are also high. Thus, there appears to be a correlation between BY stray rates and recipient stray rates, suggesting some redundancy in the metrics. Hillman stated the HCP Hatchery Committees have reviewed Mike Ford's (NMFS)[1] work, and it is clear selecting a unique BY stray rate target for each hatchery program would be difficult. Hillman said he is unsure if everyone agrees there should not be a BY stray rate target; however, there is agreement that BY stray rates need to be measured, because they inform other stray rate metrics that do have targets. He added that the BY stray rate target for Chiwawa spring Chinook salmon has not been met in any year since monitoring began in the early 1990s.

- *Maturation Sampling for Methow and Chiwawa Spring Chinook Salmon 2017 Releases*: The Rock Island HCP Hatchery Committee approved Chelan PUD's request to perform the third year of maturation sampling with USFWS. The plan includes sampling 300 Chiwawa spring Chinook salmon to determine maturation. The Wells HCP Hatchery Committee also approved Douglas PUD's request to sample 300 Methow spring Chinook salmon to determine maturation.
- *Next Steps*: The next meeting of the HCP Hatchery Committees will be on Wednesday, April 19, 2017.

III.Douglas PUD

A. Draft 2016 Douglas PUD Pikeminnow Removal Program Annual Report (Tom Kahler)

Tom Kahler said when Douglas PUD received the Final 2015 Douglas PUD Pikeminnow Removal Program Annual Report from the contractor, the Draft 2016 Douglas PUD Pikeminnow Removal Program Annual Report was also provided. Kahler said he plans to review the draft 2016 report and will provide the draft report for review to Kristi Geris for distribution to the HCP Coordinating Committees. *(Note: Kahler provided the draft report for review to Geris following the meeting on March 28, 2017, which Geris distributed to the HCP Coordinating Committees on March 29, 2017.)*

Geris sent an email to the HCP Coordinating Committees on March 29, 2017, notifying them the Draft 2016 Douglas PUD Pikeminnow Removal Program Annual Report is available for a 60-day review period, with edits and comments due to Kahler by Monday, May 29, 2017.

B. Twisp Pond Update (Tom Kahler)

Tom Kahler said, this winter, a massive pile of ice accumulated in front of the Twisp Pond intake. He said crews were finally able to install the traps last Thursday, March 23, 2017, and fish are now in the pond as of yesterday, March 27, 2017. Kirk Truscott asked about the release date for spring Chinook salmon from the Twisp Pond. Kahler said it largely depends on the weather and fish growth. He said it's still quite cold and river flow has not yet increased. He said, in past years, fish were typically released out of the Twisp Pond by mid-April; however, if the weather remains cool and wet, the release date could be delayed a few weeks.

C. DECISION: 2017 Wells HCP Action Plan (Tom Kahler)

Tom Kahler said Kristi Geris sent an email to the HCP Coordinating Committees on February 23, 2017, notifying them the Draft 2017 Wells HCP Action Plan is available for review. John Ferguson noted the HCP Tributary and Hatchery Committees already approved their respective sections, and now the plan is ready for Wells HCP Coordinating Committee approval.

Ferguson asked about the 2020 survival verification study, noting the time gap between defining the study design and conducting the study. Kahler said the timing is based on broodstock collection. He said broodstock needs to be collected in 2018 for the study, and Douglas PUD decided to start designing the study in late 2017 because the 2018 broodstock collection protocols (developed early in 2018) would need to include brood collection for study fish. Ferguson asked if Douglas PUD and Chelan PUD are on the same schedule for a survival verification study, just not the design portion, and Kahler said that is correct.

The Wells HCP Coordinating Committee representatives present approved the 2017 Wells HCP Action Plan. *(Note: Carmen Andonaegui provided WDFW's approval of the plan via email prior to the meeting on March 28, 2017.)*

The Final 2017 Wells HCP Action Plan was distributed to the HCP Coordinating Committees by Geris on March 29, 2017.

D. Wells Dam Bypass PIT-detection System (Tom Kahler)

Tom Kahler said bypass operations are scheduled to start at midnight on April 9, 2017; however, Wells Dam is receiving such high river flow, the bypass barriers have not all been installed. He said according to our bypass operating plan, some of the barriers are pulled once river flow reaches a certain level, and the current river flow is already exceeding that level. John Ferguson asked if these operations affect the expanded PIT-tag detector system in Bypass Bay 2. Kahler said part of the system is already installed (barriers in slots A and B, antennas in some of the baffles). He said the goal is to have all antennas installed in the baffles by the end of this week and also have the baffles ready to be installed, so they can be trucked onto the dam and ready for installation next week. Ferguson asked if the system will be operational by April 9, 2017. Kahler said it should be operational by April 6, 2017, because they want to ensure everything is functioning properly. He noted the lowest antenna will be installed 70 feet below the water surface. He also noted permission was granted to leave the system installed, so crews do not need to pull the baffles each year.

E. 2017 Trapping Activities at Wells Dam (Tom Kahler)

Tom Kahler distributed a hard copy of a 2017 Trapping Activities at Wells Dam Gantt Chart, and said he will provide an electronic copy of the chart to Kristi Geris for distribution to the HCP Coordinating Committees. *(Note: Kahler provided the chart to Geris following the meeting on March 28, 2017, which Geris distributed to the HCP Coordinating Committees on March 29, 2017.)*

Kahler said the YN coho salmon trapping activities at the Wells Dam fish ladders and Methow outfall were incorporated into the chart. He also said Douglas PUD is still waiting to hear from Jeff Fryer (Columbia River Tribal Fish Commission) regarding on which fish ladder Fryer will conduct sockeye salmon trapping activities. Kahler said, per usual, Douglas PUD will convene a trapping coordination meeting in April 2017.

Kirk Truscott said he spoke with Casey Baldwin about broodstock protocols and the potential for a low spring Chinook salmon return this year, and the CCT's ability to trap spring Chinook salmon at the Chief Joseph Dam fish ladder, depending on river flow. Truscott said there may be an option included in the 2017 Broodstock Collection Protocols for the CCT to trap adipose fin (ad)-clipped non-wired spring Chinook salmon at Wells Dam if the return pans out as low as expected.
John Ferguson asked if the low forecast came from the Technical Advisory Committee, and Truscott said it came from the Fishery Resource Office. He added there have only been 12 Chinook salmon counted at Bonneville Dam, whereas at this time last year there had been 90 Chinook salmon counted, and the 10-year average is 170 Chinook salmon. He said, if the CCT trapped at Wells Dam, those fish would go toward the segregated program at Chief Joseph Dam, and the CCT would trap within the confines of the trapping schedule.

Ferguson asked if there are any issues with the trap itself. Kahler said Douglas PUD plans to cover the west fish ladder trap upwell holding area, similar to the east fish ladder trap holding area, as originally proposed in 2014. He explained the east fish ladder trap is covered and has grating and padding, but the west fish ladder currently does not. He also noted that there should not be any constraints (like last year) related to the Wells FH Modernization project. Lastly, he said Douglas PUD contractors are fixing the section of the transport pipe from the west fish ladder to the hatchery that was unintentionally designed such that, if the pipe flow is not turned down at the trap, it discharges water and fish from the pipe exit at such high velocities, the fish could hit the raceway wall opposite the pipe mouth.

IV. Chelan PUD

A. DECISION: Rock Island and Rocky Reach Coho Salmon Phase Designation (Lance Keller, Alene Underwood, and Catherine Willard)

Lance Keller recalled that during the last HCP Coordinating Committees meeting on February 28, 2017, the HCP Coordinating Committees had a lengthy discussion about the proposed Rock Island and Rocky Reach Coho Phase Designation SOA, which was distributed to the HCP Coordinating Committees by Kristi Geris on February 15, 2017. Keller said the discussion ended with an action item for Chelan PUD to discuss internally recommendations provided by the HCP Coordinating Committees regarding the proposed SOA and a path forward. Keller said Chelan PUD also spoke again with the YN. Keller reiterated what Steve Hemstrom touched on last meeting, that John Skalski and Richard Townsend (Columbia Basin Research) initially conducted the analysis using only 2 years of acoustic and PIT-tag data (2010 and 2011) for the Rocky Reach Project. Keller said, during that time, Chelan PUD was concerned the dataset was not using all of the available information and requested that Skalski and Townsend conduct a more robust study. He said the 2010 projected survival was 95.94% and the 2011 projected survival was 94.35%, averaging to 95.15% for the 2-year average. He said, if Chelan PUD accepted those 2 years of data and added 1 additional year to obtain 3 years of data, as stipulated in the HCP, a survival level of only 88.71% would be needed during the third year of study to achieve Phase III (Standards Achieved). Keller said Chelan PUD chose not to accept those numbers because of the interest in a more robust dataset. Keller also noted the adult component contained in the 2010 yearling Chinook SOA, and said he told Bob Rose Chelan PUD would review adult data for the Rocky Reach Project. Keller said there was variability in those data, noting that from 2010 to 2016, estimated adult survival for coho salmon ranged from 86.6% to 100.0%; however, the total average was still 94.58%. Keller also discussed data from 2014, noting all of these data contribute to a positive story about coho salmon. Keller recalled the SOA, "HCP Phase III Standards Achieved Designation for Steelhead at Rock Island with two years of survival testing at a 10% spill level," which was approved by the Rock Island HCP Coordinating Committee on November 16, 2010, was based on less than 3 years of valid survival data (2 years). He said this is one example from the past where the HCP Coordinating Committees were satisfied with making a decision based on the available data. He and John Ferguson also noted the SOA, "Phase III Standards Achieved for 91% Combined Adult and Juvenile Spring Chinook Survival at the Rocky Reach Project," which was approved by the Rocky Reach HCP Coordinating Committee on August 30, 2011. Keller and Ferguson said aspects of this SOA are also similar to the currently proposed SOA for coho salmon, and in the 2011 SOA, the HCP Coordinating Committees accepted juvenile survival levels that were less than the

93% standard (92.37%) and comprised of four years of juvenile survival studies. Therefore, Ferguson said the concern that incorporating a level of estimated survival in the current coho phase designation SOA for Rocky Reach (92.94%) that is slightly less than the 93% standard would establish an unwanted precedent does not seem to be an issue. He did note, however, the 2011 SOA was based on the combined survival of juvenile and adult spring Chinook salmon, whereas the current SOA is based just on juvenile survival data.

Rose said, in general, the YN are comfortable with Chelan PUD's currently proposed SOA. Rose thanked Chelan PUD and the HCP Coordinating Committees for taking the time to thoroughly vet this decision. He said he agrees there is a high level of confidence that the number is sufficient to meet or exceed the standard. He said, however, the YN are still interested in paying attention to and tracking precedence. He said he does not want the HCP Coordinating Committees to begin accepting lower and lower standards. He said the YN are not so concerned about one or two SOAs; rather, he was only making points. He said, while discussing this with Keely Murdoch, she made an interesting comment, which Rose said he agrees with. Rose said Murdoch noted that when the coho salmon program is set up for the next several years, the program will be successful and will contribute many more fish than the 0.06% under discussion. Ferguson said the HCP Coordinating Committees appreciate Rose's comments, which encouraged everyone to review past decisions and governing documents.

Ferguson asked about edits to the SOA before voting. Geris noted that Carmen Andonaegui requested via email to postpone WDFW's vote until Jeff Korth is available on Thursday, March 30, 2017. Ferguson suggested voting with representatives present, and following up with WDFW afterwards. Keller clarified it was not Chelan PUD's intention when drafting one SOA for both projects to imply that survival values through the Rock Island and Rocky Reach projects can be combined or averaged. Rose said he believes his comments will be adequately captured in the meeting minutes, and no revisions to the SOA are needed for the YN. Kirk Truscott requested that the SOA be updated to be consistent with past nomenclature (e.g., "yearling spring Chinook" versus "yearling Chinook," etc.). Jim Craig requested that "Projects" be added to the title of the SOA.

The Rock Island and Rocky Reach HCP Coordinating Committees representatives present approved the Rock Island and Rocky Reach Coho Phase Designation SOA, as revised.

Keller said Chelan PUD will complete edits to the Revised Draft Rock Island and Rocky Reach Coho Phase Designation SOA, as discussed, and will provide a final SOA to Geris for distribution to the HCP Coordinating Committees. *(Note: Keller provided the final SOA to Geris on March 29, 2017, which Geris distributed to the HCP Coordinating Committees that same day.)*

Anchor QEA will communicate to WDFW what discussions took place during today's HCP Coordinating Committees meeting regarding the Revised Draft Rock Island and Rocky Reach Coho Phase Designation SOA, and will request that WDFW submit a vote via email by close of business Thursday, March 30, 2017. *(Note: Geris coordinated with WDFW, as discussed, and WDFW submitted approval of the SOA on March 30, 2017.)*

Anchor QEA will notify the HCP Hatchery Committees that the HCP Coordinating Committees approved the Rock Island and Rocky Reach Coho Phase Designation SOA, so the HCP Hatchery Committees may move forward with hatchery compensation planning. *(Note: Geris notified Sarah Montgomery about the approval, as discussed, on March 30, 2017.)*

B. Draft 2017 Rock Island and Rocky Reach Fish Spill Plan (Lance Keller)

Lance Keller said Kristi Geris sent an email to the HCP Coordinating Committees on February 22, 2017, notifying them the Draft 2017 Rock Island and Rocky Reach Fish Spill Plan is available for a 30-day review with edits and comments due to Keller by Friday, March 24, 2017. Keller said no edits were requested by the HCP Coordinating Committees on the draft plan. He recalled a question from Bob Rose about the shape of the daily spill (the gate opening pattern across the spillway). Keller said, during the early years of operation, hydroacoustic data provided some guidance, and acoustic tag survival data were also used to provide shape for spring and summer spill at Rocky Reach Dam and summer spill at Rock Island Dam. Keller also noted spill shape at both projects is the same as when the HCP survival studies were conducted.

Keller said Thad Mosey (Chelan PUD Fish Biologist and Spill Coordinator) obtains river flow estimates from Chief Joseph Dam, and based on those estimates plus tributary flows, Mosey distributes a memorandum to spill operators outlining spill shape 2 days in advance. Keller said Mosey can also monitor all spill programs in real-time, so if inaccuracies due to inaccurate flow estimates occur he can make a real-time adjustment.

Jim Craig asked if a general shape is targeted or is the shape adjusted, as needed. Keller said generally, a particular shape is targeted. Bob Rose said the YN are interested in understanding that the current spill shape is achieving what it is meant to do, as outlined in the spill plan. Kirk Truscott asked about the proposed spill pattern or gate sequence, throughout the 2017 season, along with outages. Keller explained that unit outages reduce turbine capacity resulting in more spill. He said there is a prefered spill gate sequence at Rock Island and Rocky Reach dam to provide a crown shape and also a preference for over-under gates. Truscott suggested including this type of information in the spill plan. Keller said Chelan PUD will incorporate gate sequence details into the 2017 Rock Island and Rocky Reach Fish Spill Plan and will provide the final plan to Geris for distribution to the HCP Coordinating Committees.

John Ferguson said this discussion reminded him of the total dissolved gas (TDG) discussion, and asked how much information the HCP Coordinating Committees want to hear regarding TDG issues. Keller said TDG falls under Chelan PUD's Clean Water Act Section 401 Water Quality Certification, which is the purview of the fish forum. He said TDG will be an issue this year and added it really already is an issue. Truscott asked if the Fish Passage Center provides weekly reports on TDG, and Keller said it does. The HCP Coordinating Committees agreed that routine updates from Keller on TDG were not needed because members can look up TDG data on the Fish Passage Center website at any time. Keller added that Chelan PUD will conduct gas bubble trauma monitoring in 2017 at the Rock Island Juvenile Bypass Trap, per the Fish Passage Center Smolt Monitoring Program.

C. Tumwater Dam Pacific Lamprey Update (Lance Keller)

Lance Keller said USFWS requested to receive a progress update from Chelan PUD on the Tumwater Dam Pacific Lamprey Passage Feasibility Study, which includes the anticipated schedule for completion and a brief synopsis regarding the type of information the final report will contain. Keller recalled that Pacific lamprey discussions are germane to the HCP Coordinating Committees when Pacific lamprey activities have the potential to affect passage of HCP Plan species. He said Pacific lamprey discussions are germane to the HCP Hatchery Committees when Pacific lamprey activities affect brood collection of Plan species. He said Chelan PUD voluntarily drafted a feasibility report. He said the Rocky Reach Fish Forum (RRFF) discusses Pacific lamprey monthly, and the goal of the feasibility study was to determine what would be feasible from an engineering standpoint, should action to address Pacific lamprey passage be implemented at Tumwater Dam.

Jim Craig asked if efforts will focus on the fishway itself. Keller said several alternatives are being considered and noted the current status of the report is "draft for internal review." Keller said Chelan PUD will distribute the draft report for review to the RRFF following internal review. Craig said USFWS understands these discussions will occur in the RRFF; however, he requested periodic updates in the HCP Coordinating Committees. He added that his office is involved with designing lamprey passage structures. Keller said he believes R.D. Nelle (USFWS) has shared those designs in the RRFF. Bob Rose said the YN recently completed a Pacific lamprey study at Tumwater Dam, which is summarized in a report. He said he will provide the report, "Translocation of Adult Pacific Lamprey within the Wenatchee Subbasin (2015-2016 Broodstock)," to Kristi Geris for distribution to the HCP Coordinating Committees. *(Note: Rose provided the report to Geris during the meeting on March 28, 2017, which Geris distributed to the HCP Coordinating Committees on March 29, 2017.)*

D. Draft Rocky Reach Total Dissolved Gas Alternative Analysis Report (Lance Keller)

Lance Keller said Kristi Geris sent an email to the HCP Coordinating Committees on March 1, 2017, notifying them the Draft Rocky Reach Total Dissolved Gas Alternative Analysis Report is available for review, with edits and comments due to Marcie Clement by April 1, 2017. Keller clarified that edits and comments are due to Clement by Friday, March 31, 2017. Keller said this report is step two of a 401 Water Quality Certification requirement. He recalled step one was the Five-Year Compliance Report, which the Rocky Reach HCP Coordinating Committee approved on January 27, 2015. He said these reports serve as consultation with the RRFF and HCP Coordinating Committees to determine if any additional reasonable and feasible measures may exist to meet the TDG standards, as required by the certification.

Jim Craig asked how to address incoming water that is already in exceedance. Alene Underwood explained Chelan PUD is not held responsible for TDG levels in incoming water; however, the project cannot add TDG to any existing exceedances. Tom Kahler said this is difficult, because while running the bypass at Wells Dam, it is almost impossible to not add to TDG.

E. Rocky Reach Juvenile Fish Bypass System Marked Fish Release (Lance Keller)

Lance Keller said a preseason test of marked fish release was conducted at the RRJFBS to ensure the system is operating correctly ahead of the April 1, 2017, startup at midnight. He said, on Thursday, March 23, 2017, a total of 189 marked fish were released in the bypass channel. He said all fish were collected free of any descaling injury or mortal wounds. He said the intake diversion screens were also tested in Powerhouse Turbine Units C1 and C2. He said 100 fish were flushed through each unit (200 total), of which 198 were recaptured (typically 185 to 195 are recaptured). None of the recapture fish showed any signs of injury, and there were no mortalities.

Keller said, with the cold winter, the lower end of the bypass conduit filled with ice, and crews had to introduce water into the system to remove the ice. He said another full inspection was completed after the ice was removed and the results were good. He said the sampling screen also froze in the down position, and crews had to thaw the screen and then remove it. Jim Craig asked if the screen will be removed before the winter season in future years, and Keller said the screen was only there due to maintenance activities, so this should not be an issue in future years.

F. Request to Add Catherine Willard to the HCP Coordinating Committees Email Distribution List (Lance Keller)

Lance Keller requested that Catherine Willard (Chelan PUD HCP Hatchery Committees Alternate and future Representative) be added to the HCP Coordinating Committees email distribution list, mainly to track HCP Coordinating Committees meeting minutes and discussions pertaining to the HCP Hatchery Committees. The HCP Coordinating Committees representatives present approved adding Willard to the HCP Coordinating Committees email distribution list. Kristi Geris will add Willard to the HCP Coordinating Committees email distribution list, as approved by the HCP Coordinating Committees. *(Note: Geris added Willard to the list on March 29, 2017.)*

G. Draft 2017 Rock Island and Rocky Reach HCP Action Plan (Lance Keller)

Lance Keller said Kristi Geris sent an email to the HCP Coordinating Committees on January 23, 2017, notifying them the Draft 2017 Rock Island and Rocky Reach HCP Action Plan was available for a 30-day review with edits and comments due to Keller by Wednesday, February 22, 2017. A Revised Draft 2017 Rock Island and Rocky Reach HCP Action Plan was distributed for review on January 24, 2017. USFWS provided comments on the revised draft plan on March 9, 2017.

The HCP Coordinating Committees representatives present agreed to vote via email on the Revised Draft 2017 Rock Island and Rocky Reach HCP Action Plan. Chelan PUD will resend the Revised Draft 2017 Rock Island and Rocky Reach HCP Action Plan for vote via email to Geris for distribution to the HCP Coordinating Committees. *(Note: Keller provided the revised plan to Geris on March 29, 2017.)*

Geris sent an email to the HCP Coordinating Committees on March 30, 2017, notifying them the Revised Draft 2017 Rock Island and Rocky Reach HCP Action Plan is available for review, with votes via email due to Keller (and copy Geris) by Wednesday, April 5, 2017. The Rock Island and Rocky Reach HCP HCP Coordinating Committees representatives approved the 2017 Rock Island and Rocky Reach HCP Action Plan, as revised, via email as follows: Chelan PUD and USFWS approved on March 30, 2017; NMFS approved on April 4, 2017; and WDFW, the CCT, and the YN approved on April 5, 2017.

H. Draft 2016 Rock Island and Rocky Reach HCP Annual Reports (Lance Keller)

Lance Keller said Kristi Geris sent an email to the HCP Coordinating Committees on February 16, 2017, notifying them the Draft 2016 Rock Island and Rocky Reach HCP Annual Reports are available for a 30-day review with edits and comments due to Geris by Monday, March 20, 2017. Keller said Chelan PUD received a comment from USFWS about noting certain Pacific lamprey discussions were taking place in the RRFF. Chelan PUD will address comments received on the Draft 2016 Rock Island and Rocky Reach HCP Annual Reports and will provide the revised reports to Geris for final production. *(Note: Keller provided the revised reports to Geris on March 29, 2017.)*

The Final 2016 Rock Island and Rocky Reach HCP Annual Reports were distributed to the HCP Coordinating Committees by Geris on April 6, 2017.

I. Draft 2016 Rocky Reach Juvenile Fish Bypass System Report (Lance Keller)

Lance Keller said Kristi Geris sent an email to the HCP Coordinating Committees on February 17, 2017, notifying them the Draft 2016 RRJFBS Report is available for a 30-day review, with edits and comments due to Keller by Monday, March 20, 2017.

Chelan PUD will provide the Final 2016 Rocky Reach Juvenile Fish Bypass System Report to Geris for distribution to the HCP Coordinating Committees.

V. HCP Administration

A. Next Meetings

The next scheduled HCP Coordinating Committees meeting is on April 25, 2017, to be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington.

The May 23 and June 27, 2017, meetings will be held by conference call or in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington, as is yet to be determined.

Date: June 27, 2017

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the May 23, 2017, HCP Coordinating Committees Conference Call

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met by conference call on Tuesday May 23, 2017, from 9:00 to 10:00 a.m. Attendees are listed in Attachment A to these conference call minutes.

Action Item Summary

- Tom Kahler will provide fish passage count data for winter months at Wells Dam for review regarding the timing of winter maintenance outages at Wells Dam to Kristi Geris for distribution to the Coordinating Committees (Item I-C).
- Chelan PUD will incorporate gate sequence details into the 2017 Rock Island and Rocky Reach Fish Spill Plan and will provide the final plan to Kristi Geris for distribution to the Coordinating Committees (Item I-C). *(Note: Lance Keller provided the final plan to Geris on June 26, 2017, which Geris distributed to the HCP Coordinating Committees that same day.)*
- Chelan PUD will provide the Final 2016 Rocky Reach Juvenile Fish Bypass System Report to Kristi Geris for distribution to the Coordinating Committees (Item I-C).
- Anchor QEA, LLC, will contact Mackenzie Gavery (Postdoctoral Research Associate, University of Washington/National Oceanic and Atmospheric Administration [NOAA] Northwest Fisheries Science Center) regarding possibly presenting her epigenetics research to the HCP Coordinating Committees during a future meeting (Item II-A).
- Lance Keller will inquire internally about the cause of losing the use of automated spill gates 7, 17, and 25 at Rock Island Dam, as well as the timeline for repairing the gates, and will report back to the HCP Coordinating Committees (Item IV-A).
- Bob Rose will coordinate internally to develop and provide a Yakama Nation (YN) HCP Representation Designation document for distribution to the HCP Coordinating Committees (Item V-A).
- Kristi Geris will add Keely Murdoch, the new YN HCP Coordinating Committees Representative, to the HCP Coordinating Committees email distribution lists and request access to the extranet site from Julene McGregor (Douglas PUD Information Systems Staff; Item V-A). *(Note: Geris added Murdoch to the email lists and requested access to the extranet site following the meeting on May 23, 2017.)*

- The HCP Coordinating Committees meeting on June 27, 2017, will be held in-person at the Grant PUD office in Wenatchee, Washington (Item VI-B).

Decision Summary

- The Wells HCP Coordinating Committee representatives present approved the Columbia River Inter-Tribal Fish Commission's (CRITFC's) annual request to tag sockeye salmon at Wells Dam in 2017 (Item III-A). *(Note: Kirk Truscott provided the Colville Confederated Tribes' [CCT's] approval of the request via phone call prior to the meeting on May 23, 2017.)*

Agreements

- There were no HCP Agreements discussed during today's conference call.

Review Items

- Kristi Geris sent an email to the HCP Coordinating Committees on March 29, 2017, notifying them the Draft 2016 Douglas PUD Pikeminnow Removal Program Annual Report was available for a 60-day review period, with edits and comments due to Tom Kahler by Monday, May 29, 2017.
- Kristi Geris sent an email to the HCP Coordinating Committees on April 17, 2017, notifying them a Wells Project Land-use Permit Application (Small Block LLC) was available for a 60-day review period, with edits and comments due to Tom Kahler by Friday, June 16, 2017.
- Kristi Geris sent an email to the HCP Coordinating Committees on April 27, 2017, notifying them a Wells Project Land-use Permit Application (City of Pateros) was available for a 60-day review period, with edits and comments due to Tom Kahler by Monday, June 26, 2017.

Finalized Documents

- The Final Rocky Reach Total Dissolved Gas Alternative Analysis Report was finalized following a 30-day HCP Coordinating Committees review, and was distributed to the HCP Coordinating Committees by Kristi Geris on May 23, 2017.
- The Final 2017 Rock Island and Rocky Reach Fish Spill Plan was distributed to the HCP Coordinating Committees by Kristi Geris on June 26, 2017.

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. Lance Keller added an update on the spill gate change at Rock Island Dam.

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft March 28, 2017, meeting minutes. Kristi Geris said there is one outstanding edit to discuss under Chelan PUD's discussion on the Draft Rocky Reach Total Dissolved Gas Alternative Analysis Report. Lance Keller edited a statement made by Tom Kahler about the bypass at Wells Dam, and Keller requested that Kahler approve the edit. Kahler approved the edit.

Geris said all other comments and revisions received from members of the Committees were incorporated into the revised minutes. HCP Coordinating Committees members present approved the March 28, 2017, meeting minutes, as revised. *(Note: Kirk Truscott provided the CCT's approval of the minutes via phone call prior to the meeting on May 23, 2017.)*

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on March 28, 2017, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the meeting on March 28, 2017):*

- *Alene Underwood (Chelan PUD Fish and Wildlife Program Manager) will provide Chelan PUD's comments on the Federal Columbia River Power System (FCRPS) National Environmental Policy Act (NEPA) Scoping Process to Kristi Geris for distribution to the HCP Coordinating Committees (Item I-C).*
  Underwood provided these comments to Geris following the meeting on March 28, 2017, which Geris distributed to the HCP Coordinating Committees on March 29, 2017.
- *Tom Kahler will provide fish passage count data for winter months at Wells Dam for review regarding timing of winter maintenance at Wells Dam to Kristi Geris for distribution to the HCP Coordinating Committees (Item I-C).*
  This action item will be carried forward.
- *John Ferguson will coordinate with Tracy Hillman (HCP Hatchery Committees Chairman) to obtain HCP Hatchery Committees and Wells HCP Coordinating Committee approval of the 2017 Broodstock Collection Protocols prior to the April 15, 2017 deadline to the National Marine Fisheries Service (NMFS; Item II-A).*

Ferguson discussed the timeline with Hillman following the meeting on March 28, 2017, who coordinated with the HCP Hatchery Committees to deliver the protocols by approximately April 7, 2017.

- *Douglas PUD will provide the Draft 2016 Douglas PUD Pikeminnow Removal Program Annual Report for review to Kristi Geris for distribution to the HCP Coordinating Committees (Item III-A).*
  Tom Kahler provided the draft report for review to Geris following the meeting on March 28, 2017, which Geris distributed to the HCP Coordinating Committees on March 29, 2017.
- *Douglas PUD will provide an electronic copy of the 2017 Trapping Activities at Wells Dam Gantt Chart to Kristi Geris for distribution to the HCP Coordinating Committees (Item III-E).*
  Tom Kahler provided the chart to Geris following the meeting on March 28, 2017, which Geris distributed to the HCP Coordinating Committees on March 29, 2017.
- *Chelan PUD will complete edits to the Revised Draft Rock Island and Rocky Reach Coho Phase Designation Statement of Agreement (SOA), as discussed, and will provide a final SOA to Kristi Geris for distribution to the HCP Coordinating Committees (Item IV-A).*
  Lance Keller provided the final SOA to Geris on March 29, 2017, which Geris distributed to the HCP Coordinating Committees that same day.
- *Anchor QEA, LLC, will communicate to Washington Department of Fish and Wildlife (WDFW) what discussions took place during today's HCP Coordinating Committees meeting regarding the Revised Draft Rock Island and Rocky Reach Coho Phase Designation SOA, and will request that WDFW submit a vote via email by close of business Thursday, March 30, 2017 (Item IV-A).*
  Kristi Geris coordinated with WDFW, as discussed, and WDFW submitted their approval of the SOA on March 30, 2017.
- *Anchor QEA will notify the HCP Hatchery Committees that the HCP Coordinating Committees approved the Rock Island and Rocky Reach Coho Phase Designation SOA, so the HCP Hatchery Committees may move forward with hatchery compensation planning (Item IV-A).*
  Kristi Geris notified Sarah Montgomery (HCP Hatchery Committees Support Staff) about the approval, as discussed, on March 30, 2017.
- *Chelan PUD will incorporate gate sequence details into the 2017 Rock Island and Rocky Reach Fish Spill Plan and will provide the final plan to Kristi Geris for distribution to the HCP Coordinating Committees (Item IV-B).*
  This action item will be carried forward.
- *The Yakama Nation (YN) will provide the report, "Translocation of Adult Pacific Lamprey within the Wenatchee Subbasin (2015-2016 Broodstock)," to Kristi Geris for distribution to the HCP Coordinating Committees (Item IV-C).*
  Bob Rose provided the report to Geris during the meeting on March 28, 2017, which Geris distributed to the HCP Coordinating Committees on March 29, 2017.

- *Kristi Geris will add Catherine Willard (Chelan PUD HCP Hatchery Committees Alternate) to the HCP Coordinating Committees email distribution list, as approved by the HCP Coordinating Committees (Item IV-F).*
  Geris added Willard to the list on March 29, 2017.
- *Chelan PUD will provide the Revised Draft 2017 Rock Island and Rocky Reach HCP Action Plan for vote via email to Kristi Geris for distribution to the HCP Coordinating Committees (Item IV-G).*
  Lance Keller provided the revised plan to Geris on March 29, 2017, which Geris distributed to the HCP Coordinating Committees on March 30, 2017.
- *Chelan PUD will address comments received on the Draft 2016 Rock Island and Rocky Reach HCP Annual Reports and will provide the revised reports to Kristi Geris for final production (Item VI-H).*
  Lance Keller provided the revised reports to Geris on March 29, 2017.
- *Chelan PUD will provide the Final 2016 Rocky Reach Juvenile Fish Bypass System Report to Kristi Geris for distribution to the HCP Coordinating Committees (Item IV-I).*
  Lance Keller said Chelan PUD is still addressing a few comments on this report. This action item will be carried forward.

II. HCP Tributary and Hatchery Committees Update

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman said the HCP Tributary Committees did not officially meet in May 2017; rather, the Committees attended project tours on May 10, 2017, in the Wenatchee River basin; on May 11, 2017, in the Entiat River basin; and on May 18, 2017, in the Methow River basin. This year, the HCP Tributary Committees received nine General Salmon Habitat Program proposals. All projects are cost shares. Total funds requested from the HCP Tributary Committees Plan Species Accounts equal about $612,000. The HCP Tributary Committees will attend presentations in June 2017, and during the regular monthly meeting on June 8, 2017, the Committees will evaluate the proposals and decide which projects should be submitted as final proposals. John Ferguson asked about the overall quality of the proposals this year. Hillman said there are some good ones and also a couple the HCP Tributary Committees may not recommend for submitting a final proposal. He said, for example, reviewers liked a project that will improve instream flow in the lower Icicle Creek (titled, "Cascade Orchards Flow Restoration in Icicle Creek"), which will produce an important contribution to flow in the creek during late summer and early-fall (about 7 to 8 cubic feet per second). Other projects involve restoration work where the HCP Tributary Committees may recommend a slightly different approach. The next meeting of the HCP Tributary Committees will be on Thursday, June 8, 2017.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on May 17, 2017:

- *PRESENTATION: Epigenetics*: Mackenzie Gavery shared a presentation titled, "Epigenetics: what is it and why is it relevant to hatchery practices?" The presentation included an overview of epigenetics, discussion of a specific epigenetic marks called deoxyribonucleic acid (DNA) methylation, and a presentation of results for the Methow River steelhead DNA methylation study. Epigenetics refers to heritable changes in trait or phenotype caused by a mechanism other than mutation to the DNA sequence. The epigenome of an organism can be affected by the environment, especially during early development, and even after the environmental signal is removed. In Gavery's research, she asked whether there are discernable epigenetic differences between hatchery- and natural-origin steelhead at Winthrop National Fish Hatchery. In 2014, blood and sperm samples were extracted from returning hatchery- and natural-origin adult steelhead, and a DNA methylation analysis was performed to evaluate somatic and germline cells (which are passed on to the next generation). The results showed steelhead have a heavily methylated genome compared to other species. Comparisons of differentially methylated regions between blood and sperm cells show sperm carry important epigenetic information regarding which genes are going to be turned on in the early embryo. Results also showed there are differences in DNA methylation between hatchery- and natural-origin steelhead in both somatic and germline-derived cell types. Epigenetics may play a role in the observed fitness loss of steelhead after a single generation of rearing. Epigenetics can help organisms retain and pass on information about their environment and the study of the epigenome is an emerging tool to help understand how the environment affects phenotype in hatchery fish. Gavery has a second study underway where offspring from natural-origin Methow steelhead families are divided into two groups and reared in a hatchery tank and an artificial stream. Hillman said Gavery provided an excellent presentation, recommended the HCP Coordinating Committees inquire about having Gavery present at a future meeting, and thanked USFWS for recommending Gavery to present to the HCP Hatchery Committees. Anchor QEA will contact Gavery regarding possibly presenting her epigenetics research to the HCP Coordinating Committees during a future meeting.
- *USFWS Bull Trout Consultation Update*: USFWS is currently revising the draft Biological Opinion (BiOp) for the Wenatchee subbasin programs and expects it will be finalized in mid-June 2017.
- *NMFS Consultation Update*: NMFS is working on consultation for the unlisted programs in the upper Columbia River. The proposed actions will likely be finished in June 2017. NMFS is also working on the Methow steelhead consultation. A consultation update meeting is scheduled for June 1, 2017.

- *Wells Fish Hatchery Power/Water Outage*: WDFW and Douglas PUD provided a recap and update about a power and water outage experienced at Wells Fish Hatchery. The power and water outage occurred on May 2, 2017, and water was restored overnight. Approximately 20,000 to 25,000 steelhead fry of unknown origin were lost. WDFW indicated the loss will not affect the overall production obligation for the program.
- *Wells Dam West Fish Ladder Trapping Contingencies*: Currently, WDFW is manually trapping spring Chinook salmon at the Wells Dam west fish ladder because the pipe that is used to transfer fish to the pond is under construction, which includes increasing the diameter of the pipe to 30 inches and installing a dewatering screen. Improvements are expected to be completed soon.
- *Review Hatchery Monitoring and Evaluation Plan Objectives*: The HCP Hatchery Committees are reviewing the objectives in the Hatchery Monitoring and Evaluation (M&E) Plan to verify they are consistent with the hatchery M&E timeline. The HCP Hatchery Committees have completed their review of the first few objectives with only a few changes. The review should be completed by June or July 2017.
- *Methow Steelhead Gene Flow Plan*: The HCP Hatchery Committees discussed the proportion of hatchery-origin spawners (pHOS) target for inclusion in the Methow steelhead BiOp. NMFS proposed achieving a pHOS of 0.3 for most run sizes. However, in 2013, there was also an agreement that pHOS should be closer to 0.5. The HCP Hatchery Committees are discussing how to identify a target and how to achieve it. The Committees are further discussing a phased approach, which was also discussed in 2013. These discussions are expected to continue.
- *Coho Salmon Recalculation:* The YN and Chelan PUD are coordinating on this and provided a presentation to the HCP Hatchery Committees. The goal is to use the same recalculation methods for coho salmon as were used for other species. The YN and Chelan PUD will include the final mitigation numbers in a SOA for review and approval in June 2017.
- *Update from the Upper Columbia Regional Technical Team*: The Independent Scientific Advisory Board (ISAB) is working with the Upper Columbia Salmon Recovery Board to review upper Columbia River spring Chinook salmon recovery analyses and strategies. ISAB is visiting the upper Columbia River on July 20 and 21, 2017, for presentations and site visits. Further updates will be available in June 2017. Ferguson asked about the ISAB review scope. Hillman said at this point, it is only for spring Chinook salmon, but may eventually change to steelhead.
- *Next Steps*: The next meeting of the HCP Hatchery Committees will be on Wednesday, June 21, 2017.

III. Douglas PUD

A. DECISION: CRITFC Annual Request for Sockeye Tagging at Wells Dam (Tom Kahler)

Tom Kahler said CRITFC's annual request to tag sockeye salmon at Wells Dam in 2017 (Attachment B) was distributed to the HCP Coordinating Committees by Kristi Geris on April 17, 2017. Kahler recalled this is the same request received from Jeff Fryer (CRITFC) each year.

John Ferguson said Kirk Truscott provided the CCT's approval of the request via phone call prior to the meeting on May 23, 2017, as long as the request is the same as last year's. Kahler said the only difference in this year's request from last year, is this year's letter specifies fin clips for genetic samples, which also occurred last year but was not included in the request letter. Kahler also noted that traditionally, CRITFC received assistance from the CCT and the YN; however, this year only the YN will provide assistance.

The Wells HCP Coordinating Committee representatives present approved CRITFC's annual request to tag sockeye salmon at Wells Dam in 2017. *(Note: Truscott provided the CCT's approval of the request via phone call prior to the meeting on May 23, 2017.)*

B. Trapping at Wells Dam (Tom Kahler)

Tom Kahler recalled discussing with the HCP Coordinating Committees during past meetings about the transport pipe from the west fish ladder trap to the Adult Handling Facility, where engineers had not included a dewatering section in the new pipe. Kahler said those repairs have been underway and the change order specified the repairs would be complete by mid-April 2017. He said, however, the sweep for the 30-inch pipe (the pipe turns approximately 30 degrees) needed to be custom fabricated and the manufacturer took longer than planned. He said once received, contractors discovered that the opening in the vault where the sweep is to be installed is 6 inches higher than necessary. He said a new hole was cut and the pipe flange grouted in place, to which the sweep was connected, and the whole pipe is being embedded in concrete which should be completed by today or tomorrow. He said the west ladder fish trap may be operational as early as tomorrow, depending on how long it takes for the concrete to cure. He said in the meantime, WDFW is proposing real-time trapping, where fish are conveyed from the trap chute across the ladder pool into a tote for processing. He recalled trapping for spring Chinook salmon may occur at the west fish ladder between May 1 and June 20, under a maximum 5 days per week (but no more than 3 consecutive days) at 16 hours per day.

Kahler said spring Chinook salmon numbers passing Wells Dam have been in the single digits until last Sunday, May 21, 2017, when there were 31 fish counted passing the dam. He said he expects numbers to increase moving forward.

IV. Chelan PUD

A. Spill Gate Change at Rock Island Dam (Lance Keller)

Lance Keller said a notification of spill gate changes at Rock Island Dam was distributed to the HCP Coordinating Committees by Kristi Geris on May 19, 2017. Keller said on May 18, 2017, Chelan PUD received notification that Rock Island Dam lost capability of operating one of the automated spill gates (spill gate 7). He said now, a total of three spill gates are out of service (spill gates 7, 17, and 25). Keller said it is his understanding there is no capability to manually raise an automated spill gate and hold it in an open position. He said there are 31 spill gates at Rock Island Dam, 11 of which are automated and 20 are operated manually. He said if a large spring runoff event suddenly occurs, it is expected that the functioning automated and manual gates can be opened. He said with the manual gates, staff need to remove gate sections and store the sections on either side of the dam. He said while staff are opening the manual gates, the spill capacity provided through the automated gates must be relied upon.

Keller said with having three automated gates out of operation and recently experiencing the highest river flow at Rocky Reach and Rock Island dams on record, Rock Island Dam engineers requested to convert two notch gates back to full gate operation. He said Thad Mosey (Chelan PUD Fish Biologist and Spill Coordinator) and Steve Hemstrom discussed which notch gates to convert back to full gate operation with regard to juvenile and adult fish passage and total dissolved gas (TDG) levels. Keller said Chelan PUD decided to convert notched spill gates 18 and 24 for the following reasons: 1) conversion of these gates to full gate operation is not expected to have negative impacts to juvenile fish passage; 2) gates 18 and 24 are located away from the left powerhouse entrance of the right bank adult fish ladder and should have no impact on adult fish passage; and 3) both of these gates are shallow spill gates so additional TDG from the gate conversions should be negligible. Keller said this is a temporary conversion until river flow subsides or until the automated spill gates return to service.

Bob Rose asked about tailwater egress (e.g., eddies). Keller said Rock Island Dam staff are conducting visual observations every other day and, to date, everything looks good (flow appears to be linear).

Scott Carlon asked about the cause of the failed automated spill gates, and John Ferguson asked about the timeline for fixing the failed gates. Keller said he is unsure but will inquire internally about the cause of losing the use of automated spill gates 7, 17, and 25 at Rock Island Dam, as well as the timeline for repairing the gates, and will report back to the HCP Coordinating Committees.

V. Yakama Nation

A. Yakama Nation HCP Representation Update (Bob Rose)

Bob Rose said Keely Murdoch will transition into the YN HCP Coordinating Committees Representative and Rose will become the YN HCP Coordinating Committees Alternate. Rose said Murdoch is familiar with the HCPs and has participated on the HCP Hatchery Committees for years. Rose will coordinate internally to develop and provide a YN HCP Representation Designation document for distribution to the HCP Coordinating Committees.

John Ferguson asked what to expect with the transition. Rose said he is unable to attend the HCP Coordinating Committees meeting on June 27, 2017; however, he hopes to have the designation document distributed by then. He said he anticipates participating in the July 2017 meeting, with the transition occurring by the August or September 2017 meetings.

Murdoch noted that she also cannot attend the HCP Coordinating Committees meeting on June 27, 2017. Rose said the purpose of today's discussion is to notify the HCP Coordinating Committees of the change and understand that Murdoch will now be added to the email distribution list and extranet site. Kristi Geris said she will add Murdoch to the HCP Coordinating Committees email distribution lists and request access to the extranet site from Julene McGregor. *(Note: Geris added Murdoch to the email lists and requested access to the extranet site following the meeting on May 23, 2017.)*

VI. HCP Administration

A. Chelan PUD HCP Representation Update (Kristi Geris)

Kristi Geris said a Chelan PUD HCP Representation Designation document (Attachment C) was distributed to the HCP Coordinating Committees by Kristi Geris on April 13, 2017. Geris said key changes included designating: Alene Underwood (Chelan PUD Fish and Wildlife Manager) as the new Chelan PUD HCP Policy Committees Representative; Jeff Smith (Chelan PUD Managing Director – District Services) as the new Chelan PUD HCP Policy Committees Alternate; and Catherine Willard (Chelan PUD Senior Fisheries Biologist) as the new Chelan PUD HCP Hatchery Committees Representative.

B. Next Meetings

The next scheduled HCP Coordinating Committees meeting is on June 27, 2017, to be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington.

The July 25 and August 22, 2017, meetings will be held by conference call or in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington, as is yet to be determined.

April 7, 2017

Tom Kahler
Fisheries Biologist
Public Utility District #1 of Douglas County
1151 Valley Mall Parkway
East Wenatchee, WA 98801

Dear Mr. Kahler:

Since 1995, the Columbia River Inter-Tribal Fish Commission (CRITFC) has conducted a scientific study near Wells Dam. The project is currently funded by the Bonneville Power Administration, and is entitled, "Studies into Factors Limiting the Abundance of Okanagan and Wenatchee Sockeye Salmon." CRITFC requests permission to access and conduct sampling activities at Wells Dam.

The purpose of this study is to determine the effect of temperature on the survival of sockeye salmon returning to their spawning grounds in the Okanagan Basin. It is anticipated that a maximum of 800 sockeye will be sampled for scales, fin clips for genetics samples, and tagged with PIT and Floy tags. We do not plan to do any acoustic tagging of sockeye in 2017. The sampling activity will take place daily, Monday-Friday, from late June 2017 through early August 2017, and will be coordinated with the Wells Hatchery brood stock collection programs.

The sampling team will consist of three to five individuals from two separate organizations, they are as follows: Dr. Jeff Fryer of CRITFC; Kraig Mott, Casey Heemsah, Clifford Smith, and Terri Benson of Confederated Tribes and Bands of the Yakama Nation.

Thank you for your consideration. If you have any questions or need further information, please contact Project Leader, Dr. Jeff Fryer at (503) 238-0667.

Sincerely,

Robert C. Lothrop
Interim Executive Director

RE: HCP Committees Representatives

This memo is to inform you that Chelan PUD has made a change designating their representatives to the HCP Policy Committee, their representative to the Hatchery Committees and alternative representative to the Hatchery Committees. We respectfully request that your contact information is updated as appropriate. The delegate contact information is as follows:

Policy Committee	Policy Committee (Alternate)
Alene Underwood Fish and Wildlife Manager Chelan County Public Utility District PO Box 1231; Wenatchee, WA 98807 Phone: (509) 661-4364 Email: alene.underwood@chelanpud.org	Jeff Smith Managing Director – District Services Chelan County Public Utility District PO Box 1231; Wenatchee, WA 98807 Phone: (509) 661-4379 Email: jeff.smith@chelanpud.org

Hatchery Committees	Hatchery Committees (Alternate)
Catherine Willard Senior Fisheries Biologist Chelan County Public Utility District PO Box 1231; Wenatchee, WA 98807 Phone: (509) 661-4179 Email: catherine.willard@chelanpud.org	Vacant - TBD

The representatives for the Coordinating and Tributary Committees remain unchanged. Those representatives information are as follows:

Tributary Committees	Tributary Committees (Alternate)
Steve Hays Fish & Wildlife Senior Advisor Chelan County Public Utility District PO Box 1231; Wenatchee, WA 98807 Phone: (509) 661-4181 Email: steve.hays@chelanpud.org	Jeff Osborn License Compliance Supervisor Chelan County Public Utility District PO Box 1231; Wenatchee, WA 98807 Phone: (509) 661-4176 Email: jeff.osborn@chelanpud.org

Coordinating Committees	Coordinating Committees (Alternate)
Lance Keller Senior Fisheries Biologist Chelan County Public Utility District PO Box 1231; Wenatchee, WA 98807 Phone: (509) 661-4299 Email: lance.keller@chelanpud.org	Steve Hemstrom Senior Fisheries Biologist Chelan County Public Utility District PO Box 1231; Wenatchee, WA 98807 Phone: (509) 661-4281 Email: steven.hemstrom@chelanpud.org

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: August 23, 2017

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the June 27, 2017, HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met in-person at the Grant PUD Office in Wenatchee, Washington, on Tuesday June 27, 2017, from 10:00 to 11:45 a.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Tom Kahler will provide fish passage count data for winter months at Wells Dam for review regarding timing of winter maintenance at Wells Dam to Kristi Geris for distribution to the Coordinating Committees (Item I-B).
- Chelan PUD will provide the Final 2016 Rocky Reach Juvenile Fish Bypass System Report to Kristi Geris for distribution to the Coordinating Committees (Item I-B). *(Note: Lance Keller provided the final report to Geris on June 28, 2017, which Geris distributed to the HCP Coordinating Committees that same day.)*
- Anchor QEA will contact Mackenzie Gavery (Postdoctoral Research Associate, University of Washington/National Oceanic and Atmospheric Administration [NOAA] Northwest Fisheries Science Center) regarding possibly presenting her epigenetics research to the HCP Coordinating Committees during a future meeting (Item I-B).
- Bob Rose will coordinate internally to develop and provide a Yakama Nation (YN) HCP Representation Designation document for distribution to the HCP Coordinating Committees (Item I-B).
- Kristi Geris will coordinate with Tracy Hillman (HCP Hatchery Committees Chairman) and Sarah Montgomery (HCP Hatchery Committees Support Staff) to obtain meeting and WebEx information for Jeff Jorgensen's (NOAA Northwest Fisheries Science Center) presentation to the HCP Hatchery Committees on August 16, 2017, on a life-cycle model for Wenatchee River spring Chinook salmon, which Geris will distribute to the HCP Coordinating Committees (Item II-A). *(Note: this presentation has been postponed to the HCP Hatchery Committees meeting on September 20, 2017.)*
- Chelan PUD will provide a Rocky Reach Dam large unit repair update during an HCP Coordinating Committees meeting in late-summer 2017 (Item III-B).

- Chelan PUD will provide a Rock Island Dam Powerhouse 1 maintenance update during the HCP Coordinating Committees conference call on July 25, 2017 (Item III-C).
- Kristi Geris will add Chad Jackson, potentially the new Washington Department of Fish and Wildlife (WDFW) HCP Coordinating Committees Representative, and Mike Tonseth, likely a new WDFW HCP Coordinating Committees Alternate, to the HCP Coordinating Committees email distribution lists and request access to the HCP Coordinating Committees extranet site from Julene McGregor (Douglas PUD Information Systems Staff; Item VI-A). *(Note: Geris added Jackson and Tonseth to the email lists and requested access to the extranet site following the meeting on June 27, 2017.)*
- The HCP Coordinating Committees meeting on July 25, 2017, will be held by conference call (Item VII-B). *(Note: due to lack of agenda items, the HCP Coordinating Committees meeting on July 25, 2017, has been canceled. The August 22, 2017, meeting will be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington.)*

Decision Summary

- There were no HCP Decision Items approved during today's meeting.

Agreements

- HCP Coordinating Committees representatives present agreed to add Chad Jackson and Mike Tonseth to the HCP Coordinating Committees email distribution lists and provide them both with access to the HCP Coordinating Committees extranet site because Jackson will potentially become the WDFW HCP Coordinating Committees Representative and Tonseth will likely be a new WDFW HCP Coordinating Committees Alternate (Item VI-A).

Review Items

- There are no items that are currently out for review.

Finalized Documents

- There are no documents that have been recently finalized.

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. The following revisions were requested:

- Tom Kahler added updates on the Wells Hatchery Modernization and Wells Dam bypass.

- Jim Craig added a notification about subyearling spring Chinook salmon rearing in the Columbia River.
- Jeff Korth added an update on WDFW HCP Coordinating Committees representation.

B. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on May 23, 2017, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the meeting on May 23, 2017):*

- *Tom Kahler will provide fish passage count data for winter months at Wells Dam for review regarding the timing of winter maintenance outages at Wells Dam to Kristi Geris for distribution to the Coordinating Committees (Item I-C).*
  This action item will be carried forward.
- *Chelan PUD will incorporate gate sequence details into the 2017 Rock Island and Rocky Reach Fish Spill Plan and will provide the final plan to Kristi Geris for distribution to the Coordinating Committees (Item I-C).*
  Lance Keller provided the final plan to Geris on June 26, 2017, which Geris distributed to the HCP Coordinating Committees that same day.
- *Chelan PUD will provide the Final 2016 Rocky Reach Juvenile Fish Bypass System Report to Kristi Geris for distribution to the Coordinating Committees (Item I-C).*
  This action item will be carried forward. *(Note: Lance Keller provided the final report to Geris on June 28, 2017, which Geris distributed to the HCP Coordinating Committees that same day.)*
- *Anchor QEA, LLC, will contact Mackenzie Gavery (Postdoctoral Research Associate, University of Washington/National Oceanic and Atmospheric Administration [NOAA] Northwest Fisheries Science Center) regarding possibly presenting her epigenetics research to the HCP Coordinating Committees during a future meeting (Item II-A).*
  This action item will be carried forward.
- *Lance Keller will inquire internally about the cause of losing the use of automated spill gates 7, 17, and 25 at Rock Island Dam, as well as the timeline for repairing the gates, and will report back to the HCP Coordinating Committees (Item IV-A).*
  This will be discussed during today's meeting.
- *Bob Rose will coordinate internally to develop and provide a Yakama Nation (YN) HCP Representation Designation document for distribution to the HCP Coordinating Committees (Item V-A).*
  This action item will be carried forward.
- *Kristi Geris will add Keely Murdoch, the new YN HCP Coordinating Committees Representative, to the HCP Coordinating Committees email distribution lists and request access to the extranet site from Julene McGregor (Douglas PUD Information Systems Staff; Item V-A).*

Geris added Murdoch to the email lists and requested access to the extranet site following the meeting on May 23, 2017.

C. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft May 23, 2017, conference call minutes. Kristi Geris said she incorporated distribution of the Final 2017 Rock Island and Rocky Reach Fish Spill Plan into the action items and finalized documents sections of the minutes. She said all other comments and revisions received from members of the Committees were also incorporated into the revised minutes and there were no outstanding edits or questions to discuss. HCP Coordinating Committees members present approved the May 23, 2017, conference call minutes, as revised. WDFW abstained, because a WDFW representative was not present during the May 23, 2017, conference call.

II. HCP Tributary and Hatchery Committees Update

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Tributary Committees meeting on June 8, 2017:

- *Budget Amendment – Clear Creek Fish Passage Project*: The Rocky Reach HCP Tributary Committee received a budget amendment request from Trout Unlimited for the Clear Creek Fish Passage Project, requesting to move $2,000 from "Project Materials and Supplies" to "Professional Services and Permitting." The Rocky Reach HCP Tributary Committee approved the budget amendment. The amendment will not change the total budget amount.
- *Budget Amendment – Permitting Nutrient Enhancement in the Chiwawa River Basin Project*: The Rock Island HCP Tributary Committee received a budget amendment request from Cascade Columbia Fisheries Enhancement Group (CCFEG) for the Permitting Nutrient Enhancement in the Chiwawa River Basin Project, requesting to move $1,028 from "Professional Services" and "Indirect/Admin/Overhead" to "Sponsor Salaries and Benefits." The Rock Island HCP Tributary Committee approved the budget amendment. Jeff Korth said he thought this project was already completed. Hillman said the U.S. Fish and Wildlife Service (USFWS) expressed concern over placing nutrients on bull trout redds; however, after revising the treatment plan this is no longer an issue. John Ferguson asked if nutrient enhancement has started, and Hillman said not yet. Ferguson asked if nutrients are depleted in the Chiwawa River. Hillman said based on studies conducted by CCFEG and Pace Engineers, nutrients are low in the river. He added that macroinvertebrate species richness is relatively high, but abundance of each species is low.

- *Budget Amendment – White River Floodplain Connection (River Mile 3.4) Project*: The Rock Island HCP Tributary Committee received a budget amendment request from CCFEG for the White River Floodplain Connection (River Mile 3.4) Project, requesting to move all available funds from construction to other tasks. The Committee questioned how the project will be completed if all the money is taken out of construction; therefore, the Rock Island HCP Tributary Committee denied the request. Hillman said he contacted the project lead who indicated the rest of the funding is covered under another source. The HCP Coordinating Committees asked who owns the land where the project is taking place, and Hillman said part of the land is owned by WDFW and some is privately owned.
- *Time Extension*: The Rock Island HCP Tributary Committee received a time extension request from Trout Unlimited for the Barkley Irrigation Project. The sponsor indicated that construction on the project is unlikely to begin until fall 2017; therefore, the sponsor asked to extend the project end date from May 31, 2017, to December 31, 2018. The Rock Island HCP Tributary Committee approved the time extension.
- *General Salmon Habitat Program Draft Proposals*: The HCP Tributary Committees received nine draft proposals. Among those nine proposals, four were selected for final proposals. The other five projects may submit final proposals; however, it is unlikely they would be approved for funding. Full proposals are due on June 30, 2017. The proposed projects are in the Wenatchee, Entiat, and Methow River basins.
- *Small Projects Program Proposal*: The HCP Tributary Committees received a Small Projects Program application from Chelan County Natural Resources Department (CCNRD) titled, "Poison Canyon Restoration." Poison Canyon has a highly entrenched stream and is a tributary to Sand Creek, which is a tributary to Mission Creek. CCNRD proposed to install 20 wood structures to help aggrade the channel. The total cost of the project is $73,330, and the sponsor requested $38,160 from the HCP Tributary Committees, but they declined the opportunity to fund the project. Hillman explained, the issue is that several HCP Tributary Committees representatives have completed similar projects and such highly designed structures are unnecessary to achieve the project's purposes. He said the project is over-engineered and too expensive. CCNRD also proposed installing game cameras and piezometers, which the HCP Tributary Committees do not agree are needed. CCNRD proposed installing one structure per day, when the HCP Tributary Committees believe two or more structures can be constructed per day. CCNRD also needs to consider anchoring, so the wood does not get flushed out of the canyon. The HCP Tributary Committees are working with the sponsor to develop a cheaper, more effective proposal, and CCNRD will likely resubmit. Tom Kahler noted that Poison Canyon has a lot of erodible soils. Hillman agreed and said the sponsor just lacked the technical background on how to aggrade a small stream; however, he added that the proposal was very well-written.

- *Independent Scientific Advisory Board Visit*: The Independent Scientific Advisory Board will be visiting Wenatchee, Washington, from July 19 to 21, 2017. One day is for visiting the Wenatchee River basin, one day is for visiting the Methow River basin, and one day is for presentations. Kahler said he believes the plan now is to visit the Methow River basin at a later date, because all three components were too much to cover in a 3-day period.
- *Next Steps*: The next meeting of the HCP Tributary Committees will be on July 13, 2017, when the HCP Tributary Committees will be evaluating the final General Salmon Habitat Program proposals.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on June 21, 2017:

- *Tumwater Dam Pacific Lamprey Passage Feasibility Study Update*: In the Rocky Reach Fish Forum, concerns were raised about Pacific lamprey passage issues at Tumwater Dam. The way the fish ladder is currently designed is not conducive to Pacific lamprey passage. The question is whether improvements can be made to improve Pacific lamprey passage. To address this question, Chelan PUD has funded a feasibility study. In the HCP Hatchery Committees, Alene Underwood (Chelan PUD HCP Policy Representative) provided an update on the status of the feasibility study. During the HCP Hatchery Committees meeting, Underwood indicated that technical staff at the District have been expecting to receive the feasibility study report for the past few months; however, the report is still under review by Chelan PUD's upper management. Chelan PUD is evaluating what their legal requirement is regarding Pacific lamprey passage at Tumwater Dam and the biological benefit that a passage structure at the dam will provide. Specifically, Chelan PUD is working on three items: 1) distributing the feasibility study as soon as possible; 2) determining regulatory nexus and requirements including off-license mitigation; and 3) preparing a biological benefit assessment to determine how passage improvements will influence future abundance. The report should be available in the next couple of months. Jim Craig recalled that when Bryan Nordlund (National Marine Fisheries Service [NMFS], retired) served on the HCP Coordinating Committees, Nordlund expressed concern that the denil structure could potentially exclude the largest of the Chinook salmon species (i.e., it was a caudal tail amplitude issue). Mike Tonseth (WDFW HCP Hatchery Committees Representative) noted that the structure was designed for sockeye salmon. Hillman also noted that Steve Rainey (USFWS consultant) designed the current fishway.
- *USFWS Bull Trout Consultation Update*: USFWS has made little progress on bull trout consultations due to other pressing issues.
- *NMFS Consultation Update*: NMFS provided an update on consultation for the six unlisted programs in the upper Columbia River, including: Wenatchee summer Chinook salmon,

Chelan Falls summer Chinook salmon, Wells summer Chinook salmon, Methow summer Chinook salmon, Priest Rapids fall Chinook salmon, and Ringold upriver bright fall Chinook salmon. The Ringold program will likely be a direct Section 7 consultation with the U.S. Army Corps of Engineers. The NMFS General Counsel prefers using the Section 4(d) process for Endangered Species Act (ESA) coverage for the other five programs rather than a Section 10 incidental take permit. Section 4(d) has a more flexible timeline, provides a wider range of actions under which a program can operate, and provides a continuing form of coverage. Section 10 is very specific, it has an expiring form of coverage, and operation changes could result in re-consultation. However, the language in the HCP stipulates Section 10 for ESA coverage. The PUDs are talking to their respective attorneys to determine if Section 4(d) is a workable alternative.

- *Review Hatchery Monitoring and Evaluation Plan Objectives*: The HCP Hatchery Committees have been reviewing the objectives in the Hatchery Monitoring and Evaluation (M&E) Plan to verify they are consistent with the updates made to the hatchery M&E timeline. The review is complete. Language will be added to the plan, mostly in the section on straying. Hillman explained that stray rates for within population and among populations are related to ESA criteria defined by the Upper Columbia Technical Recovery Team (UCTRT) and included in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan. Brood year stray rate, on the other hand, is not described in the Recovery Plan or UCTRT document and therefore those documents did not provide a criterion for brood year stray rate. Consequently, the HCP Hatchery Committees are discussing whether they need to have a target for brood year stray rate. The current brood year stray rate target in the Hatchery M&E Plan is 5%. There is no literature supporting a specific brood year stray rate target; however, some literature indicates stray rates of natural-origin fish can range anywhere from 1 to 100% depending on what spawning aggregate is considered. Hillman noted that changes can be made to programs that could affect the stray rates; however, complete brood year returns have to be reported years after any changes because fish from those brood years have not yet returned, so this is always being evaluated retrospectively. The HCP Hatchery Committees will continue to measure and evaluate a target for brood year stray rates in light of other metrics. The genetics component is also still under review. Kirk Truscott asked how the HCP Hatchery Committees can make changes if there is no target to apply it against. Tonseth said it comes down to accountability.
- *Methow Steelhead Gene Flow:* The Wells HCP Hatchery Committee continued their discussion on steelhead gene flow in the Methow River basin. The Wells HCP Hatchery Committee is working toward a proportionate natural influence (PNI) target of 0.67 or greater for in-basin. Depending on steelhead escapement levels, a basin-wide PNI can be achieved by setting percent hatchery-origin spawners (pHOS) targets for specific areas (i.e., some areas have low pHOS and others have high or fluctuating pHOS, so long as PNI can be achieved basin-wide).

Korth asked what a low pHOS is, and Tonseth said 0.25. Hillman added that the pHOS in the conservation zone would be divided between programs such that conservation programs would have a pHOS target of 0.20 and the safety-net program would have a pHOS target of 0.05. Tonseth clarified this is for run escapements larger than 500 fish. He also added this is modeled similarly to Methow spring Chinook salmon. Hillman said discussions are ongoing.

- *Hatcheries and Life Cycle Modeling*: The NOAA Northwest Fisheries Science Center is modeling effects of hatchery programs on the Wenatchee spring Chinook salmon life cycle. Hillman invited the senior modeler, Jeff Jorgensen, to present these studies to the HCP Hatchery Committees during their meeting on August 16, 2017. Hillman suggested the HCP Coordinating Committees also attend the presentation. Kristi Geris will coordinate with Hillman and Sarah Montgomery to obtain meeting and WebEx information for Jorgensen's presentation to the HCP Hatchery Committees, which Geris will distribute to the HCP Coordinating Committees. *(Note: this presentation has been postponed to the HCP Hatchery Committees meeting on September 20, 2017.)*
- *Draft Hatchery M&E Annual report*: The HCP Hatchery Committees are currently reviewing the Draft 2016 Chelan PUD and Grant PUD Hatchery M&E Annual Report. Comments are due by July 15, 2017.
- *Next Steps*: The next meeting of the HCP Hatchery Committees will be on July 19, 2017.

III. Chelan PUD

A. Tumwater Dam Pacific Lamprey Passage Feasibility Study Progress Update (Lance Keller)

Lance Keller said Jim Craig requested that Chelan PUD provide an update on the Tumwater Dam Pacific Lamprey Passage Feasibility Study; however, Tracy Hillman covered this under the HCP Hatchery Committees update. Keller asked Craig if he had further questions at this time, and Craig said Hillman's update was adequate.

B. Rocky Reach Large Unit Repair Update (Lance Keller)

Lance Keller said Rocky Reach Dam has four large turbine units, C8, C9, C10, and C11, which are the northern-most units and were built in 1961. Keller said in 2013, one unit (C10) started leaking oil and metal particles were found in an oil strainer. He said mechanic crews investigated this and discovered the stainless steel rod that delivers oil to the servo motor was machined too thin and had developed a hairline crack. He said Chelan PUD determined this crack could lead to catastrophic failure and because all large units were designed similarly, Chelan PUD decided to take the four large units out of service. Keller said Chelan PUD then worked with the Rocky Reach HCP Coordinating Committee and Bryan Nordlund and ultimately welded blocks to fix the blades on the large units at a specific angle, which was selected to be the most hydraulically efficient (and best for fish passage) at full turbine flow.

Keller said Chelan PUD last provided a Rocky Reach large unit repair update to the HCP Coordinating Committees in 2014 that included the following timeline for repairing the units assuming no further issues developed:

Schedule for Rocky Reach Large Unit Repair, 2014

Turbine Unit	Return to Service
C8	December 2017
C9	October 2016
C10	December 2020
C11	November 2019

Keller said after providing this timeline during the HCP Coordinating Committees meeting on May 24, 2016, Chelan PUD notified the HCP Coordinating Committees that cracks were identified in the wheels of the bridge crane required to hoist the turbines for repair. He recalled that the repair of the bridge crane was fast tracked internally by making an emergency declaration and is scheduled to be back in service in 2017. He said with the bridge crane back in service this year, the updated timeline for repairing the large units is as follows:

Schedule for Rocky Reach Large Unit Repair, 2017

Turbine Unit	Return to Service
C8	Fourth Quarter 2017
C9	First Quarter 2019
C10	First Quarter 2020
C11	First Quarter 2021

Keller noted that the return-to-service date for C11 is the same year Chelan PUD will conduct the HCP 10-year check-in survival study for Rocky Reach Dam. He said if the unit repairs cannot be completed on schedule, Chelan PUD determined C11 is the preferred unit to be offline during a survival study. He explained that given C11 is the northern-most unit, being offline will not cause a shift in flow nor provide a calm, central area for predators to stage in the immediate tailrace.

Jim Craig asked if the servo rods will be completely replaced, and Keller said yes. John Ferguson said with C8 scheduled to be back in service this fall, he suggested that Chelan PUD provide another Rocky Reach Dam large unit repair update during an HCP Coordinating Committees meeting in late-summer 2017. Keller agreed. Jeff Korth asked if the large units will remain in a fixed position once the new servo rods are installed. Keller said no, the units will be restored to their Kaplan configuration.

C. Rock Island Powerhouse 1 Maintenance Update (Lance Keller)

Lance Keller said he was unable to obtain a Rock Island Powerhouse 1 maintenance update in time for today's meeting; therefore, Chelan PUD will provide this update during the HCP Coordinating Committees conference call on July 25, 2017.

D. Spill Gate Change at Rock Island Dam (Lance Keller)

Lance Keller recalled providing an update during the HCP Coordinating Committees conference call on May 23, 2017, about the notification from May 18, 2017, that Rock Island Dam lost capability of operating automated spill gate 7. Keller said the issue with spill gate 7, coupled with two other spill gates being out of service, resulted in reduced capacity to respond to a significant flow event; therefore, two notch gates were converted back to full gate operation. He said this discussion resulted in an action item for Chelan PUD to explain the cause of losing the use of automated spill gates 7, 17, and 25 at Rock Island Dam, as well as the timeline for repairing the gates.

Keller explained that the spill gates at Rock Island Dam are suspended on large cables. He said on spill gate 7, one cable became unattached; therefore, when one end of the gate raised up, the other end did not, damaging the gate and guiderails. He said river flow needs to decrease in order to deploy divers for repairs. He said currently, spill gate 7 is jammed in place.

Keller said spill gates 17 and 25 are in a similar condition. He said spill gate 17, during operation, had the gear shaft twisted in half in the gear box, causing one end of the gate to raise and the other end not. He said again, the gate was damaged and the gear box needs to be replaced. He said replacement parts are 20 weeks out. Keller said after the spill gate 17 failure, mechanics observed the same cracks in spill gate 25 and removed that gate from service. Keller added, however, that spill gate 25 has not yet failed. Upon review it was also discovered that the gear box was undersized for the operation, and engineers are looking into replacement with a new gear box. He said Chelan PUD is hopeful the spill gates will be equipped with new gear boxes and back in service by spring 2018.

John Ferguson asked about the other automated spill gates. Keller said all other gates have been inspected and they are in good condition. He added that anytime a failure such as this occurs, Chelan PUD inspects all other similar structures.

Jeff Korth asked how the gates are replaced. Keller said the gates are removed in sections, and each section is held in place using a crane.

Kirk Truscott asked how often inspections are conducted on the spill gates, because there seems to be a trend of aging parts failing at the project. He said it may behoove Chelan PUD to inspect and replace parts before they fail. Keller agreed there have been some opportunities for better planning and to be more proactive. He added, however, it is still difficult with Rock Island Dam because once it is determined parts are at the end of their lifespan, repairs still take a long time because the parts are so old, typically a redesign is needed and parts need to be located.

Keller said Chelan PUD is hoping for a modern-day fix for the gear boxes, and have extra parts on hand for when the others gates show signs of possible failure.

IV. Douglas PUD

A. Wells Hatchery Modernization Update (Tom Kahler)

Tom Kahler said the modernization is expected to be complete by the end of August 2017. John Ferguson suggested convening an HCP Coordinating Committees meeting at the dam after the modernization is complete, including a tour of the upgrades. Kahler agreed this is a good idea and noted there is a conference room at the hatchery.

B. Wells Dam Bypass Update (Tom Kahler)

Tom Kahler recalled that bypass barriers have been pulled from spill bay 6 nearly all spring 2017. He said river flow out of Grand Coulee Dam is diminishing and barriers will likely be reinstalled in spill bay 6 in the next week.

Kahler said the newly installed passive integrated transponder (PIT)-tag detection system in spill bay 2 is operating well. He said when spill is high, detections are low; however, when spill is low, detections increase. He noted there were a few orphan PIT tag detections on June 23, 2017.

Jeff Korth asked about total dissolved gas out of Chief Joseph Dam. Kahler said he does not have those data available at this time and the Douglas PUD biologist who monitors those data has been in the field for the past couple of weeks.

V. USFWS

A. Subyearling Spring Chinook Salmon Rearing in the Columbia River (Jim Craig)

Jim Craig said USFWS now has genetic data from their M&E program in the Entiat River basin which indicate that subyearling ESA-listed spring Chinook salmon are outmigrating, residing, and rearing in the mainstem Columbia River. Craig said to date, fisheries managers believed the only subyearling Chinook salmon rearing in the Columbia River were of the non-listed summer Chinook salmon variety. He added that subyearling spring Chinook salmon have a life history which is difficult to monitor. He said follow-up emails with Scott Carlon also revealed this life history trait in the Deschutes River (i.e., subyearling spring Chinook salmon leave the tributaries in the fall and overwinter in the mainstem Deschutes River).

Kirk Truscott asked if USFWS is PIT-tagging fish out of the Entiat River basin, and Craig said yes. Craig said he is concerned there is no juvenile monitoring during the fall when a lot of subyearlings emigrate from the Entiat River basin.

VI. WDFW

A. WDFW HCP Coordinating Committees Representation (Jeff Korth)

Jeff Korth said his last day before retirement is Friday, June 30, 2017. Korth said WDFW opened the position for Northcentral Regional Fish Program Manager. He said there were three applicants, including Chad Jackson. Korth said Jackson is the front runner, because of his extensive management experience. Korth said interviews for his replacement will be conducted July 13, 2017. He said WDFW has also been considering Mike Tonseth to serve as a WDFW HCP Coordinating Committees Alternate, particularly to keep close connections to HCP Hatchery Committees topics. *(Note: Tonseth is also the WDFW HCP Hatchery Committees Representative.)*

Korth requested to add Jackson and Tonseth to the HCP Coordinating Committees email distribution lists and provide them both with access to the HCP Coordinating Committees extranet site, because Jackson will potentially become the WDFW HCP Coordinating Committees Representative and Tonseth will likely be a new WDFW HCP Coordinating Committees Alternate. HCP Coordinating Committees representatives present agreed to Korth's request.

Kristi Geris will add Jackson and Tonseth to the HCP Coordinating Committees email distribution lists and request access to the HCP Coordinating Committees extranet site from Julene McGregor. *(Note: Geris added Jackson and Tonseth to the email lists and requested access to the extranet site following the meeting on June 27, 2017.)*

VII. HCP Administration

A. Jeff Korth Farewell (All)

The HCP Coordinating Committees and Tracy Hillman thanked Jeff Korth for his contributions to the HCPs and fisheries world and said it has been a pleasure to work with Korth over the years.

A farewell lunch was planned for Korth at McGlinn's at 12:00 p.m.

B. Next Meetings

The next scheduled HCP Coordinating Committees meeting is on July 25, 2017, to be held by conference call. *(Note: due to lack of agenda items, the HCP Coordinating Committees meeting on July 25, 2017, has been canceled.)*

The August 22, 2017, meeting will be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington.

The September 26, 2017, meeting will be held by conference call or in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington, as is yet to be determined.

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: September 27, 2017

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the August 22, 2017, HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met in-person at the Grant PUD Office in Wenatchee, Washington, on Tuesday August 22, 2017, from 10:00 a.m. to 12:15 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Bob Rose will coordinate internally to develop and provide a Yakama Nation (YN) HCP Representation Designation document for distribution to the HCP Coordinating Committees (Item I-C). *(Note: Rose provided a designation letter [Attachment B] to Kristi Geris following the HCP Coordinating Committees meeting on August 22, 2017, which Geris distributed to the HCP Coordinating Committees on August 23, 2017.)*
- Kristi Geris will coordinate with Tracy Hillman (HCP Hatchery Committees Chairman) and Sarah Montgomery (HCP Hatchery Committees Support Staff) to obtain meeting and WebEx information for Jeff Jorgensen's (National Oceanic and Atmospheric Administration [NOAA] Northwest Fisheries Science Center) presentation to the HCP Hatchery Committees on September 20, 2017, on a life-cycle model for Wenatchee River spring Chinook salmon, which Geris will distribute to the HCP Coordinating Committees (Item I-C). *(Note: Montgomery provided the HCP Hatchery Committees September 20, 2017, agenda with this information to the HCP Coordinating Committees on September 19, 2017.)*
- Chelan PUD will provide a Rocky Reach Dam large unit repair update during an HCP Coordinating Committees meeting in late-summer 2017 (Item I-C).
- John Ferguson will provide the paper, "The evolutionary basis of premature migration in Pacific salmon highlights the utility of genomics for informing conservation," by Daniel Prince et al., to Kristi Geris and Tracy Hillman for distribution to the HCP Coordinating and Hatchery Committees (Item II-A). *(Note: Ferguson provided the paper [Attachment C] to Geris and Hillman following the HCP Coordinating Committees meeting on August 22, 2017, which Hillman distributed to the HCP Hatchery Committees that same day, and Geris distributed to the HCP Coordinating Committees on August 23, 2017.)*
- Tom Kahler will discuss internally the feasibility to implement a temporary 1.0-foot fishway-entrance head differential from 22:00 to 04:00 daily during September 2017 to improve Pacific

Lamprey passage at Wells Dam ("lamprey operations"), in 1- or 2-day blocks (Item IV-A). *(Note: Kahler confirmed Wells Dam can accommodate the 2-day block design for head differentials at the fishway entrances, as distributed to the HCP Coordinating Committees by Kristi Geris on August 25, 2017.)*

- Anchor QEA will coordinate with Douglas PUD and the Aquatic Settlement Work Group (Aquatic SWG) regarding the Wells HCP Coordinating Committee discussion and HCP Decision about the Aquatic SWG Lamprey Operations Statement of Agreement (SOA; Item IV-A). *(Note: the Aquatic SWG convened a conference call on August 28, 2017, to discuss the HCP Decision about the Aquatic SWG Lamprey Operations SOA.)*
- Chelan PUD will provide a Rock Island Dam Powerhouse 1 Turbine Units B1 to B4 Rehabilitation Fact Sheet to Kristi Geris for distribution to the HCP Coordinating Committees (Item V-A). *(Note: Lance Keller provided the rehabilitation work submittal [Attachment H] to Geris on August 23, 2017, which Geris distributed to the HCP Coordinating Committees that same day.)*
- Anchor QEA will contact Mackenzie Gavery (Postdoctoral Research Associate, University of Washington/NOAA Northwest Fisheries Science Center) regarding possibly presenting her epigenetics research during the HCP Coordinating Committees meeting on October 24, 2017 (Item VI-B). *(Note: Gavery confirmed she can present her research in-person during the HCP Coordinating Committees meeting on October 24, 2017.)*
- The HCP Coordinating Committees meeting on September 26, 2017, will be held by conference call (Item VI-B).

Decision Summary

- Wells HCP Coordinating Committee representatives present approved the Aquatic SWG Lamprey Operations SOA, contingent upon: 1) Aquatic SWG review of 2013 radio-telemetry data regarding changes in fishway approach and ladder passage behavior of Pacific Lamprey when the fishway entrances are operated at a head differential of 1.0 foot; 2) change in hours of operation to 22:00 to 04:00; 3) consideration of 1- or 2-day block operations (the Wells HCP Coordinating Committee prefers 2-day blocks); 4) Aquatic SWG in-season management of operations based on analysis of daily fish counts, including discontinuing operations if negative impacts from the operation are observed; and 5) a post-season report being provided to the Wells HCP Coordinating Committee, which reviews results of the operation based on fish counts (Item IV-A).
- Wells HCP Coordinating Committee representatives approved via email the Wells HCP Coordinating Committee SOA, "To implement temporary fishway 'lamprey operations' in alternating 3-day blocks with normal operations during the 2017 Pacific Lamprey migration at Wells Dam," as follows: Douglas PUD approved on August 30, 2017, and the National Marine

Fisheries Service (NMFS), U.S. Fish and Wildlife Service (USFWS), Washington Department of Fish and Wildlife (WDFW), the YN, and the Colville Confederated Tribes (CCT) approved on August 31, 2017 (Item IV-A).

Agreements

- There were no HCP Agreements discussed during today's meeting.

Review Items

- There are no items that are currently out for review.

Finalized Documents

- There are no documents that have been recently finalized.

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. The following revisions were requested:

- Tom Kahler explained that Douglas PUD did not develop the Aquatic SWG Lamprey Operations SOA and was not a party advocating the operations; rather, Douglas PUD approved requesting Wells HCP Coordinating Committee concurrence with the proposed modified operations at Wells Dam. Kahler said, therefore, he does not believe Douglas PUD should lead this HCP Decision Item. Patrick Verhey said WDFW will take the lead on this discussion.
- Ferguson added notification of a recent paper by Prince et al., which may be of interest to the HCP Hatchery and Coordinating Committees.

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft June 27, 2017, meeting minutes. Kristi Geris said all comments and revisions received from members of the Committees were incorporated into the revised minutes and there were no outstanding edits or questions to discuss. HCP Coordinating Committees members present approved the June 27, 2017, meeting minutes, as revised. The YN abstained, because a YN representative was not present during the June 27, 2017, meeting.

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on June 27, 2017, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the meeting on June 27, 2017):*

- *Tom Kahler will provide fish passage count data for winter months at Wells Dam for review regarding timing of winter maintenance at Wells Dam to Kristi Geris for distribution to the Coordinating Committees (Item I-B).*
  Kahler recalled the initial impetus for this action item was regarding potentially starting the annual winter maintenance at Wells Dam in mid-November before the Thanksgiving holiday, rather than late-November or early December (in the interest of accommodating time off associated with the holiday season and avoiding freezing temperatures). He said this year, maintenance crews determined it is not feasible to start the necessary work before Thanksgiving; therefore, Kahler suggested removing this action item for now and revisiting it later, if needed. *(Note: Kahler later clarified that the current schedule is to begin winter maintenance starting the week of November 27, 2017, and it seems the first time this topic may resurface is in 2019, when the Thanksgiving holiday falls on the last week in November.)*
- *Chelan PUD will provide the Final 2016 Rocky Reach Juvenile Fish Bypass System Report to Kristi Geris for distribution to the Coordinating Committees (Item I-B).*
  Lance Keller provided the final report to Geris on June 28, 2017, which Geris distributed to the HCP Coordinating Committees that same day.
- *Anchor QEA will contact Mackenzie Gavery regarding possibly presenting her epigenetics research to the HCP Coordinating Committees during a future meeting (Item I-B).*
  Anchor QEA contacted Gavery, who indicated she is available to provide her presentation during the HCP Coordinating Committees meetings on September 26, October 24, or November 28, 2017. This will be further discussed during today's meeting.
- *Bob Rose will coordinate internally to develop and provide a YN HCP Representation Designation document for distribution to the HCP Coordinating Committees (Item I-B).*
  Rose said a designation letter was provided to the Priest Rapids Coordinating Committee and he will contact Paul Ward (YN) to obtain a letter for the HCP Coordinating Committees. This action item will be carried forward. *(Note: Rose provided a designation letter [Attachment B] to Kristi Geris following the HCP Coordinating Committees meeting on August 22, 2017, which Geris distributed to the HCP Coordinating Committees on August 23, 2017.)*

- *Kristi Geris will coordinate with Tracy Hillman and Sarah Montgomery to obtain meeting and WebEx information for Jeff Jorgensen's presentation to the HCP Hatchery Committees on August 16, 2017, on a life-cycle model for Wenatchee River spring Chinook salmon, which Geris will distribute to the HCP Coordinating Committees (Item II-A).*
  This presentation has been postponed until the HCP Hatchery Committees meeting on September 20, 2017. This action item will be carried forward.
- *Chelan PUD will provide a Rocky Reach Dam large unit repair update during an HCP Coordinating Committees meeting in late-summer 2017 (Item III-B).*
  This action item will be carried forward.
- *Chelan PUD will provide a Rock Island Dam Powerhouse 1 maintenance update during the HCP Coordinating Committees conference call on July 25, 2017 (Item III-C).*
  This will be discussed during today's meeting.
- *Kristi Geris will add Chad Jackson, potentially the new WDFW HCP Coordinating Committees Representative, and Mike Tonseth, likely a new WDFW HCP Coordinating Committees Alternate, to the HCP Coordinating Committees email distribution lists and request access to the HCP Coordinating Committees extranet site from Julene McGregor (Douglas PUD Information Systems Staff; Item VI-A).*
  Geris added Jackson and Tonseth to the email lists and requested access to the extranet site following the meeting on June 27, 2017.
- *The HCP Coordinating Committees meeting on July 25, 2017, will be held by conference call (Item VII B).*
  Due to lack of agenda items, the HCP Coordinating Committees meeting on July 25, 2017, was canceled.

II. HCP Tributary and Hatchery Committees Update

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman reported that the HCP Tributary Committees did not meet in August 2017; however, he updated the HCP Coordinating Committees on select actions and discussions that occurred during the HCP Tributary Committees meeting on July 13, 2017, as follows:

- *Beaver Fever: Restoring Ecosystem Function Project*: The Rock Island HCP Tributary Committee received a budget amendment request from Trout Unlimited requesting to use $10,000 under Construction and Permitting to purchase a hydraulic post driver to install beaver-dam analogs. The request was denied because equipment purchased by a project sponsor with Plan Species Account funds becomes the property of the Committee. The HCP Tributary Committees prefer not to get involved in equipment storage, maintenance, and liability. Hillman said one exception is when the Wells HCP Tributary Committee purchased and stored piezometers, which are easy to store and have little to no risk for injury. He said the HCP Tributary Committees reviewed four budget amendment requests during the meeting on July 13, 2017, and this was the only request that was denied.

- *Clear Creek Fish Passage and Instream Flow Enhancement Project*: Hillman said this budget amendment request was approved in August 2017. The Rocky Reach HCP Tributary Committee received a scope change and budget amendment request from Trout Unlimited to add activities to the deliverables and for an additional $77,174.40 to complete the project. Hillman said the sponsor is helping facilitate water supply system upgrades to the Thousand Trails Leavenworth campground resort, which currently draws water from Clear Creek to supply irrigation and potable water to the resort. He said the work involves drilling a domestic well, which requires a lot of permitting. He said the sponsor has already invested about the same amount of money that is being requested. He noted that budget amendment requests typically involve moving money from one line item to another, and do not usually involve requesting more money; however, the request was approved because the upgrades will provide a lot of benefit, notably to two Endangered Species Act (ESA)-listed salmonids. He said this project was originally a Small Projects Program Proposal; it is now a General Salmon Habitat Program Proposal, with a total Rocky Reach HCP Tributary Committee contribution of $146,674.40. Jim Craig asked about the flow through Clear Creek in this area, and Hillman said he did not know the base flow, but the project would increase base flows by about 0.5 cubic feet per second. Hillman said the sponsor also received funding from the Upper Columbia Salmon Recovery Board to remove the existing water diversion structure.
- *Poison Canyon Restoration Project*: Hillman recalled this Small Projects Program Proposal, which was submitted to the Rock Island HCP Tributary Committee in June 2017 from the Chelan County Natural Resources Department (CCNRD). The purpose of the project was to aggrade incised reaches within Poison Canyon by installing wood jams to improve instream flows and water quality. Poison Canyon is a tributary in the Mission Creek watershed. The original proposal was declined because the project was overly engineered and too expensive. CCNRD resubmitted the application, which addressed the Committees' concerns and reduced costs by almost half. The total cost of the project is $37,918, the sponsor requested $21,600 from HCP Tributary Funds, and the Rock Island HCP Tributary Committee approved the request.
- *Cottonwood Bridge Removal Project*: The Rocky Reach HCP Tributary Committee received a Small Projects Program application from Chelan-Douglas Land Trust to remove an illegally built bridge. The funding would be used to remove the steel and creosoted railroad ties that make up the Cottonwood Bridge; however, would not include removing the abutments. The total cost of the project is $95,000, the sponsor requested $21,000 from HCP Tributary Funds, and the Rocky Reach HCP Tributary Committee approved the request. Removal of the bridge

is the beginning of a restoration effort for floodplain enhancement on the Cottonwood property located adjacent to the Entiat River.

- *M2 WDFW Flow Connection Project*: Hillman noted that "M2" represents the middle reach of the Methow River. He said the purpose of this project is to remove a small levee, which blocks off floodplain habitat, located at river mile 46.8 on the Methow River. The total cost of the project is $78,828, the sponsor requested $11,824 from HCP Tributary Funds, and the Wells HCP Tributary Committee approved the request. Hillman said most of the affected land is owned by WDFW. In order for the adjacent landowner to support the project, the sponsor will install a fence between the WDFW property and the adjacent landowner.
- *M2 Mid-Sugar Acquisition Project*: The purpose of this project is to acquire 17.3 acres of riparian and floodplain habitat including about 1,300 feet of stream bank and 550 feet of side channel near river mile 42.2 on the Methow River. The total cost of the project is $291,268, the sponsor requested $43,690 from HCP Tributary Funds, and the Wells HCP Tributary Committee approved the request.
- *Piscine Passage Design for Brush and Minnow Creeks Project*: Cascade Columbia Fisheries Enhancement Group (CCFEG) requested funding to produce designs and submit permits for projects that will restore fish passage and connectivity within Minnow and Brush creeks, tributaries to the Chiwawa River. The total cost of the project is $162,500, the sponsor requested $52,500 from HCP Tributary Funds, and the HCP Tributary Committees elected not to fund this project, because: 1) Chinook salmon are only present in the lower 200 meters of Brush Creek; and 2) the Brush Creek culvert is about 1 mile upstream of the confluence with the Chiwawa River. Therefore, there is low biological benefit associated with the project. Additionally, beavers use the culverts for building beaver dams. Hillman noted that the USFWS will fund part of Minnow Creek design.
- *Methow Basin Barrier and Diversion Assessment Project*: CCFEG would like to complete a comprehensive and standardized assessment of all fish barriers in the Methow River basin, and prioritize barrier sites for restoration. The total cost of the project is $206,650, the sponsor requested $40,000 from HCP Tributary Funds, and the Wells HCP Tributary Committee approved the request. John Ferguson said he thought something like this would have already been completed in the Methow River basin. Hillman said there have been some piecemeal efforts; however, a comprehensive assessment has not yet been completed.

- *2017 General Salmon Habitat Program Project Summary:* Hillman projected the following summary table of 2017 General Salmon Habitat Program Projects:

Project Name	**Sponsor[1]**	**Total Cost**	**Request from HCP-TC**	**HCP-TC Contribution[2]**
M2 WDFW Flow Connection	MSRF	$78,828	$11,824	W: $11,824
M2 Mid-Sugar Acquisition	MSRF	$291,268	$43,690	W: $43,690
Piscine Passage Design for Brush and Minnow Creeks	CCFEG	$162,500	$52,500	$0
Methow Basin Barrier and Diversion Assessment	CCFEG	$206,650	$40,000	W: $40,000
	Total:	**$739,246**	**$148,014**	**$95,514**

[1] CCFEG = Cascade Columbia Fisheries Enhancement Group; MSRF = Methow Salmon Recovery Foundation.
[2] RI = Rock Island Plan Species Account; RR = Rocky Reach Plan Species Account; W = Wells Plan Species Account.

- *HCP Tributary Committees Logo*: The HCP Tributary Committees approved the following logo:

- *Next Steps*: The next meeting of the HCP Tributary Committees will be on September 14, 2017.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on August 16, 2017:

- *Draft Chelan PUD Coho Salmon Mitigation SOA*: Chelan PUD submitted the Draft Chelan PUD Coho Salmon Mitigation SOA to the HCP Hatchery Committees for review. Recall, the HCP Coordinating Committees previously approved a 7 percent Coho salmon hatchery compensation rate. The SOA is available for a 30-day review, with comments due to Chelan PUD on September 14, 2017. Chelan PUD will request approval of this SOA during the HCP Hatchery Committees meeting on September 20, 2017.
- *Draft 2018 Chelan PUD Hatchery Monitoring and Evaluation (M&E) Implementation Plan*: The Rock Island and Rocky Reach HCP Hatchery Committees reviewed and approved the 2018 Chelan PUD Hatchery M&E Implementation Plan.
- *USFWS Bull Trout Consultation Update*: USFWS is working on the Methow steelhead consultation and plans to write a coverage memorandum similar to the one completed for spring Chinook salmon. USFWS is also working on finalizing the Biological Opinion for the Wenatchee subbasin programs.

- *NMFS Consultation Update*: NMFS is working on finalizing the proposed action for the unlisted programs in the upper Columbia River. Recall, Douglas and Chelan PUDs were discussing with their respective attorneys whether Section 4(d) was a workable alternative for ESA coverage rather than a Section 10 incidental take permit. The PUDs have now identified their preferred ESA pathway; Douglas PUD will use Section 10 coverage and Chelan PUD will use Section 4(d) coverage. Hillman said Ringold Hatchery, which is operated under the U.S. Army Corps of Engineers (USACE), is part of the consultation package. NMFS is initiating consultation with USACE, and Mike Tonseth added that coordination calls have now been arranged between WDFW, NMFS, USFWS, and USACE.
- *Wenatchee Spring Chinook Salmon Update*: WDFW reported that about 1,300 spring Chinook salmon have passed Tumwater Dam. WDFW surplused 302 male Chinook salmon, which were mostly jacks. The Chiwawa spring Chinook salmon program met its production obligation target; however, the natural-origin target was not met because: 1) there were few adult natural-origin fish and they were difficult to acquire; 2) the Chiwawa weir was not operational as early in the season as intended because of high flows; and 3) mechanical issues took the Chiwawa weir out of operation for 1 week at a critical point during the trapping effort. The program is four females short of its natural-origin target. Tonseth said four adult returns from the conservation program were used to make up the difference.
- *Chelan Falls Trap*: Chelan PUD reported that the Chelan Falls summer Chinook salmon program is 19 females short of its broodstock collection target. The trap is shutdown this week for habitat restoration work in the Chelan River. Trapping will continue next week and stop at the end of the month. Tonseth said, as of this morning, a decision was made to forego operating the trap for another week, and the program will acquire 19 females from the Entiat National Fish Hatchery.
- *Genetic Monitoring Update:* The HCP Hatchery Committees decided to ask the WDFW Genetics Laboratory to provide a short paper identifying appropriate objectives, questions, and analyses for evaluating the effects of hatchery programs on fish genetics.
- *Spring Chinook Salmon in the Methow Basin: Status of Adult Management and Translocation to the Chewuch River*: Hillman recalled the HCP Hatchery Committees' plan to translocate spring Chinook salmon from the Methow program to the Chewuch River to evaluate the efficacy of adult translocation as a surrogate to early-term imprinting in order to address homing fidelity issues in Methow spring Chinook salmon. WDFW reported that this year, the Methow spring Chinook salmon program may not meet the natural-origin target of 122 fish, which means the Chewuch translocation study will not occur this year.
- *M&E Plan for PUD Hatchery Programs 2017 Update*: The HCP Hatchery Committees have been updating their Hatchery M&E Plan. They are currently working on the genetics objectives, Non-target Taxa of Concern section, and Adaptive Management section. Over the next several

months, the HCP Hatchery Committees will identify important changes in each hatchery program. Hillman said in many cases there are data dating back to the 1970s; however, there have been changes throughout the years. He said, for example, for a given period of time there may have been no changes in operations (status quo), but during other periods, there may have been major changes in operations (e.g., change in release numbers). These changes will represent important interruptions in the data time series, and the HCP Hatchery Committees want to analyze these changes separately.

- *Next Steps*: The next meeting of the HCP Hatchery Committees will be on September 20, 2017, when Jeff Jorgensen will present on a life-cycle model for Wenatchee River spring Chinook salmon. Recall, Kristi Geris will provide the WebEx information to the HCP Coordinating Committees, for those interested in calling into the presentation.

B. Prince et al. Paper (John Ferguson)

John Ferguson notified the HCP Coordinating Committees that a paper was recently published, which could potentially have huge implications for spring Chinook salmon management in the basin. He said the HCP Hatchery Committees may also be interested in the paper. He said he will provide the paper, "The evolutionary basis of premature migration in Pacific salmon highlights the utility of genomics for informing conservation," by Daniel Prince et al., to Kristi Geris and Tracy Hillman for distribution to the HCP Coordinating and Hatchery Committees. *(Note: Ferguson provided the paper [Attachment C] to Geris and Hillman following the HCP Coordinating Committees meeting on August 22, 2017, which Hillman distributed to the HCP Hatchery Committees that same day, and Geris distributed to the HCP Coordinating Committees on August 23, 2017.)*

III. Douglas PUD

A. Wells Dam Bypass Operations Update (Tom Kahler)

Tom Kahler said, per the Douglas PUD 2017 Bypass Operating Plan, bypass operations at Wells Dam were terminated on August 19, 2017, at 24:00.

IV. WDFW

A. DECISION: Aquatic SWG Lamprey Operations SOA (Patrick Verhey)

John Ferguson said the Aquatic SWG has been discussing Pacific Lamprey passage at Wells Dam since January 2017 and during the last Aquatic SWG meeting on August 9, 2017, the Aquatic SWG agreed to request Wells HCP Coordinating Committee concurrence, "to implement a temporary 1.0-foot fishway-entrance head differential for Pacific Lamprey from 17:00 to 00:59 daily during the 2017 Pacific Lamprey migration at Wells Dam," as described in the Lamprey Operations SOA (approved August 16, 2017; Attachment D), which was distributed to the HCP Coordinating Committees by Kristi Geris on August 17, 2017.

Ferguson said the SOA, as written, is the same request approved by the Wells HCP Coordinating Committee in past years. He said, however, there was also some discussion about shifting the lamprey operations window. He said based on past radio-telemetry data, Ralph Lampman (YN) recommended 21:00 to 05:59 as the best timing for Pacific Lamprey passage with the least overlap with steelhead, and Chinook, coho, and sockeye salmon passage. Ferguson said Bob Rose suggested 22:00 to 03:59 as a possible operations window, based on existing Columbia and Snake rivers projects Pacific Lamprey passage data.

Patrick Verhey said results from past lamprey operations, as described in Attachment D, were inconclusive due to low sample sizes. He said this year, Pacific Lamprey passage numbers are much higher, which could provide more substantive results. He said considering this, USFWS initiated the discussion of implementing lamprey operations at Wells Dam in 2017, and WDFW drafted the SOA. Verhey said, Lampman and Rose then suggested different lamprey operations windows; however, considering the limited review time, the Aquatic SWG decided to submit the same request as approved in past years to increase the likelihood of Wells HCP Coordinating Committee approval this year. Verhey said perhaps after further analysis, implementing alternate time windows can be considered for future years.

Rose said he believes it is important to note that at all Columbia and Snake rivers dams, Pacific Lamprey passage times are the same. He said movement begins around sunset, is strong through about midnight, and then stops at 04:00. He said he understands Verhey's comment about conducting further analyses; however, he is uncertain about what a sufficient analysis would entail (i.e., to what degree of data are needed to present to the Wells HCP Coordinating Committee to approve moving the time window?). He said no one wants to slow progress, which is why the Aquatic SWG presented the same SOA as approved in past years, so as to at least have an agreement in place for 2017. Verhey agreed.

Tom Kahler said he is curious why everyone is convinced the lamprey operations described in the SOA will benefit Pacific Lamprey. He recalled, when Douglas PUD conducted Dual-Frequency Identification Sonar (DIDSON) and radio-telemetry studies at Wells Dam, these data indicated that fish swam more easily at the 1-foot versus 1.5-foot head differential; however, the DIDSON study could not provide information regarding Pacific Lamprey approach to the fishway entrances, which would require radio-telemetry or acoustic-telemetry studies to determine. Radio-telemetry studies indicate many fewer fish attempting to pass at the 1-foot head differential than at the 1.5-foot differential. He said if an operational change will be implemented at Wells Dam, he wants to be sure the Aquatic SWG and Wells HCP Coordinating Committee are sure the change is benefiting passage, not impeding it. He said currently, about 60 to 70 Pacific Lamprey have been counted passing Wells Dam this year. He said it seems these fish are passing the dam with no issues, and there is no evidence passage is being impeded.

Kirk Truscott said he has the same comments as Kahler. Truscott said he recalls the DIDSON study years had so few fish, the data were not significant. He said, however, the RT studies had a larger sample size, which indicated a roughly 16 percent improvement in passage once fish were in the fish ladder at a 1-foot head differential; however, there was about a 200 percent decrease in approaches under the 1.0-foot head differential. He said, therefore, while the lamprey operations may improve passage in the lower fish ladder, the overall numbers passing the dam do not improve as a whole.

Ferguson asked about the sample sizes. Truscott said he recalls about 35 fish approached at the 1.5-foot head differential and about 12 fish approached at the 1-foot head differential.

Rose said there are no substantive data, which is why he proposes installing more antennas at the fishway entrances at Wells Dam. He added that much larger projects have higher passage numbers, and he finds it hard to believe Pacific Lamprey have a hard time locating the entrances at Wells Dam. He said by the time Pacific Lamprey reach Wells Dam they are already tired, and he believes if there is a lower velocity passage route, fish will find it.

Ferguson asked for thoughts or concerns about lamprey operations effecting Plan species. Truscott said statistically, there was no significant difference in passage; however, steelhead and coho salmon overlap the most with the adult Pacific Lamprey migration. He said there was a consistent delay in steelhead passage; however, not significant. Ferguson asked how delay was measured. Kahler said delay was measured using passive integrated transponder (PIT) tag data only, because DIDSON was not capable of measuring delay. He said PIT-tag detections for steelhead migrating from Rocky Reach Dam to Wells Dam indicated travel time was a little slower.

Truscott said his biggest concern is not impacts to Plan species; rather, he wants to make sure a change in fish ladder passage will not hinder approach conditions for Pacific Lamprey. He suggested approving the Lamprey Operations SOA, contingent that the Aquatic SWG has reviewed and understands these radio-telemetry data. He asked if these data on differences in fishway approach were discussed within the Aquatic SWG, and Verhey said not to his recollection. Kahler expressed surprise at this, considering the Douglas PUD representatives on the Aquatic SWG stated they have attempted to discuss the differences in approach on multiple occasions, without generating any apparent interest from the rest of the SWG.

Ferguson asked about the reasoning behind a 17:00 start time, and Truscott noted this is a peak passage time for Chinook salmon. Kahler said, specifically, 16:00 to 17:00 is the second highest passage hour for Chinook salmon, based on Wells Dam window count data from 1998 to 2016.

Kahler distributed hard copies of Wells Dam count-window data for Pacific Lamprey, steelhead, and Chinook salmon (Attachment E), which Geris distributed electronically to the HCP Coordinating Committees on August 23, 2017. Kahler said for most salmonids, Wells Dam count window passage times from Pool 19 (lower fish ladder) to Pool 68 (near the fish ladder exit) is about 2 hours, plus about 28 minutes for gallery time. He said most salmonids travel back and forth between fishways before choosing a fishway to ascend, making it difficult to say when fish actually entered and exited the fish ladders. He said, however, in general it takes salmonids no more than 3 hours to travel from the fish ladder entrance to the count window.

Kahler said for Pacific Lamprey, based on the radio-telemetry studies, the maximum travel time was 38 hours, the minimum was 4 hours, and average was 5.5 hours. Truscott said if 17:00 is close to the peak passage time for Chinook salmon and it takes about 3 hours to travel through the Wells Dam fish ladders, those fish would be arriving to the entrances at about 14:00, which may be the reasoning behind a 17:00 start time for lamprey operations.

Truscott asked about lag time between changes in head differentials. Kahler said the fish pumps at Wells Dam are operated using a programmable logic controller, so changes happen automatically and the difference between head differentials is rapid (he guessed about 10 minutes).

Ferguson asked what the current average river flow is past Wells Dam during September, and Kahler said about 85,000 cubic feet per second.

Mike Tonseth asked about night lighting through the fish ladders. Kahler said the lights are always on in the fish ladders; however, there are no lights in the collection galleries. Tonseth noted that Pacific Lamprey are more darkness-oriented than Chinook salmon. Kahler said he wondered whether the ladder lighting could be set on a cycle, and he said this has never been implemented.

Verhey asked the Wells HCP Coordinating Committee about considering a shift in the time period to later in the evening, so the end time would capture the end of the Pacific Lamprey passage period but not affect steelhead passage. Truscott suggested 22:00 for the start time and 04:00 for the end time to accommodate Chinook salmon and steelhead passage.

Keely Murdoch suggested implementing lamprey operations on alternate dates (i.e., block operations). She said this way, Pacific Lamprey passage can be monitored and evaluated with and without the modified head differential. Rose agreed and suggested implementing 1- or 2-day blocks and asked if this is feasible. Ferguson asked how these blocks would be evaluated. Rose suggested keeping it simple, such as a passage count difference. Jim Craig said there does not seem to be much of difference between implementing 1- versus 2-day blocks. Scott Carlon questioned whether 1 day is enough. Murdoch said the advantage of a 1-day block is it results in the most replicates. Verhey suggested 2-day blocks may result in more expression, in case fish are waiting for higher flow. Kahler said he will discuss internally the feasibility to implement a temporary 1.0-foot fishway-entrance head differential from 22:00 to 04:00 daily during September 2017 to improve Pacific Lamprey passage at Wells Dam (lamprey operations), in 1- or 2-day blocks. *(Note: Kahler confirmed Wells Dam can accommodate the 2-day block design for head differentials at the fishway entrances, as distributed to the HCP Coordinating Committees by Geris on August 25, 2017.)*

Wells HCP Coordinating Committee representatives present approved the Aquatic SWG Lamprey Operations SOA (Attachment D), contingent upon: 1) Aquatic SWG review of 2013 radio-telemetry data regarding changes in fishway approach and ladder passage behavior of Pacific Lamprey when the fishway entrances are operated at a head differential of 1.0 foot; 2) change in hours of operation to 22:00 to 04:00; 3) consideration of 1- or 2-day block operations (the Wells HCP Coordinating Committee prefers 2-day blocks); 4) Aquatic SWG in-season management of operations based on analysis of daily fish counts, including discontinuing operations if negative impacts from the operation are observed; and 5) a post-season report being provided to the Wells HCP Coordinating Committee, which reviews results of the operation based on fish counts.

Anchor QEA will coordinate with Douglas PUD and the Aquatic SWG regarding the Wells HCP Coordinating Committee discussion and HCP Decision about the Aquatic SWG Lamprey Operations SOA (Attachment D).

Note—
The Aquatic SWG convened a conference call on August 28, 2017, to discuss the HCP Decision about the Aquatic SWG Lamprey Operations SOA (Attachment D). After discussing the contingencies of approval, the Aquatic SWG agreed to all contingencies; however, modified implementing the lamprey operations in 2-day blocks to 3-day blocks. The Aquatic SWG Lamprey Operations SOA was updated to incorporate the Wells HCP Coordinating Committees' contingencies, including the 3-day blocks, and was approved by the Aquatic SWG on August 28, 2017 (Attachment F). Douglas PUD also drafted a Wells HCP Coordinating Committee SOA to formalize approval of the new Aquatic SWG SOA, which was distributed to the Wells HCP Coordinating Committee for email approval by Geris on August 30, 2017. Wells HCP Coordinating Committee representatives approved via email the Wells HCP Coordinating Committee SOA, "To implement temporary fishway 'lamprey operations' in alternating 3-day blocks with normal operations during the 2017 Pacific Lamprey migration at Wells Dam," (Attachment G) as follows: Douglas PUD approved on August 30, 2017, and NMFS, USFWS, WDFW, the YN, and the CCT approved on August 31, 2017.

V. Chelan PUD

A. Rock Island Powerhouse 1 Maintenance Update (Lance Keller)

Lance Keller recalled staff noticed cracks in the turbine blades of Units B1 to B4 of Powerhouse 1, which is the original powerhouse at Rock Island Dam. He said the cracked areas were fixed and the blades were determined to be crack-free; however, during follow-up inspections, staff discovered that additional cracks had formed. Keller said pieces of the blades were sent out for metallurgic analysis and results indicated the blades were at the end of their lifespan. He said Chelan PUD then conducted an in-depth analysis and decided on a rehabilitation option, which was vetted with the Rock Island HCP Coordinating Committee before Chelan PUD provided the recommendation to the Federal Energy Regulatory Commission. Keller said Chelan PUD requested and received bids for the rehabilitation work in December 2016, and a company named Andritz Hydro (based in Austria, with a location in the United States) provided a bid for completing all needed work before the 10-year check-in scheduled for Rock Island Dam in 2020.

Keller said Andritz Hydro recently conducted a finite metal analysis and identified parts which have a high probability of failing in less than 50 years, including: 1) rotor poles; 2) generator shaft; and 3) wicket gate body and stems. Keller said Units B1, B3, and B4, each have 20 bodies and stems per unit. He said previously, in Unit B2, mechanics had identified that 14 of 20 wicket gate stems were failing, which were repaired at the time of discovery. Keller said Chelan PUD had to request a contract amendment from the Board of Commissioners. He said these repairs are within the scope of the contract; however, they will cost more.

Kirk Truscott asked if these additional repairs have any ramifications to the schedule. Keller said because the failing parts were caught early enough, the repairs should not impact the schedule. He added, if failing parts are discovered in one unit, those parts are ordered for all units so waiting on these same parts will not be an issue in the future.

Mike Tonseth asked if Powerhouse 1 Units B1 to B4 are all offline now. Keller said yes, all units were taken offline immediately for safety. Tonseth asked if the resulting change in flow affected adult fish passage. Keller said yes, a change in adult fish passage has been observed, as passage through the left fish ladder had decreased (located closest to Powerhouse 1 Units B1 to B4) and an increase has been observed through the right and center fish ladders.

Patrick Verhey asked if replacing the turbine blades includes replacing the runners. Keller said yes, the turbine blades and runners are being rehabilitated to be as fish friendly as possible. He said the number of blades will be decreased as well. Truscott asked if the units will remain in a fixed position. Keller said yes, the rehabilitated will be a fixed blade configuration. He added that the fact sheet previously distributed to the HCP Coordinating Committees summarizes the changes quite well. He said he will provide the Rock Island Dam Powerhouse 1 Turbine Units B1 to B4 Rehabilitation Fact Sheet to Kristi Geris for distribution to the HCP Coordinating Committees. *(Note: Keller provided the rehabilitation work submittal [Attachment H] to Geris on August 23, 2017, which Geris distributed to the HCP Coordinating Committees that same day.)*

B. Rocky Reach and Rock Island Summer Spill (Lance Keller)

Lance Keller reviewed summer spill updates, as follows:

Rock Island Dam

Keller recalled, on May 26, 2017, summer spill was initiated at Rock Island Dam, shifting from a daily average spill target of 10 percent (spring spill) to 20 percent of the daily average river flow at Rock Island Dam. Keller said given the water year, Rock Island Dam was already spilling well above 10 percent at that time.

Keller said a Rock Island Dam end of summer spill notification was distributed to the HCP Coordinating Committees by John Ferguson on August 18, 2017. Keller recalled the criteria to shutdown summer spill includes: 1) Data Access in Real Time (DART) must have estimated that 95 percent of the juvenile subyearling Chinook salmon run has passed the project; and 2) daily subyearling Chinook salmon index counts at the juvenile bypass system must be 0.3 percent or less of the cumulative subyearling index total for any 3 out of 5 consecutive-day period. Keller said, as of August 18, 2017, the total cumulative subyearling Chinook salmon index count was more than 62,000 smolts, with an estimated passage of 99.4 percent of the total run having passed Rock Island Dam. He said in the previous week, counts had been below 0.3 percent of the total index. He said based on these data, Chelan PUD ended summer spill at Rock Island Dam on August 18, 2017, at 00:00, per the Rock Island Fish Spill Plan.

Rocky Reach Dam

Keller said on May 26, 2017, summer spill was initiated at Rocky Reach Dam, shifting to a daily average spill target of 9 percent of the daily average river flow at Rocky Reach Dam.

Keller said on July 30, 2017, about 1,200 juvenile subyearling Chinook salmon passed Rocky Reach Dam, and since that time, daily fish counts lingered in the 100s, and recently dwindled below 100. He said yesterday, on August 21, 2017, the daily subyearling Chinook salmon index count was 0.15 percent of the total index, which was the first time this season the index count was below 0.3 percent. He said currently, DART is estimating more than 99 percent of the juvenile subyearling Chinook salmon run has passed the project. He said Chelan PUD suspects criteria will be met to end summer spill within the next couple of days. *(Note: a Rocky Reach Dam end of summer spill notification was distributed to the HCP Coordinating Committees by Kristi Geris on August 25, 2017.)*

VI. HCP Administration

A. WDFW HCP Coordinating Committees Representation Designation Update (John Ferguson)

John Ferguson said a WDFW HCP Coordinating Committees representation designation letter (Attachment I) was distributed to the HCP Coordinating Committees by Kristi Geris on August 14, 2017. Ferguson said Chad Jackson is the new technical representative, Patrick Verhey is the new alternate, and Mike Tonseth is support staff.

B. Next Meetings

The next scheduled HCP Coordinating Committees meeting is on September 26, 2017, to be held by conference call.

John Ferguson recalled Anchor QEA's action item to contact Mackenzie Gavery regarding possibly presenting her epigenetics research during a future HCP Coordinating Committees meeting. HCP Coordinating Committees representatives present requested that Gavery present her research during the HCP Coordinating Committees meeting on October 24, 2017. Ferguson said Anchor QEA will contact Gavery with this request. *(Note: Gavery confirmed she can present her research in-person during the HCP Coordinating Committees meeting on October 24, 2017.)*

The October 24, 2017, meeting will be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington.

The November 28, and December 26, 2017, meetings will be held by conference call or in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington, as is yet to be determined.

RE: Change of Voting Representation – Mid Columbia HCP's

Dear John,

By this letter we notify the Mid-Columbia Coordinating Committees (including the Wells, Rocky Reach and Rock Island Coordinating Committees) of an important change in our representation on these Committees. Henceforth, Keely Murdoch will serve as our voting member and Bob Rose will become the alternate voting member. We have found it necessary to assign Bob a larger workload in the upcoming FCRPS NEPA process and must make this change for that reason.

Please notify the HCP Coordinating Committee members of this change in personnel. Thank You.

Sincerely,

Paul Ward, Manager

Yakama Nation Fisheries

EVOLUTIONARY GENETICS

The evolutionary basis of premature migration in Pacific salmon highlights the utility of genomics for informing conservation

Daniel J. Prince,[1,2] Sean M. O'Rourke,[1]* Tasha Q. Thompson,[1]* Omar A. Ali,[1] Hannah S. Lyman,[1] Ismail K. Saglam,[1,3] Thomas J. Hotaling,[4] Adrian P. Spidle,[5] Michael R. Miller[1,2]†

The delineation of conservation units (CUs) is a challenging issue that has profound implications for minimizing the loss of biodiversity and ecosystem services. CU delineation typically seeks to prioritize evolutionary significance, and genetic methods play a pivotal role in the delineation process by quantifying overall differentiation between populations. Although CUs that primarily reflect overall genetic differentiation do protect adaptive differences between distant populations, they do not necessarily protect adaptive variation within highly connected populations. Advances in genomic methodology facilitate the characterization of adaptive genetic variation, but the potential utility of this information for CU delineation is unclear. We use genomic methods to investigate the evolutionary basis of premature migration in Pacific salmon, a complex behavioral and physiological phenotype that exists within highly connected populations and has experienced severe declines. Strikingly, we find that premature migration is associated with the same single locus across multiple populations in each of two different species. Patterns of variation at this locus suggest that the premature migration alleles arose from a single evolutionary event within each species and were subsequently spread to distant populations through straying and positive selection. Our results reveal that complex adaptive variation can depend on rare mutational events at a single locus, demonstrate that CUs reflecting overall genetic differentiation can fail to protect evolutionarily significant variation that has substantial ecological and societal benefits, and suggest that a supplemental framework for protecting specific adaptive variation will sometimes be necessary to prevent the loss of significant biodiversity and ecosystem services.

INTRODUCTION

Invaluable economic, ecological, and cultural benefits are being lost worldwide as biodiversity decreases due to human actions (*1*–*3*). Legislation that provides a framework to protect unique species and population segments below the species level exists in many countries throughout the world (*4*, *5*). Protection is achieved by assessing the health of a defined conservation unit (CU), and if the unit is at risk, attempts are made to preserve/restore critical habitat and restrict stressors until the risk is eliminated. Assessing risk and developing a protection strategy is not possible without first establishing unit boundaries. Because the number of units that can be effectively managed is resource-limited (*6*), the delineation of units should be strategic and should prioritize evolutionary significance (*4*, *7*–*11*). Several criteria, such as genetic and ecological exchangeability (*10*), have been proposed for assessing evolutionary significance for CU delineation, but directly evaluating these criteria in natural populations is difficult (*5*).

Genetic methods play a pivotal role in the process of delineating CUs (*10*, *12*). To this end, genetic data from different regions of the genome are combined to produce measurements of overall genetic differentiation between populations. These measurements represent typical regions of the genome and serve as a proxy for evolutionary significance (*13*, *14*). However, because most genomic regions are primarily influenced by gene flow and genetic drift as opposed to selection, these measurements may fail to account for important adaptive differences between populations (*12*). Recent advances in genetic methodology facilitate the identification and evolutionary analysis of adaptively important loci (*15*–*22*) and provide an alternative way to assess evolutionary significance, but the utility of these loci for CU delineation is unclear and disputed (*12*, *23*–*27*).

Pacific salmon (*Oncorhynchus* spp.) provide a unique opportunity to investigate the application of genetic tools to the conservation of biodiversity below the species level (*4*, *6*, *28*–*30*). Despite extensive conservation efforts, Pacific salmon have been extirpated from almost 40% of their historical range in the contiguous United States, and many remaining populations have experienced marked declines and face increasing challenges from climate change (*31*–*35*). Reintroduction attempts of extirpated populations are largely unsuccessful because precise natal homing across highly heterogeneous environments has resulted in divergent selection and abundant local adaptation (*19*, *36*–*38*). Thus, maintaining existing stocks is critical for preserving the species themselves as well as the communities and ecosystems that rely on their presence (*39*). Genetic methods have been used extensively in delineating CUs in Pacific salmon [referred to as evolutionarily significant units (ESUs) or distinct population segments (DPSs) depending on the species] and, as a consequence of patterns of gene flow, have resulted in units that primarily reflect geography (*40*–*43*). Although current ESUs and DPSs certainly protect adaptive differences between distant populations, adaptations within highly connected populations are not necessarily protected (*10*, *34*). However, the evolutionary significance of these adaptations and the potential long-term consequences of not independently protecting them are poorly understood.

Perhaps the most recognized example of differential adaptation within highly connected populations of Pacific salmon is variation in adult migration timing (also called run timing) (*44*–*46*). In contrast

to typical adult salmon that mature sexually before freshwater migration, premature migrating individuals have a complex behavioral and physiological adaptation that allows them to access distinct habitats, distributing ocean-derived nutrients higher into watersheds, and spawn earlier in the season (*46*). Because of their distinct migration time and high fat content (*47*), premature migrating populations also provide additional, more-coveted, and culturally important harvest opportunities (*48*). For example, indigenous peoples in the Klamath Basin in northern California celebrated the return of premature migrating salmon with ceremonies that progressed upriver with the salmon migration (*49*).

Premature migrating populations have suffered grossly disproportionate impacts from human actions, such as dam building, mining, and logging, because of their extended time in freshwater and reliance on headwater habitat (*14*, *34*, *40*, *42*, *46*, *50*, *51*). With few exceptions (for example, some interior Columbia Basin locations), genetic analyses find little differentiation between proximate premature and mature migrating populations (*13*, *52*–*59*), and as a result, they are generally grouped into the same ESU or DPS (*40*, *42*). Therefore, despite the extirpation or substantial decline of premature migrating populations, the ESUs or DPSs to which they belong usually retain relatively healthy mature migrating populations and thus have low extinction risk overall (*14*, *40*, *42*). Here, we investigate the genetic and evolutionary basis of premature migration to explore potential consequences of not independently protecting this beneficial adaptation as well as the utility of genomics for informing conservation.

RESULTS

Initial genomic analysis consistent with current steelhead DPS delineations

Dramatic examples of premature migration are observed in coastal (noninterior) populations of steelhead (anadromous rainbow trout; *Oncorhynchus mykiss*) and Chinook salmon (*Oncorhynchus tshawytscha*). In these populations, premature migrating individuals (called summer steelhead or spring Chinook) use receding spring flows during freshwater migration to reach upstream habitat before hostile summer conditions in the lower watershed, hold for several months in deep cool pools while their gametes mature, then spawn at similar times to mature migrating individuals that have just entered freshwater (*44*, *46*). We began our investigation by compiling a set of 148 steelhead samples from five coastal locations across four DPSs in California and Oregon (Fig. 1A). Four of the locations (Eel, New, Siletz, and North Umpqua) represent the few remaining watersheds with significant wild premature migrating populations. The fifth location, Scott, contains only mature migrating individuals. Our sampling focused as much as possible on individuals that could be confidently categorized as premature or mature migrating based on collection date and location (Fig. 1B and table S1).

To collect high-resolution genomic information from these samples, we prepared individually barcoded restriction site associated DNA (RAD) libraries, sequenced them using paired-end Illumina technology, and aligned the sequence reads to a recent draft of the rainbow trout genome (tables S1 and S2) (*60*). We then used a probabilistic framework to discover SNPs and genotype them in each individual (*61*). A total of 9,864,960 genomic positions were interrogated in at least 50% of individuals, and 615,958 SNPs (that is, segregating sites) were identified ($P < 10^{-6}$). Of these SNPs, 215,345 had one genotype posterior greater than 0.8 in at least 50% of individuals. Population structure characterization and genome-wide analyses in nonmodel organisms are typically carried out with far fewer SNPs (*62*). We conclude that the sequence data obtained are appropriate for genome-wide measurements and high-resolution analyses of specific genomic regions.

To characterize the genetic structure of these populations, we performed PCA and estimated pairwise F_{ST} using genome-wide genotype data (*63*). The first two PCs revealed four distinct groups corresponding to the four current DPSs (Fig. 1C). Siletz and North Umpqua, which are two different locations within the Oregon Coast DPS, did not break into distinct groups until PC6 (Fig. 1D), indicating relatively low genetic differentiation between distinct locations within a DPS. In all cases, individuals with different migration phenotypes from the same location were in the same group. The pairwise F_{ST} estimates also revealed strong genetic differentiation between locations but little differentiation between migration phenotypes from the same location (Fig. 1E). The mean pairwise F_{ST} between migration groups from the same location was 0.032 (range, 0.018 to 0.039; $n = 3$), whereas the mean between groups from different locations was 0.125 (range, 0.049 to 0.205; $n = 25$). The combination of this genetic structure and observations of hybridization between premature and mature migrating individuals (*53*) suggests higher rates of gene flow between different migration groups from the same location than between groups from different locations. Thus, as found in previous analyses, the overall genetic structure among steelhead populations is predominantly influenced by geography, as opposed to migration phenotype. We conclude that measurements of overall genetic differentiation from genome-wide SNP data are consistent with current steelhead DPS delineations.

Premature migrating steelhead explained by a single allelic evolutionary event at a single locus

To identify genomic loci associated with premature migration, we performed association mapping of migration category. We used a likelihood ratio test (*64*) with λ correction for population stratification (*65*) to compare 181,954 SNPs between migration categories in North Umpqua and found 14 SNPs that were significant (Bonferroni-corrected α level: $P < 0.05$). Strikingly, all of these SNPs were located within a 211,251–base pair (bp) region (568,978 to 780,229) on a single 1.95-Mb scaffold (Fig. 2A; fig. S1, A and B; and table S3). Furthermore, when this analysis was repeated with Eel individuals using 170,678 SNPs, we obtained a similar pattern of association (Fig. 2B; fig. S1, C and D; and table S3). The strongest associated SNPs in both sample locations were flanking two restriction sites approximately 50 kb apart and located just upstream and within a gene identified as *GREB1L* (Fig. 2C; see Discussion for more information on *GREB1L*). The strength of these associations was unexpected given the phenotypic complexity of premature migration and the relatively low number of samples analyzed. We conclude that the same single locus is strongly associated with migration phenotype in at least two DPSs.

To investigate the evolutionary history of this locus, we sequenced three amplicons, each of approximately 500 bp, from the *GREB1L* region in all individuals from all populations (Fig. 2C and tables S1, S4, and S5) and used these sequences to construct a haplotype tree based on parsimony (*66*). Strikingly, the tree contained two distinct monophyletic groups corresponding to migration phenotype (Fig. 2D). For 123 of 129 individuals, both haplotypes separated into the appropriate migration category clade. The remaining six individuals (four Siletz and two North Umpqua samples originally classified as mature migrating) had one haplotype in each migration category clade (Fig. 2D), suggesting heterozygosity at the causative polymorphism(s). Furthermore, although there was little differentiation within the mature migration clade, premature migration haplotypes from Siletz and North Umpqua were

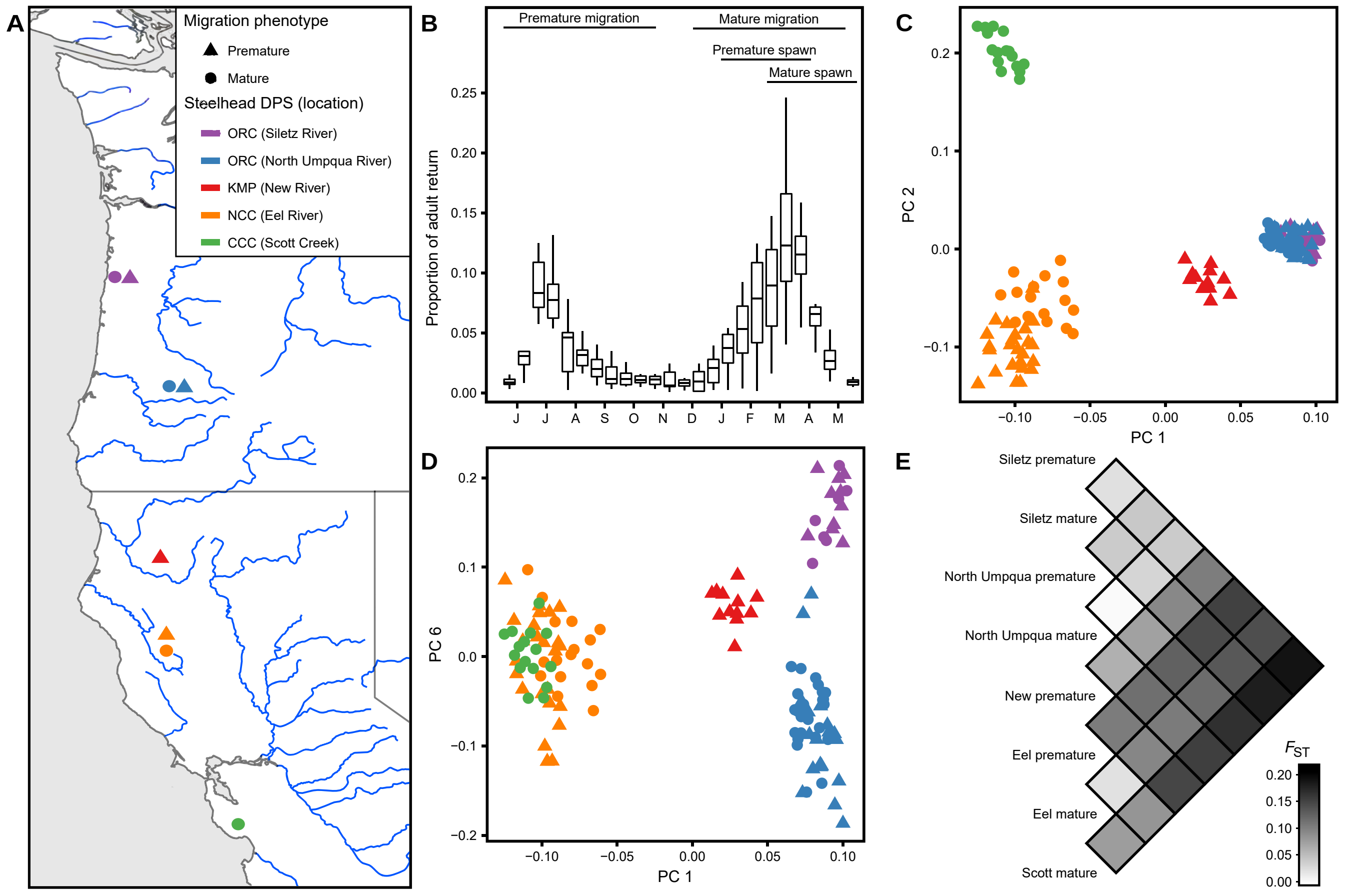

Fig. 1. Genetic structure of premature and mature migrating steelhead populations. (**A**) Map of steelhead sample locations and migration phenotypes; color indicates location, and shape indicates migration phenotype. (**B**) Bimonthly proportion of annual adult steelhead return over Winchester Dam on the North Umpqua River (2003 to 2013); horizontal bars depict migration and spawn timing of premature and mature migrating populations. (**C** and **D**) Principal component analysis (PCA) and (**E**) pairwise F_{ST} estimates using genome-wide single-nucleotide polymorphism (SNP) data.

more divergent from the mature migration clade than those from Eel and New (Fig. 2D; see Discussion for more information on heterozygotes and differentiation within the premature clade). The overall tree topology is inconsistent with premature migration alleles originating from independent evolutionary events in different locations because separate mutational events would be expected to occur on different haplotype backgrounds and result in premature migration alleles having a polyphyletic origin (*15*). We conclude that there is a nearly complete association between variation at this locus and migration category and that the premature migration alleles from all locations arose from a single evolutionary event.

To examine the evolutionary mechanisms leading to the dispersal of the premature migration allele as well as reconcile the difference between patterns of variation at the *GREB1L* locus and overall genetic structure, we summarized patterns of genetic variation using two estimators of θ ($4N\mu$). One estimator is based on average pairwise differences (θ_π) (*67*), and the other is based on the number of segregating sites (θ_S) (*68*). When genome-wide data were used, both estimators produced similar θ values for each migration category (Fig. 2E). The *GREB1L* region of mature migrating individuals also produced θ values similar to the genome-wide analysis. However, premature migrating individuals from North Umpqua had strikingly lower θ values (Fig. 2E) and a significantly skewed site frequency spectrum (SFS) (Tajima's $D = -2.08$; $P = 0.001$) (*69*) indicative of strong, recent positive selection in the *GREB1L* region. Premature migrating individuals from Eel also had reduced θ values in the *GREB1L* region (premature: $\theta_\pi/\text{kb} = 2.48$, $\theta_S/\text{kb} = 2.67$; mature: $\theta_\pi/\text{kb} = 3.59$, $\theta_S/\text{kb} = 4.00$), but the SFS was not significantly skewed, consistent with an older selection event. Although both demography and selection can reduce nucleotide diversity and skew the SFS, this pattern is specific to the *GREB1L* region as opposed to genome-wide, implicating selection as the cause. Furthermore, the combination of a stronger signature of selection and a more divergent sequence pattern in the northern premature migration haplotypes is consistent with a northward movement of the premature migration allele. We conclude that, upon entering new locations via straying, positive selection allowed the premature migration allele to persist despite ongoing hybridization with local mature migrating populations.

Premature migrating Chinook also explained by a single allelic evolutionary event in GREB1L region

To broaden our investigation into premature migration, we compiled a set of 250 Chinook samples from nine locations across five ESUs in California, Oregon, and Washington (Fig. 3A). Similar to steelhead, our sampling focused as much as possible on individuals that could be confidently categorized as premature or mature migrating based on collection time and location (table S6). We then prepared individually

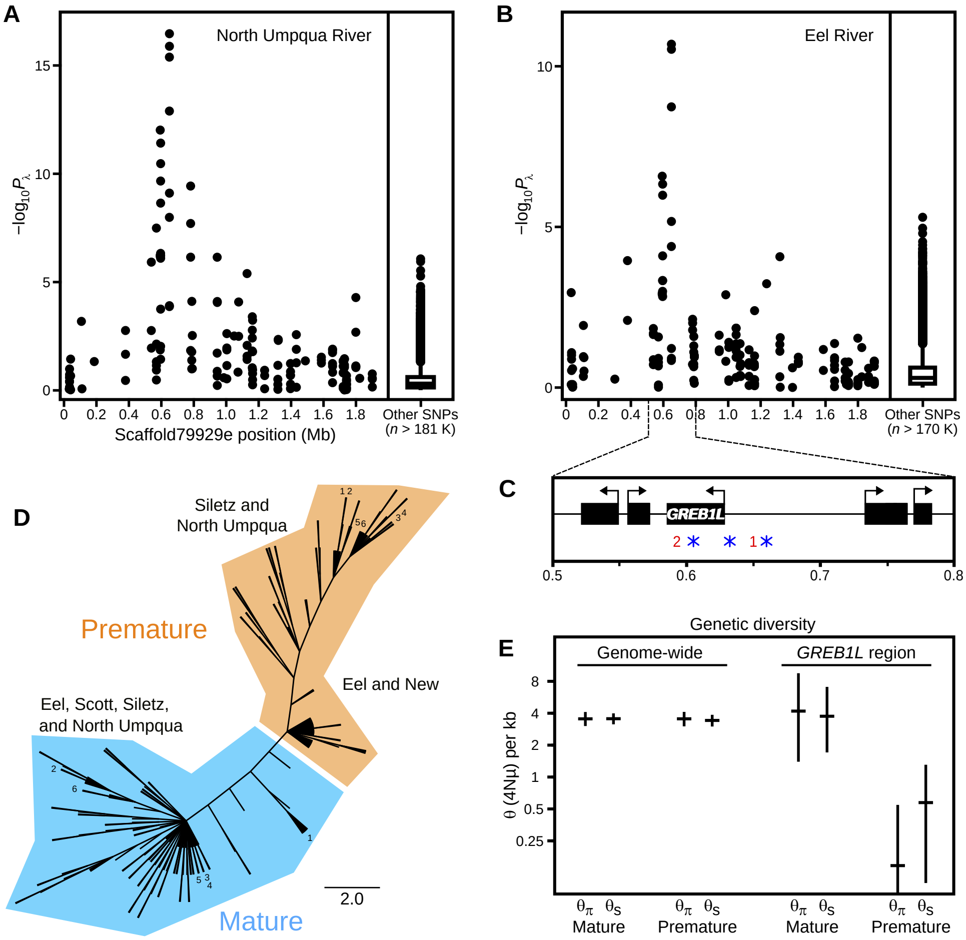

Fig. 2. Genetic and evolutionary basis of premature migration in steelhead. Association mapping of migration category in (**A**) North Umpqua River and (**B**) Eel River steelhead. (**C**) Gene annotation of region with strong association; red numbers indicate genomic positions of two restriction sites flanked by strongest associated SNPs, and blue asterisks indicate positions of amplicon sequencing. (**D**) Phylogenetic tree depicting maximum parsimony of phased amplicon sequences from all individuals; branch lengths, with the exception of terminal tips, reflect nucleotide differences between haplotypes; numbers identify individuals with one haplotype in each migration category clade. (**E**) Genome-wide and *GREB1L* region diversity estimates in North Umpqua for each migration category with 95% confidence intervals from coalescent simulations.

barcoded RAD libraries, sequenced them using paired-end Illumina technology, and aligned the sequence reads to the same rainbow trout reference assembly used above (tables S6 and S7). No reference genome is available for Chinook, and rainbow trout, which diverged from Chinook approximately 10 to 15 million years ago (*70*, *71*), is the closest relative with a draft genome assembly. With the methods described above, a total of 3,910,009 genomic positions were interrogated in at least 50% of individuals and 301,562 SNPs were identified ($P < 10^{-6}$). Of these SNPs, 55,797 had one genotype posterior greater than 0.8 in at least 50% of individuals. Although the alignment success was lower and subsequent SNP discovery and genotyping produced fewer SNPs compared to steelhead, the large number of SNPs discovered and genotyped should still be adequate for downstream analysis.

To characterize the genetic structure of these populations, we performed PCA and estimated pairwise F_{ST} using the genotype information described above. The first two PCs revealed four groups: the largest group contained all coastal ESUs, the second contained the two Puget Sound ESU locations, and the last two groups corresponded to the two locations within the Upper Klamath–Trinity Rivers ESU and were only differentiated by the second axis (Fig. 3B). In all cases, individuals from the same location but with different migration phenotypes were in the same group, and locations within groups became differentiated as additional PCs were examined. The mean pairwise F_{ST} between migration categories from the same location was 0.037 (range, 0.009 to 0.093; $n = 7$), and the mean between groups from different locations was 0.097 (range, 0.021 to 0.199; $n = 113$) (Fig. 3C). Thus, similar to what we found in steelhead, the overall genetic structure is strongly influenced by geography, as opposed to migration phenotype. We conclude that measurements of overall genetic differentiation from genome-wide SNP data are consistent with current Chinook ESUs.

To investigate the genetic architecture and evolutionary basis of premature migration in Chinook, we conducted association mapping with 114,036 SNPs using a generalized linear framework with covariate correction for population stratification (*65*, *72*). Strikingly, we again found a single significant peak of association (Bonferroni-corrected α level: $P < 0.05$) that contained five SNPs within 57,380 bp (537,741 to 595,121) in the same *GREB1L* region identified in steelhead (Fig. 3D and table S8). We next examined allele frequencies at these five SNPs and found a strong and consistent shift between all premature and mature migrating populations independent of location (Fig. 3E). Thus,

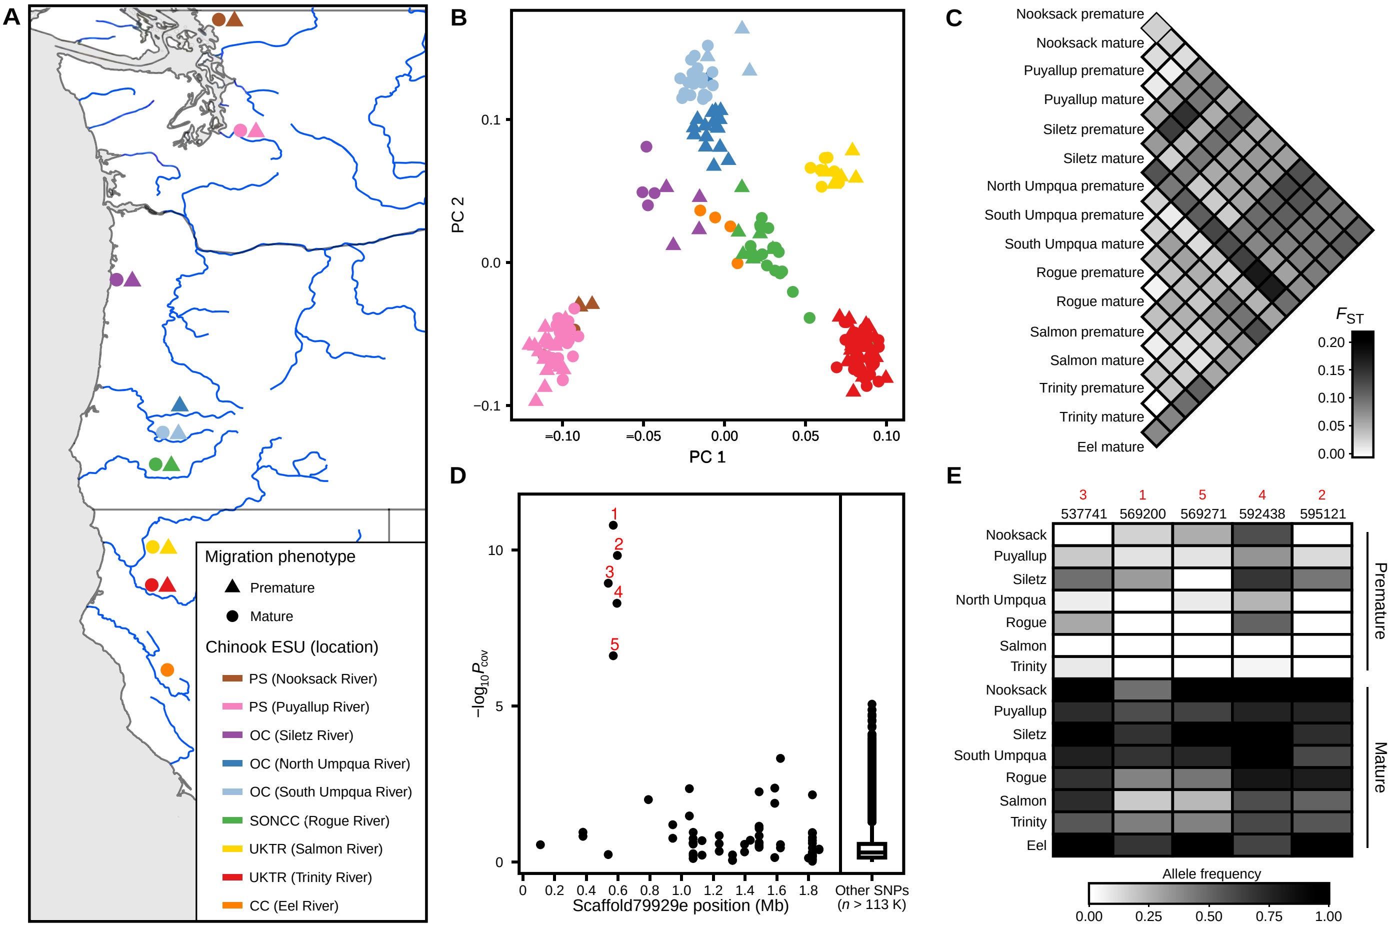

Fig. 3. Genetic and evolutionary basis of premature migration in Chinook. (**A**) Map of Chinook sample locations and migration phenotypes; color indicates location, and shape indicates migration category. (**B**) PCA and (**C**) pairwise F_{ST} estimates using genome-wide SNP data. (**D**) Association mapping of migration category in Chinook; red numbers indicate significant SNPs. (**E**) Allele frequency shift at significant SNPs between premature and mature migrating populations. Black numbers indicate SNP position on scaffold79929e.

despite having a lower genomic resolution and fewer samples per location, these results demonstrate that the *GREB1L* region is also the primary locus associated with premature migration in Chinook. Furthermore, the shift of allele frequencies in the same direction between premature and mature migrating populations across all locations is inconsistent with the premature migration alleles in Chinook being a product of multiple independent evolutionary events. Although the genomic region was consistent between species, the SNPs identified in Chinook were distinct from those in steelhead (tables S3 and S8). That is, the premature and mature migrating Chinook haplotypes are more similar to each other than to either of the steelhead haplotypes and vice versa, suggesting independent allelic evolutionary events in each species. We conclude that the same evolutionary mechanism used in steelhead, with a single allelic evolutionary event in the *GREB1L* region that subsequently spread to different locations, also explains premature migration in Chinook.

DISCUSSION

Our association analysis across multiple populations in each of two different species, as well as an independent analysis on Klickitat River steelhead (*73*), suggests that either the function or the regulation of *GREB1L* is modified in premature migrating individuals. Both *GREB1L* and its paralog *GREB1* are ubiquitous in and highly conserved across vertebrates. Although *GREB1* is known to encode a nuclear hormone receptor coactivator (*74*) and has been implicated in diverse biological processes (*75–80*), relatively little is known about *GREB1L*. However, a recent study found that *GREB1L* is differentially regulated by feeding and fasting in AgRP (agouti-related protein) neurons of the hypothalamic arcuate nucleus in mice (*81*). The strength of the associations, as well as the known role of AgRP neurons in modulating diverse behavior and metabolic processes such as foraging and fat storage (*81*, *82*), provides evidence for and an explanation of how the complex premature migration phenotype could be controlled by this single locus. An alternative explanation is that the *GREB1L* region only influences a subset of the phenotypic components of premature migration and that other important loci were not identified because of technical or biological reasons. Regardless, our results indicate that an appropriate genotype at this locus is necessary for successful premature migration.

Given that premature migration alleles at this locus are critical for premature migration, our results on the evolutionary history of these alleles provide important insights into the potential for premature migration to persist during declines and reemerge if lost. Finding

Attachment C

that the same locus is associated with premature migration in both steelhead and Chinook indicates that genetic mechanisms capable of producing this phenotype are very limited. Although some loci can be predisposed to functionally equivalent mutations in relatively short evolutionary time scales (*83*, *84*), this does not appear to be the case with the *GREB1L* region. In predisposed loci, several independent mutations with the same phenotypic effect are observed in different populations of a single species (*83*, *84*). In contrast, our survey of many populations revealed only one evolutionary event that produced a premature migration allele in each species despite the 10 to 15 million years since they diverged (*70*, *71*). Regardless of whether or not additional allelic evolutionary events have occurred (for example, in the interior Columbia Basin), our finding that a broad array of populations shares alleles from a single evolutionary event suggests that mutational events that create new premature migration alleles are rare. Thus, if current premature migration alleles are lost, new premature migration alleles and the phenotype they promote cannot be expected to reevolve in time frames relevant to conservation planning (for example, tens to hundreds of years).

The rarity of mutational events that produce premature migration alleles at this locus highlights the importance of existing premature migration alleles. Unlike alleles with a small effect on phenotype, alleles with a large effect on phenotype are expected to be rapidly lost from a population when there is strong selection against the phenotype they promote (*85*). An important exception to this is when an allele is recessive and therefore masked in the heterozygous state (*15*, *85*). Thus, the inheritance pattern of the *GREB1L* locus has critical implications for the persistence of premature migration alleles during declines of the premature migration phenotype. Although our sampling focused on migration peaks (Fig. 1B) and was not designed to investigate the migration phenotype of heterozygotes, the recently published Klickitat data (*73*) included samples collected outside the migration peaks. Strikingly, a reanalysis of these data suggests that the same haplotype is associated with premature migration (Fig. 4A and table S3) and that heterozygotes display an intermediate phenotype (Fig. 4B and fig. S2). This explains the high frequency of heterozygotes in our Siletz mature migrating samples (4 of 10), which were collected before the peak of mature migration and far upstream in the watershed (table S1). Thus, the premature migration allele does not appear to be masked in the heterozygous state and cannot be expected to be maintained as standing variation in populations that lack the premature migration phenotype.

Two additional lines of evidence suggest that the premature migration allele will not be maintained as standing variation in mature migrating populations. First, the combination of the strong bimodal phenotypic distribution that is usually observed (for example, Fig. 1B) and the ecology of premature migration (see Introduction) (*44*, *46*) suggests a general pattern of disruptive selection against individuals with an intermediate phenotype (for example, heterozygotes). Although heterozygotes are expected to be produced by hybridization in locations where both migration categories exist (for example, we observed two heterozygotes in North Umpqua, which has the lowest genetic differentiation between migration groups; Fig. 1E), their presence does not suggest that the premature migration allele will be maintained by mature migrating populations. Second, the genetic differentiation between premature migration haplotypes from California and Oregon steelhead (Fig. 2D) indicates that, unlike mature migration alleles, premature migration alleles are not freely moving across this area. This result reveals that mature migrating populations do not act as an influential source or conduit of premature migration alleles despite being abundant and broadly distributed. Therefore, premature migrating populations appear ultimately necessary for both the maintenance and spread of these alleles.

Previously, studies revealing that overall genetic structure among populations of steelhead and Chinook primarily reflects geography (as opposed to migration phenotype) suggested that premature migration evolved independently in many locations within each species (*13*, *54*, *59*). This implied that premature migration is evolutionarily replaceable over time frames relevant to conservation planning (*13*) and is not an important component in the evolutionary legacy of the species (*14*). Although these interpretations were logical given the data available at that time, our results demonstrate that the evolution was not independent in each location but instead relied on preexisting genetic variation. Thus, although evolving the premature migration phenotype in new locations could be rapid if robust premature migrating populations are present in proximate locations, the widespread extirpation and decline of premature migrating populations (*14*, *34*, *40*, *42*, *46*, *50*, *51*) has greatly diminished the potential restoration and expansion (for example, into new habitats that become available with climate

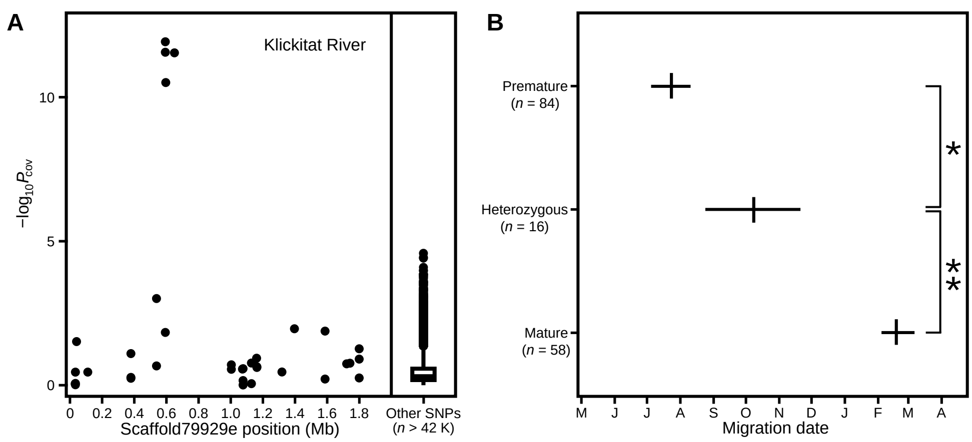

Fig. 4. Inheritance pattern of *GREB1L* locus. (**A**) Association mapping of migration date in Klickitat River steelhead. (**B**) Mean migration date and 95% confidence interval of the mean in Klickitat River steelhead categorized as homozygous for the premature migration allele, heterozygous, and homozygous mature. $*P = 0.00574$; $**P = 2.95 \times 10^{-5}$.

change) of premature migration across at least a substantial proportion of the range for both species (*19*).

Future work characterizing the distribution of premature migration alleles would improve our understanding of the extent to which the potential restoration and expansion of the premature migration phenotype has been diminished. For example, testing for the presence of premature migration alleles in locations where the phenotype has recently been extirpated would reveal how quickly these alleles are lost and potential restoration options. One possibility is that some heterozygotes still exist in these locations and could be used to restore the premature migration phenotype. The alternative is that the premature migration allele has already been lost and restoration of the phenotype would require introducing the allele from an outside population. Regardless, the results presented here will serve as a foundation for future work to determine optimal strategies for the conservation and restoration of premature migrating populations. Additionally, given the complex premature migration phenotype and evolutionary importance of premature migration alleles, future work that provides mechanistic insight into the *GREB1L* locus [for example, identifying the causative polymorphism(s) and characterizing expression profiles] could have important implications for areas ranging from conservation to biomedicine.

The combination of three key results from this study has broad conservation implications, which highlight the utility of genomics for informing conservation. First, we present an example of how a single allele at a single locus can have economic, ecological, and cultural importance. Second, we show that mutations producing an important allele can be very rare from an evolutionary perspective, suggesting that the allele will not readily reevolve if lost. Last, we observe that patterns of significant adaptive allelic variation can be completely opposite from patterns of overall genetic differentiation. Together, our results demonstrate that CUs reflecting overall genetic differentiation can fail to protect evolutionarily significant variation that has substantial ecological and societal benefits, and suggest that a supplemental framework for protecting specific adaptive variation will sometimes be necessary to prevent the loss of significant biodiversity and ecosystem services.

MATERIALS AND METHODS

Sample collection and molecular biology

Fin clips were taken from live adults or post-spawn carcasses (tables S1 and S6), dried on Whatman qualitative filter paper (grade 1), and stored at room temperature. DNA was extracted with either the DNeasy Blood and Tissue Kit (Qiagen) or a magnetic bead–based protocol (*22*) and quantified using Quant-iT PicoGreen dsDNA Reagent (Thermo Fisher Scientific) with an FLx800 Fluorescence Reader (BioTek Instruments).

SbfI RAD libraries were prepared with well and plate (when applicable) barcodes using either the traditional or new RAD protocol (*22*) and sequenced with paired-end 100-bp reads on an Illumina HiSeq 2500 (tables S2 and S7). In some cases, the same sample was included in multiple libraries to improve sequencing coverage.

For amplicon sequencing, genomic DNA extractions were rearrayed into 96-well plates and diluted 1:40 with low TE buffer (pH 8.0; 10 mM tris-HCl and 0.1 mM EDTA). Two microliters of this diluted sample was used as polymerase chain reaction (PCR) template for each of the three amplicons in the *GREB1L* region (Fig. 2 and table S4). Multiple forward primers were synthesized for each amplicon. Each forward primer contained a partial Illumina adapter sequence, a unique inline plate barcode, and the amplicon-specific sequence (tables S4 and S5). Initial PCRs were performed in 96-well plates using OneTaq DNA polymerase (New England Biolabs) at the recommended conditions with an annealing temperature of 61°C and 35 cycles. These reaction plates were then combined into a single plate that preserved the well locations. The pooled PCR products were cleaned with Ampure XP beads (Beckman Coulter), and a second round of PCR with eight cycles was performed to add the remaining Illumina adapter sequence and a unique TruSeq barcode to each well (tables S4 and S5). From each final PCR, 2 μl was removed, pooled, and purified with Ampure XP beads. The final amplicon library was sequenced with paired-end 300-bp reads on an Illumina MiSeq.

RAD analysis

RAD sequencing data were demultiplexed by requiring a perfect barcode and partial restriction site match (*22*). Sequences were aligned to a slightly modified version of a recent rainbow trout genome assembly (see scaffold79929e assembly and annotation) (*60*) using the backtrack algorithm of Burrows-Wheeler Aligner (BWA) (*86*) with default parameters. SAMtools (*87*) was used to sort, filter for proper pairs, remove PCR duplicates, and index binary alignment map (BAM) files (tables S2 and S7). In cases where the same sample was sequenced in multiple libraries, BAM files from the same sample were merged before indexing using SAMtools (tables S1, S2, S6, and S7).

Additional BAM file sets were generated to account for technical variation among samples. To minimize variation associated with the two distinct library preparation protocols used in Chinook (table S7) (*22*), we generated a set of single-end BAM files for Chinook that contained only trimmed reads from the restriction site end of the RAD fragments. To prepare these files, we trimmed these reads to 75 bp from the 3′ end after removing 5 bp from the 5′ end. Next, paired-end alignments were performed and processed as above. Last, reads from the variable end of RAD fragments were removed (table S7). To remove variation associated with variable sequencing depth, we generated a set of subsampled BAM files by using SAMtools to randomly sample approximately 120,000 alignments from paired-end BAM files for steelhead and approximately 60,000 alignments from single-end BAM files for Chinook. Subsampling to a lower number of alignments allows more individuals to be included in the analysis. We determined the optimal alignment numbers for subsampling by testing a variety of thresholds and determining the minimum before which the sample groupings started to become dispersed in PCA.

All RAD analyses were performed using Analysis of Next Generation Sequencing Data (ANGSD) (*61*) with a minimum mapping quality score (minMapQ) of 10, a minimum base quality score (minQ) of 20, and the SAMtools genotype likelihood model (GL 1) (*88*). Unless otherwise noted, samples with less alignments than required for subsampling were excluded (tables S1 and S6), and only sites represented in at least 50% of the included samples (minInd) were used.

PCA and association mapping were performed by identifying polymorphic sites (SNP_pval 1e-6), inferring major and minor alleles (doMajorMinor 1) (*72*), estimating allele frequencies (doMaf 2) (*64*), and retaining SNPs with a minor allele frequency of at least 0.05 (minMaf). For PCA, subsampled BAM files were used and genotype posterior probabilities were calculated with a uniform prior (doPost 2). The ngsCovar (*89*) function implemented in ngsTools (*63*) was used to calculate a covariance matrix from called genotypes. For association mapping, paired-end BAM files were used with two distinct tests. The frequency test with known major and minor alleles (doAsso 1) implements a likelihood ratio test using read counts (*64*). This test has good statistical power even with lower coverage data but does not allow the inclusion of covariates to correct for population stratification. The score test (doAsso 2) uses a generalized linear framework on posterior genotype probabilities (*72*). This test allows the inclusion of covariates to correct for population stratification but has less statistical power than the frequency test. For the Umpqua and Eel steelhead associations, the frequency test with λ correction for population stratification (*65*) was used because there were relatively few samples and a weak population structure. λ is the ratio of observed and expected median χ^2 values and used to correct the observed χ^2 values before converting them to *P* values (fig. S1, A and C, and table S3) (*65*). For the Chinook association, the score test with covariate correction for population stratification was used because there were many samples and a complex population structure (fig. S1E). The positions of each sample along the first 15 PCs were used as covariates.

Genome-wide F_{ST} between population pairs was estimated by first estimating an SFS for each population (doSaf) (*90*) using paired-end BAM files for steelhead and single-end BAM files for Chinook. Two-dimensional SFS and global F_{ST} (weighted) between each population pair were then estimated using realSFS (*61*).

To calculate Watterson's θ (*68*), Tajima's θ (*67*), and Tajima's *D* (*69*), we used SFS that were estimated as described above as priors (pest) with paired-end BAM files to calculate each statistic for each site (doThetas), which were averaged to obtain a single value for each statistic (*91*). The analysis was restricted to 565,000 to 785,000 bp of scaffold79929e for the *GREB1L* region analysis.

The coalescent simulation program ms (*92*) was used to determine 95% confidence intervals for the θ estimates from 10,000 simulations under a neutral demographic model. The input number of chromosomes was equal to the number of individuals used to calculate the θ statistics. For genome-wide confidence intervals, 100 independent loci and an input θ of 1, which is the approximate θ of a single RAD tag, were used. For the *GREB1L* region confidence intervals, a single locus and the empirical θ estimates were used. The significance of the empirical Tajima's *D* value was evaluated by generating a Tajima's *D* distribution from 10,000 ms simulations under a neutral demographic model. A single locus and the average between empirical values of Watterson's and Tajima's θ values in the *GREB1L* region were used. A Tajima's *D* distribution was also generated using the extremes of the θ confidence intervals, and the empirical value remained significant.

Allele frequencies were estimated (doMaf 1) (*64*) for the significant Chinook SNPs in each population that had at least four individuals with enough alignments for subsampling. Paired-end BAM files were used with the reference genome assembly as the prespecified major allele (doMajorMinor 4). Because some populations had low sample sizes, all samples were included regardless of alignment number.

Amplicon analysis

Amplicon sequence data were demultiplexed by requiring perfect barcode and primer matches. Sequences were aligned to the reference genome assembly described above using the BWA-SW algorithm (*93*) with default parameters, and SAMtools was used to sort, filter for proper pairs, and index BAM files (table S5).

Phylogenetic analysis was performed on samples in which two or more amplicons had at least 20 alignments (tables S1 and S5). Genotypes for all sites were called using ANGSD with the SAMtools genotype likelihood model, a uniform prior, and a posterior cutoff of 0.8. The genotype output file was parsed and converted into biallelic consensus sequences, with an IUPAC (International Union of Pure and Applied Chemistry) nucleotide code denoting heterozygous positions. These consensus sequences were input into fastPHASE (*94*) to produce 1000 output files that each contained two phased haplotype sequences per individual. Default parameters were used except that a distinct subpopulation label was specified for each of the five locations and base calls with a posterior of less than 0.8 were converted to Ns (unknown bases). Parsimony trees were then constructed from each fastPHASE output, and a consensus tree was called using PHYLIP (*66*).

In the initial phylogenetic analysis, one sample from the Eel River that was originally classified as premature migrating clustered in the mature migration clade (table S1). A PCA specific to the Eel River placed this sample at an intermediate position between mature migrating and premature migrating sample groups. Furthermore, this was the only Eel River sample that was homozygous for a haplotype on chromosome Omy05 associated with residency (*20*). Examination of the original sampling information revealed that this fish was much smaller than others and collected upstream from the main premature steelhead holding area (*56*), suggesting that it was a resident trout as opposed to an anadromous steelhead. Therefore, this sample was removed, and the analysis was rerun.

Scaffold79929e assembly and annotation

Our initial RAD analysis was aligned against a published reference genome assembly (*60*) and identified highly associated SNPs on three independent scaffolds. Given the state of the assembly, the sizes of the scaffolds with highly associated SNPs, and the positions of the highly associated SNPs on the scaffolds, we hypothesized that these scaffolds might be physically linked despite not being connected in the current assembly. We aligned four large-insert mate-pair libraries to the published assembly to look for linkages and estimate the distance between linked scaffolds (table S9). A perfect sequence match was required, and alignments to regions with high coverage were discarded. The resulting alignments from all libraries strongly supported a linear assembly with a total size of 1,949,089 bp that included the three associated scaffolds as well as four others (tables S9 and S10). This assembled scaffold was named scaffold79929e (e for extended) and added to the published assembly, and the seven independent scaffolds that composed it were removed to create the modified reference assembly used in this study.

Scaffold79929e was annotated with MAKER (*95*) using rainbow trout and Atlantic salmon (*Salmo salar*) EST (expressed sequence tag) sequences from the NCBI (National Center for Biotechnology Information) database, the UniProt/Swiss-Prot database for protein homology, a rainbow trout repeat library (*60*) for masking, AUGUSTUS (human) and SNAP (mamiso) gene predictors, a maximum intron size of 20,000 bp for evidence alignments, and otherwise default parameters.

Klickitat steelhead analysis

Single-end RAD data from 237 Klickitat River steelhead samples (*73*) were aligned to the modified rainbow trout genome as described above. SAMtools (*87*) was used to remove unaligned reads, sort, index, and randomly subsample BAM files to 500,000 reads to reduce the effect of PCR duplicates (*96*). All subsequent analyses were performed on subsampled BAM files using ANGSD (*61*).

Association mapping was performed using the score test (doAsso 2), with the migration date at Lyle Falls (May 1 set to day 1) (*73*) as a quantitative proxy for the premature migration phenotype (yQuant) because more direct measures (for example, gonadal maturation and body fat content at freshwater entry) were not available (this information is difficult to obtain and may require lethal sampling). The positions of each sample along the first nine PCs were used as covariates to correct for population stratification (fig. S1F). The PCA used to generate covariates was performed as described above.

Genotype data from the four associated SNPs were used to categorize individuals as homozygous for the mature migration allele, heterozygous, or homozygous premature. Genotypes were called (doGeno 4) with a uniform prior (doPost 2) and a posterior probability cutoff of 0.8 (postCutoff 0.8). Seven hundred fifty-one of 948 genotypes passed this cutoff. Two SNPs were flanking sites on the same RAD tag, had near-perfect consistency between genotype calls, and were treated as a single genotype for categorization. For an individual to be categorized as homozygous or heterozygous, all called genotypes were required to be in agreement and at least two of the three genotypes must have been called. A total of 158 samples passed these requirements, whereas 51 failed because less than two genotypes were called and 28 failed because of disagreement between called genotypes.

Migration date means were calculated with May 1 set to day 1 because it is an approximate date for the beginning of premature migration at Lyle Falls (*73*). Confidence intervals of the means were calculated by bootstrapping with 1000 replicates. The significance of differences in mean migration date between genotype categories was evaluated with Welch's *t* test. May 1 is somewhat arbitrary, and a subset of premature migrating individuals likely ascends Lyle Falls before this date (fig. S2). Furthermore, some individuals may enter freshwater then hold below Lyle Falls for an extended period before ascending to spawn. In either of these scenarios, individuals would be assigned a migration date indicative of mature migration, even though they were premature migrating. With the available information, we cannot be sure which individuals migrated under these scenarios. However, setting May 1 to day 1 is a conservative approach that, if anything, should underestimate the significance of the differences between mean migration dates for each genotype (Fig. 4B and fig. S2).

Wells Aquatic Settlement Work Group
FINAL
Statement of Agreement
To implement a temporary 1.0-foot Fishway-entrance Head Differential for Pacific Lamprey from 17:00 to 00:59 daily during the 2017 Pacific Lamprey Migration at Wells Dam
Date of Approval: 16 August 2017

Statement

The Wells Aquatic Settlement Work Group (Aquatic SWG) requests concurrence from the Wells Habitat Conservation Plan Coordinating Committee (Wells HCP-CC) to operate the Wells Dam fishway collection galleries at a 1.0-foot head differential from 17:00 to 00:59 daily from September 1 to September 30, 2017.

Background

Douglas PUD and the Aquatic SWG continue to evaluate ways to improve ladder entrance efficiency for adult Pacific Lamprey (lamprey) attempting to pass Wells Dam. In 2009 and 2010, reduced head differentials were tested at the entrances to the Wells Dam fishways to assess whether there was an effect of differences in entrance velocities on the passage of lamprey. Concurrently, salmonid passage was monitored to assess whether a reduction in head differential negatively influenced salmonid use of the fishway.

Due to limited numbers of test lamprey in recent years and the relatively large run of lamprey currently being experienced this year, the Aquatic SWG is requesting to temporarily reduce fishway entrance head differentials at Wells Dam.

The Aquatic SWG believes there may be a benefit to lamprey by reducing head differential, and there does not appear to be a significant impact to migrating salmonids[1]. This is based on results of a radio-telemetry study conducted in 2013.

The Wells HCP-CC approved studies in 2009 and 2010 at Wells Dam which used Dual Frequency Identification Sonar (DIDSON) technology to observe the behavior of lamprey attempting to pass the fishway entrances under different operating conditions. The Wells HCP-CC subsequently approved a differential flow study in 2013 and 2014, but low lamprey counts were observed at Wells Dam these years, which reduced the statistical power of treatments.

Qualitative results of 2013 and 2014 studies indicate that lamprey entrance efficiency may be enhanced by reducing the collection-gallery-to-tailwater head differential from 1.5-feet to 1.0-foot between 17:00 and 0:59 hours during the peak of the lamprey migration season. Post-hoc analyses indicated the eight-hour period selected for testing had the lowest diel salmonid passage activity and highest diel lamprey activity. Analysis of data on the passage of salmonids during the DIDSON studies indicated no significant difference in passage rates of steelhead or sockeye, Chinook, or coho salmon between the two head differentials tested (1.0-foot or 1.5-feet).

[1] Refer to Section 5 of the April 2012 Assessment of Salmonid Passage Responses to Different Flow Velocities at Wells Dam Fishway for additional information regarding impacts to salmonids.

As a temporary and experimental measure, the Aquatic SWG proposes to operate the Wells Dam fishway entrances with a 1-foot differential at night as a means of enhancing lamprey passage for 2017. These operations would begin September 1 and end on September 30, 2017.

DIDSON technology will not be available at the time of this change in head differential; therefore, currently tagged lamprey in the Columbia River, along with upstream fishway ladder counts on the left and right banks of Wells Dam, will be used to test the effectiveness of this 1.0-foot head differential measure.

Wells Aquatic Settlement Work Group
FINAL
Statement of Agreement
To implement a temporary 1.0-foot Fishway-entrance Head Differential for Pacific Lamprey from 22:00 to 04:00 in 3-day blocks alternating with 3-day blocks of normal fishway operating criteria during the 2017 Pacific Lamprey Migration at Wells Dam
Date of Approval: 28 August 2017

Statement

The Wells Aquatic Settlement Work Group (Aquatic SWG) agrees to operate the Wells Dam fishway collection galleries at a 1.0-foot head differential from 22:00 to 04:00 ("lamprey operations"), in five pairs of 3-day block operations from September 1 to September 30, 2017.

Background

Douglas PUD and the Aquatic SWG continue to evaluate ways to improve ladder entrance efficiency for adult Pacific Lamprey (lamprey) attempting to pass Wells Dam. In 2009 and 2010, reduced head differentials were tested at the entrances to the Wells Dam fishways to assess whether there was an effect of differences in entrance velocities on the passage of lamprey. Concurrently, salmonid passage was monitored to assess whether a reduction in head differential negatively influenced salmonid use of the fishway.

Due to limited numbers of test lamprey in recent years and the relatively large run of lamprey currently being experienced this year, the Aquatic SWG is requesting to temporarily reduce fishway entrance head differentials at Wells Dam.

The Aquatic SWG believes there may be a benefit to lamprey by reducing head differential, and there does not appear to be a significant impact to migrating salmonids[1]. This is based on results of a radio-telemetry study conducted in 2013.

The Wells HCP-CC approved studies in 2009 and 2010 at Wells Dam which used Dual Frequency Identification Sonar (DIDSON) technology to observe the behavior of lamprey attempting to pass the fishway entrances under different operating conditions. The Wells HCP-CC subsequently approved a differential flow study in 2013 and 2014, but low lamprey counts were observed at Wells Dam these years, which reduced the statistical power of treatments.

Qualitative results of 2013 and 2014 studies indicate that lamprey entrance efficiency may be enhanced by reducing the collection-gallery-to-tailwater head differential from 1.5-feet to 1.0-foot between 17:00 and 0:59 hours during the peak of the lamprey migration season. Post-hoc analyses indicated the eight-hour period selected for testing had the lowest diel salmonid passage activity and highest diel lamprey activity. Analysis of data on the passage of salmonids during the DIDSON studies indicated no significant difference in passage rates of steelhead or sockeye, Chinook, or coho salmon between the two head differentials tested (1.0-foot or 1.5-feet).

[1] Refer to Section 5 of the April 2012 Assessment of Salmonid Passage Responses to Different Flow Velocities at Wells Dam Fishway for additional information regarding impacts to salmonids.

As a temporary and experimental measure, the Aquatic SWG proposes to operate the Wells Dam fishway entrances with a 1-foot differential at night as a means of enhancing lamprey passage for 2017. These operations would begin September 1 and end on September 30, 2017. To evaluate the efficacy of the modified operations, those operations will occur in 3-day blocks alternating with 3-day blocks of normal fishway operations, as a means of potentially identifying differences in dam-passage behavior resulting from modified fishway-entrance conditions.

During 2017 temporary lamprey operations the Aquatic SWG members will monitor Pacific Lamprey at Wells Dam from September 1 to September 30, 2017, via the Columbia River Data Access in Real Time (DART) database, and if so interested, will monitor steelhead, and Coho and Chinook salmon passage under the lamprey operations. Based on monitoring of the Pacific Lamprey fish ladder count data, if an Aquatic SWG member feels the lamprey operations are not producing the expected passage conditions, the member will notify all Aquatic SWG members by email and discuss the topic via email or request a coordination call. Additionally, lamprey operations will be implemented, as described, unless observational data clearly suggest and the Aquatic SWG members agree the operations should not continue.

DIDSON technology will not be available at the time of this change in head differential; therefore, currently tagged lamprey in the Columbia River, along with upstream fishway ladder counts on the left and right banks of Wells Dam, will be used to test the effectiveness of this 1.0-foot head differential measure. Following the completions of the temporary 2017 lamprey operations Douglas PUD, potentially in coordination with Columbia Basin Research or LGL Limited, will develop and provide to the Aquatic SWG and Wells HCP-CC, a post-season technical memorandum describing results of the 2017 lamprey operations, based on fish count data.

Wells HCP Coordinating Committee
FINAL
Statement of Agreement
To implement temporary fishway "lamprey operations" in alternating 3-day blocks with normal operations during the 2017 Pacific Lamprey Migration at Wells Dam
Date of Approval: 31 August 2017

Statement

The Wells HCP Coordinating Committee agrees to implement a temporary 1.0-foot fishway-entrance head differential for Pacific Lamprey from 22:00 to 04:00 in 3-day blocks alternating with 3-day blocks of normal fishway operating criteria during the 2017 Pacific Lamprey Migration at Wells Dam, from September 1 to September 30, 2017.

Background

At their August 22, 2017 meeting, the Wells HCP Coordinating Committee (CC) reviewed a request from the Wells Aquatic Settlement Work Group (Aquatic SWG) to implement fishway operations at Wells Dam intended to facilitate fishway entrance by Pacific Lamprey (lamprey operations). The CC reviewed data on lamprey and salmonid passage timing, and conditionally approved the requested lamprey operations provided that the Aquatic SWG, 1) review the 2013 radio-telemetry study report to determine whether the proposed actions would indeed improve lamprey passage considering the equivocal results of that study (specifically considering effects of reduced head differential on lamprey attraction to the fishway entrances); 2) accept the CC's alternative diel schedule of lamprey operations (CC approved 22:00-04:00); 3) accept a block design intended to identify lamprey response to lamprey operations (2 days at 1 foot, alternating with 2 days at 1.5 feet); 4) provide the CC with a report on lamprey response to 2017 lamprey operations; and 5) accept adaptive management of operations such that if a negative response to lamprey operations was observed, those operations could be discontinued before the end of September.

The Aquatic SWG accepted the conditions approved by the CC, but changed the block duration from 2-day blocks to 3-day blocks (see final SOA approved by the Aquatic SWG attached below).

Wells Aquatic Settlement Work Group
FINAL
Statement of Agreement
To implement a temporary 1.0-foot Fishway-entrance Head Differential for Pacific Lamprey from 22:00 to 04:00 in 3-day blocks alternating with 3-day blocks of normal fishway operating criteria during the 2017 Pacific Lamprey Migration at Wells Dam
Date of Approval: 28 August 2017

Statement

> The Wells Aquatic Settlement Work Group (Aquatic SWG) agrees to operate the Wells Dam fishway collection galleries at a 1.0-foot head differential from 22:00 to 04:00 ("lamprey operations"), in five pairs of 3-day block operations from September 1 to September 30, 2017.

Background

Douglas PUD and the Aquatic SWG continue to evaluate ways to improve ladder entrance efficiency for adult Pacific Lamprey (lamprey) attempting to pass Wells Dam. In 2009 and 2010, reduced head differentials were tested at the entrances to the Wells Dam fishways to assess whether there was an effect of differences in entrance velocities on the passage of lamprey. Concurrently, salmonid passage was monitored to assess whether a reduction in head differential negatively influenced salmonid use of the fishway.

Due to limited numbers of test lamprey in recent years and the relatively large run of lamprey currently being experienced this year, the Aquatic SWG is requesting to temporarily reduce fishway entrance head differentials at Wells Dam.

The Aquatic SWG believes there may be a benefit to lamprey by reducing head differential, and there does not appear to be a significant impact to migrating salmonids[1]. This is based on results of a radio-telemetry study conducted in 2013.

The Wells HCP-CC approved studies in 2009 and 2010 at Wells Dam which used Dual Frequency Identification Sonar (DIDSON) technology to observe the behavior of lamprey attempting to pass the fishway entrances under different operating conditions. The Wells HCP-CC subsequently approved a differential flow study in 2013 and 2014, but low lamprey counts were observed at Wells Dam these years, which reduced the statistical power of treatments.

Qualitative results of 2013 and 2014 studies indicate that lamprey entrance efficiency may be enhanced by reducing the collection-gallery-to-tailwater head differential from 1.5-feet to 1.0-foot between 17:00 and 0:59 hours during the peak of the lamprey migration season. Post-hoc analyses indicated the eight-hour period selected for testing had the lowest diel salmonid passage activity and highest diel lamprey activity. Analysis of data on the passage of salmonids during the DIDSON studies indicated no significant difference in passage rates of steelhead or sockeye, Chinook, or coho salmon between the two head differentials tested (1.0-foot or 1.5-feet).

---

[1] Refer to Section 5 of the April 2012 Assessment of Salmonid Passage Responses to Different Flow Velocities at Wells Dam Fishway for additional information regarding impacts to salmonids.

As a temporary and experimental measure, the Aquatic SWG proposes to operate the Wells Dam fishway entrances with a 1-foot differential at night as a means of enhancing lamprey passage for 2017. These operations would begin September 1 and end on September 30, 2017. To evaluate the efficacy of the modified operations, those operations will occur in 3-day blocks alternating with 3-day blocks of normal fishway operations, as a means of potentially identifying differences in dam-passage behavior resulting from modified fishway-entrance conditions.

During 2017 temporary lamprey operations the Aquatic SWG members will monitor Pacific Lamprey at Wells Dam from September 1 to September 30, 2017, via the Columbia River Data Access in Real Time (DART) database, and if so interested, will monitor steelhead, and Coho and Chinook salmon passage under the lamprey operations. Based on monitoring of the Pacific Lamprey fish ladder count data, if an Aquatic SWG member feels the lamprey operations are not producing the expected passage conditions, the member will notify all Aquatic SWG members by email and discuss the topic via email or request a coordination call. Additionally, lamprey operations will be implemented, as described, unless observational data clearly suggest and the Aquatic SWG members agree the operations should not continue.

DIDSON technology will not be available at the time of this change in head differential; therefore, currently tagged lamprey in the Columbia River, along with upstream fishway ladder counts on the left and right banks of Wells Dam, will be used to test the effectiveness of this 1.0-foot head differential measure. Following the completions of the temporary 2017 lamprey operations Douglas PUD, potentially in coordination with Columbia Basin Research or LGL Limited, will develop and provide to the Aquatic SWG and Wells HCP-CC, a post-season technical memorandum describing results of the 2017 lamprey operations, based on fish count data.

Washington, DC 20426

Re: Rock Island Hydroelectric Project, FERC No. 943
Continuation of Rehabilitation Work (Units B1-B4)

Dear Secretary Bose:

As the Federal Energy Regulatory Commission (Commission or FERC) is aware, the Public Utility District No. 1 of Chelan County, Washington (Chelan PUD) has been engaged in a long-standing effort to rehabilitate the units in the First Powerhouse (PH1) at its Rock Island Hydroelectric Project, FERC No. 943 (Project). This effort began with the rehabilitation of Unit B10, which Chelan PUD completed in 2008,[1] followed by the completion of rehabilitation work for Unit B9 in 2012.[2] Chelan PUD originally advised the Commission of its planned rehabilitation of these units, together with Units B5, B6, and B7, in 2003.[3]

The purpose of this letter is to advise the Commission of its intent to continue its rehabilitation effort at the Project's PH1 by rehabilitating the turbine-generators for Units B1-B4. A detailed description of Chelan PUD's plans for Units B1-B4 appears below.

Consistent with how this rehabilitation program has progressed to date, and pursuant to Chelan PUD's consultation with Commission staff on April 29, 2016, prior Commission approval of the rehabilitation work for Units B1-B4 will not be required for this work. The rehabilitation of Units B1-B4 will not involve any change to the maximum hydraulic capacity of 220,000 cubic feet per second currently authorized under the Project's license, nor will it result in any increase

---

1 *Pub. Util. Dist. No. 1 of Chelan County*, 135 FERC ¶ 62,207 (2011) (acknowledging the completion of the Unit B10 rehabilitation and adjusting annual charges for the unit).

2 *See Pub. Util. Dist. No. 1 of Chelan County*, 146 FERC ¶ 62,055 (2014) (acknowledging the completion of the Unit B9 rehabilitation and adjusting annual charges for the unit).

3 *See* Letter from Charles J. Hosken, Public Utility District No. 1 of Chelan County, to Magalie R. Salas, Federal Energy Regulatory Commission, Project No. 943-000 (filed Oct. 29, 2003). As noted in Attachment A herein, Chelan PUD anticipates completing the rehabilitation for Units B5, B6 and B7 in the 2016-22 timeframe.

in the Project's authorized installed capacity, which for each of these units is 20,700 kilowatts.[4] Moreover, because Chelan PUD will only be replacing equipment that is reaching the end of its useful life with comparable equipment, the rehabilitation of Units B1-B4 will not involve a "substantial change" or "substantial alteration" to the approved Project works under Standard Articles 2 and 3 of the Project license.[5]

Although no prior Commission approvals are required for this next phase of the rehabilitation program, Chelan PUD will continue to provide the Commission updates of its progress. After each turbine-generator unit is rehabilitated, Chelan PUD will notify the Commission of the date on which the rehabilitated unit went on line and its capacity in order to confirm whether there will be a need to revise the authorized installed capacity or annual charges for the Project. After rehabilitation work is completed, Chelan PUD will file "as-built" exhibits with the Commission.

In addition, as detailed below and in Attachment B, Chelan PUD has consulted with Washington State Department of Ecology and the Habitat Conservation Plan (HCP) Coordinating Committee, comprised of federal and state resource agencies and Tribes, regarding potential environmental effects of the rehabilitation work.

<u>Proposed Rock Island Rehabilitation</u>

Chelan PUD intends to rehabilitate the 20.7 MW Kaplan turbine-generators in the Rock Island PH1. These units have been in service since the early1930s. The proposed rehabilitation work will begin in 2018 and continue into 2020. The following outlines the proposed work, schedule and environmental considerations. Attachment A provides Chelan PUD's estimated rehabilitation schedule for PH1.

The rehabilitation will not result in a change to generator nameplate or authorized project hydraulic capacity (220,000 cubic feet per second (cfs) or authorized capacity, 20,700 kilowatt (kW). No civil works will be necessary, including no changes to the diameter of the intake or draft tube discharge structures, height of wicket gates, or stator core. The units will continue to operate with fixed blades, the same conditions that met the Habitat Conservation Plan's no-net impact.

The rehabilitation will change the turbine horsepower (HP) from 32,000 HP to about 30,000 HP. The head for PH1 units will be updated to 39.7 feet to be consistent with other updated PH1 rehabilitated units and PH2. A smaller oil-free hub with no gaps will be installed, along with new fixed propeller runners optimized for the current operating head and flow. Currently, the units contain manually adjustable Nagler-type propeller turbines. The units will have more efficient four-blade turbines instead of six-blades. Governor controls will be replaced.

---

4 *See* 18 C.F.R. § 4.201(b)

5 *See Pub. Util. Dist. No. 1 of Chelan County*, 46 FERC ¶ 61,033, at p. 61,208 (1989) (Ordering Paragraph (E), adopting Form L-5 into the license); *see also* 16 U.S.C. § 803(b) (prohibiting "substantial alteration or addition not in conformity with the approved plans . . . without the prior approval of the Commission"); *e.g., International Falls Power Co.*, 66 FERC ¶ 61,086 at p. 61,114-17 (1994).

Upon installation and testing, revised best gate capacities for the units will be submitted to the Commission.

Estimated Return to Service Dates – Powerhouse 1

1. Unit B1 – Quarter 1 2020
2. Unit B2 – Quarter 3 2019
3. Unit B3 – Quarter 2 2019
4. Unit B4 – Quarter 1 2019

Environmental Considerations

The rehabilitation work will not adversely affect aquatic resources or Chelan PUD's obligations under the HCP. Modern turbine design with tighter operating tolerances and fixed blade angle positioned for optimum flow conditions supporting efficient power generation will benefit fish passage survival. Additionally, laminar flow conditions associated with peak generating capability equate to providing fish the best possible flow conditions for turbine route passage. In 2013, the HCP Coordinating Committee approved Chelan PUD's 2013 Comprehensive Progress Report that concluded Chelan PUD had reached no net impact at Rock Island with respect to all planned species.[6] Chelan PUD's achievement of no net impact in 2013 was successfully achieved while operating the vintage 1933 units. The proposed rehabilitation work will not alter the HCP Coordinating Committee's 2013 finding of no net impact and in fact, Chelan PUD anticipates that the new modern design of present day turbines will offer additional survival benefit of fish passing through the rehabbed B1-4 units. A project survival standard check-in study is scheduled for 2020 (post B1-4 rehab) to verify continued achievement of the juvenile survival standard. The schedule has all PH1 units in operation by April 2020 providing the best chance for success during the 2020 HCP check-in.

Consultation

Chelan PUD has kept the HCP Coordinating Committee apprised of maintenance work occurring at the Rock Island Project. On October 25, Chelan PUD Director of Engineering and Project Management, Brett Bickford provided the HCP Coordinating Committee an overview of maintenance work planned on Units B1-B4. On November 15, Chelan PUD provided a draft of this letter to the HCP Coordinating Committee for the agencies' and committee's comments. Additionally, Chelan PUD has kept the Washington State Department of Ecology apprised of the work occurring at Rock Island. On Dec. 16, Chelan PUD provided Ecology with a copy of the draft letter for comment. Documentation, including comments received and Chelan PUD responses are included in Attachment B.

[6] Statement of Agreement, Approval of Rock Island and Rocky Reach HCPs 2013 Comprehensive Progress Report (Approved February 26, 2013).

Conclusion

Chelan PUD appreciates the support of Commission staff and federal and state resource agencies as it continues with this important rehabilitation program for the Rock Island Hydroelectric Project. Should you have any questions regarding this matter, please contact me.

(Draft 11/15/2016 – for HCP Coordinating Committee 30-day Review)

Ms. Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street NE
Washington, DC 20426

Re: Rock Island Hydroelectric Project, FERC No. 943
Continuation of Rehabilitation Work (Units B1-B4)

Dear Secretary Bose:

As the Federal Energy Regulatory Commission (Commission or FERC) is aware, the Public Utility District No. 1 of Chelan County, Washington (Chelan PUD) has been engaged in a long-standing effort to rehabilitate the units in the First Powerhouse (PH1) at its Rock Island Hydroelectric Project, FERC No. 943 (Project). This effort began with the rehabilitation of Unit B10, which Chelan PUD completed in 2008,[1] followed by the completion of rehabilitation work for Unit B9 in 2012.[2] Chelan PUD originally advised the Commission of its planned rehabilitation of these units, together with Units B5, B6, and B7, in 2003.[3]

The purpose of this letter is to advise the Commission of its intent to continue its rehabilitation effort at the Project's PH1 by rehabilitating the turbine-generators for Units B1-B4. A detailed description of Chelan PUD's plans for Units B1-B4 appears below.

Consistent with how this rehabilitation program has progressed to date, and pursuant to Chelan PUD's consultation with Commission staff on April 29, 2016, prior Commission approval of the rehabilitation work for Units B1-B4 will not be required for this work. The rehabilitation of Units B1-B4 will not involve any change to the maximum hydraulic capacity of 220,000 cubic

---

2 *See Pub. Util. Dist. No. 1 of Chelan County*, 146 FERC ¶ 62,055 (2014) (acknowledging the completion of the Unit B9 rehabilitation and adjusting annual charges for the unit).

3 *See* Letter from Charles J. Hosken, Public Utility District No. 1 of Chelan County, to Magalie R. Salas, Federal Energy Regulatory Commission, Project No. 943-000 (filed Oct. 29, 2003). As noted in Attachment A herein, Chelan PUD anticipates completing the rehabilitation for Units B5, B6 and B7 in the 2016-22 timeframe.

feet per second currently authorized under the Project's license, nor will it result in any increase in the Project's authorized installed capacity, which for each of these units is 20,700 kilowatts.[4] Moreover, because Chelan PUD will only be replacing equipment that is reaching the end of its useful life with comparable equipment, the rehabilitation of Units B1-B4 will not involve a "substantial change" or "substantial alteration" to the approved Project works under Standard Articles 2 and 3 of the Project license.[5]

Although no prior Commission approvals are required for this next phase of the rehabilitation program, Chelan PUD will continue to provide the Commission updates of its progress. After each turbine-generator unit is rehabilitated, Chelan PUD will notify the Commission of the date on which the rehabilitated unit went on line and its capacity in order to confirm whether there will be a need to revise the authorized installed capacity or annual charges for the Project. After rehabilitation work is completed, Chelan PUD will file "as-built" exhibits with the Commission.

In addition, as detailed below and in Attachment B, Chelan PUD has consulted with the Habitat Conservation Plan (HCP) Coordinating Committee, comprised of federal and state resource agencies and Tribes, regarding potential environmental effects of the rehabilitation work.

<u>Proposed Rock Island Rehabilitation</u>

Chelan PUD intends to rehabilitate the 20.7 MW Kaplan turbine-generators in the Rock Island PH1. These units have been in service since the early 1930s. The proposed rehabilitation work will begin in 2018 and continue through 2020. The following outlines the proposed work, schedule and environmental considerations. Attachment A provides Chelan PUD's estimated rehabilitation schedule for PH1.

The rehabilitation will not result in a change to generator nameplate or authorized project hydraulic capacity (220,000 cubic feet per second (cfs) or authorized capacity, 20,700 kilowatt (kW). No civil works will be necessary, including no changes to the diameter of the intake or draft tube discharge structures, height of wicket gates, or stator core. The units will continue to operate with fixed blades, the same conditions that met the Habitat Conservation Plan's no-net impact.

The rehabilitation will change the turbine horsepower (HP) from 32,000 HP to about 30,000 HP. The head for PH1 units will be updated to 39.7 feet to be consistent with other updated PH1 rehabilitated units and PH2. A smaller oil-free hub with no gaps will be installed, along with new fixed propeller runners optimized for the current operating head and flow. Currently, the units contain manually adjustable Nagler-type propeller turbines. The units will have more efficient four-blade turbines instead of six-blades. Governor controls will be replaced.

---

4 *See* 18 C.F.R. § 4.201(b)

5 *See Pub. Util. Dist. No. 1 of Chelan County*, 46 FERC ¶ 61,033, at p. 61,208 (1989) (Ordering Paragraph (E), adopting Form L-5 into the license); *see also* 16 U.S.C. § 803(b) (prohibiting "substantial alteration or addition not in conformity with the approved plans . . . without the prior approval of the Commission"); *e.g.*, *International Falls Power Co.*, 66 FERC ¶ 61,086 at p. 61,114-17 (1994).

Upon installation and testing, revised best gate capacities for the units will be submitted to the Commission.

Estimated Schedule – Powerhouse 1

1. Unit B1 – 2020
2. Unit B2 – 2019
3. Unit B3 – 2019
4. Unit B4 – 2018

Environmental Considerations

The rehabilitation work will not adversely affect aquatic resources or Chelan PUD's obligations under the HCP. Modern turbine design with tighter operating tolerances and fixed blade angle positioned for optimum flow conditions supporting efficient power generation will benefit fish passage survival. Additionally, laminar flow conditions associated with peak generating capability equate to providing fish the best possible flow conditions for turbine route passage. In 2013, the HCP Coordinating Committee approved Chelan PUD's 2013 Comprehensive Progress Report that concluded Chelan PUD had reached no net impact at Rock Island with respect to all planned species.[6] Chelan PUD's achievement of no net impact in 2013 was successfully achieved while operating the vintage 1933 units. The proposed rehabilitation work will not alter the HCP Coordinating Committee's 2013 finding of no net impact and in fact, Chelan PUD anticipates that the new modern design of present day turbines will offer additional survival benefit of fish passing through the rehabbed B1-4 units. A project survival standard check-in study is scheduled for 2020 (post B1-4 rehab) to verify continued achievement of the juvenile survival standard. The schedule has all PH1 units in operation by April 2020 providing the best chance for success during the 2020 HCP check-in.

Consultation

Chelan PUD has kept the HCP Coordinating Committee apprised of maintenance work occurring at the Rock Island Project. On October 25, Chelan PUD Director of Engineering and Project Management, Brett Bickford provided the HCP Coordinating Committee an overview of maintenance work planned on Units B1-B4. On November 15, Chelan PUD provided a draft of this letter to the HCP Coordinating Committee for the agencies' and committee's comments. Documentation, including comments received and Chelan PUD responses are included in Attachment B.

Conclusion

Chelan PUD appreciates the support of Commission staff and federal and state resource agencies as it continues with this important rehabilitation program for the Rock Island Hydroelectric Project. Should you have any questions regarding this matter, please contact me.

Sent: Friday, January 06, 2017 3:41 PM
To: Smith, Michelle; Osborn, Jeff; Sokolowski, Rosana
Subject: FW: For your Review Please: Draft FERC B1-B4 Notification Letter

All,

I called Breean to check in with her regarding our response (see below) to her question regarding our B1-B4 notification letter. Breean said she did not have any further questions and that Ecology is good with us sending the letter to FERC, knowing that we will continue to keep them informed and coordinate within our projects to minimize TDG exceedances.

Thank you,

Marcie Clement | **Water Resources Specialist**

Breean,

Thank you, for your comments and reviewing the letter so quickly. The units will be rehabbed one at a time, over a period of 3 to 4-years. We coordinate operations between Rocky Reach and Rock Island projects to minimize TDG levels. We will continue our efforts to minimize TDG and will keep you informed as we progress through the rehab work. We will also keep you informed of any TDG exceedances, if they develop. Please don't hesitate to email or call me with any additional questions.

Thank you,

Marcie Clement | **Water Resources Specialist**

Subject: RE: For your Review Please: Draft FERC B1-B4 Notification Letter

Good morning,

My apologies for the delayed response. Thank you for the notification. I think I will defer to the fish agencies regarding propeller designs and such. However, my only comment, or question rather, is do you foresee any change in operations that could affect water quality, specifically higher spill with a lower generation capacity, since the rehab activity will likely be occurring outside of spill season when the facility must meet the 110%?

Otherwise, that's it from me.

Mark and Breean,

Early January, we are planning to send FERC the attached notification letter related to rehabilitation of Rock Island Powerhouse 1 units B1 through B4. Even though we've provided you with updates related to the Rock Island rehab work, we wanted to make sure you and members of the HCP Coordinating Committee were given opportunity to review the letter before sending it to the FERC. We appreciate your time to review and provide any comments.

Thank you both, and please don't hesitate to call if you have any questions.

(Draft – for Ecology and HCP Coordinating Committee Review)

Ms. Kimberly D. Bose, Secretary
Federal Energy Regulatory Commission
888 First Street NE
Washington, DC 20426

Re: Rock Island Hydroelectric Project, FERC No. 943
Continuation of Rehabilitation Work (Units B1-B4)

Dear Secretary Bose:

As the Federal Energy Regulatory Commission (Commission or FERC) is aware, the Public Utility District No. 1 of Chelan County, Washington (Chelan PUD) has been engaged in a long-standing effort to rehabilitate the units in the First Powerhouse (PH1) at its Rock Island Hydroelectric Project, FERC No. 943 (Project). This effort began with the rehabilitation of Unit B10, which Chelan PUD completed in 2008,[1] followed by the completion of rehabilitation work for Unit B9 in 2012.[2] Chelan PUD originally advised the Commission of its planned rehabilitation of these units, together with Units B5, B6, and B7, in 2003.[3]

The purpose of this letter is to advise the Commission of its intent to continue its rehabilitation effort at the Project's PH1 by rehabilitating the turbine-generators for Units B1-B4. A detailed description of Chelan PUD's plans for Units B1-B4 appears below.

Consistent with how this rehabilitation program has progressed to date, and pursuant to Chelan PUD's consultation with Commission staff on April 29, 2016, prior Commission approval of the rehabilitation work for Units B1-B4 will not be required for this work. The rehabilitation of Units B1-B4 will not involve any change to the maximum hydraulic capacity of 220,000 cubic

[1] *Pub. Util. Dist. No. 1 of Chelan County*, 135 FERC ¶ 62,207 (2011) (acknowledging the completion of the Unit B10 rehabilitation and adjusting annual charges for the unit).

[2] *See Pub. Util. Dist. No. 1 of Chelan County*, 146 FERC ¶ 62,055 (2014) (acknowledging the completion of the Unit B9 rehabilitation and adjusting annual charges for the unit).

[3] *See* Letter from Charles J. Hosken, Public Utility District No. 1 of Chelan County, to Magalie R. Salas, Federal Energy Regulatory Commission, Project No. 943-000 (filed Oct. 29, 2003). As noted in Attachment A herein, Chelan PUD anticipates completing the rehabilitation for Units B5, B6 and B7 in the 2016-22 timeframe.

feet per second currently authorized under the Project's license, nor will it result in any increase in the Project's authorized installed capacity, which for each of these units is 20,700 kilowatts.[4] Moreover, because Chelan PUD will only be replacing equipment that is reaching the end of its useful life with comparable equipment, the rehabilitation of Units B1-B4 will not involve a "substantial change" or "substantial alteration" to the approved Project works under Standard Articles 2 and 3 of the Project license.[5]

Although no prior Commission approvals are required for this next phase of the rehabilitation program, Chelan PUD will continue to provide the Commission updates of its progress. After each turbine-generator unit is rehabilitated, Chelan PUD will notify the Commission of the date on which the rehabilitated unit went on line and its capacity in order to confirm whether there will be a need to revise the authorized installed capacity or annual charges for the Project. After rehabilitation work is completed, Chelan PUD will file "as-built" exhibits with the Commission.

In addition, as detailed below and in Attachment B, Chelan PUD has consulted with the Habitat Conservation Plan (HCP) Coordinating Committee, comprised of federal and state resource agencies and Tribes, regarding potential environmental effects of the rehabilitation work.

Proposed Rock Island Rehabilitation

Chelan PUD intends to rehabilitate the 20.7 MW Kaplan turbine-generators in the Rock Island PH1. These units have been in service since the early1930s. The proposed rehabilitation work will begin in 2018 and continue through 2020. The following outlines the proposed work, schedule and environmental considerations. Attachment A provides Chelan PUD's estimated rehabilitation schedule for PH1.

The rehabilitation will not result in a change to generator nameplate or authorized project hydraulic capacity (220,000 cubic feet per second (cfs) or authorized capacity, 20,700 kilowatt (kW). No civil works will be necessary, including no changes to the diameter of the intake or draft tube discharge structures, height of wicket gates, or stator core. The units will continue to operate with fixed blades, the same conditions that met the Habitat Conservation Plan's no-net impact.

The rehabilitation will change the turbine horsepower (HP) from 32,000 HP to about 30,000 HP. The head for PH1 units will be updated to 39.7 feet to be consistent with other updated PH1 rehabilitated units and PH2. A smaller oil-free hub with no gaps will be installed, along with new fixed propeller runners optimized for the current operating head and flow. Currently, the units contain manually adjustable Nagler-type propeller turbines. The units will have more efficient four-blade turbines instead of six-blades. Governor controls will be replaced.

---

5 *See Pub. Util. Dist. No. 1 of Chelan County*, 46 FERC ¶ 61,033, at p. 61,208 (1989) (Ordering Paragraph (E), adopting Form L-5 into the license); *see also* 16 U.S.C. § 803(b) (prohibiting "substantial alteration or addition not in conformity with the approved plans . . . without the prior approval of the Commission"); *e.g., International Falls Power Co.*, 66 FERC ¶ 61,086 at p. 61,114-17 (1994).

Upon installation and testing, revised best gate capacities for the units will be submitted to the Commission.

Estimated Schedule – Powerhouse 1

1. Unit B1 – 2020
2. Unit B2 – 2019
3. Unit B3 – 2019
4. Unit B4 – 2018

Environmental Considerations

The rehabilitation work will not adversely affect aquatic resources or Chelan PUD's obligations under the HCP. Modern turbine design with tighter operating tolerances and fixed blade angle positioned for optimum flow conditions supporting efficient power generation will benefit fish passage survival. Additionally, laminar flow conditions associated with peak generating capability equate to providing fish the best possible flow conditions for turbine route passage. In 2013, the HCP Coordinating Committee approved Chelan PUD's 2013 Comprehensive Progress Report that concluded Chelan PUD had reached no net impact at Rock Island with respect to all planned species.[6] Chelan PUD's achievement of no net impact in 2013 was successfully achieved while operating the vintage 1933 units. The proposed rehabilitation work will not alter the HCP Coordinating Committee's 2013 finding of no net impact and in fact, Chelan PUD anticipates that the new modern design of present day turbines will offer additional survival benefit of fish passing through the rehabbed B1-4 units. A project survival standard check-in study is scheduled for 2020 (post B1-4 rehab) to verify continued achievement of the juvenile survival standard. The schedule has all PH1 units in operation by April 2020 providing the best chance for success during the 2020 HCP check-in.

Consultation

Chelan PUD has kept the HCP Coordinating Committee apprised of maintenance work occurring at the Rock Island Project. On October 25, Chelan PUD Director of Engineering and Project Management, Brett Bickford provided the HCP Coordinating Committee an overview of maintenance work planned on Units B1-B4. On November 15, Chelan PUD provided a draft of this letter to the HCP Coordinating Committee for the agencies' and committee's comments. Documentation, including comments received and Chelan PUD responses are included in Attachment B.

Conclusion

Chelan PUD appreciates the support of Commission staff and federal and state resource agencies as it continues with this important rehabilitation program for the Rock Island Hydroelectric Project. Should you have any questions regarding this matter, please contact me.

John Ferguson, Facilitator
Habitat Conservation Plan Coordinating Committee
720 Olive Way, Suite 1900
Seattle, WA 98101

Dear Mr. Ferguson:

This letter is to request a change in the Washington Department of Fish and Wildlife's (WDFW) staff representation on the Habitat Conservation Plan Coordinating Committee (HCP-CC).

Effective immediately, Chad Jackson (Region 2 Fish Program Manager) will serve as WDFW's primary voting member on the HCP-CC. Patrick Verhey (Energy and Major Project Section Biologist) will serve as WDFW's alternate voting member on the HCP-CC.

Additionally, I would like to add Mike Tonseth (Upper Columbia ESA/HCP Biologist) to the list of HCP-CC attendees. Mike's role will be as technical advisor to Chad and Patrick. Finally, please make sure Chad, Patrick, and Mike are added to the HCP-CC email distribution list and receive access to the document repository. If any additional process or procedures are required to process my request, please let me know.

Thank you for your assistance.

Sincerely,

Jim Brown
WDFW Region 2 Director

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: October 25, 2017

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the September 26, 2017, HCP Coordinating Committees Conference Call

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met by conference call on Tuesday September 26, 2017, from 10:00 to 11:30 a.m. Attendees are listed in Attachment A to these conference call minutes.

Action Item Summary

- Chelan PUD will provide a Rocky Reach Dam large unit repair update during the HCP Coordinating Committees meeting on October 24, 2017 (Item I-C).
- Kristi Geris will coordinate with Tracy Hillman and will notify the HCP Coordinating Committees of the date the HCP Hatchery Committees plan to tour the new Wells Fish Hatchery (tentatively scheduled for November 2017; Item II-A).
- Lance Keller will evaluate how well the percentage of the fish run covered by annual spill based on daily fish bypass index counts, which is the current approach used to estimate the percentage, compares to the percentage estimated using detections of passive integrated transponder (PIT)-tagged fish passing through the juvenile fish bypass system at Rocky Reach Dam (Item III-A).
- Douglas PUD will present Pacific Lamprey and salmonid count data for the time period when Lamprey Operations were implemented at Wells Dam (September 1 through September 30, 2017) during the HCP Coordinating Committees meeting on October 24, 2017 (Item IV-A).
- Kristi Geris will contact Mackenzie Gavery (Postdoctoral Research Associate, University of Washington/National Oceanic and Atmospheric Administration [NOAA] Northwest Fisheries Science Center) to confirm a 10:00 a.m. start time to present her epigenetics research during the HCP Coordinating Committees meeting on October 24, 2017 (Item V-B). *(Geris contacted Gavery, who confirmed she can present at the proposed 10:00 a.m. start time.)*
- Kristi Geris will coordinate with Tracy Hillman and will notify the HCP Coordinating Committees of the WebEx and call-in number to attend a presentation by Barry Berejikian (NOAA Northwest Fisheries Science Center) regarding his ongoing research on steelhead in Hood Canal and how it might apply to steelhead hatchery issues in the Twisp River, during the HCP Hatchery Committees meeting on October 18, 2017 (Item V-B). *(Sarah Montgomery*

distributed the agenda with this information to the HCP Coordinating Committees on October 17, 2017.)

- The HCP Coordinating Committees meeting on October 24, 2017, will be held in-person at the Grant PUD office in Wenatchee, Washington (Item V-B).

Decision Summary

- There were no HCP Decision Items approved during today's conference call.

Agreements

- There were no HCP Agreements discussed during today's conference call.

Review Items

- Sarah Montgomery (HCP Hatchery Committees Support Staff) sent an email to the HCP Coordinating Committees on September 15, 2017, notifying them the Draft 2017 Rock Island and Rocky Reach Fish Spill Program Report is available for review. Edits and comments on the report are due to Lance Keller by Monday, October 16, 2017 (Item III-B).

Finalized Documents

- There are no documents that have been recently finalized.

I. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. Lance Keller removed the Rock Island Powerhouse Maintenance Update, because no updates are available at this time. Keller said Chelan PUD will present updates on the maintenance to the HCP Coordinating Committees when key updates and information become available.

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft August 22, 2017 meeting minutes. Kristi Geris said a third revised version of the minutes were distributed to the HCP Coordinating Committees prior to the conference call on September 26, 2017. She said new revisions were from Tom Kahler, which are tracked in redline strikeout, and mainly applied to the Aquatic Settlement Work Group (SWG) Lamprey Operations Statement of Agreement (SOA) discussion. Geris said there was also one other revision regarding a comment by Mike Tonseth under the HCP Hatchery

Committees update, which Tonseth clarified. HCP Coordinating Committees members present approved the August 22, 2017 meeting minutes, as revised.

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees meeting on August 22, 2017, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the meeting on August 22, 2017):*

- *Bob Rose will coordinate internally to develop and provide a Yakama Nation (YN) HCP Representation Designation document for distribution to the HCP Coordinating Committees (Item I-C).*
  Rose provided a designation letter to Kristi Geris following the HCP Coordinating Committees meeting on August 22, 2017, which Geris distributed to the HCP Coordinating Committees on August 23, 2017.
- *Kristi Geris will coordinate with Tracy Hillman and Sarah Montgomery to obtain meeting and WebEx information for Jeff Jorgensen's (NOAA Northwest Fisheries Science Center) presentation to the HCP Hatchery Committees on September 20, 2017, on a life-cycle model for Wenatchee River spring Chinook salmon, which Geris will distribute to the HCP Coordinating Committees (Item I-C).*
  Montgomery distributed this information, as described in the agenda for the HCP Hatchery Committees meeting on September 20, 2017, to the HCP Coordinating Committees on September 19, 2017.
- *Chelan PUD will provide a Rocky Reach Dam large unit repair update during an HCP Coordinating Committees meeting in late-summer 2017 (Item I-C).*
  This action item will be carried forward and discussed during the HCP Coordination Committees meeting on October 24, 2017.
- *John Ferguson will provide the paper, "The evolutionary basis of premature migration in Pacific salmon highlights the utility of genomics for informing conservation," by Daniel Prince et al., to Kristi Geris and Tracy Hillman for distribution to the HCP Coordinating and Hatchery Committees (Item II-A).*
  Ferguson provided the paper to Geris and Hillman following the HCP Coordinating Committees meeting on August 22, 2017, which Hillman distributed to the HCP Hatchery Committees that same day and Geris distributed to the HCP Coordinating Committees on August 23, 2017.
- *Tom Kahler will discuss internally the feasibility to implement a temporary 1.0-foot fishway-entrance head differential from 22:00 to 04:00 daily during September 2017 to improve Pacific Lamprey passage at Wells Dam ("lamprey operations"), in 1- or 2-day blocks (Item IV-A).*

Kahler confirmed Wells Dam can accommodate the 2-day block design for head differentials at the fishway entrances, as distributed to the HCP Coordinating Committees by Kristi Geris on August 25, 2017.

- *Anchor QEA will coordinate with Douglas PUD and the Aquatic Settlement Work Group (Aquatic SWG) regarding the Wells HCP Coordinating Committee discussion and HCP Decision about the Aquatic SWG Lamprey Operations SOA (Item IV-A).*
  The Aquatic SWG convened a conference call on August 28, 2017, to discuss the HCP Decision about the Aquatic SWG Lamprey Operations SOA.
- *Chelan PUD will provide a Rock Island Dam Powerhouse 1 Turbine Units B1 to B4 Rehabilitation Fact Sheet to Kristi Geris for distribution to the HCP Coordinating Committees (Item V-A).*
  Lance Keller provided the rehabilitation work submittal to Geris on August 23, 2017, which Geris distributed to the HCP Coordinating Committees that same day.
- *Anchor QEA will contact Mackenzie Gavery regarding possibly presenting her epigenetics research during the HCP Coordinating Committees meeting on October 24, 2017 (Item VI-B).*
  Gavery confirmed she can present her research in-person during the HCP Coordinating Committees meeting on October 24, 2017.

II. HCP Tributary and Hatchery Committees Update

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman reported that the HCP Tributary Committees did not meet in September 2017 and will next meet on October 12, 2017, if necessary.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on September 20, 2017:

- *DECISION: Chelan PUD Coho Salmon Mitigation SOA*: Chelan PUD requested approval of their Coho Salmon Mitigation SOA; however, the Colville Confederated Tribes (CCT) asked for additional time to discuss the SOA internally, as well as with the YN. The CCT may propose revisions to the SOA for review during the HCP Hatchery Committees meeting on October 18, 2017.
- *Tumwater Feasibility Study for Pacific Lamprey Update*: Chelan PUD has been working on a feasibility study for Pacific lamprey passage at Tumwater Dam. The contractor is currently addressing questions received from Chelan PUD, and an updated study will be available for review to the fish forums and HCP Coordinating Committees in October 2017. Hillman added that Chelan PUD and the Washington Department of Fish and Wildlife (WDFW) observed adult Pacific lamprey passing the count window at Tumwater Dam. Hillman said about 14 adults had been observed as of September 20, 2017. Jim Craig asked about fish management at the dam,

specifically, if managers were routing passage through the denil. Hillman said these fish passed during non-trapping times; however, WDFW does have video of adult Pacific lamprey passing via the denil and trapping structure. John Ferguson asked about a total count to date, but Hillman said he is uncertain about counts after September 20, 2017. Hillman also noted that the YN had been conducting Pacific lamprey translocation efforts in the Wenatchee River basin the week of, and the week preceding, the HCP Hatchery Committees meeting.

- *Transition Plan for Douglas PUD Hatcheries:* Douglas PUD notified the HCP Hatchery Committees that they terminated their contract with WDFW to operate the Wells and Methow fish hatcheries. The termination includes a 90-day transition period per the contract, which may be extended. During the meeting, parties to the HCPs made it clear they would like to see a longer transition period. Douglas PUD indicated they are not opposed to a longer period (e.g., 120 days); however, no determination to extend the transition period has been made. Douglas PUD is in the process of hiring new hatchery staff and drafting a transition plan. The Wells HCP Hatchery Committee indicated they want Douglas PUD to coordinate with the Committee during the transition. Douglas PUD will continue contracting with WDFW for hatchery monitoring and evaluation (M&E) work.
- *Wells Fish Hatchery Modernization:* The Wells Fish Hatchery Modernization project is nearly complete. Douglas PUD extended the contract end date past August 31, 2017, so the contractor can finish a few minor items. The HCP Hatchery Committees will visit the facility this fall. Ferguson said Kristi Geris will coordinate with Hillman and will notify the HCP Coordinating Committees of the date the HCP Hatchery Committees plan to tour the new Wells Fish Hatchery. Hillman noted that this will likely take place in November 2017.
- *U.S. Fish and Wildlife Service Bull Trout Consultation Update*: The U.S. Fish and Wildlife Service (USFWS) completed edits and responses to comments on the Biological Opinion (BiOp) for the Wenatchee subbasin programs. The BiOp is now undergoing USFWS internal review.
- *National Marine Fisheries Service Consultation Update*: The National Marine Fisheries Service (NMFS) intends to finish the proposed action for the Upper Columbia River unlisted summer Chinook salmon programs. NMFS is now incorporating edits and comments received from reviewers.
- *PRESENTATION: Wenatchee Spring Chinook Salmon Life Cycle Modeling*: Jeff Jorgensen presented the Wenatchee spring Chinook salmon life-cycle model, which is a tool that NOAA and their collaborators are developing to understand the effects of habitat, predation (avian and pinnipeds), dams, hatchery, harvest, and climate on salmon survival. The model is a complex matrix model, which tracks salmon survival and abundance throughout their life cycle. The hatchery component of the model includes proportionate natural influence (PNI) targets, proportion of hatchery-origin spawners, hatchery-origin recruits, and natural-origin recruits. Based on results from the relative reproductive success studies, the model applies a

progeny discount depending on PNI scores. Jorgensen shared results of different model runs, and among the scenarios modeled, hatcheries, pinniped predation, and ocean conditions had relatively large effects on salmon survival and quasi-extinction risk. Jorgensen concluded by talking about further additions to the model, including juvenile Chinook salmon survival in Lake Wenatchee, egg-to-fry and fry-to-parr survival, and developing a better model to predict continuous stream temperatures in space and time. Hillman said the HCP Hatchery Committees provided Jorgenson with feedback, and they may ask Jorgenson to run a few scenarios to help the Committees with their studies. Ferguson asked if this Wenatchee spring Chinook salmon life-cycle model can be considered as up and running, calibrated, and usable now, and Hillman said it is. Hillman said NOAA is still working to improve the model, but the model is already producing results. Hillman also noted that the development of the Wenatchee model has more data available than other models in other river basins, as a result of PUD-funded hatchery M&E programs and Bonneville Power Administration-funding.

- *Draft 2017 Hatchery M&E Plan for PUD Hatchery Programs Update*: The HCP Hatchery Committees are currently reviewing revisions to the Hatchery M&E Plan, including changes to the adaptive management and Non-Target Taxa of Concern sections. Hillman is currently drafting an appendix to the Hatchery M&E Plan titled, "Estimation of Carrying Capacity." The HCP Hatchery Committees will review the appendix during the HCP Hatchery Committees meeting on October 18, 2017. The Committees hope to finalize the plan and share it with the Independent Scientific Advisory Board.
- *Next meeting*: The next meeting of the HCP Hatchery Committees will be on October 18, 2017.

III. Chelan PUD

A. Draft 2017 Rock Island and Rocky Reach Fish Spill Program Report (Lance Keller and Thad Mosey)

Lance Keller said Thad Mosey (Chelan PUD Fish Biologist and Spill Coordinator) will present the Draft 2017 Rock Island and Rocky Reach Fish Spill Program Report (Attachment B), which was distributed to the HCP Coordinating Committees by Sarah Montgomery on September 15, 2017.

Spring Spill – Rock Island

Mosey said the juvenile fish bypass system at Rock Island Dam was operational on March 29, 2017. He said over-under gates were installed, which are designed to allow full river flow to pass through the gates. He said, as in previous years, he expected to observe an increase in sockeye salmon numbers once the bypass was operational; however, this was not the case this year with sockeye salmon, Chinook salmon, or steelhead. He said numbers eventually did increase by April 14, 2017, and upstream hatchery releases were scheduled to start April 15, 2017. He said based on this information, he felt confident to start spring spill on April 17, 2017. Mosey said he kept in touch with the bypass crew over the weekend preceding April 17, 2017, and numbers increased significantly. He said to ensure all fish spill gates were being employed, he had the operators incorporate six notch spill gates. He said even with hydraulic spill, spring spill at Rock Island Dam officially started on April 16, 2017, and he noted that the percent of run targets were met. He said if spring spill had started on April 17, 2017, as initially estimated, the percent of run with spill targets would have been missed. He then reviewed the spring spill data for Rock Island Dam presented in Attachment B.

Summer Spill – Rock Island and Rocky Reach

Mosey said in early May 2017, Chelan PUD began monitoring daily counts of subyearling Chinook smolts at both the Rock Island and Rocky Reach Juvenile Fish Bypass Facilities. He said Chelan PUD was also coordinating with the CCT and Douglas PUD regarding upcoming fish releases. Mosey recalled that the 2017 Rock Island and Rocky Reach Fish Spill Plan states, "summer spill will start at midnight no later than the day on which the estimated 1-percentile passage point is reached." He said on May 25, 2017, it appeared that counts of subyearlings at both facilities had reached 1%; therefore, summer spill at Rock Island Dam and Rocky Reach Dam officially started on May 26, 2017.

Mosey reviewed the summer spill data for Rock Island and Rocky Reach dams presented in Attachment B. He said summer spill operations at Rock Island and Rocky Reach dams ended on August 18 and 25, 2017, respectively, after meeting the criteria of covering 95% of the subyearling outmigration and subyearling index counts from the corresponding juvenile bypass sampling facility were 0.3 percent of the cumulative run for 3 of 5 consecutive days.

Mosey said, despite the hydraulic spill at Rock Island Dam from March to late-June 2017, the spring and summer spill programs at Rock Island and Rocky Reach dams went smoothly this year with regard to monitoring numbers and coordination with dam operators.

Kirk Truscott asked if there is a comment period open for this report. Kristi Geris said based on the distribution date, a 30-day comment period means edits and comments on the report are due to Keller by Monday, October 16, 2017.

Truscott asked if the percentage of the fish run covered by annual spill is based on daily fish bypass index counts. Keller said this is correct. Truscott noted that there is also a database of PIT-tagged fish passing through the juvenile fish bypass system at Rocky Reach Dam. Keller said this is also correct. Truscott asked, how well do these two data sources correspond to one another? Keller said he does not have this information available at this time; however, he will evaluate the data and provide a response to Geris for distribution to the HCP Coordination Committees.

IV. Douglas PUD

A. Wells Dam Fishway Operations for Pacific Lamprey Update (Tom Kahler)

Tom Kahler said he just emailed Pacific lamprey data from Wells Dam showing block comparisons (Attachment C) to Kristi Geris, which Geris forwarded to the HCP Coordinating Committees during the meeting on September 26, 2017. Kahler said 4 of 5 blocks[1] have been implemented to date[2]. He said the Pacific lamprey run at Wells Dam has already peaked and is now tapering off.

Kahler said most fish seem to be passing between 00:00 and 10:00. He said there are some differences in passage from the 1-foot to 1.5-foot head differentials, with more fish tending to be counted under the normal 1.5-foot head operation; however, the differences were subtle. He noted that around 05:00 to 06:00 passage is increasing, and then drops at the 1-foot head differential, but peaks at the 1.5-foot head differential. He recalled that if there seemed to be an alarming interference with passage, these block operations would be discontinued; however, he said nothing alarming has been observed to date.

John Ferguson agreed with Kahler's comments, and added that the emails exchanged within the Aquatic SWG are reporting similar findings. Ferguson said there does not seem to be an apparent pattern between block and normal operations; although, he did note a slight difference in the 06:00 to 08:00 hour period.

Kahler said civil twilight during September is around 20:00 to 21:00. He said if darkness is a cue to start entering and ascending the fish ladder, and if what was concluded from the radio-telemetry studies is accurate (i.e., under the 1-foot head differential fish more readily passed through the lower portion of the fish ladder), then one would expect to see a pattern of more fish passing the count windows in hours 01:00 to 04:00 during the 1.0-foot operations because those fish would have entered the fishways during the normal operating differential (hours 20:00-22:00), but would have more readily ascended the lower ladder once the 1.0-foot-differential operations commenced at 22:00 hours.

---

[1] Note: A block equals three consecutive days where the Wells Dam fishway entrances are operated at a head differential of 1.0 foot (versus the usual 1.5 foot), from 22:00 to 04:00 daily. On days between the blocks, the fishway entrances are operated at a normal head differential of 1.5 foot.

[2] Note: Block 1 = September 1 to 3; Block 2 = September 7 to 9; Block 3 = September 13 to 15; Block 4 = September 19 to 21; and Block 5 = September 25 to 27, 2017.

Kirk Truscott said about 260 Pacific lamprey passed Wells Dam, and he asked how this compares to the overall conversion between Rocky Reach and Wells dams. Kahler said there were about 23,000 Pacific lamprey counted at Rocky Reach Dam, so the conversion is miniscule (about 0.01 percent).

Kahler said Douglas PUD will present Pacific Lamprey and salmonid count data for the time period when Lamprey Operations were implemented at Wells Dam (September 1 through September 30, 2017), during the HCP Coordinating Committees meeting on October 24, 2017.

B. Transition Plan for Douglas PUD Hatcheries (Tom Kahler)

Tom Kahler said Douglas PUD already contacted and has had conversations with the individual Wells HCP Coordinating and Hatchery Committees representatives prior to this conference call. He said this agenda item was requested by Bob Rose, who is not in attendance today. Kahler said he is open to further discuss anything the Committee members would like to hear about.

John Ferguson asked for an update on the Douglas PUD transition plan. Kahler said the transition plan is currently under internal review and it should be available for distribution by the end of the week. He said Douglas PUD provided the transition plan's table of contents to the HCP Hatchery Committees for review. He said Douglas PUD asked the HCP Hatchery Committees to let them know if the table of contents is missing anything. He said no comments have been received to date. He said if no comments are received, Douglas PUD plans to proceed with the plan, as written.

Kahler said the hiring process is underway for hatchery staffing, with the idea to have hatchery supervisors in place first, and have them fully engaged in filling the rest of the positions with the best qualified staff.

Kahler said Douglas PUD plans to continue their current hatchery M&E contract with WDFW. He said the idea is to have Douglas PUD and WDFW M&E personnel continuing to work together in the same roles they have had, with potentially additional roles arising. He said maintaining the hatchery M&E contract with WDFW is very practical. He said this is a role WDFW has already played, and they have a very intimate knowledge of the M&E components. He said Douglas PUD has had a great working relationship with these folks.

Ferguson asked about extending the 90-day transition period to 120 days. Kahler said 90 days is stipulated in the contract, which is why Douglas PUD is operating under this timeframe. He said Douglas PUD is also open to extending the timeframe. He said there is a lot to accomplish in 90 days, which is doable; however, additional time may be more comfortable. He said he is unaware of an offer from WDFW for a longer transition period.

Chad Jackson said WDFW looks forward to seeing Douglas PUD's transition plan at the end of this week. Jackson said WDFW has been waiting on this plan before appointing a point of contact for the transition and proposing an extended time period. Kahler said he did not believe the transition plan is a prerequisite for establishing a point person; however, Douglas PUD will conform, as needed.

Ferguson invited Commissioner Dave Graybill (WDFW) to ask questions and provide his perspectives. Commissioner Graybill said WDFW is eager to work with Douglas PUD. He said the concern is that WDFW does not yet have enough details to fully understand the process. He said the Wells facility and the HCP Plan species being reared there are precious resources. He said WDFW will be watched very carefully, and this transition needs to be executed carefully. He said he is glad to hear that Douglas PUD, from his perspective, agrees this is not a 90-day process. He said once WDFW has received Douglas PUD's transition plan, a point of contact for WDFW will be established.

Ferguson asked if WDFW has been discussing who might be the person to assign the point of contact after receiving the transition plan. Jackson said a specific staff member has not yet been identified. He said there are a number of potential staff persons; however, selecting the most appropriate person depends on the details (e.g., how much work this will entail). He said WDFW is already thinking about this, but needs more details on the transition plan.

V. HCP Administration

A. Extranet Access for Sarah Montgomery (John Ferguson)

John Ferguson said Sarah Montgomery was given administrative access to the HCP Coordinating Committees Extranet site from Julene McGregor (Douglas PUD Information Systems Staff), in order to provide back-up assistance for Kristi Geris. Geris recalled that historically, administrative support staff have been added to email distribution lists and given extranet access without HCP Coordinating Committees approval. Ferguson asked if the HCP Coordinating Committees had any concerns about this, and no concerns were expressed.

B. Next Meetings

The next scheduled HCP Coordinating Committees meeting is on October 24, 2017, to be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington.

John Ferguson recalled that Mackenzie Gavery accepted the invitation to present her epigenetics research during the HCP Coordinating Committees meeting on October 24, 2017. The HCP Coordinating Committees proposed a 10:00 a.m. start time for Gavery's presentation, with the monthly HCP Coordinating Committees meeting to follow. Kristi Geris will contact Gavery to confirm a 10:00 a.m. start time will work for her. *(Geris contacted Gavery, who confirmed she can present at the proposed 10:00 a.m. start time.)*

Tom Kahler said the HCP Hatchery Committees invited Barry Berejikian (NOAA Northwest Fisheries Science Center) to discuss his ongoing research on steelhead in Hood Canal and how it might apply to steelhead hatchery issues in the Twisp River, during the HCP Hatchery Committees meeting on October 18, 2017. Kahler suggested that HCP Coordinating Committees members also attend the meeting, if interested. Geris will coordinate with Tracy Hillman and will notify the HCP Coordinating Committees of the WebEx and call-in number to attend a presentation by Berejikian.

The November 28, 2017, December 26, 2017, and January 23, 2018, meetings will be held by conference call or in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington, as is yet to be determined.

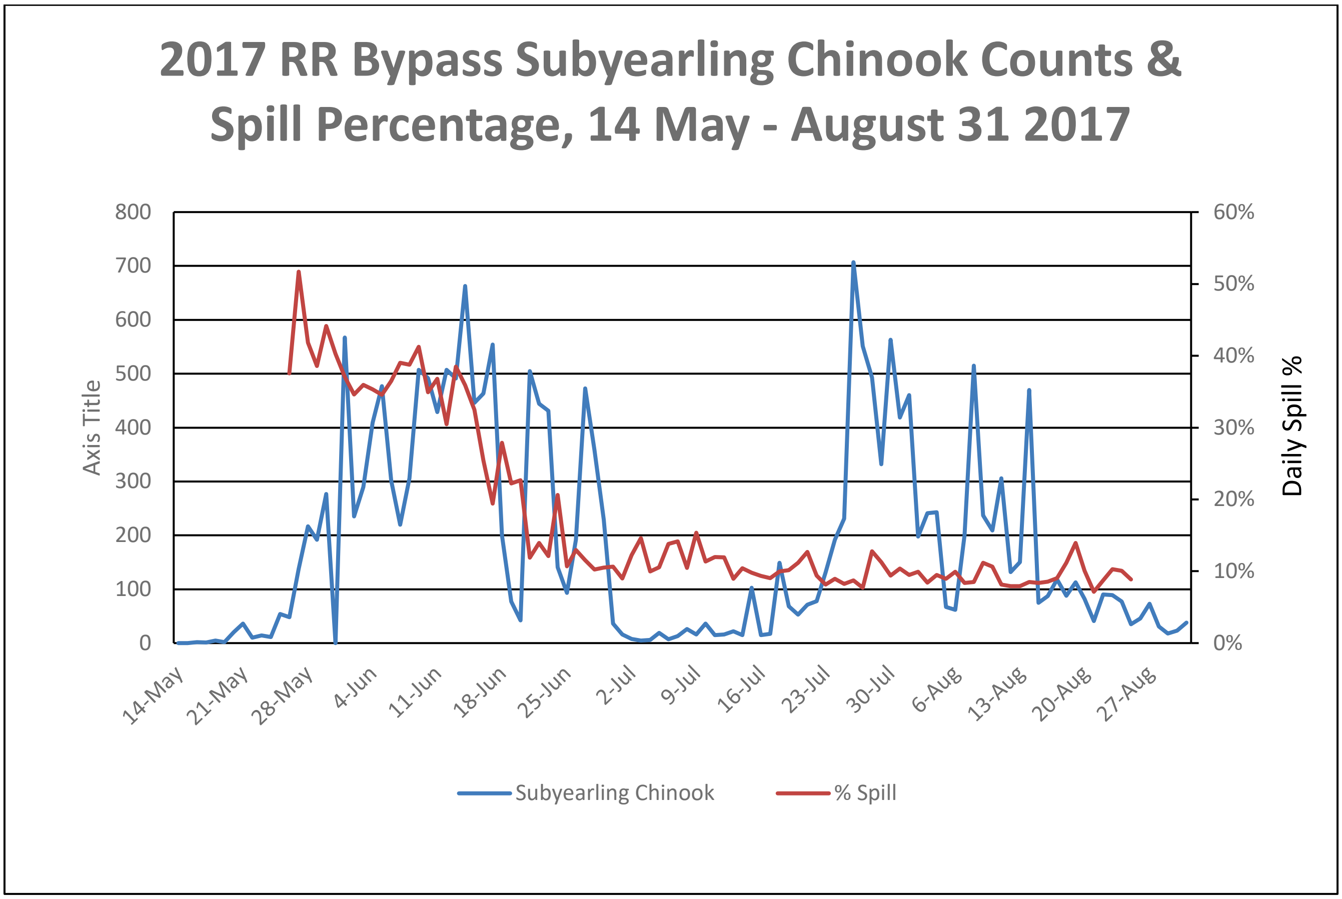
Rocky Reach and Rock Island HCPs
Draft 2017 Fish Spill Report

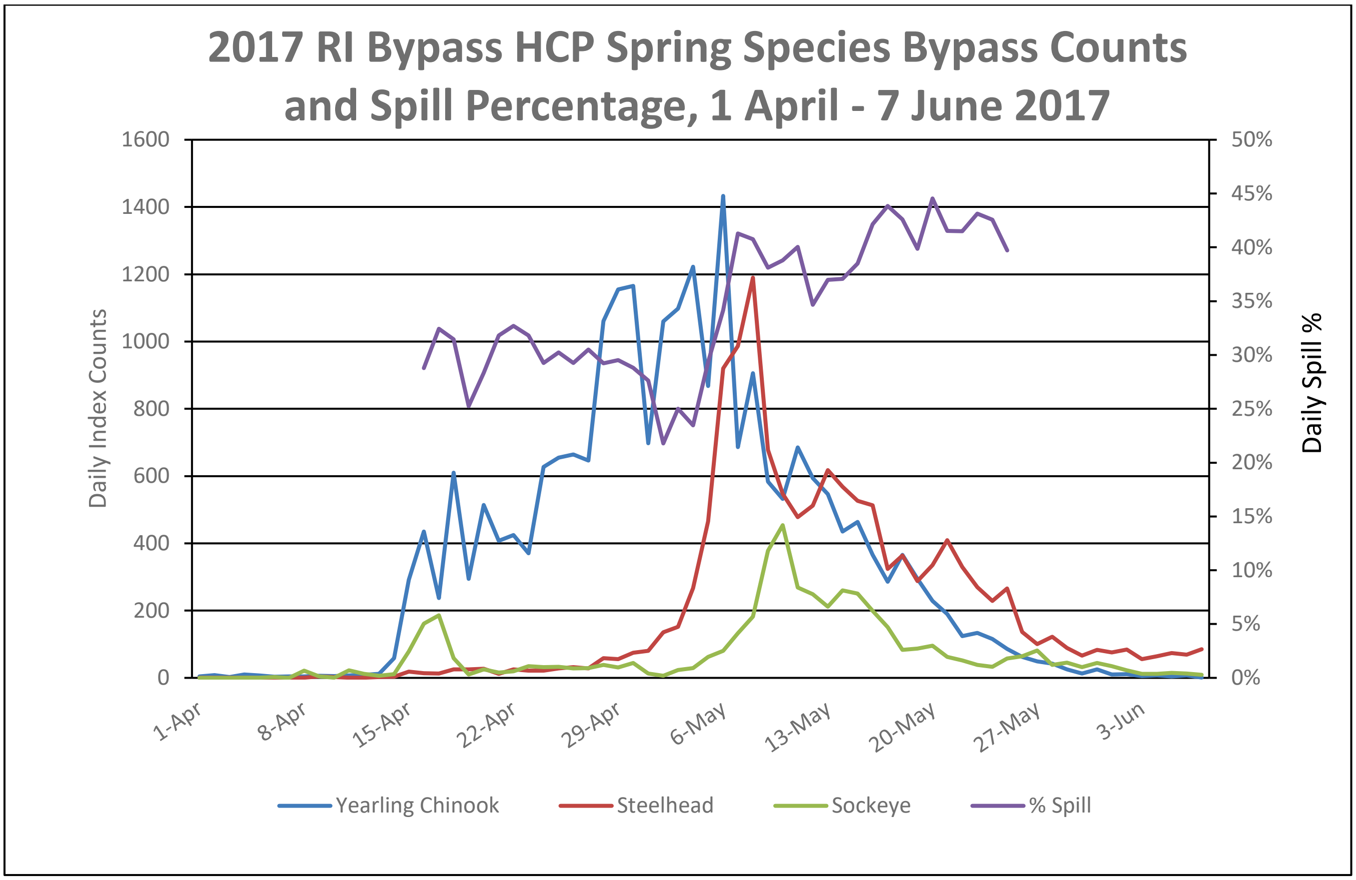
2017 ROCKY REACH
Summer Spill

Target species:	Subyearling Chinook
Spill target percentage:	9% of day average river flow
Spill start date:	26 May, 0001 hours
Spill stop date:	25 August, 2400 hours
95% Est. passage date:	14 August
Percent of run with spill:	98.5% on 25 August (estimated as of 31 August)
Cumulative index count:	27,404 subyearling Chinook (as of 31 August)
Summer spill percentage:	21.74% (9.06% fish spill, plus 12.68% forced spill)
Avg river flow at RR:	149,598 cfs (26 May - 25 August)
Avg spill rate at RR:	32,518 cfs (26 May - 25 August)
Total spill days:	92



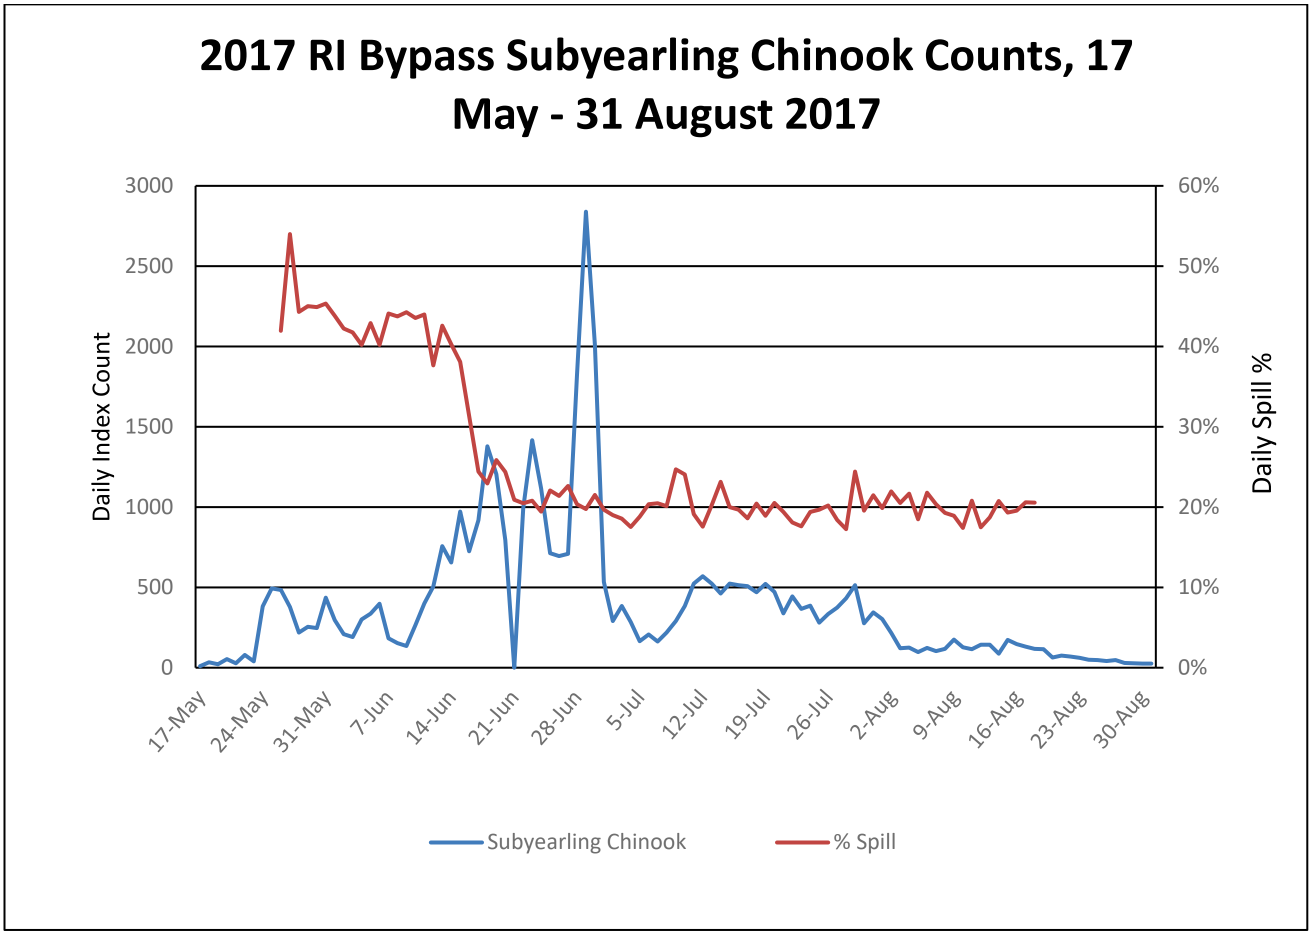
<u>2017 ROCK ISLAND</u>
Spring Spill

Target species:	Yearling Chinook, steelhead, sockeye
Spill target percentage:	10% of day average river flow
Spill start date:	16 April, 0001 hours
Spill stop date:	25 May, 2400 hours (immediate increase to 20% summer spill)
Percent of run with spill:	Yearling Chinook – 98.4%; steelhead – 99.8%; sockeye – 97.0% (spring and summer fish spill combined)
Cumulative index count:	50,604 yearling Chinook**;** 32,135 steelhead**;** 11,117 sockeye (as of 31 August)
Spring spill percentage:	35.22% (9.69% fish spill, plus 25.53% forced spill)
Avg river flow at RI:	227,790 cfs (16 April – 25 May)
Avg spill flow at RI:	80,222 cfs (16 April – 25 May)
Total spill days:	40



Summer Spill

Target species:	Subyearling Chinook
Spill target percentage:	20% of day average river flow
Spill start date:	26 May, 0001 hours
Spill stop date:	18 August, 2400 hours
95% Est. passage date:	5 August
Percent of run with spill:	97.5% on 18 August (estimated as of 31 August)
Cumulative index count:	63,579 subyearling Chinook (as of 31 August)
Summer spill percentage**:**	29.47% (19.89% fish spill, plus 9.58% forced spill)
Avg river flow at RI:	162,085 cfs (26 May - 18 August)
Avg spill flow at RI:	47,774 cfs (26 May - 18 August)
Total spill days:	85



Juvenile Index Counts 2007-2017 from the Rocky Reach Juvenile Fish Bypass Sampling Facility and Rock Island Bypass Trap Smolt Monitoring Program (SMP) 1 April – 31 August (Tables 1 and 2).

Table 1. Rocky Reach Juvenile Bypass index sample counts, 2007-2017

Species	2007	2008	2009	2010	2011	2012	2013	2014*	2015	2016	2017
Sockeye	169,937	136,206	40,758	724,394	67,879	384,224	199,497	553,645	53,575	1,374,418	**60,432**
Steelhead	4,532	8,721	6,309	4,931	5,683	4,902	2,528	5,270	4,157	1,478	**2,928**
Yearling Chinook	18,080	38,394	18,946	33,840	24,400	95,207	29,018	15,871	32,220	41,676	**37,302**
Subyearling Chinook	13,496	11,820	11,944	59,751	17,246	5,774	22,073	22,327	37,104	8,905	**27,404**

Table 2. Rock Island Smolt Monitoring Program index sample counts, 2007-2017

Species	2007	2008	2009	2010	2011	2012	2013	2014*	2015	2016	2017
Sockeye	16,410	38,965	4,926	37,404	18,697	46,788	25,111	38,596	4,128	56,638	**11,117**
Steelhead	18,482	22,780	17,636	17,194	28,408	16,957	15,099	28,299	12,549	17,663	**32,135**
Yearling Chinook	23,714	22,562	9,225	11,802	26,407	25,759	28,324	26,429	16,762	44,784	**50,604**
Subyearling Chinook	15,686	15,940	8,189	23,205	27,397	27,298	17,170	34,527	15,349	13,270	**63,579**

***** In 2014, as directed by the HCP, Chelan PUD conducted bypass operations outside of the normal operating period of 1 April to 31 August to assess achievement of bypass operations for 95% of the subyearling Chinook outmigration. The Rocky Reach juvenile fish bypass operated from 1 April through 15 September, and the Rock Island bypass facility at powerhouse 2 operated from 1 April through 15 September.

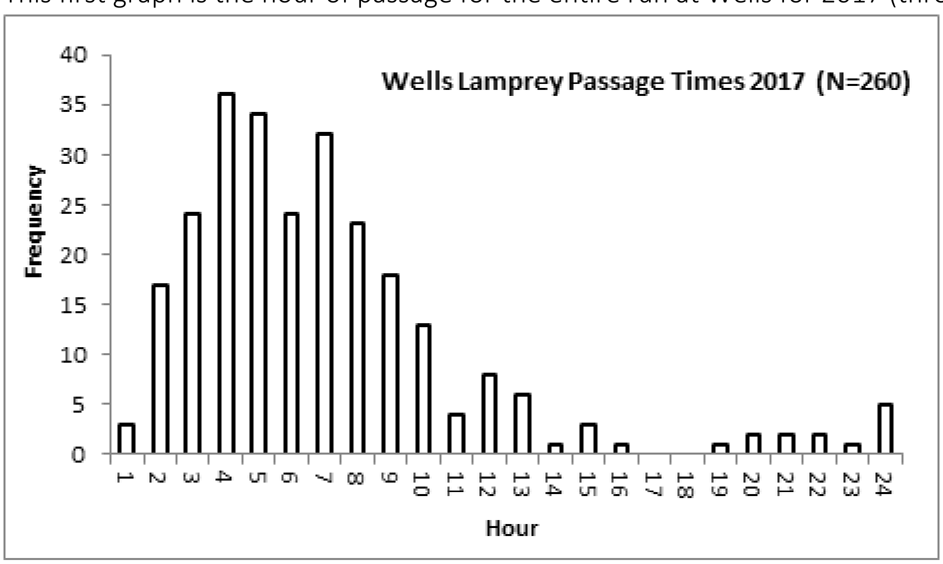
Subject: Pacific Lamprey data from Wells

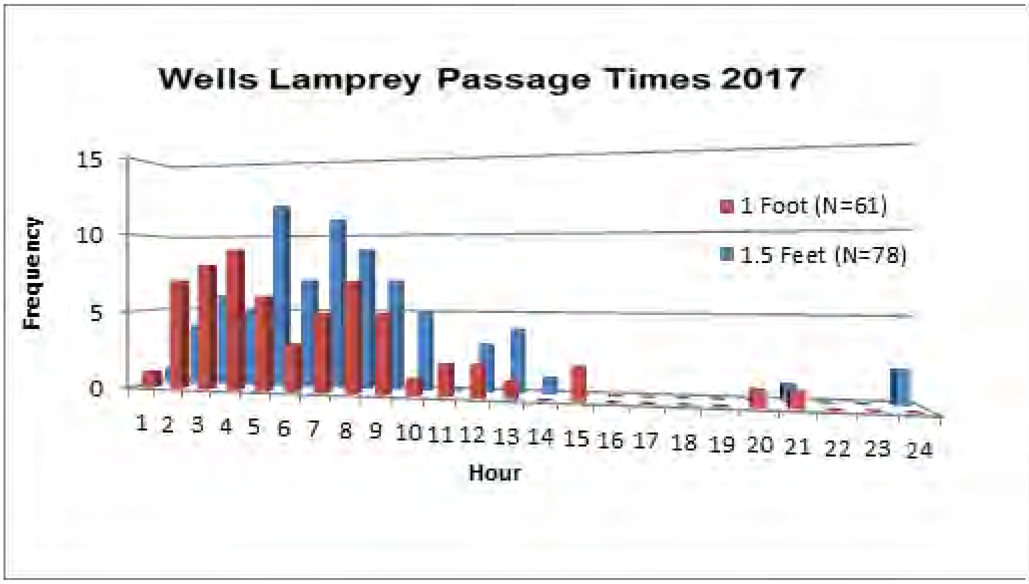
Hi Kristi,

Here's the latest from the block comparison of Pacific Lamprey passage at Wells.

This first graph is the hour of passage for the entire run at Wells for 2017 (through 9/24)



This second graph is the hour of passage for Pacific Lamprey at Wells during the comparison of fishway head-differentials (through 9/24, which comprises nearly four complete blocks)



Thanks,

Tom

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: December 13, 2017

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the October 24, 2017, HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met at the Grant PUD Office in Wenatchee, Washington, on Tuesday October 24, 2017, from 10:00 a.m. to 1:30 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Kristi Geris will coordinate with Tracy Hillman and will notify the HCP Coordinating Committees of the date the HCP Hatchery Committees plan to tour the new Wells Fish Hatchery (tentatively scheduled for early 2018; Item II-C).
- Kristi Geris will locate the presentation, "Potential to improve the conservation benefits of steelhead hatcheries," presented by Barry Berejikian (National Oceanic and Atmospheric Administration [NOAA] Northwest Fisheries Science Center) during the HCP Hatchery Committees meeting on October 18, 2017, and will distribute the presentation to the HCP Coordinating Committees (Item III-A). *(Note: Geris distributed Berejikian's presentation to the HCP Coordinating Committees on October 26, 2017.)*
- Douglas PUD will: 1) incorporate comments received on the Transition Plan for Wells and Methow Fish Hatcheries, and provide the updated plan to Kristi Geris for distribution to the HCP Coordinating Committees; 2) either incorporate sections of the Memorandum of Understanding (MOU) into the transition plan or distribute the MOU to the HCP Coordinating Committees; and 3) check on the status of the Operations Plan (Item IV-B). *(Note: Sections of the MOU were incorporated into the final transition plan, and Tom Kahler provided the final plan to Geris on November 7, 2017, which Geris distributed to the HCP Coordinating Committees that same day.)*
- Douglas PUD, in coordination with Richard Townsend (Columbia Basin Research), will incorporate wild yearling Chinook salmon passage data for 2017 into the corrected Draft 2017 Wells Dam Passage Dates Analysis (Item IV-C).
- Douglas PUD, in coordination with Richard Townsend, will include wild yearling Chinook salmon passage data for all years of analyses in an addendum to the Draft 2017 Wells Dam Passage Dates Analysis (Item IV-C).

- Douglas PUD will provide a proposal on which study species to use for the Douglas PUD 2020 Survival Verification Study for the Wells HCP Coordinating Committee to consider, and will convene a conference call for discussion, if necessary (Item IV-D).
- Chelan PUD will provide the Final 2017 Rock Island and Rocky Reach Fish Spill Program Report to Kristi Geris for distribution to the HCP Coordinating Committees (Item V-A).
- Chelan PUD will provide a written list of the repairs planned for the Rocky Reach Dam fish ladders during the 2017/2018 winter maintenance outage, and 2014 passage data, for Rocky Reach HCP Coordinating Committee consideration and vote via email (Item V-D). *(Note: Keller provided the list of repairs and 2014 passage data to Kristi Geris following the meeting on October 24, 2017, which Geris distributed to the HCP Coordinating Committees on October 25, 2017.)*
- Chad Jackson will provide an official Washington Department of Fish and Wildlife (WDFW) HCP Hatchery Committees Representation Designation Letter to Kristi Geris for the administrative record (Item VI-A). *(Note: Jackson provided this letter to Geris on November 6, 2017, which Geris distributed to the HCP Coordinating Committees and to Sarah Montgomery [Anchor QEA] for distribution to the HCP Hatchery Committees that same day.)*
- Kristi Geris will coordinate with Denny Rohr (Priest Rapids Coordinating Committee [PRCC] Facilitator) and the PRCC regarding rescheduling the HCP Coordinating Committees meeting in December 2017 (Item VI-B). *(Note: Geris coordinated with Rohr, who indicated the PRCC plans to meet on December 13, 2017; therefore, the HCP Coordinating Committees meeting on December 26, 2017, has been rescheduled to December 12, 2017.)*
- The HCP Coordinating Committees meeting on December 26, 2017, has been rescheduled to December 12, 2017, to accommodate the Christmas holiday and best coordinate with the PRCC, and will be held by conference call or in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington, as is yet to be determined (Item VI-B).

Decision Summary

- Rock Island and Rocky Reach HCP Coordinating Committees members present approved the 2017 Rock Island and Rocky Reach Fish Spill Program Report, with the Colville Confederated Tribes (CCT) abstaining (Item V-A).

Agreements

- HCP Coordinating Committees members present agreed to cancel the HCP Coordinating Committees meeting on November 28, 2017, due to lack of agenda items and a scheduling conflict with the U.S. Army Corps of Engineers (USACE's) 2017 Anadromous Fish Evaluation Program (AFEP) Annual Review (Item VI-B).

- The Rocky Reach HCP Coordinating Committee agreed via email to Chelan PUD's request to begin the 2017/2018 winter maintenance work period at Rocky Reach Dam, 3 weeks earlier than usual to allow more time to complete required work. Rather than beginning work during the first week in January (per usual), maintenance work will begin on December 11, 2017. Approvals were as follows: Chelan PUD, National Marine Fisheries Service (NMFS), WDFW, and the CCT approved November 1, 2017, and U.S. Fish and Wildlife Service (USFWS) and the Yakama Nation (YN) approved November 2, 2017 (Item V-D).

Review Items

- A corrected Draft 2017 Wells Dam Passage Dates Analysis was distributed to the HCP Coordinating Committees by Kristi Geris on October 23, 2017. The draft analysis is available for a 30-day review period, with edits and comments due to Tom Kahler by November 22, 2017 (Item IV-C).
- A written list of the repairs planned for the Rocky Reach Dam fish ladders during the 2017/2018 winter maintenance outage, and 2014 passage data, were distributed to the HCP Coordinating Committees by Kristi Geris on October 25, 2017. Rocky Reach HCP Coordinating Committee votes are due to Lance Keller (with a copy to Geris) via email by Friday, November 3, 2017 (Item V-D). *(Note: the Rocky Reach HCP Coordinating Committee approved this request; see Agreements)*
- Kristi Geris notified the Rock Island HCP Coordinating Committee on November 15, 2017, that an Application for Non-Capacity Amendment is available for a 30-day review period, with edits and comments due to Jeff Osborn (Chelan PUD) by December 15, 2017.

Finalized Documents

- The Final Public Transition Plan for Wells and Methow Fish Hatcheries was distributed to the HCP Coordinating Committees by Kristi Geris on November 7, 2017 (Item IV-B).

I. University of Washington/NOAA Northwest Fisheries Science Center

A. PRESENTATION: Epigenetics (Mackenzie Gavery)

Mackenzie Gavery (Postdoctoral Research Associate, University of Washington/NOAA Northwest Fisheries Science Center) shared the presentation, "Epigenetics: what is it and why is it relevant to hatchery practices?" (Attachment B), which was distributed to the HCP Coordinating Committees by Kristi Geris on September 27, 2017.

The presentation included an overview of epigenetics, discussion of a specific epigenetic marker called deoxyribonucleic acid (DNA) methylation, and a presentation of DNA methylation data from Methow River steelhead. Epigenetics refers to heritable changes in trait or phenotype caused by a mechanism other than a mutation to the DNA sequence. The epigenome of an organism provides the instruction for which genes should be expressed, and is influenced by the environment, especially during early development, and even after the environmental signal is removed. Gavery's research investigated whether there are discernable epigenetic differences between hatchery- and natural-origin steelhead at Winthrop National Fish Hatchery. In 2014, blood and sperm samples extracted from returning hatchery- and natural-origin adult steelhead were used in a DNA methylation analysis to evaluate somatic and germline cells (which are passed on to the next generation). The results indicated steelhead have a heavily methylated genome compared to other species. Comparisons of differentially methylated regions between blood and sperm cells show sperm carry important epigenetic information regarding which genes are going to be turned on in the early embryo. Results also showed there are differences in DNA methylation between hatchery- and natural-origin steelhead in both somatic and germline-derived cell types. Epigenetics can help organisms retain and pass on information about their environment and the study of the epigenome is an emerging tool to help understand how the environment affects the phenotypes of hatchery fish. Gavery has a second study underway where offspring from natural-origin Methow steelhead families are divided into two groups and reared in a hatchery tank and an artificial stream.

II. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. The following revisions were requested:

- Tom Kahler added: 1) Draft 2017 Wells Dam Passage Dates Analysis; 2) choice of study species for the Douglas PUD 2020 Survival Verification Study.
- Lance Keller added: 1) 2017 Rock Island and Rocky Reach Fish Spill Program Report; 2) Rocky Reach Dam fish ladder, request for an early winter maintenance outage.

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft September 26, 2017 conference call minutes. Kristi Geris said the revised minutes were distributed to the HCP Coordinating Committees by Sarah Montgomery on October 17, 2017. Geris said all comments and revisions received from members of the Committees were incorporated into the revised minutes. She noted that a few edits were reflected in tracked changes; however, there were no outstanding issues to be discussed. HCP Coordinating Committees members present approved the September 26, 2017 conference call minutes, as revised. The YN abstained, because a YN representative was not present during the September 26, 2017 conference call.

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees conference call on September 26, 2017, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the meeting on September 26, 2017):*

- *Chelan PUD will provide a Rocky Reach Dam large unit repair update during the HCP Coordinating Committees meeting on October 24, 2017 (Item I-C).*
  This will be discussed during today's meeting.
- *Kristi Geris will coordinate with Tracy Hillman and will notify the HCP Coordinating Committees of the date the HCP Hatchery Committees plan to tour the new Wells Fish Hatchery (tentatively scheduled for November 2017; Item II-A).*
  Geris said the tour has been postponed to early 2018, due to uncertainty of a construction completion date. This action item will be carried forward.
- *Lance Keller will evaluate how well the percentage of the fish run covered by annual spill based on daily fish bypass index counts, which is the current approach used to estimate the percentage, compares to the percentage estimated using detections of passive integrated transponder (PIT)-tagged fish passing through the juvenile fish bypass system at Rocky Reach Dam (Item III-A).*
  Keller provided subyearling Chinook salmon PIT detections at the Rocky Reach Juvenile Fish Bypass System (RRJFBS) in 2017 compared to index counts to Sarah Montgomery on October 17, 2017, which Montgomery distributed to the HCP Coordinating Committees that same day. Kirk Truscott said he has not yet thoroughly reviewed these data, but will contact Keller if any questions arise.
- *Douglas PUD will present Pacific Lamprey and salmonid count data for the time period when Lamprey Operations were implemented at Wells Dam (September 1 through September 30, 2017) during the HCP Coordinating Committees meeting on October 24, 2017 (Item IV-A).*
  This will be discussed during today's meeting.
- *Kristi Geris will contact Mackenzie Gavery to confirm a 10:00 a.m. start time to present her epigenetics research during the HCP Coordinating Committees meeting on October 24, 2017 (Item V-B).*
  Geris contacted Gavery, who confirmed she can present at the proposed 10:00 a.m. start time.
- *Kristi Geris will coordinate with Tracy Hillman and will notify the HCP Coordinating Committees of the WebEx and call-in number to attend a presentation by Barry Berejikian (NOAA Northwest Fisheries Science Center) regarding his ongoing research on steelhead in Hood Canal and how it*

might apply to steelhead hatchery issues in the Twisp River, during the HCP Hatchery Committees meeting on October 18, 2017 (Item V-B).
Sarah Montgomery distributed the agenda with this information to the HCP Coordinating Committees on October 17, 2017.

III. HCP Tributary and Hatchery Committees Update

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman reported that the HCP Tributary Committees did not meet in October 2017 and will next meet on November 9, 2017. Hillman also announced that Steve Hays (Chelan PUD) plans to retire at the end of 2017. Hillman said the HCP Tributary Committees are planning a farewell party for Hays during the November meeting, and Hays will also provide a presentation on the Chelan River habitat restoration work.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on October 18, 2017:

- *Draft 2018 Hatchery Monitoring and Evaluation Implementation Plan*: Douglas PUD submitted the Draft Douglas PUD 2018 Hatchery Monitoring and Evaluation (M&E) Implementation Plan to the HCP Hatchery Committees for review. There is little change in the plan from the previous year. Comments are due to Douglas PUD by December 1, 2017, and the plan will likely be approved during the HCP Hatchery Committees meeting in December 2017.
- *Wells Hatchery Transition Plan*: Douglas PUD distributed the Draft Transition Plan for the Wells and Methow Fish Hatcheries in mid-October 2017, and the HCP Hatchery Committees are reviewing and providing comments back to Douglas PUD as soon as possible. USFWS provided a few comments during the meeting on October 18, 2017. Douglas PUD reported that managers have now been hired for the Methow and Wells fish hatcheries. The plan is to have the transition completed within the 90-day period; however, some items may need a longer transition period, which will be evaluated on a case-by-case basis.
- *PRESENTATION: Potential to improve the conservation benefits of steelhead hatcheries*: Barry Berejikian provided a presentation on his work with steelhead in Hood Canal. Briefly, Berejikian discussed: 1) approaches for egg collection, rearing, and release for small hatchery programs; 2) effects on abundance and genetic diversity; 3) alternative rearing strategies to improve smolt performance and reduce domestication; and 4) developing practical and flexible rearing strategies for conservation programs. Based on his work, Berejikian found: a) collecting eggs from redds using hydraulic sampling can increase effective population size in small conservation programs; b) this method works best for steelhead in rain-driven systems or for summer-spawning fish; and c) natural spawning of steelhead can be increased

in the short-term and in the generation post-supplementation. Berejikian also discussed the heritability of fitness loss in steelhead and the effects of rearing steelhead to age-2 (S2) smolt. He said body size at time of release affects downstream migration (i.e., migration timing and survival) and survival in seawater. He noted that age-1 (S1) smolts experience size-selective mortality and possibly respond to selection, while S2 smolts experience no size-selective mortality or possible response to selection (i.e., low heritability); however, S2 smolts experience higher rates of residualism and precocious maturation. Therefore, not all hatcheries can or should implement S2 smolt programs. Berejikian indicated that a useful approach to improve steelhead smolting is to sort parr by size after 8 weeks post-ponding. Larger fish (greater than 60 millimeters [mm]) would receive high rations and be released as S1 smolts; smaller fish (less than 60 mm) would experience modulated growth and be released as S2 smolts. Hillman said Berejikian's presentation was extremely informative and recommended that the HCP Coordinating Committees obtain a copy. Kristi Geris said she would locate and forward a copy of the presentation to the HCP Coordinating Committees. *(Note: Geris distributed Berejikian's presentation to the HCP Coordinating Committees on October 26, 2017.)*

- *Twisp Steelhead Program*: Following Barry Berejikian's presentation, the HCP Hatchery Committees discussed implementing Berejikian's methodologies for the Twisp Steelhead Program. However, the HCP Hatchery Committees noted that hydraulic mining of eggs from redds in the Twisp River is likely not appropriate given that it is a snow-fed stream and high flows would preclude hydraulic sampling. The HCP Hatchery Committees discussed several alternatives including releasing S1 or S2 smolts, or both, and the idea of combining the Twisp and Winthrop programs, but still allowing local adaptation. The HCP Hatchery Committees also discussed the use of spawning channels, which could be a substitute to hydraulic sampling. A small group agreed to prepare a white paper on management alternatives for Twisp River steelhead, which the HCP Hatchery Committees will review during the meeting on November 15, 2017.
- *NMFS Consultation Update*: NMFS provided an update on consultation for the unlisted programs in the upper Columbia River. NMFS is requesting initiation of consultation from Chelan PUD, Grant PUD, and WDFW, which will serve as an official request to NMFS to begin consultation. Once NMFS receives the requests, NMFS will respond with a letter of sufficiency.
- *USFWS Bull Trout Consultation Update*: USFWS is working to get the Biological Opinion for the numerous Wenatchee subbasin programs signed this week. USFWS is also coordinating with NMFS on the Methow River steelhead consultation, consultation for the hatchery programs for unlisted Chinook salmon stocks in the upper Columbia River, and re-initiation of Mitchell Act consultation for the Ringold fall Chinook salmon program with USACE. USFWS

also completed consultation on maintenance of the Nason Creek Acclimation Facility intake structure.

- *Draft 2017 Hatchery M&E Plan for PUD Hatchery Programs*: The HCP Hatchery Committees are currently reviewing updated sections of the Hatchery M&E Plan for PUD Hatchery Programs. Specifically, the Committees are reviewing Section 7.2 (Non-target Taxa of Concern), Section 8 (Adaptive Management), and Appendix 1 (Estimation of Carrying Capacity). The HCP Hatchery Committees will review and hopefully approve the updated sections during the meeting on November 15, 2017. The HCP Hatchery Committees hope to finalize the plan and share it with the Independent Scientific Advisory Board before the Board completes their review.
- *Timeline of Changes in Hatchery Programs*: The HCP Hatchery Committees are preparing timelines for hatchery programs within the Wenatchee River and Methow River basins to help determine how interruptions in time series data will affect statistical analyses. The HCP Hatchery Committees are currently reviewing spring Chinook salmon timelines, and next will develop timelines for steelhead and summer Chinook salmon. This task will likely be completed by late-2017 or early 2018.
- *Next meeting*: The next meeting of the HCP Hatchery Committees will be on November 15, 2017.

IV. Douglas PUD

A. Pacific Lamprey and Salmonid Count Data during Lamprey Operations at Wells Dam (Tom Kahler)

Tom Kahler said Andrew Gingerich (Douglas PUD Aquatic Settlement Work Group [SWG] Technical Representative) is currently drafting a report which summarizes Pacific lamprey and salmonid data responses to the "lamprey operations"[1] implemented at Wells Dam in 2017 (September 1 to 30). Kahler said the report is not yet ready for distribution; however, he distributed hard copies of *Wells Dam count window data for Pacific lamprey, steelhead, and Chinook and Coho salmon* (Attachment C), which Kristi Geris distributed electronically to the HCP Coordinating Committees on October 25, 2017. Kahler recalled that the Pacific lamprey count window data previously distributed on September 26, 2017, reported Wells Dam count window data on the y-axis. He said the current version reports the proportion of total Pacific lamprey on the y-axis, which he noted, still shows similar results compared to the previous graphs. He said Pacific lamprey at the fishway entrance seemed to pass easier at the lower head differential, which he said makes sense considering the layout of the collection gallery. He noted a higher proportion of fish passing during the 0200 to 0500

[1] A temporary 1.0-foot fishway-entrance head differential from 22:00 to 04:00 daily in alternating 3-day blocks with normal operations.

hours, and low points in the data during the 0600, 0700, and 0900 hours. He also noted that coho salmon initially appear to pass more during the 1-foot head differential (as shown on page 5 of Attachment C); however, this trend may actually be due to the coho salmon run shape (as shown on page 6 of Attachment C). He said ultimately, observations are purely speculative. He said overall, Douglas PUD did not observe any alarming differences in Pacific lamprey or salmonid passage between the lamprey operations and normal operations.

John Ferguson asked what, "proportion of" means. Kahler explained that "proportion of" represents the number of fish of a species that passed Wells Dam in 1 hour divided by the total number that passed during all time periods.

Keely Murdoch recalled, based on past Pacific lamprey studies at Wells Dam, that it seemed easier for Pacific lamprey to pass the fishway at the 1-foot head differential; however, the concern was that it was harder for Pacific lamprey to locate the fish ladder at the reduced head differential. She asked if this is a correct recollection. Kahler said this is correct. He also clarified the difference between the fish ladder and the fishway. He said the fishway includes the collection gallery, while the actual fish ladder is located at the upstream end of the collection gallery. He said salmonids seem to react best to a 1.5-foot head differential; however, a 1.0-foot head differential is also acceptable in other systems. He said past radio-telemetry studies at Wells Dam indicated that fewer Pacific lamprey entered the fish ladder at a 1.0-foot head differential (i.e., less attractive entrance); however, passage times were faster at the 1.0-foot head differential for those fish that successfully entered.

Murdoch recalled the small sample sizes of past studies, and asked if the differences are statistically significant. Kahler said this question falls under the purview of the Aquatic SWG. He said the Wells HCP Coordinating Committee was tasked to monitor affects to salmonids. He added, not to dismiss the question, but he does not have the answer to this question. He said it would be ideal to run this type of analysis over the entire run to obtain a greater sample size. Kirk Truscott also noted that without active tags there is no way to know which fish actually entered the fish ladder under the 1.0- or 1.5-foot head differential, nor is there a way to evaluate statistically the efficacy of locating the collection gallery.

B. Transition Plan for Douglas PUD Hatcheries (Tom Kahler)

Tom Kahler said the draft Transition Plan for Wells and Methow Fish Hatcheries was distributed to the HCP Hatchery Committees for review on October 16, 2017. He said Douglas PUD discussed the draft plan with WDFW and is expecting to receive written comments, which Douglas PUD plans to incorporate into a revised draft plan before distributing to the HCP Coordinating Committees for review. Chad Jackson said WDFW sent written comments to Shane Bickford (Douglas PUD Natural Resources Supervisor) and Gary Ivory (Douglas PUD General Manager) on October 18, 2017. Kahler said Bickford has been out of the office, and Jackson said he will forward the comments to Kahler.

Kirk Truscott asked about a review deadline for the HCP Hatchery Committees to submit comments on the draft plan. Kahler said the review period was left open-ended; however, Douglas PUD would like to receive comments as soon as possible.

John Ferguson asked when the HCP Coordinating Committees might expect the revised draft plan to be available for review. Kahler said it depends on the nature of the WDFW comments. Jackson said the comments range from straight-forward edits to clarifications, and include some items which may require internal discussion (for example, regarding fish health and euthanasia). Kahler said Bickford will be back in the office on October 27, 2017, and they will review and discuss the WDFW comments at that time.

Kahler said Douglas PUD has hired all hatchery staff at every level. He said some staff have already started, most start November 6, 2017, and the last will start by November 16, 2017.

Ferguson asked if WDFW has assigned a point of contact for the transition. Jackson said he and Eric Kinne (WDFW; Hatcheries Division Manager) have been appointed as contacts.

Truscott asked if Douglas PUD is developing an updated Operations Plan, including a production plan, with the hatchery modernization. Kahler said yes, Ken Ferjancic at HDR Engineering, Inc., is working on an Operations Plan. Kahler said he is unsure of the current status of the plan. He said some production will remain the same and other parts will be new. He said Greg Mackey (Douglas PUD HCP Hatchery Committees Representative) is the contact person to answer questions about production.

Jackson also noted that there is a draft MOU between WDFW and Douglas PUD which outlines a comingled workforce through the end of November 2017. Jackson said WDFW already provided comments on the draft MOU, including requesting a section on contingencies in case certain tasks are not complete by the November 2017 deadline. Truscott asked if details about process are included in the MOU, and Mike Tonseth (WDFW) said there should be.

Kahler said Douglas PUD will: 1) incorporate comments received on the Transition Plan for Wells and Methow Fish Hatcheries, and provide the updated plan to Kristi Geris for distribution to the HCP Coordinating Committees; 2) either incorporate sections of the MOU into the transition plan or distribute the MOU to the HCP Coordinating Committees; and 3) check on the status of the Operations Plan. *(Note: Sections of the MOU were incorporated into the final transition plan, and Kahler provided the final plan to Geris on November 7, 2017, which Geris distributed to the HCP Coordinating Committees that same day.)*

Kahler said the Operations Plan is somewhat of a living document as Douglas PUD continues to learn how to use the modernized facilities most optimally (e.g., optimized water usage, computer programming). Kahler also noted that manufacturer technical representatives, and Douglas PUD technicians, mechanics, Natural Resources and hatchery staff witnessed the commissioning of the new equipment, which was also video recorded so there will be video tutorials available for new staff.

C. Draft 2017 Wells Dam Passage Dates Analysis (Tom Kahler)

Tom Kahler said a *Draft 2017 Wells Dam Passage Dates Analysis* was distributed to the HCP Coordinating Committees by Sarah Montgomery on October 20, 2017, and a corrected analysis (Attachment D) was distributed to the HCP Coordinating Committees by Kristi Geris on October 23, 2017.

Kahler said the Wells HCP includes a requirement to provide bypass passage for greater than or equal to 95% of the migrations of both spring- and summer-migrating Plan Species at Wells Dam. He said when the spring spill season ends at 24:00, the summer spill season begins immediately after at 00:00. He said bypass dates at Wells Dam were established based on 20 years of fyke net and acoustic studies. He said initially, based on arrival dates, the bypass was operated from April 12 to August 26. He said the Wells HCP also includes a requirement to reevaluate bypass dates every 10 years. He said, because there was no desire to revisit fyke netting, and PIT detection was available at the RRJFBS, passage times at Rocky Reach Dam and travel times between Rocky Reach and Wells dams were used to back-calculate probable passage times at Wells Dam. He clarified that this methodology (PIT-tag passage dates) is used for all species except sockeye salmon. He said sockeye salmon passage dates are determined based on sampling at the RRJFBS, because there are not many PIT-tagged fish in the system. He said the Data Access in Real Time program is then used to calculate what percentage of fish migrate through the project during various time periods (as described in Table 2 of Attachment D). He said in 2012, bypass operation dates were modified to run from April 9 to August 19, to provide better coverage for the spring run.

Kahler said in 2017, Wells Dam bypass operations provided passage for: 99.85% for yearling Chinook salmon; 100% for steelhead; 99.99% for sockeye salmon; 100% for coho salmon; and 99.59% for subyearling Chinook salmon.

Scott Carlon noted the assumed 2-day travel time for subyearling Chinook salmon, and asked if PIT-tag data were used to confirm this. Kahler said there are no actual measured travel times for subyearlings, because they tend to pass Wells Dam on river-left and PIT detection at the dam is on river-right. Kirk Truscott asked how upstream hatchery release dates relate to subyearling passage dates at Rocky Reach Dam. Kahler said they vary from 2 to greater than 70 days. He added that it is unclear when subyearlings leave the Wells reservoir. He said there needs to be more PIT-tag detections at Wells Dam Bypass Bay 2 (PIT-Tag Information System code: WEJ) and subsequent detections at Rocky Reach Dam.

Keely Murdoch asked, regarding spring Chinook salmon, if there has ever been an attempt to parse out wild versus hatchery, or is the sample size for the wild run too small? Kahler said this year, the wild run past Wells Dam was about 230-something; so very small. Murdoch said data were presented at the 2017 Salmon Recovery Conference indicating that wild fish migrate earlier than hatchery fish for spring Chinook salmon. She asked, among the few fish which migrate before the passage period, what proportion of the wild run does this really represent? She said if the entire run is dominated by hatchery fish, the estimated migration proportions may not be accurate for the wild portion.

Truscott said this has been a reoccurring subject raised in the HCP Coordinating Committees. He said it is an interesting subject; however, the HCPs do not distinguish proportional protection between natural versus hatchery fish. He said the HCPs only require providing spill for yearling Chinook salmon, including hatchery, wild, spring, and summer. He said if something undesirable is observed, the task is to determine what can be done to improve the metric.

Kahler said the introduction of the Wells HCP states, "This Agreement is intended to constitute a comprehensive and long-term adaptive management plan for Plan Species and their habitat as affected by the Project." Kahler said obviously, negotiation of the HCPs preceded a lot of information that is now known. He said the HCPs were written with a different mindset of what recovery looks like. He said Douglas PUD considers the Wells HCP as a recovery plan. He said Douglas PUD attempts to accomplish what is possible, in coordination with the Wells HCP Coordinating Committee, and with what data are available. He said for 2017, when only wild yearling data were considered, the proportion of passage covered was only 92.96%. He said to achieve 95%, bypass operations were 3 days late. He noted to keep in mind, these data are based on Rocky Reach Dam detections which start April 1, and there are no data available indicating what passage looked like before April 1.

Truscott said this is when data obtained from the tributary arrays and screw traps could be useful. Kahler noted, when the lower Methow River PIT-tag array is functional it can be useful; however, he said this array is best for adults. He added that WDFW is proposing to replace this array with one in a better location to improve reliability. Mike Tonseth said the array has already been replaced and was moved from river mile 1.2 to 5. Kahler said this new location should greatly improve detections, and Tonseth said this location also has better protection from river ice.

Truscott noted that in years with early spring freshets, detection of a large proportion of migrating fish may still be missed. John Ferguson asked if the HCP Coordinating Committees need to have a discussion about climate change possibly causing earlier freshets. Ferguson also asked if Douglas PUD should ask Richard Townsend to incorporate the new detection site into next year's analysis.

Kahler said if there is interest, wild counts for yearlings and subyearlings can be incorporated into the analysis. He said Douglas PUD is also open to discussing a new bypass operations start date; however, this discussion needs to happen before February 28, 2018, when the Aquatic SWG submits the Wells Dam Bypass Operations Plan to the Washington State Department of Ecology.

Truscott said he believes adding wild counts to the analysis would be useful. He also asked what additional information is available to justify an alternative bypass operation start date at Rocky Reach Dam.

Jim Craig said he can look into available screw trap data in the Entiat River to help inform this question. Kahler suggested also looking into Methow and Wenatchee rivers-specific data on entry to the Columbia River. *(Note: Craig provided yearling Chinook salmon emigration timing data at rotary screw traps in the Methow, Entiat, and Wenatchee rivers, which support the need for earlier bypass operation start dates, to Geris on October 26, 2017, which Geris distributed to the HCP Coordinating Committees that same day.)*

Kahler noted that when the Wells HCP Coordinating Committee approved the most recent bypass operations dates (April 9 to August 19), the approval included contingency language stating that the "current timing of bypass operations will continue annually, unless modified as a result of future investigations that demonstrate an inadequacy of these dates at providing bypass passage for greater than or equal to 95% of the migrations of both spring- and summer-migrating Plan Species at Wells Dam." Kahler said this means the Wells HCP Coordinating Committee has the capacity to change the bypass operations dates at any time within the 10-year review interval specified in the HCP, if data support it.

Truscott said he believes what is needed is a hard discussion on how and when monitoring is operated. He asked if there is real interest in operating the Rocky Reach Dam bypass earlier than April 1; and if so, what is involved in making this decision?

Lance Keller said the Rocky Reach Dam bypass is a complicated system and it is not as simple as just turning it on, as off-season maintenance of the entire bypass system begins September 1 and continues until the following mid-March, which allows enough time to test the system prior to the April 1 startup date. Keller said internal stakeholder engagement is also an issue, because a staffing increase is needed to operate the bypass as well as monitor fish condition. Truscott noted that the Rocky Reach HCP Coordinating Committee has approved operating the bypass longer in the season; therefore, it seems a Rocky Reach HCP Coordinating Committee representative could propose to operate the bypass earlier. Keller added that in 2014, the bypass was operated outside of the usual April 1 to August 31 timeframe in order to verify operations covered 95% of the outmigration for Plan Species, per the Rocky Reach HCP. He recalled that operations were extended to September 15, because the Rocky Reach HCP Coordinating Committee expressed concerned that the subyearling Chinook salmon run timing lasted beyond August 31.

Ferguson noted Table 4 in Attachment D, where the last column ("Bypass ended this many days after the 95% standard was achieved") includes some years where days are in the double-digits. Ferguson suggested these data may indicate the possibility of shutting down the bypass earlier in the season.

Kahler said historic fyke net data for Wells Dam show subyearlings moving in the first two weeks in July, peaking in late-July into early August, and dropping off in the third week of August. He said he would not want to shut down the bypass much earlier than August 19 to be sure to catch the peak of the subyearling migration.

Kahler said Douglas PUD, in coordination with Townsend, will incorporate wild yearling Chinook salmon passage data for 2017 into the corrected Draft 2017 Wells Dam Passage Dates Analysis that was distributed to the HCP Coordinating Committees by Geris on October 23, 2017. Kahler said this version is also currently available for a 30-day review period, with edits and comments due to Kahler by November 22, 2017. Kahler said Douglas PUD, in coordination with Townsend, will also include wild yearling Chinook salmon passage data for all years of analyses, in an addendum to the Draft 2017 Passage Dates Analysis.

Kahler said another metric to flesh out is travel time for subyearlings. He discussed using passage times for Chinook salmon released as subyearlings from Chief Joseph Hatchery and dividing the time by half; however, he noted that sometimes subyearlings do not migrate immediately, so simply dividing passage times by half may not be accurate. He concluded that more reasonable data are needed to get at this question.

Kahler said if the HCP Coordinating Committees want to formally address potential earlier bypass operation dates in 2018 for Wells Dam, a decision is needed by the HCP Coordinating Committees meeting in January 2018 (considering the Aquatic SWG's deadline to Washington State Department of Ecology on February 28, 2018). Keller said for Rocky Reach Dam, he would need to take a request back to Chelan PUD to discuss internally, but implementing a change to the start date in 2018 would be difficult.

D. Choice of Study Species for 2020 Survival Verification Study (Tom Kahler)

Tom Kahler recalled that non-listed (Endangered Species Act), Wells Hatchery stock, yearling summer Chinook salmon were used for the Douglas PUD 2010 Survival Verification Study. He said spring Chinook salmon were not chosen because they are Endangered Species Act-listed, and based on discussions with Bob Rose, Tom Scribner (YN), and Cory Kamphaus (YN), there was no interest in using coho salmon. Kahler said the 2010 release locations included: 1) at the mouth of the

Methow River; 2) in the Wells Dam tailrace; and 3) per a request from the CCT in regard to Section 4.2.1 of the Wells HCP, at the mouth of the Okanogan River. Kahler said study fish were PIT-tagged. He said half of the study fish were released in the Wells Dam tailrace, and the other half were released at each river mouth proportional to the historic natural and hatchery production originating from that river (it was previously determined that release numbers would be fewer to the Okanogan River mouth compared to the Methow River mouth). Kahler said it is now time to begin thinking about which species to use for the 2020 Survival Verification Study.

Keely Murdoch said if the YN can collect extra coho salmon for this study and find a place to raise them, this may be the best option. Kahler noted that there are no coho salmon in the Okanogan River. He said if this species is chosen there will only be a Methow River release, and he asked if the CCT want an Okanogan River component. He also noted that roughly 75,000 PIT-tags are needed to get sufficient detections at Rocky Reach Dam to meet precision targets and a sufficient number of returning adults to meet the delayed mortality requirement of Wells HCP, Section 4.1.4.

Kirk Truscott asked if Douglas PUD would consider using acoustic tags. Kahler said, although the Wells HCP does not necessarily stipulate a PIT-tag study, Section 4.1.4 of the Wells HCP requires testing for "direct, indirect, and delayed mortality as it relates to the Project." Kahler said the only way to evaluate this is with PIT-tags. He said because of low smolt-to-adult return ratios (SARs), delayed mortality cannot be evaluated using acoustic tags.

Truscott said there are acoustic receivers in the Wells pool up to Chief Joseph Dam, and acoustic receivers in the Wells Dam tailrace for white sturgeon M&E. He asked what opportunity is there to use acoustic tags on a smaller number of fish, for example, spring Chinook salmon yearlings.

Lance Keller said in 2004, Chelan PUD conducted a PIT- versus acoustic-tag comparative study, and for the Rock Island Dam project there was no difference based on a side-by-side analysis.

Truscott asked what a 75,000-sample size is based on. Kahler said this is what is needed to achieve precision standards. Truscott asked if there is a SARs standard in the Wells HCP. Kahler said the idea behind SARs is, are there enough adults returning to generate a valid adult survival standard to differentiate a Project effect? He said a bad year for SARs would create issues. Truscott asked what would happen if PIT-tags were used and poor SARs were encountered? He added that if spring Chinook salmon are not being considered because of the 75,000 PIT-tags needed, he said only needing 2,700 acoustic tags may change minds. Kahler noted that Douglas PUD did use spring Chinook salmon one year and had 99.7% survival from the mouth of the Methow River.

John Ferguson asked when Douglas PUD needs a decision, and Kahler said in time to be included in the 2018 Broodstock Collection Protocols. Kahler said Douglas PUD will be collecting broodstock for the 2020 study next summer (2018). Mike Tonseth said the first draft of the protocols will be distributed in early February 2018; therefore, a decision will be needed no later than the HCP Coordinating Committees meeting in January 2018.

Kahler said Douglas PUD will provide a proposal on which study species to use for the Douglas PUD 2020 Survival Verification Study for the Wells HCP Coordinating Committee to consider, and will convene a conference call for discussion, if necessary.

V. Chelan PUD

A. DECISION: 2017 Rock Island and Rocky Reach Fish Spill Program Report (Lance Keller)

Lance Keller said Sarah Montgomery sent an email to the HCP Coordinating Committees on September 15, 2017, notifying them the Draft 2017 Rock Island and Rocky Reach Fish Spill Program Report was available for review. Edits and comments on the report were due to Keller by Monday, October 16, 2017.

Kirk Truscott said he was unable to review the report; therefore, the CCT abstains from voting.

Rock Island and Rocky Reach HCP Coordinating Committees members present approved the 2017 Rock Island and Rocky Reach Fish Spill Program Report, with the CCT abstaining.

Keller said Chelan PUD will provide the Final 2017 Rock Island and Rocky Reach Fish Spill Program Report to Kristi Geris for distribution to the HCP Coordinating Committees.

B. Rocky Reach Dam Large Unit Repair Update (Lance Keller)

Lance Keller recalled providing a Rocky Reach Dam large unit repair update during the HCP Coordinating Committees meeting on June 27, 2017, at which time he also provided an updated timeline for completion of repairs. Keller recalled the shift in deadlines was due to issues with the bridge crane, which moves the length of the powerhouse and is used to hoist the turbines and components for repairs. He said cracks were identified in the wheels of the bridge crane, which is currently being repaired. He said the large unit repairs are still on the same schedule described in June 2017, as follows:

Schedule for Rocky Reach Dam Large Unit Repair, 2017

Turbine Unit	Return to Service
C8	Fourth Quarter 2017
C9	First Quarter 2019
C10	First Quarter 2020
C11	First Quarter 2021

Keller noted that the repair schedule is set to be complete in time for Chelan PUD to conduct the HCP 10-year check-in survival study for Rocky Reach Dam. He said if necessary, Chelan PUD determined that turbine unit C11 is the preferred unit to be offline during a survival study. He explained that given C11 is the northern-most unit, being offline will not cause a shift in flow nor provide a calm, central area for predators to stage in the immediate tailrace.

John Ferguson asked when discussions need to begin within the HCP Coordinating Committees for the Rocky Reach Dam 2021 check-in study. Keller said he envisions these discussions to begin in 2018. He said the Rocky Reach Project has less lead time compared to the Wells Project, because Chelan PUD uses the RRJFBS to determine the run-of-the-river dominant species.

C. Rock Island Dam Powerhouse 2 Rehabilitation (Lance Keller)

Lance Keller said the Chelan PUD Board of Commissioners is now being engaged in planning for the rehabilitation of Powerhouse 2 at Rock Island Dam. Keller said an economic analysis of Powerhouse 2, which was built in the 1970s, recommended a rehabilitation, versus a full overhaul, to extend the lifespan of the system by an additional 40 years. Keller explained the rehabilitation timeline and other key dates, as follows:

Schedule for Rock Island Dam Powerhouse 2 Rehabilitation

Activity	Date
10-year check-in	2020
Begin rehabilitation	Third Quarter 2021
Complete rehabilitation	First Quarter 2029
10-year check-in	2030

Keller noted the window of time between the next 10-year check-in at Rock Island Dam and the beginning of the rehabilitation. He said this timing was proposed in case the need for additional studies arise during the 10-year check-in. He also noted that the completion date includes all 8 units.

Keller said in-depth analyses will be regularly conducted throughout the duration of the rehabilitation. He said parts will be refurbished and sandblasted to ensure they are structurally sound. He said machine tolerances will be returned to their original specifications. He said the runners will stay the same, and there will be no changes to the name plate discharge or horsepower.

Kirk Truscott and Chad Jackson asked if the rehabilitation might affect relicensing in 2028. Keller said, in general, he does not believe the rehabilitation should impact the relicensing process; however, Chelan PUD's relicensing group has been engaged in this discussion.

D. Rocky Reach Dam Fish Ladder, Request for Early Winter Maintenance Outage (Lance Keller)

Lance Keller said on October 20, 2017, the Rocky Reach Dam maintenance crew notified him of potential time constraints to complete the amount of work and unique projects planned for the 2017/2018 winter maintenance work period at Rocky Reach Dam. Keller said Chelan PUD is requesting Rocky Reach HCP Coordinating Committee agreement to begin the 2017/2018 winter maintenance work period at Rocky Reach Dam, 3 weeks earlier than usual to allow more time to complete required work. Rather than beginning work during the first week in January (per usual), maintenance work would begin on December 11, 2017.

Keller reviewed key projects driving this request, as follows:

- **Butterfly valve actuator** – a preventative maintenance inspection is due (conducted every 3 years)
- **Middle spillway entrance gate** – an in-depth inspection is due
- **Middle spillway entrance fish fence** – once installed, this fence will be deployed in the area adjacent to a dewatered middle spillway to prevent fish from retreating into the middle spillway, which will assist with fish rescue activities
- **Attraction water pump C** – the intermediate bearing needs an inspection
- **Traveling water screen** (screens the intake water that turns the attraction water pumps) – the pinch bolts on the south screen need an inspection
- **Picket barrier screens** – reduce spacing (Chelan PUD plans to reduce the 1-inch spacing to 3/4-inch for Pacific lamprey)
- **Attraction water pump intake** – slight modification needed
- **30-inch raw water valve** (located behind the auxiliary water system, which needs to be offline and dewatered to repair the water valve) – needs repair by a contractor (one of which did not seem confident the work can be completed within the normal outage)

Keller said while he discussed these projects with the maintenance crew, he did not identify anything too much out of the ordinary; however, staff is limited and one issue can cause a needed inspection or repair to fall off this list.

Keller said in 2014, the count system at Rocky Reach Dam was operated through the end of the year to monitor for any possible passage effects, primarily due to a concern over steelhead. He said in 2014, the total steelhead run past Rocky Reach Dam was 1,894 fish. He said from December 11, 2014, to December 31, 2014, there were 7 wild steelhead, 10 adipose-clipped steelhead, and 4 adult bull trout observed passing the Rocky Reach Dam count window. He said based on this year's counts to date, he expects these numbers to be even lower in 2017.

John Ferguson asked when Chelan PUD needs a response to this request. Keller said the request is slightly time-sensitive because of the 30-inch raw water valve out for bid. He said increasing the winter outage window will increase the number of contractors willing to bid on the project.

Chad Jackson requested that Chelan PUD provide a written list of the repairs and the 2014 passage data reviewed, and a vote via email. Ferguson suggested a voting deadline of Friday, November 3, 2017. Keller agreed to this deadline and said he will provide the requested information by the end of the day. *(Note: Keller provided the list of repairs and 2014 passage data to Kristi Geris following the meeting on October 24, 2017, which Geris distributed to the HCP Coordinating Committees on October 25, 2017.)*

Kirk Truscott asked what will happen if the extension is not approved. Keller said Chelan PUD will need to prioritize the maintenance and complete as much as time allows. Truscott noted that there are criteria established for fish ladders to be offline for a reason, but there is a regular request for deviating from these criteria. He asked if this request is because, even with double-staffing the work still cannot be completed, or is it just to save money? Keller said Chelan PUD determined how many labor hours are required to complete these repairs, and there is a deficit to complete the needed repairs. He said Chelan PUD does not have the workforce to complete the needed work. He added that the 30-inch raw water valve requiring a contractor also needs additional time. He said if the early outage is not approved, there is a good chance Chelan PUD will be asking for an extension at the backend of the maintenance period because the fish ladder cannot be brought back online until the 30-inch raw water line work is completed.

Keller recalled Chelan PUD's request last year for an extension of the winter maintenance outage at Rocky Reach Dam; however, maintenance crews were unable to complete everything and the fish ladder was back online on February 14, 2017. Ferguson asked if last year's unfinished work is on this year's list. Keller said no, that work can wait another year.

Keller said he will discuss Truscott's comments internally with Chelan PUD.

The Rocky Reach HCP Coordinating Committee agreed via email to Chelan PUD's request to begin the 2017/2018 winter maintenance work period at Rocky Reach Dam, 3 weeks earlier than usual to allow more time to complete required work. Rather than beginning work during the first week in January (per usual), maintenance work will begin on December 11, 2017. Approvals were as follows: Chelan PUD, NMFS, WDFW, and the CCT approved November 1, 2017, and USFWS and the YN approved November 2, 2017.

VI. HCP Administration

A. WDFW HCP Hatchery Committees Representation Designation Update (John Ferguson)

Chad Jackson has been added to the HCP Hatchery Committees email distribution list and has been given access to the HCP Hatchery Committees Extranet site, per a request from Mike Tonseth (WDFW HCP Hatchery Committees Representative). Jackson has replaced Jeff Korth (WDFW, retired) as the WDFW HCP Hatchery Committees Alternate. *(Note: recall, HCP Coordinating Committees approval is not needed to add HCP representatives and alternates to the email lists and extranet sites; however, granting this type of access typically occurs after an official designation letter is received from the Party.)*

Jackson will provide an official WDFW HCP Hatchery Committees Representation Designation Letter to Kristi Geris for the administrative record. *(Note: Jackson provided this letter to Geris on November 6, 2017, which Geris distributed to the HCP Coordinating Committees and to Sarah Montgomery for distribution to the HCP Hatchery Committees that same day.)*

B. Next Meetings

The HCP Coordinating Committees noted that the USACE's 2017 AFEP Annual Review is scheduled for November 28 to 29, 2017, in Richland, Washington, which conflicts with the HCP Coordinating Committees meeting on November 28, 2017. HCP Coordinating Committees members present agreed to cancel the HCP Coordinating Committees meeting on November 28, 2017, due to lack of agenda items and a scheduling conflict with the 2017 AFEP Annual Review.

John Ferguson said the next scheduled HCP Coordinating Committees meeting is on December 26, 2017, 1 day after the Christmas holiday. Kristi Geris said she will coordinate with Denny Rohr and the PRCC regarding rescheduling the HCP Coordinating Committees meeting in December 2017. *(Note: Geris coordinated with Rohr, who indicated the PRCC plans to meet on December 13, 2017; therefore, the HCP Coordinating Committees meeting on December 26, 2017, has been rescheduled to December 12, 2017, to accommodate the Christmas holiday and best coordinate with the PRCC.)*

The next scheduled HCP Coordinating Committees meeting is on December 12, 2017, to be held by conference call or in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington, pending agenda items.

The January 23 and February 27, 2018 meetings will be held by conference call or in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington, as is yet to be determined.

Outline

- Epigenetics Basics
  - Definitions
  - DNA methylation
    - Functions
    - Environment
    - Epigenetic inheritance
- Why is epigenetics relevant to hatchery practices?
  - DNA methylation data from Methow River steelhead

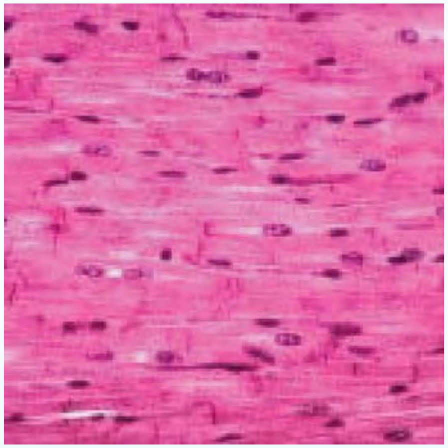
Epigenetics

- Heritable changes in trait or phenotype, caused by a mechanism other than mutation to the DNA sequence

Epigenetics

- Heritable changes in trait or phenotype, caused by a mechanism other than mutation to the DNA sequence

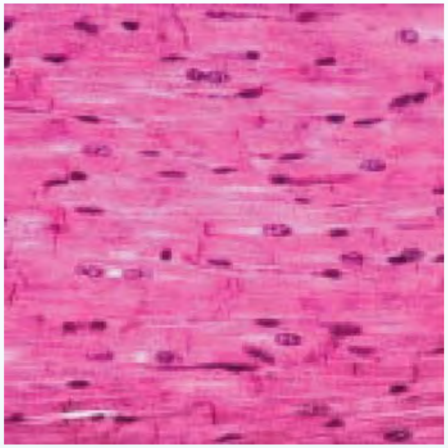
All of these cell types contain the same DNA.. so why do they look so different?



Epigenetics

- Heritable changes in trait or phenotype, caused by a mechanism other than mutation to the DNA sequence

All of these cell types contain the same DNA.. so why do they look so different?



If DNA is the ‘hardware’, the epigenome is the ‘software’. It provides the instructions to regulate the genome

Epigenetic Marks

- Histone modifications
  - Acetylation
  - Methylation
- DNA methylation
- Non-coding RNAs
  - micro RNA (miRNA)

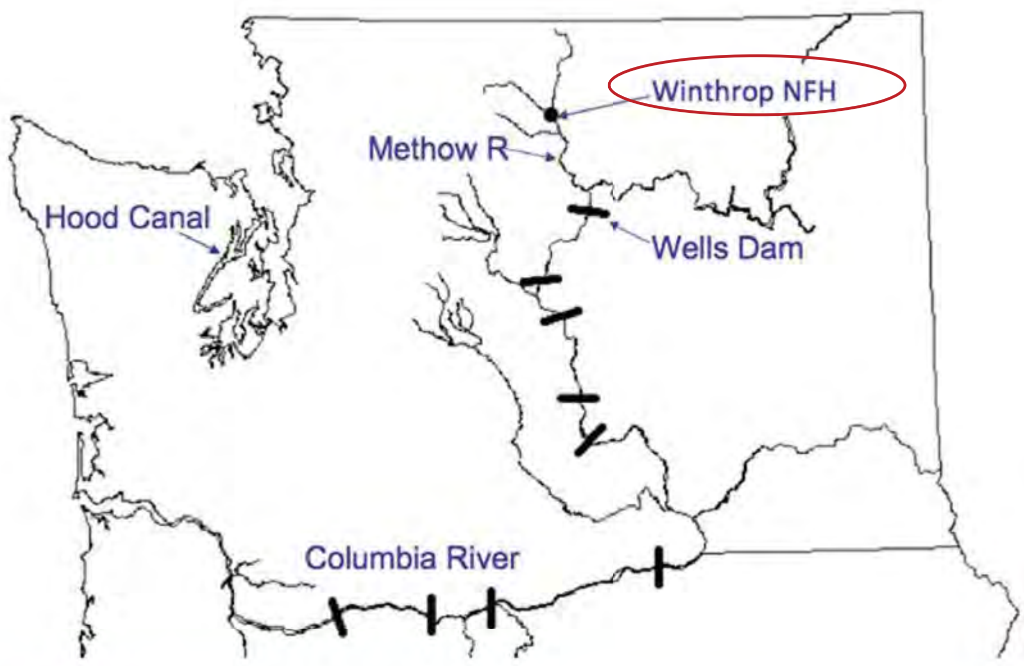
Steelhead & Epigenetics

Are there discernible epigenetic differences between hatchery and wild origin steelhead?

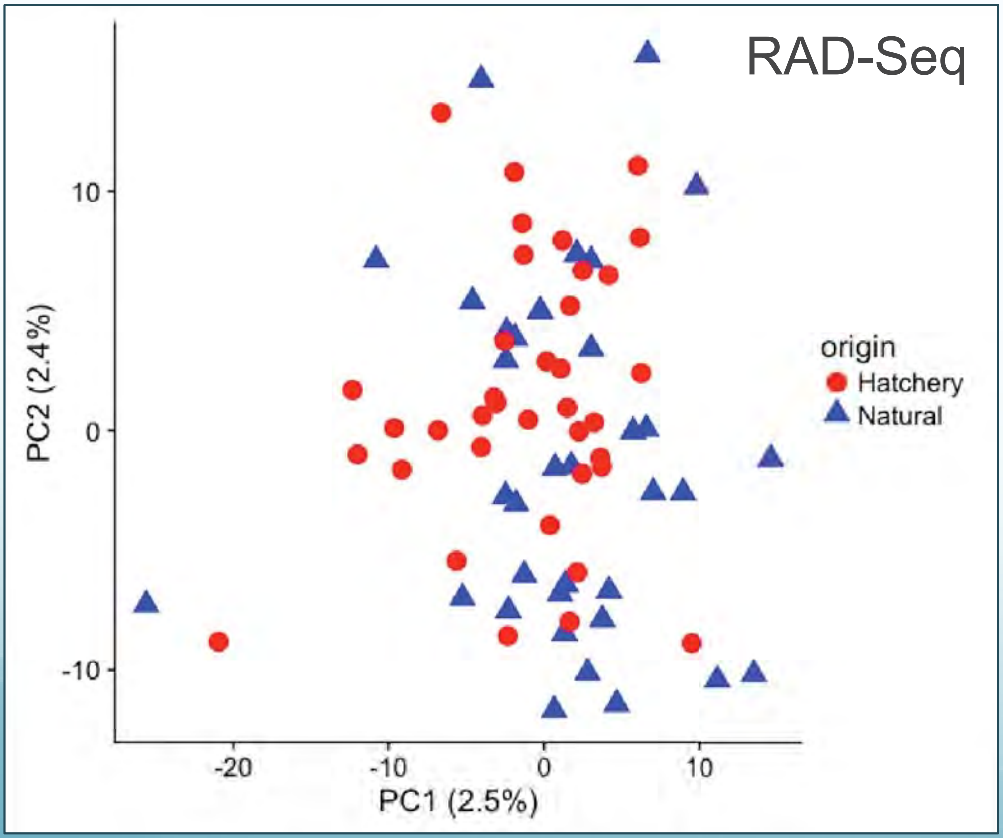


Steelhead & Epigenetics

- Returning adult fish were collected in 2014
- Identified as hatchery or natural origin
- Collected sperm and blood

Steelhead & Epigenetics

- Returning adult fish were collected in 2014
- Identified as hatchery or natural origin
- Collected sperm and blood



Approach

- DNA methylation analysis
  - Red Blood Cells (RBC)
  - Sperm

Results: RRBS

- Measured over 112,000 100bp regions in the genome
- Steelhead have a heavily methylated genome
  - 86% of CG are methylated in RBC
  - 94% of CG are methylated in Sperm

Attachment B

Cell-type Specific Methylation

Cell-type Specific Methylation

- How are epigenetic variation and genetic variation interrelated?

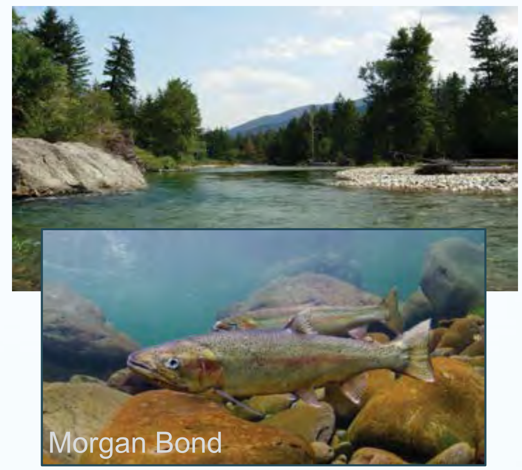
Summary

There are differences in DNA methylation between natural and hatchery origin steelhead

- How do these DNA methylation changes affect gene expression and ultimately phenotype?
- Which environmental parameters are influencing DNA methylation?
- How are epigenetic variation and genetic variation interrelated?
- Are environmentally-induced epigenetic changes transgenerationally inherited?

Concluding Remarks

- Epigenetics can help organisms *retain* (*and potentially pass on*) information about their environment.



- Epigenetics is an emerging tool to help understand how the environment affects phenotype in hatchery-reared fish, which could aid in minimizing heritable fitness loss in these populations.

23 October 2017

Introduction

This analysis summarizes the outmigration that has been monitored at the juvenile sampling facility at Rocky Reach Dam or detected at the Rocky Reach Bypass PIT-tag detector for five stocks of salmonids (Coho salmon, yearling and subyearling Chinook salmon, steelhead, and sockeye salmon) for the period 2006-2017. The proportions of each stock covered by the bypass operations at Wells Dam can be estimated using daily counts at Rocky Reach Dam, adjusting for the travel time from Wells to Rocky Reach dams. Table 1 has the average travel times based on Douglas PUD's 2010 PIT-tag study for yearling Chinook salmon, and acoustic-tag studies for steelhead and sockeye salmon. Due to a dearth of PIT-tag or acoustic-tag studies performed with subyearling Chinook, travel time was assumed to be 2 days. Coho travel time was assumed to match that of yearling Chinook, and preliminary PIT-tag data appears to validate this assumption (Appendix, Table A1).

Table 1: Average travel times from Wells tailrace to Rocky Reach Dam, based on study results or assumptions of similarity to surrogate species.

Stock	Travel time
Yearling Chinook salmon	5 days
Subyearling Chinook salmon	2 days
Steelhead	2 days
Sockeye salmon	2 days
Coho salmon	5 days

Plots of the annual cumulative proportion of the outmigration for spring migrants (yearling Chinook, steelhead, sockeye, and coho), and subyearling Chinook in the summer had fairly consistent start and end dates at Rocky Reach (Figure 1). The timing of bypass operations for the spring outmigration at Wells from 2004 through 2011 was from 00:00 April 12th through 24:00 June 13th of each year for the "spring" spill season, and from 00:00 June 14th through 24:00 August 26th for the "summer" spill season. For 2012 and beyond, the Wells Habitat Conservation Plan (HCP) Coordinating Committee approved the modification of the timing of bypass operations at Wells Dam as follows: bypass operations commenced at 00:00 on April 9th and continued through 24:00 on August 19th. This current timing of bypass operations will continue annually, unless modified as a result of future investigations that demonstrate an inadequacy of these dates at providing bypass passage for ≥95% of the migrations of both spring- and summer-migrating Plan Species at Wells Dam.

Results

The proportions of passage during the Wells bypass operations in 2017 were 99.85% for yearling Chinook salmon, 100% for steelhead, 99.99% for sockeye salmon, 100% for coho salmon, and 99.59% for subyearling Chinook salmon. The 2017 results for all monitored species were all consistent with historical trends, 2006–2017 (Table 2).

To assess the effectiveness of the selected start date for bypass operations, Table 3 compares the start date for bypass operations each year with the date on which the 5th percentile of the cumulative yearling Chinook salmon outmigration passed Wells Dam that year. For yearling Chinook salmon in 2017, the start date for bypass operations was 8 days earlier than necessary to achieve the HCP standard of providing bypass passage for ≥95% of the migration.

Similarly, Table 4 compares the actual termination date for bypass operations with the date on which bypass operations covered 95% of the subyearling Chinook salmon outmigration. In each year, an earlier termination of bypass operations would have been possible without jeopardizing the achievement of the HCP standard of providing a bypass route for ≥95% of outmigrating subyearling Chinook salmon. For subyearling Chinook salmon in 2017, the termination of bypass operations at midnight on August 19 was 13 days later than required to achieve the HCP standard of providing bypass passage for ≥95% of the migration.

Table 2. Total proportion of each stock's migration affected by bypass operations (spring, summer) at Wells Dam, based on travel times from Wells Dam to Rocky Reach Dam, the cumulative proportion of the annual migration of each stock at Rocky Reach, and the start and stop dates of Wells bypass operations, 2006-2017.

Table 3. A comparison of the actual start date for bypass operations at Wells Dam for the last ten years versus the date on which the 5th percentile of the yearling Chinook salmon migration passed Wells Dam that year, 2008-2017. Operations begin at 00:01 for the date listed in column 2. "Proportion bypass ops would have covered" indicates the proportion of the migration that would have been provided a bypass passage route had bypass operations started at 00:01 on the date that the 5th percentile of the migration passed Wells Dam (column 5). "Bypass start date timing" (column 8) indicates whether the bypass start date was earlier or later than the date on which the 5th percentile of the yearling Chinook migration passed Wells Dam, and by how many days.

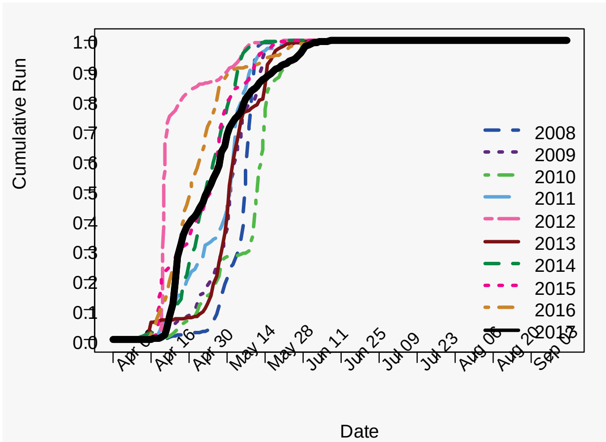
Migration Year	Actual bypass start date	Cumulative proportion passed before 00:01	Proportion Covered by Bypass Ops	Date on which the 5th percentile passed	Cumulative proportion passed before 00:01	Proportion bypass ops would have covered	Bypass start date timing
2008	April 12	0.0025	0.9975	May 3	0.0406	0.9594	21 days early
2009	April 12	0.0116	0.9884	April 19	0.0436	0.9564	7 days early
2010	April 12	0.0067	0.9933	April 22	0.0410	0.9590	10 days early
2011	April 12	0.0085	0.9915	April 15	0.0446	0.9554	3 days early
2012	April 9	0.0004	0.9996	April 15	0.0115	0.9885	6 days early
2013	April 9	0.0171	0.9829	April 10	0.0240	0.9760	1 day early
2014	April 9	0.0169	0.9831	April 16	0.0386	0.9614	7 days early
2015	April 9	0.0012	0.9988	April 13	0.0210	0.9790	4 days early
2016	April 9	0.0028	0.9972	April 12	0.0380	0.9620	3 days early
2017	April 9	0.0015	0.9985	April 17	0.0428	0.9572	8 days early

Table 4. A comparison of the actual stop date for bypass operations at Wells Dam for the last ten years, versus the stop date necessary to have covered at least 95% of the subyearling Chinook salmon outmigration that year. Operations are assumed to end at 24:00 for the date listed.

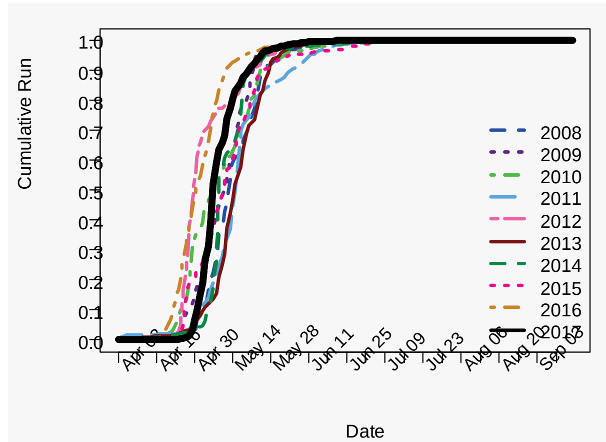
Migration Year	Actual bypass stop date	Cumulative proportion passed by 24:00 of actual stop date	Date on which the 95% standard was achieved	Cumulative proportion passed by 24:00 of the date on which the 95% standard was achieved	Bypass ended this many days after the 95% standard was achieved
2008	August 26	0.9887	August 19	0.9502	7
2009	August 26	0.9911	August 22	0.9709	4
2010	August 26	0.9936	August 10	0.9537	16
2011	August 26	0.9959	July 25	0.9528	32
2012	August 19	0.9930	July 29	0.9502	22
2013	August 19	0.9933	August 7	0.9592	12
2014	August 19	0.9696	August 15	0.9524	4
2015	August 19	0.9997	July 19	0.9559	31
2016	August 19	0.9984	July 28	0.9554	22
2017	August 19	0.9959	August 6	0.9533	13

Figure 1. Passage dates at Rocky Reach Dam for spring and summer migrating stocks, 2008-2017. Cumulative proportions are based on the expanded counts obtained from sampling daily from 1 April – 31 August (or through 4 September in 2008 and 15 September in 2014).

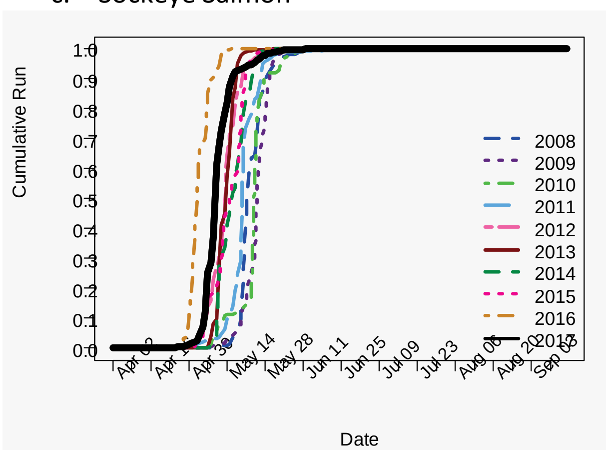
a. Yearling Chinook Salmon



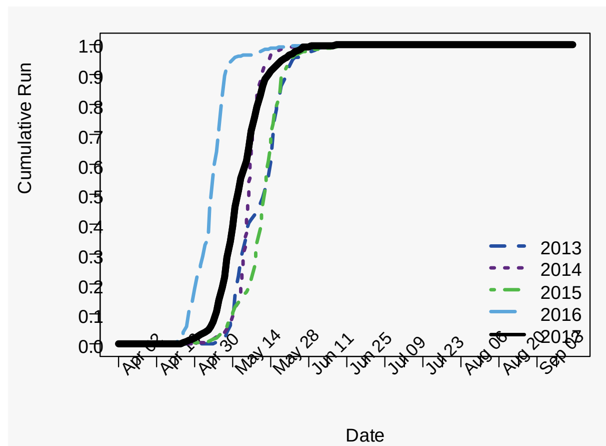
b. Steelhead



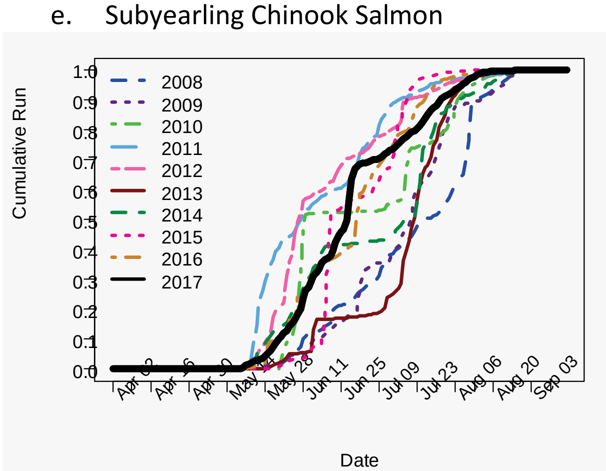
c. Sockeye Salmon



d. Coho Salmon



e. Subyearling Chinook Salmon



Appendix

This is the second year of the availability of PIT-tag detections at Wells Dam (WEJ), with 269 unique tag codes identified. These comprised 114 Chinook Salmon, 27 Coho Salmon, 127 Steelhead, and 1 Sockeye Salmon. As these numbers are too few to estimate any credible survival estimates, Table A1 summarizes the number of detections and estimated travel times between Wells and Rocky Reach Dam. It is hoped that future runs will be detected at higher numbers to enable a more detailed correction to the outmigration distribution estimated for Wells Dam.

Table A1. Travel Time summary for detected PIT-tagged fish at both Wells and Rocky Reach PIT-tag detectors in 2017.

			Travel Time (days)	
Run Species	Detected at Wells Dam	Detected at Rocky Reach Dam	Mean (SE)	Range
Yearling Chinook	114	21	6.7 (1.8)	1.3 – 29.0
Coho	27	11	5.4 (0.8)	2.2 - 10.0
Steelhead	127	41	1.9 (0.2)	0.8 - 6.6
Sockeye	1	0

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Coordinating Committees

Date: January 25, 2018

From: John Ferguson, HCP Coordinating Committees Chairman

cc: Kristi Geris

Re: Final Minutes of the December 12, 2017 HCP Coordinating Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Coordinating Committees met at the Grant PUD Office in Wenatchee, Washington, on Tuesday December 12, 2017, from 10:00 a.m. to 12:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Kristi Geris will coordinate with Tracy Hillman and will notify the HCP Coordinating Committees of the date the HCP Hatchery Committees plan to tour the new Wells Fish Hatchery (tentatively scheduled for spring 2018; Item II-C).
- Chelan PUD will provide the Final 2017 Rock Island and Rocky Reach Fish Spill Program Report to Kristi Geris for distribution to the HCP Coordinating Committees (Item II-C). *(Note: Lance Keller provided the final report to Geris following the HCP Coordinating Committees meeting on December 12, 2017, which Geris distributed to the HCP Coordinating Committees on December 13, 2017.)*
- The Rock Island HCP Coordinating Committee will submit edits, comments, or indication of no comments on the Application for Non-Capacity Amendment for Coyote Dunes, to Jeff Osborn (Chelan PUD) and Lance Keller (and copy Kristi Geris) no later than December 15, 2017 (Item III-B). *(Note: all Rock Island HCP Coordinating Committee representatives responded to Chelan PUD by December 14, 2017.)*
- Kristi Geris will resend the email detailing the Application for Non-Capacity Amendment for Coyote Dunes for review, to the Rock Island HCP Coordinating Committee (Item III-B). *(Note: this email was re-distributed to the HCP Coordinating Committees by Geris on December 13, 2017.)*
- Lance Keller will verify internally that Chelan PUD has addressed cultural resource impacts, if any, associated with the Application for Non-Capacity Amendment for Coyote Dunes (Item III-B). *(Note: Keller verified that Chelan PUD has initiated the appropriate actions regarding addressing potential cultural resource impacts associated with this amendment, as explained in an email distributed to the HCP Coordinating Committees by Keller following the meeting on December 12, 2017, and by Kristi Geris on December 13, 2017.)*

- Douglas PUD will further review run-timing data for wild and hatchery yearling Chinook salmon with regard to Wells Dam bypass operation dates, and will report back to the HCP Coordinating Committees (Item IV-B).
- The Wells HCP Coordinating Committee will submit edits and comments on the Draft 2017 Wells Dam Passage Dates Analysis to Tom Kahler no later than January 5, 2018 (Item IV-B).
- Douglas PUD will provide a matrix outlining the pros and cons for potential study species to use in the Douglas PUD 2020 Survival Verification Study (including such details as species selection, release location, and tag type), for further discussion and decision in January 2018 (Item IV-C). *(Note: Tom Kahler provided this matrix to Kristi Geris on January 17, 2018, which Geris distributed to the HCP Coordinating Committees that same day.)*
- The HCP Coordinating Committees meeting on January 23, 2018, will be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington (Item V-A).

Decision Summary

- There were no HCP Decision Items approved during today's meeting.

Agreements

- There were no HCP Agreements discussed during today's meeting.

Review Items

- A second Draft 2017 Wells Dam Passage Dates Analysis was distributed to the HCP Coordinating Committees by Kristi Geris on December 7, 2017. The draft analysis is available for review with edits and comments due to Tom Kahler by January 5, 2018 (Item IV-B).
- An Application for Non-Capacity Amendment for Coyote Dunes was distributed to the Rock Island HCP Coordinating Committee by Kristi Geris on November 15, 2017. The application is available for a 30-day review period with edits, comments, or indication of no comments, due to Jeff Osborn and Lance Keller (with a copy to Geris) by December 15, 2017 (Item III-B). *(Note: all Rock Island HCP Coordinating Committee representatives responded to Chelan PUD by December 14, 2017.)*
- The Draft 2017 Wells Post-Season Bypass Report (including the appended Draft 2017 Wells Dam Passage Dates Analysis) was distributed to the Wells HCP Coordinating Committee by Kristi Geris on December 29, 2017. The draft report is available for a 60-day review period, with edits and comments due to Tom Kahler by February 27, 2018.

- The Draft 2018 Wells Dam Gas Abatement Plan and Bypass Operating Plan was distributed to the Wells HCP Coordinating Committee by Kristi Geris on January 16, 2018. The draft plan is available for review with edits and comments due to Tom Kahler by February 12, 2018.
- The Draft 2018 Wells HCP Action Plan was distributed to the Wells HCP Coordinating Committee by Kristi Geris on January 22, 2018. The draft plan is available for a 30-day review period, with edits and comments due to Tom Kahler by February 21, 2018.
- The Draft 2017 Rocky Reach Juvenile Fish Bypass System Report, Draft 2017 Rock Island Smolt and Gas Bubble Trauma Evaluation Report, Draft 2018 Rocky Reach Juvenile Fish Bypass System Operations Plan, Draft 2018 Rock Island Bypass Monitoring Plan, and Draft 2018 Rock Island and Rocky Reach Action Plan were distributed to the Rocky Reach and Rock Island HCP Coordinating Committees by Kristi Geris on January 22, 2018. The draft documents are available for a 30-day review period, with edits and comments due to Lance Keller by February 21, 2018.

Finalized Documents

- The Final 2017 Rocky Reach and Rock Island Fish Spill Program Report, which was approved by the Rocky Reach and Rock Island HCP Coordinating Committees during the HCP Coordinating Committees meeting on October 24, 2017, was distributed to the HCP Coordinating Committees by Kristi Geris on December 13, 2017 (Item II-C).
- The Final Douglas PUD 2016 Pikeminnow Program Annual Report, which was approved by the Wells HCP Coordinating Committee after no disapprovals were received prior to the 60-day review deadline on May 29, 2017, was distributed to the HCP Coordinating Committees by Kristi Geris on December 29, 2017.
- The Final 2016 Rock Island Smolt Monitoring Program and Gas Bubble Trauma Report, Final 2016 Rock Island and Rocky Reach Pikeminnow Control Program Summary Report, and Final 2017 Rock Island Bypass Monitoring Plan were distributed to the HCP Coordinating Committees by Kristi Geris on January 5, 2018. The Rocky Reach and Rock Island HCP Coordinating Committees approved these documents after no disapprovals were received prior to the 30-day review deadline on February 22, 2017.
- The Final 2017 Rocky Reach Juvenile Fish Bypass System Operations Plan was distributed to the HCP Coordinating Committees by Kristi Geris on January 5, 2018. The Rocky Reach HCP Coordinating Committee approved the plan after no disapprovals were received prior to the 30-day review deadline on March 20, 2017.

I. HCP Tributary and Hatchery Committees Update

John Ferguson suggested Tracy Hillman provide the HCP Tributary and Hatchery Committees update prior to discussing today’s other agenda items, to accommodate Hillman’s travel schedule.

A. HCP Tributary and Hatchery Committees Update (Tracy Hillman)

Tracy Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Hatchery Committees meeting on November 15, 2017:

- *Coho Salmon Statement of Agreement*: The Rocky Reach and Rock Island HCP Hatchery Committees approved the Statement of Agreement (SOA) regarding Chelan PUD's coho salmon obligation, which includes methodology for meeting the obligation. This version, however, does not include a funding arrangement with the Yakama Nation (YN), which will be determined in a separate SOA following further coordination with the YN and the Colville Confederated Tribes (CCT).
- *Steelhead Program Surplus Brood Year 2017*: Douglas PUD indicated that their steelhead program has an excess of about 7,600 fish in the Twisp River program, an excess of about 87,000 in the Columbia River program, and a shortage of about 27,000 fish in the Methow River program. Following discussion, the Wells HCP Hatchery Committee agreed to: 1) release all Twisp River No Net Impact and inundation program steelhead on-station at time of release; 2) release all Methow River inundation program fish on-station at time of release; 3) retain the approximately 210,000 Columbia River Safety Net program fish on-station for release; 4) release the target of 160,000 Columbia River Safety Net program fish, plus a surplus to make up the shortfall in the Methow River inundation program release, for a total release of about 339,000 fish or less; and 5) remove additional surplus fish from the Columbia River Safety Net program and release in non-anadromous waters under direction of the Washington Department of Fish and Wildlife (WDFW).
- *Wells and Methow Fish Hatcheries Transition*: Douglas PUD has fully staffed both the Wells and Methow fish hatcheries. As of November 15, 2017, the transition was on track to be completed within 90 days. Douglas PUD hired a veterinarian, and is also working to finalize all other paperwork and responsibilities.
- *Summer Chinook Salmon Spawning Update*: Douglas PUD indicated the full program egg take was acquired, with a possible surplus. Hatchery staff collected an additional 18 females during an outbreak of columnaris, and the Yakima River restoration program also helped to spawn fish.
- *National Marine Fisheries Service Consultation Update*: The National Marine Fisheries Service (NMFS) received the official initiation of consultation request for the unlisted programs in the upper Columbia River, and will be responding with letters of sufficiency to the applicants. Also, the Draft Upper Columbia River Summer/Fall and Fall Chinook Salmon Biological Opinion (BiOp) will go to General Counsel for review, and then to the applicants for review. Finishing this BiOp by the end of the year is a priority.
- *U.S. Fish and Wildlife Service Bull Trout Consultation Update*: The U.S. Fish and Wildlife Service (USFWS) is working on the BiOp for the batch of Wenatchee subbasin programs, and hopes to

obtain signatures this week. USFWS is also making progress on the Methow River steelhead consultation, which was anticipated to be complete by the end of November 2017. Finally, USFWS received additional information for the unlisted programs in the upper Columbia River, which will inform the effects analysis. The schedule for completing a letter of concurrence depends on when NMFS is able to initiate consultation.

- *Draft Hatchery Monitoring and Evaluation Plan for PUD Hatchery Programs, 2017 Update*: The HCP Hatchery Committees approved the Hatchery Monitoring and Evaluation Plan for PUD Hatchery Programs, 2017 Update, as revised. The approved plan has been shared with the Upper Columbia Salmon Recovery Board (UCSRB) and Independent Scientific Advisory Board (ISAB). The HCP Hatchery Committees also shared the final plan with those conducting on-the-ground hatchery monitoring.
- *Timeline of Changes in Hatchery Programs*: The HCP Hatchery Committees are preparing and reviewing timelines of major hatchery program changes to help inform statistical analyses for the statistical and comprehensive reports. This has been completed for spring Chinook salmon, and focus will now shift to summer Chinook and sockeye salmon, and steelhead,
- *Upper Columbia Salmon Recovery Board Hatchery Summary Report*: Greer Maier (UCSRB) presented on "Integrated Recovery," and discussed the UCSRB's Draft Hatchery Summary Report. HCP Hatchery Committees representatives and other reviewers provided comments on the draft summary report, and UCSRB is currently reviewing and addressing those comments. UCSRB hopes to obtain approval of the summary report during their meeting on December 31, 2017. The next step for UCSRB is to prepare summary reports for hydropower and harvest. John Ferguson asked about the status of the ISAB report summarizing their review of the status of upper Columbia River spring Chinook salmon, and Tom Kahler said the report will be available in March 2018.
- *Next meeting*: The next meeting of the HCP Hatchery Committees will be on January 17, 2018.

Hillman updated the HCP Coordinating Committees on the following actions and discussions that occurred during the HCP Tributary Committees meeting on November 9, 2017:

- *Frazer Creek – Lazy K Property Appraisal Project*: The HCP Tributary Committees received a Small Projects Program Application from Methow Salmon Recovery Foundation to appraise the value of a 20-acre parcel along Frazer Creek in the Methow River basin. Acquiring the property would allow stream restoration in a site where the 2017 flood plugged a culvert causing the stream to cut deep gullies through the property. The total cost of the project is about $1,400, which only covers coordination with the landowner and appraiser, and billing and administration work. The HCP Tributary Committees elected not to fund the appraisal, because most of the property does not border the stream and restoring this site would have little biological benefit.

- *Upper Beaver Creek – Anderson Property Appraisal Project*: The HCP Tributary Committees received another Small Projects Program Application from Methow Salmon Recovery Foundation to appraise the value of a 1.6-acre parcel along Beaver Creek in the Methow River basin. Acquiring the property would allow stream restoration in a site where the 2017 flood avulsed through the Anderson property and damaged the County road. The cost of the project is about $1,400, which only covers coordination with the landowner and appraiser, and billing and administration work. After receiving additional information from the sponsor, the HCP Tributary Committees elected not to fund the appraisal, because the Committees were uncomfortable acquiring the property without an analysis of the vulnerability of the road from the stream.
- *PRESENTATION: Chelan River Restoration*: Steve Hays (Chelan PUD) presented on the Chelan River Restoration project, which was funded by Chelan PUD. Hays discussed riverine conditions before hydropower development, requirements under the first two licenses, and objectives and agreements under the most recent license. Hays played a video which showed the evolution of the river during the restoration process and how it changed. He then described Chelan PUD's robust monitoring program and discussed results. He concluded by stating the restoration work has created high quality habitat, which is being used by salmonids, including cutthroat trout.
- *PRESENTATION: Effectiveness of Enhancement Projects*: Hillman provided a presentation on the effectiveness of tributary habitat enhancement projects, which is based on a report Hillman and his coauthors (Phil Roni [Cramer Fish Sciences] and Jen O'Neal [Natural Systems Design]) prepared for the Bonneville Power Administration (BPA). The report addresses six policy-level questions about the success of enhancement actions, and was used as part of the Federal Columbia River Power System BiOp. Well-over 1,000 pieces of literature were reviewed and 617 reports met the criteria for relevance. The report focused on identifying characteristics of successful projects and also reasons why some failed. Hillman concluded by providing recommendations for enhancement work in the future.
- *Sponsorship Request*: The UCSRB asked the HCP Tributary Committees about helping sponsor the Upper Columbia Science Conference. Each HCP Tributary Committee agreed to donate $1,000 to the conference, which identifies the HCP Tributary Committees as "Gold Sponsors."
- *Next meeting*: The next meeting of the HCP Tributary Committees will be on January 11, 2018.

II. Welcome

A. Review Agenda (John Ferguson)

John Ferguson welcomed the HCP Coordinating Committees and reviewed the agenda. Ferguson asked for any additions or changes to the agenda. The following revisions were requested:

- Lance Keller added the Application for Non-Capacity Amendment for Coyote Dunes.
- Tom Kahler added a Wells Dam fishway maintenance update.

B. Meeting Minutes Approval (John Ferguson)

The HCP Coordinating Committees reviewed the revised draft October 24, 2017 meeting minutes. Kristi Geris said there was one outstanding comment when the revised minutes were distributed, under Douglas PUD's Draft 2017 Wells Dam Passage Dates Analysis discussion. Geris said the comment was about the new location of the lower Methow River passive integrated transponder (PIT)-tag array, which Mike Tonseth later clarified has been moved from river mile 1.2 to 5. Geris said all other comments and revisions received from members of the Committees were incorporated into the revised minutes. HCP Coordinating Committees members present approved the October 24, 2017 meeting minutes, as revised.

C. Last Meeting Action Items (John Ferguson)

Action items from the HCP Coordinating Committees conference call on October 24, 2017, and follow-up discussions, were as follows. *(Note: italicized text corresponds to agenda items from the meeting on October 24, 2017):*

- *Kristi Geris will coordinate with Tracy Hillman and will notify the HCP Coordinating Committees of the date the HCP Hatchery Committees plan to tour the new Wells Fish Hatchery (tentatively scheduled for early 2018; Item II-C).*
  Geris said Hillman indicated the HCP Hatchery Committees decided to postpone the tour until later next year. Geris said although no date was set, it will likely occur next spring. This action item will be carried forward.
- *Kristi Geris will locate the presentation, "Potential to improve the conservation benefits of steelhead hatcheries," presented by Barry Berejikian (National Oceanic and Atmospheric Administration [NOAA] Northwest Fisheries Science Center) during the HCP Hatchery Committees meeting on October 18, 2017, and will distribute the presentation to the HCP Coordinating Committees (Item III-A).*
  Geris distributed Berejikian's presentation to the HCP Coordinating Committees on October 26, 2017.

- *Douglas PUD will: 1) incorporate comments received on the Transition Plan for Wells and Methow Fish Hatcheries, and provide the updated plan to Kristi Geris for distribution to the HCP Coordinating Committees; 2) either incorporate sections of the Memorandum of Understanding (MOU) into the transition plan or distribute the MOU to the HCP Coordinating Committees; and 3) check on the status of the Operations Plan (Item IV-B).*
  Sections of the MOU were incorporated into the final transition plan, and Tom Kahler provided the final plan to Geris on November 7, 2017, which Geris distributed to the HCP Coordinating Committees that same day.
- *Douglas PUD, in coordination with Richard Townsend (Columbia Basin Research), will incorporate wild yearling Chinook salmon passage data for 2017 into the corrected Draft 2017 Wells Dam Passage Dates Analysis (Item IV-C).*
  Data were incorporated, as discussed, and an updated analysis was distributed to the HCP Coordinating Committee by Kristi Geris on December 7, 2017. This will be further discussed during today's meeting.
- *Douglas PUD, in coordination with Richard Townsend, will include wild yearling Chinook salmon passage data for all years of analyses in an addendum to the Draft 2017 Wells Dam Passage Dates Analysis (Item IV-C).*
  This will be discussed during today's meeting.
- *Douglas PUD will provide a proposal on which study species to use for the Douglas PUD 2020 Survival Verification Study for the Wells HCP Coordinating Committee to consider, and will convene a conference call for discussion, if necessary (Item IV-D).*
  This will be discussed during today's meeting.
- *Chelan PUD will provide the Final 2017 Rock Island and Rocky Reach Fish Spill Program Report to Kristi Geris for distribution to the HCP Coordinating Committees (Item V-A).*
  This action item will be carried forward. (Note: Lance Keller provided the final report to Geris following the HCP Coordinating Committees meeting on December 12, 2017, which Geris distributed to the HCP Coordinating Committees on December 13, 2017.)
- *Chelan PUD will provide a written list of the repairs planned for the Rocky Reach Dam fish ladders during the 2017/2018 winter maintenance outage, and 2014 passage data, for Rocky Reach HCP Coordinating Committee consideration and vote via email (Item V-D).*
  Keller provided the list of repairs and 2014 passage data to Kristi Geris following the meeting on October 24, 2017, which Geris distributed to the HCP Coordinating Committees on October 25, 2017.
- *Chad Jackson will provide an official Washington Department of Fish and Wildlife (WDFW) HCP Hatchery Committees Representation Designation Letter to Kristi Geris for the administrative record (Item VI-A).*

Jackson provided this letter to Geris on November 6, 2017, which Geris distributed to the HCP Coordinating Committees and to Sarah Montgomery [Anchor QEA] for distribution to the HCP Hatchery Committees that same day.

- *Kristi Geris will coordinate with Denny Rohr (Priest Rapids Coordinating Committee [PRCC] Facilitator) and the PRCC regarding rescheduling the HCP Coordinating Committees meeting in December 2017 (Item VI-B).*
  Geris coordinated with Rohr, who indicated the PRCC plans to meet on December 13, 2017; therefore, the HCP Coordinating Committees meeting on December 26, 2017, has been rescheduled to December 12, 2017.

III. Chelan PUD

A. Rocky Reach and Rock Island Adult Fishway Maintenance Updates (Lance Keller)

Lance Keller reviewed maintenance updates at Rock Island Dam and Rocky Reach Dam, as follows:

<u>Rock Island Dam</u>

Right Ladder

Keller said the right ladder at Rock Island Dam was taken offline for annual winter maintenance on December 4, 2017. He said a fish rescue was conducted in the upper fishway that same day, and in the lower fishway on December 6, 2017. He said all fish were successfully rescued and released in a healthy state. He reviewed species that were recovered across both efforts, as follows:

Species	Stage/length	Clip	Count	Condition	PIT-tag
rainbow/steelhead	juvenile	ad-present	51	NR	No
		ad-clipped	4	NR	No
	12 inches	ad-clipped	2	NR	No
	14 inches	ad-clipped	2	NR	No
	20 inches	ad-present	1	NR	No
Chinook salmon	juvenile	ad-present	20	NR	No
	adult	ad-present	5	NR	No
		ad-clipped	1	NR	No
redside shiner	NR	NA	2	NR	No
bull trout	8 inches	NA	1	Excellent	No
	10 inches	NA	1	Excellent	Yes

Notes:
ad = adipose
NA = not applicable
NR = not reported
PIT = passive integrated transponder

Keller noted that the one PIT-tagged bull trout was listed as orphan. He also noted there were no mortalities encountered. John Ferguson asked where the rescued fish were released, and Keller said rescued fish are released in the Rock Island Dam forebay.

Left Ladder

Keller said the left ladder at Rock Island Dam will be taken offline for annual winter maintenance on December 18, 2017.

Middle Ladder

Keller said the middle ladder at Rock Island Dam will be taken offline for annual winter maintenance when either the right or left fish ladder is returned to service. He noted that this year, the middle ladder will be the shortest ladder outage at Rock Island Dam.

Keller said all fishways at Rock Island Dam should be back to service by mid-February 2018. He said this is earlier than the usual end of February return to service date.

Rocky Reach Dam

Keller recalled that the Rocky Reach HCP Coordinating Committee agreed to Chelan PUD's request to begin the 2017/2018 winter maintenance work period at Rocky Reach Dam, 3 weeks earlier than usual to allow more time to complete required work. Keller said as agreed, the upper adult fish ladder at Rocky Reach Dam was taken offline for annual winter maintenance on December 11, 2017. He said a fish rescue was conducted in the upper ladder that same day, while the lower ladder remained watered with entrances open. He reviewed species that were recovered from the upper ladder, as follows:

<table>
<tr><th>Species</th><th>Stage/length</th><th>Clip</th><th>Count</th><th>Condition</th><th>PIT-tag</th></tr>
<tr><td rowspan="2">rainbow/steelhead</td><td rowspan="2">juvenile</td><td>ad-present</td><td>54</td><td>NR</td><td>No</td></tr>
<tr><td>ad-clipped</td><td>9</td><td>NR</td><td>No</td></tr>
<tr><td rowspan="2">Pacific lamprey</td><td rowspan="2">adult</td><td>NA</td><td>232</td><td>NR</td><td>No</td></tr>
<tr><td>NA</td><td>2</td><td>NR</td><td>Yes</td></tr>
<tr><td>whitefish</td><td>NR</td><td>NA</td><td>34</td><td>NR</td><td>No</td></tr>
</table>

Notes:
ad = adipose
NA = not applicable
NR = not reported
PIT = passive integrated transponder

Keller said, considering the large Pacific lamprey run this year, crews were prepared to encounter a large number of Pacific lamprey, and 234 fish is the most encountered in a long time. He said two Pacific lamprey were PIT-tagged with full-duplex tags, which Keller suspects are from the adult PIT-tagging effort Steve Hemstrom is conducting in coordination with the Rocky Reach Fish Forum. Keller said all 234 Pacific lamprey were released to a calm, quiet area in the Rocky Reach Dam forebay.

Ferguson noted the ongoing translocation efforts lead by Ralph Lampman (YN) and in association with the Douglas PUD Aquatic Settlement Work Group. Ferguson suggested Chelan PUD coordinate with Lampman about possibly using Pacific lamprey from fish rescues for translocation efforts upstream of Wells Dam. Keller said he believes Lampman is aware of annual fish rescue numbers. Keller said Chelan PUD would want to continue releasing PIT-tagged fish in the Rocky Reach Dam forebay for monitoring and evaluation purposes; however, Chelan PUD may be open to ideas for non-PIT-tagged fish. Keller said similar to Rock Island Dam, there were also no mortalities encountered at Rocky Reach Dam.

Keller said the lower ladder will be dewatered in the coming days. He reiterated that all weirs in the lower fishway remained fully submerged while dewatering the upper fishway, so fish will not become stranded and are able to exit the fishway. Kirk Truscott asked about the logistics of dewatering the upper fishway, but not the lower. Keller said the upper fishway exits are closed and the water drains via gravity to a level equal to the current tailwater elevation, with the lower ladder and all weirs remaining fully submerged. He said the water elevation in the lower fishway will follow the tailrace elevation until the entrance gates are deployed and the remaining water is pumped from the lower fishway, at which point crews are present for the lower fishway fish rescue. Truscott also asked if the number of clipped and non-clipped O. mykiss (*Oncorhynchus mykiss*) were similar to other years. Keller said there seemed to be more resident fish versus migrating. He added that crews did interrogate every fish for PIT tags.

B. Application for Non-Capacity Amendment for Coyote Dunes (Lance Keller)

Lance Keller said Kristi Geris notified the Rock Island HCP Coordinating Committee on November 15, 2017, that an Application for Non-Capacity Amendment for Coyote Dunes is available for a 30-day review period, with edits and comments due to Jeff Osborn by December 15, 2017. Keller also asked that Rock Island HCP Coordinating Committee representatives submit indication of no comments, if this is the case, in order to create a complete consultation record to submit to the Federal Energy Regulatory Commission. Geris said she will resend the email detailing the Application for Non-Capacity Amendment for Coyote Dunes for review, to the Rock Island HCP Coordinating Committee. *(Note: this email was re-distributed to the HCP Coordinating Committees by Geris on December 13, 2017,* *and all Rock Island HCP Coordinating Committee representatives responded to Chelan PUD by December 14, 2017.)*

Keller said the proposal is for two changes to the Olds Bridge recreation site, which is the area south of "north end bridge" (Odabashian Bridge) in Wenatchee, Washington. He said changes include: 1) changing the name of the site to "Coyote Dunes Natural Area"; and 2) adjusting the area of the site and designating the site to be a passive recreation area on approximately 26 acres of land owned by Chelan PUD.

Kirk Truscott asked if the amendment includes moving dirt. Keller said no, there will be some restoration in the uplands, but there will be no in-water work. Keely Murdoch asked if a cultural resource survey is needed or has been conducted. Keller said to his knowledge, Chelan PUD has reviewed and addressed the requirements associated with cultural resources. Murdoch said she asked because for the YN, someone other than her needs to review and approve actions related to cultural resources. Keller said he will verify internally that Chelan PUD has addressed cultural resource impacts, if any, associated with the Application for Non-Capacity Amendment for Coyote Dunes. *(Note: Keller verified that Chelan PUD has initiated the appropriate actions regarding addressing potential cultural resource impacts associated with this amendment, as explained in an email distributed to the HCP Coordinating Committees by Keller following the meeting on December 12, 2017, and by Kristi Geris on December 13, 2017.)*

C. Integrated Recovery Technical Advisory Team (Greer Maier)

Greer Maier said she is the Science Program Manager at UCSRB (the Board). Maier said she has been with the Board since 2007, when the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan was written. She said part of this recovery plan is to determine what recovery strategies can be integrated across all four H's (habitat, harvest, hydropower, and hatcheries), how to achieve recovery by creating partnerships, and how the Board can help facilitate positive change. She said this effort started with developing the Habitat Summary Report in 2014, where information was gathered to date on habitat restoration efforts. She said next, the Hatchery Summary Report was developed, which will hopefully be approved next week. She said now, focus is shifting to the Hydropower Summary Report. She said part of this process is understanding who is involved (in hydropower).

Maier said the Integrated Recovery Technical Advisory Team (IRTAG) was convened 5 years ago to review and provide input on these summary reports. She said the IRTAG meets twice per year in Wenatchee, Washington. She said it is optimal to have at least one representative present from each Mid-Columbia PUD (Grant, Chelan, and Douglas PUDs), and she said it has also been helpful to have Keely Murdoch and Casey Baldwin present to represent the YN and the CCT, respectively.

Maier said this effort starts with these background summaries, or summary reports. She said next comes shared learning, presentations at Board meetings, and then open discussions about the issues and how the Board can play a role in coming up with solutions and obtaining funding. She said, however, these summary reports for all four H's need to be complete before the subsequent discussions can start.

Tom Kahler asked if UCSRB would also report on the Federal Columbia River Power System (i.e., fish passage and survival at the federal projects). Maier said yes, as well as BPA, WDFW, and USFWS. She said she has also been in touch with Grant PUD and the PRCC.

John Ferguson asked if the Board has formally requested representation. Maier said the request is fairly informal, and is essentially what she is doing today. Kahler said he has been elected to represent Douglas PUD. Lance Keller said he was elected to represent Chelan PUD. Maier said the first meeting will be in early spring 2018.

Ferguson asked about the regulatory context of the recovery plan. He asked, what requirement does the recovery plan meet, what authority does this plan have, and how does it affect ongoing programs? Maier said the plan is advisory and all participation is voluntary. She said this effort is supported by specific salmon recovery funds. She said there is political value with the Board, but there is also interest in pursuing how to contribute in other arenas. She said the recovery plan has also been adopted by NOAA, but is voluntary. She said the plan also affects obtaining permits in terms of status of species.

Maier said she would like to touch base with the HCP Coordinating Committees again, when the process is further down the road. She said a copy of the Hatchery Summary Report was provided to the HCP Hatchery Committees for review and comment. She said this is an open process, that she wants accurate information, and asks for everyone to participate so the process has everyone involved.

Kirk Truscott asked, considering various workloads, can chapters be distributed as they are completed instead of all at once (entire draft document). Maier said the document is written all at once, not iteratively; however, she can work on distributing sections separately, or can try parsing out the information.

Ferguson asked about the schedule for the Hydropower Summary Report. Maier said efforts for this report will be ramping up in February or March 2018, which is when the first meeting might be scheduled. She said she hopes to identify people contributing to this report by January 2018. She said she also hopes to have a draft report by spring 2018, and finish the report by the end of 2018. She said this might be a bit ambitious considering the other reports took 2 to 3 years to complete.

IV. Douglas PUD

A. Wells Dam Fishway Maintenance Update (Tom Kahler)

Tom Kahler reviewed maintenance updates at Wells Dam, as follows:

West Fishway

Kahler said dewatering of the west fishway at Wells Dam (ladder and collection gallery) for annual winter maintenance has been postponed because unforeseen problems delaying the necessary replacement of a walkway over the AWS intakes in the tailrace have prevented the installation of the bulkheads in those intakes. He said dewatering was initially supposed to take place on the morning of December 5, 2017; however, it will now take place the week of December 18, 2017. *(Note: the west fishway was taken out of service for annual maintenance on the morning of December 27, 2017.)*

Kahler said installation of the bulkheads in the fish-pump intakes in the forebay was completed on the afternoon of December 5, 2017, in preparation for the fish rescue through the entire fishway. He said, therefore, the ladder is in operation; however, the AWS attraction flow to the collection gallery is not. Therefore, there is very little head differential at the fishway entrance, but flow from the ladder into the collection gallery will attract fish already in the gallery, and any fish using the ladder will be able to exit.

Kahler recalled at Wells Dam, major versus routine maintenance is alternated between fishways each year. He said this year, the west fishway will receive the more extensive maintenance.

East Fishway

Kahler said the east fishway at Wells Dam will be taken offline for annual winter maintenance once the west fishway is complete. He said this year, only routine maintenance will be performed on the east fishway. He guessed the fishway will be dewatered in late-January 2018, and should return to service a couple of weeks after.

Kirk Truscott asked, historically, if a large number of whitefish are typically rescued from the Wells Dam fishways. Kahler said yes, both Mountain and Lake whitefish. He said operators started pulsing water through the upper ladder in preparation for the fishway outage, which whitefish do not appear to like and so they move out.

B. 2017 Wells Dam Passage Dates Analysis (Tom Kahler)

Tom Kahler said a corrected Draft 2017 Wells Dam Passage Dates Analysis was distributed to the HCP Coordinating Committees by Kristi Geris on October 23, 2017. The draft analysis was available for a 30-day review period, with edits and comments due to Kahler by November 22, 2017. Kahler said per his action item from the HCP Coordinating Committees meeting on October 24, 2017, to incorporate wild migrants only, a second version of the corrected Draft 2017 Wells Dam Passage Dates Analysis (Attachment B) was distributed to the HCP Coordinating Committees by Geris on December 7, 2017. Kahler said he already identified edits needed to the text of this latest version; however, the edits will not change the data.

Kahler said based on this analysis, when considering wild yearling Chinook salmon migrants only, there is quite a difference compared to the combined (hatchery and wild) run. He said, for example, Table 5 of Attachment B demonstrates how the yearling Chinook salmon wild-only sample sizes are disproportionate to the run at large sample sizes. He added that wild yearling Chinook salmon migrate approximately 2 weeks earlier compared to hatchery fish. He said some fish managers also expect the freshets to shift (occur earlier) over time if climate change continues. He said if this happens, hatchery releases may also need shifting. *(Note: Jim Craig noted a typo in Table 5 under wild only PIT tags in 2015, which Kahler said he will correct in the next iteration of this document.)*

Kahler said, however, the same is not true for subyearling Chinook salmon, as shown in Table 7 of Attachment B. He said here, the wild PIT-tagged and hatchery groups are not so different from one another. Kirk Truscott noted that for subyearling Chinook salmon, wild fish typically emigrate later than hatchery fish.

John Ferguson asked what these new data mean in terms of a path forward. Kahler said the Wells HCP standard says nothing about parsing out wild versus hatchery fish; therefore, yes, the Wells Project met the standard. He said, however, he believes the intent of the HCP was not to systematically under-protect.

Truscott reviewed Table 6 of Attachment B. He noted that about 14% of wild spring Chinook salmon did not receive protection under spill in 2013 and 2015. He caveated that those years were moderate-to-low water years. He also noted in 2014, about 18% of wild spring Chinook salmon did not receive protection under spill, which he believes is a fairly healthy portion of the wild run. Ferguson asked, considering the small sample size, are those numbers being skewed by 1 or 2 fish? He asked if more needs to be understood about when these fish start migrating to understand the importance of the data. Kahler said this is something Douglas PUD is concerned about and would like to investigate more. He said in 2017, spill was provided for 92.92% of the wild run; however, Wells Dam was spilling a lot of water beginning mid-March, and it is not as though those fish passing before April 9 were not provided protection. He said Douglas PUD is interested in better understanding the shape of the wild spring Chinook salmon distribution.

Truscott said based on these PIT tag data (detections at Rocky Reach Dam with the assumed 5-day travel time to Wells Dam), spring Chinook salmon are beginning to migrate before the Twisp River screw trap is operational. Kahler said Charlie Snow's (WDFW) crew also started electrofishing and tagging in the tributaries sometime around 2012 to 2014, and Kahler is unsure of what the mix is between screw trap and electrofishing. Ferguson asked if the new PIT-tag detector in spillbay 2 at Wells Dam can be used to verify the assumed 5-day travel time between Wells and Rocky Reach dams. Kahler said this analysis is ongoing, as described on page 12 of Attachment B; however, not many fish have been detected at both Wells and Rocky Reach dams. He said the issue is when there is so much spill most fish do not pass via that spillbay with PIT-tag detection.

Kahler said Douglas PUD will further review run-timing data for wild and hatchery yearling Chinook salmon with regard to Wells Dam bypass operation dates, and will report back to the HCP Coordinating Committees. Ferguson asked if changing the bypass operation dates at Wells Dam will need to be memorialized in an SOA, and Kahler said this is correct. Craig noted that hatchery managers will also need to know ahead of time to adjust their programs, as needed.

Kahler said Douglas PUD is still accepting comments on the Draft 2017 Wells Dam Passage Dates Analysis. The Wells HCP Coordinating Committee will submit edits and comments on the draft analysis to Kahler no later than January 5, 2018.

Truscott said he appreciates Douglas PUD's willingness to look into these passage dates further.

C. Douglas PUD 2020 Survival Verification Study - Study Species (Tom Kahler)

Tom Kahler said he has not yet developed a proposal on which study species to use for the Douglas PUD 2020 Survival Verification Study. He said the most practical approach would be to use yearling summer Chinook salmon. He said with summers there is no Endangered Species Act issue, and this species does not have the same level of concern for straying. He recalled the last survival verification study consisted of 15 replicate releases of 667 yearling Chinook salmon at the mouth of the Okanogan River; 2,000 in the Methow River; and 2,667 in the Wells Dam tailrace. He said based on more current data, this split may change. He said all study fish were PIT-tagged. He said Douglas PUD may just propose to repeat the same study methods.

John Ferguson asked if there will be enough adult returns, and Kahler said he believes precision was met before. Kirk Truscott asked about releasing at the mouth of the Okanogan River, noting that Project effects reach farther upstream than just at the mouth. Kahler said the Wells HCP specifically states a release will be at the mouth. Truscott said inundation reaches up 11 miles, and he knows a lot of non-indigenous fish are present in the inundation zone.

Keely Murdoch said for clarification, when this topic was last discussed Kahler mentioned YN reluctance for using coho salmon for a study species; however, after further discussions with colleagues the YN would be supportive of using coho salmon if the Wells HCP Coordinating Committee chooses to do so. Kahler said Douglas PUD is also open to using coho salmon; however, Douglas PUD's proposal would still be for yearling summer Chinook salmon. Ferguson asked if using coho salmon will change releases. Kahler said yes, because there are no Okanogan River coho salmon. He said using coho salmon may be simpler. He said in terms of Project effects, there have been four studies using yearling Chinook salmon (2 studies) and steelhead (2 studies), but no coho salmon. He said consistency helps to fully understand effects, but he acknowledged there are also several other considerations.

Truscott recalled during the HCP Coordinating Committees meeting on October 24, 2017, there was discussion about using PIT tags versus acoustic tags. Truscott said it seems Douglas PUD prefers PIT tags. Ferguson recalled that the Wells HCP requires testing for delayed mortality, which cannot be evaluated using acoustic tags. Truscott said he is suggesting acoustic tags because then the sample size can be lower and spring Chinook salmon can be used to evaluate how they differ from yearling summer Chinook salmon. Kahler said Douglas PUD is wary of using acoustic tags. Lance Keller recalled that in in 2004, Chelan PUD conducted a PIT- versus acoustic-tag comparative study, and for the Rock Island Dam project there was no difference based on a side-by-side analysis. Scott Carlon said he favors acoustics because of the ability to evaluate behavioral data. He also asked Truscott if he is referring to using hatchery spring Chinook salmon, and Truscott said this is correct. Kahler added that historically, Douglas PUD has not needed to use acoustic tags because there has been no need to determine route-specific survival at Wells Dam.

Kahler said a decision needs to be made in time for drafting the annual Broodstock Collection Protocols. He said this is needed by February 2018 at the latest, but January 2018 is more practical. Ferguson suggested that Douglas PUD provide a matrix outlining the pros and cons for potential study species to use in the Douglas PUD 2020 Survival Verification Study (including such details as species selection, release location, and tag type), for further discussion and decision in January 2018. *(Note: Kahler provided this matrix to Kristi Geris on January 17, 2018, which Geris distributed to the HCP Coordinating Committees that same day.)*

V. HCP Administration

A. Next Meetings

The next scheduled HCP Coordinating Committees meeting is on January 23, 2017, to be held in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington.

John Ferguson said he will be unable to attend in-person; however, he will call into the meeting.

The February 27 and March 27, 2018 meetings will be held by conference call or in-person at the Grant PUD Wenatchee Office in Wenatchee, Washington, as is yet to be determined.

7 December 2017

1. Introduction

This analysis summarizes the outmigration timing that has been monitored at the juvenile sampling facility at Rocky Reach Dam or detected at the Rocky Reach Bypass PIT-tag detector for five stocks of salmonids (Coho salmon, yearling and subyearling Chinook salmon, steelhead, and sockeye salmon) for the period 2012-2017. The proportions of each stock covered by the bypass operations at Wells Dam can be estimated using daily counts at Rocky Reach Dam, adjusting for the travel time from Wells to Rocky Reach dams. Table 1 has the average travel times based on Douglas PUD's 2010 PIT-tag study for yearling Chinook salmon, and acoustic-tag studies for steelhead and sockeye salmon. Since there are no PIT-tag or acoustic-tag studies measuring travel times of subyearling Chinook, travel time was assumed to be 5 days, which is approximately one-half of the median travel time (11 days) to Rocky Reach Dam of PIT-tagged wild subyearling Chinook released at the mouth of the Okanogan River in 2017. Coho travel time was assumed to match that of yearling Chinook, and preliminary PIT-tag data appears to validate this assumption (Appendix, Table A1).

Table 1: Average travel times from Wells tailrace to Rocky Reach Dam, based on study results or assumptions of similarity to surrogate species.

Stock	Travel time
Yearling Chinook salmon	5 days
Subyearling Chinook salmon	5 days
Steelhead	2 days
Sockeye salmon	2 days
Coho salmon	5 days

Plots of the annual cumulative proportion of the outmigration for spring migrants (yearling Chinook, steelhead, sockeye, and coho salmon), and subyearling Chinook salmon in the summer have fairly consistent start and end dates across years at Rocky Reach Dam (Figure 1). The timing of bypass operations at Wells Dam from 2012 through 2017 was from 00:00 April 9th through 24:00 on August 19th. This current timing of bypass operations will continue annually, unless modified as a result of future investigations that demonstrate an inadequacy of these dates at providing bypass passage for ≥95% of the migrations of both spring- and summer-migrating Plan Species at Wells Dam.

2. Results

2.1 Bypass coverage, 2012–2017

For each Plan Species, the proportions of migrations that passed during the Wells bypass operations in 2017 were 99.85% for yearling Chinook salmon (combined hatchery and wild), 100% for steelhead, 99.99% for sockeye salmon, 100% for coho salmon, and 99.70% for subyearling Chinook salmon (combined hatchery and wild). The 2017 results for all monitored Plan Species were consistent with historical trends, 2012–2017 (Table 2). However, evaluating the wild component of the yearling Chinook run revealed that the effectiveness of the annual start date for bypass operations was strongly influenced by the origin of the yearling Chinook used in the analysis (see Section 2.2).

Though Table 2 shows the annual estimated proportion of migration passing Wells Dam prior to, during, and post bypass operations required for fish passage, Tables 3 and 4 are presented to highlight the stocks that may be at risk of not achieving the 95% coverage (yearling Chinook salmon passage prior to bypass operations, and subyearling Chinook salmon passage post bypass operations).

To assess the effectiveness of the selected start date for bypass operations, Table 3 compares the start date for bypass operations each year with the date on which the 5th percentile of the cumulative yearling Chinook salmon outmigration passed Wells Dam that year. For yearling Chinook salmon (combined hatchery and wild) in 2017, the start date for bypass operations was 8 days earlier than necessary to achieve the HCP standard of providing bypass passage for ≥95% of the migration. However, for wild only, the start date for bypass operations was 3 days late (see Section 2.2).

Similarly, Table 4 compares the actual termination date for bypass operations with the date on which bypass operations covered 95% of the subyearling Chinook salmon outmigration. In each year, an earlier termination of bypass operations would have been possible without jeopardizing the achievement of the HCP standard of providing a bypass route for ≥95% of outmigrating subyearling Chinook salmon. For combined hatchery and wild subyearling Chinook salmon in 2017, the termination of bypass operations at midnight on August 19 was 13 days later than required to achieve the HCP standard of providing bypass passage for ≥95% of the migration.

Table 2. Total proportion of each stock's migration affected by bypass operations at Wells Dam, based on travel times from Wells Dam to Rocky Reach Dam, the cumulative proportion of the annual migration of each stock at Rocky Reach, and the start and stop dates of Wells bypass operations, 2012-2017. Hatchery and wild-origin PIT-tagged releases above Wells Dam are included for both yearling and subyearling Chinook for the years 2012-2017.

+Proportion estimated using only PIT-tagged releases above Wells Dam.

Table 3. A comparison of the actual start date for bypass operations at Wells Dam for the last 10 years versus the date on which the 5th percentile of the PIT-tagged yearling Chinook salmon migration passed Wells Dam that year, 2012-2017. Operations begin at 00:01 for the date listed in column 2. “Proportion bypass operations would have covered” indicates the proportion of the migration that would have been provided a bypass passage route had bypass operations started at 00:01 on the date that the 5th percentile of the migration passed Wells Dam (column 5). “Bypass start date timing” (column 8) indicates whether the bypass start date was earlier or later than the date on which the 5th percentile of the yearling Chinook migration passed Wells Dam, and by how many days.

Migration Year	Actual bypass start date	Cumulative proportion passed before 00:01	Proportion Covered by Bypass Ops	Date on which the 5th percentile passed	Cumulative proportion passed before 00:01	Proportion bypass ops. would have covered	Bypass start date timing
Hatchery & Wild							
2012	April 9	0.0022	0.9978	April 15	0.0269	0.9731	6 days early

2.2 Comparing Migration Timing and Passage Proportions of PIT-tagged Hatchery and Wild-origin Yearling Chinook Released above Wells Dam

The yearling Chinook migration timing at Wells Dam was estimated using 1) the unadjusted daily counts of PIT-tagged fish released above Wells Dam; and 2) the unadjusted daily counts of PIT-tagged wild-origin fish released above Wells Dam. While wild yearling Chinook salmon are the preferable group to determine bypass coverage of the summer migration, it is also the smallest group, with each individual having a greater impact on passage proportion (Table 5). The number of hatchery yearling Chinook salmon is much larger, but passage timing is susceptible to hatchery release timing. For the six years that comparison of migration timing between PIT-tagged hatchery and wild-origin yearling Chinook released above Wells Dam is possible, wild PIT-tagged yearling Chinook salmon appear to outmigrate up to two weeks earlier than the hatchery-released yearling Chinook salmon (Figure 2).

With the observed differences in the passage timing of the hatchery and wild yearling Chinook salmon, bypass operations were not equally effective in covering ≥95% of the migrations (see Table 6). Bypass operations conveyed 99.9% to 100% of hatchery yearling Chinook salmon migrations in 2012–2017. In contrast, bypass operations at Wells Dam conveyed from 81.03% to 95.62% of the wild PIT-tagged yearling Chinook salmon migrations, achieving the ≥95% standard in only 2012.

Table 5. Total detections of yearling Chinook salmon at Rocky Reach Dam by year and group.

Group	2012	2013	2014	2015	2016	2017

2.3 Comparing Migration Timing and Passage Proportions of PIT-tagged Hatchery and Wild-origin Subyearling Chinook Released above Wells Dam

The subyearling Chinook migration timing at Wells Dam was estimated using 1) the unadjusted daily counts of PIT-tagged hatchery and wild fish released above Wells Dam; and 2) the unadjusted daily counts of PIT-tagged wild-origin fish released above Wells Dam. Each has the same caveats as the yearling Chinook salmon in regard to comparative migration sizes (Table 7). For the three years (2015–2017) that comparison of migration timing between PIT-tagged hatchery and wild-origin subyearling Chinook released above Wells Dam is possible, wild PIT-tagged subyearling Chinook salmon appear to outmigrate up to a month later than the hatchery-released subyearling Chinook salmon (Figure 3).

Despite differences in the passage timing of hatchery and wild subyearling Chinook salmon, bypass operations were effective in covering ≥95% of the migration for each (Table 8). Bypass operations covered 100% of the hatchery subyearling Chinook salmon in 2015–2017, and from 96.11% to 100% for PIT-tagged wild subyearling Chinook salmon. It therefore appears the timing of the bypass operations at Wells Dam is robust, conveying all segments of the subyearling Chinook salmon outmigration.

Table 7. Total detections of subyearling Chinook salmon at Rocky Reach Dam by year and group.

Group	2012	2013	2014	2015	2016	2017
Hatchery, Wild and Unknown PITs	913	1,998	899	1,052	2,303	5,308
Wild only PITs	913	1,998	899	577	1,413	3,701

3. Discussion

In 2017, when considering combined wild- and hatchery-origin fish, the bypass operations covered between 99.70% and 100% of the outmigrations of the five Plan Species at Wells Dam. These coverage rates in 2017 are typical of past performance, 2012–2016 (Table 2). Using PIT-tagged subyearling (i.e. 2015-2017) and yearling Chinook (i.e. 2012-2017) salmon, run timing of hatchery and wild fish were examined separately, (Tables 6 & 8). Evaluation of the migrations of the wild components of the Chinook outmigrations in 2017 revealed that the start date for bypass operations at Wells Dam failed to provide bypass operations for ≥95% of the migration of yearling Chinook, while the end date for bypass operations succeeded in providing bypass operations for ≥95% of the migration of subyearling Chinook. Expanding the evaluation of wild Chinook migrants to past years showed that the bypass termination date in use since 2012 was adequate for providing bypass operations for ≥95% of the migration of both hatchery and wild subyearling Chinook. However, the April 9 start date for bypass operations succeeded in providing bypass operations for ≥95% of the migration of wild PIT-tagged yearling Chinook in only 1 of 6 bypass seasons since 2012.

4. Appendix

Using Wells Dam PIT-tag Detections

2017 was the second year with available PIT-tag detections at Wells Dam (WEJ), with 269 unique tag codes identified. These comprised 114 Chinook salmon, 27 Coho salmon, 127 steelhead, and 1 sockeye salmon. As these numbers are too few to estimate any credible survival estimates, Table A1 summarizes the number of detections and estimated travel times between Wells and Rocky Reach Dam. It is hoped that future runs will be detected at higher numbers to enable a more detailed correction to the outmigration distribution estimated for Wells Dam. Results suggest the values in Table 1 are reasonable adjustments for travel time.

Table A1. Travel time summary for detected PIT-tagged fish at both Wells and Rocky Reach PIT-tag detectors in 2017.

			Travel Time (days)	
Run Species	Detected at Wells Dam	Detected at Rocky Reach Dam	Mean (SE)	Range
Yearling Chinook	114	21	6.7 (1.8)	1.3 – 29.0
Coho	27	11	5.4 (0.8)	2.2 - 10.0
Steelhead	127	41	1.9 (0.2)	0.8 - 6.6
Sockeye	1	0

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Hatchery Committees

Date: February 16, 2017

From: Tracy Hillman, HCP Hatchery Committees Chairman

cc: Sarah Montgomery, Anchor QEA, LLC

Re: Final Minutes of the January 18, 2017, HCP Hatchery Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Hatchery Committees meeting was held at the Grant PUD office in Wenatchee, Washington, on Wednesday, January 18, 2017, from 9:00 a.m. to 12:30 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Sarah Montgomery and Tracy Hillman will renumber the Hatchery Monitoring and Evaluation (M&E) Plan appendices and append them to the Hatchery M&E Plan (Item I-A). *(Note: this item is ongoing.)*
- Sarah Montgomery will add a summary table to the draft summary of the 5-Year Hatchery M&E Review process (Item I-A). *(Note: this item is ongoing.)*
- Keely Murdoch will research who is leading the Columbia River Inter-Tribal Fish Commission's (CRITFC's) parentage-based tagging effort in order to coordinate with Mclain Johnson (Washington Department of Fish and Wildlife [WDFW]) about genetic sampling (Item IV-E). *(Note: this item is ongoing.)*
- Justin Yeager and Brett Farman will discuss internally the Douglas PUD Twisp gamete request and provide National Marine Fisheries Services' (NMFS') vote to the Hatchery Committees (Item II-A). *(Note: Farman provided NMFS approval on January 27, 2017.)*
- Douglas PUD will review WDFW's white paper, "Twisp Steelhead Hatchery Broodstock Issues," which Sarah Montgomery distributed to the Hatchery Committees on January 18, 2017, and provide comments to Mike Tonseth (Item II-B).
- Greg Mackey will coordinate with Chelan and Grant PUDs to develop a statement of agreement (SOA) describing the components in the proposed Hatchery M&E Reporting Timeline, which Sarah Montgomery distributed to the Hatchery Committees on January 13, 2017 (Item IV-C). *(Note: Mackey sent the draft SOA to Montgomery on February 13, 2017, which she distributed to the Hatchery Committees.)*
- Hatchery Committees members will review the Upper Columbia Salmon Recovery Board (UCSRB) Draft Hatchery Report and provide edits and comments to Greer Maier (UCSRB) by

January 31, 2017, and invite Maier to discuss comments in person at an upcoming Hatchery Committees meeting (Item IV-D).

- McLain Johnson will revise the timeline for conducting genetic analysis for HCP program species incorporating suggestions provided during the Hatchery Committees January 18, 2017, meeting (Item IV-E).
- McLain Johnson and WDFW geneticists will perform a power analysis to inform genetic analysis intervals and intensity for HCP program species (Item IV-E).
- Todd Pearsons (Grant PUD) will write a white paper about factors affecting the brood year stray rates of hatchery fish and considerations for revising stray rate targets (Item IV-F). *(Note: Pearsons sent his paper, "Stray Rate Targets for Hatchery Programs" to Sarah Montgomery on February 6, 2017, which she distributed to the Hatchery Committees.)*

Decision Summary

- The Rocky Reach, Rock Island, and Wells Hatchery Committees approved Douglas PUD, Chelan PUD, and WDFW's request for gametes from four female and four male Twisp River hatchery-origin steelhead that WDFW will collect at the Twisp Weir in 2017 for use in pilot studies on egg-to-fry survival, as follows: Douglas PUD, Chelan PUD, WDFW, U.S. Fish and Wildlife Service (USFWS), Yakama Nation (YN), and Colville Confederated Tribes (CCT) approved on January 18, 2017; and NMFS approved via email on January 27, 2017.

Agreements

- The Hatchery Committees agreed they will hold back-to-back meetings with the Priest Rapids Coordinating Committee Hatchery Sub-Committee (PRCC HSC) at Grant PUD's Wenatchee, Washington, office, with the Hatchery Committees meeting from 9 a.m. to as late as 12:30 p.m., unless prevented by lengthy agenda items or logistical constraints. *(Note: this was discussed as a joint item during the PRCC HSC November 17, 2016, meeting.)*

Review Items

- Sarah Montgomery sent an email to the Hatchery Committees on January 18, 2017, notifying them the Chelan PUD 2017 Draft Action Plan is available for review, with comments due to Catherine Willard. *(Note: the hatchery portion of the Chelan PUD 2017 Draft Action Plan will be a decision item at the Hatchery Committees February 15, 2017, meeting.)*

Finalized Documents

- No documents have been finalized recently.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the October 19, 2016, Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the Hatchery Committees and asked for any additions or changes to the agenda. The following revisions were requested:

- Mike Tonseth added a discussion about the Twisp steelhead program.
- Tonseth added a joint item regarding the off-ladder adult fish trap (OLAFT) at Priest Rapids Dam.

The Hatchery Committees reviewed the revised draft October 19, 2016 meeting minutes. Sarah Montgomery said there are several outstanding comments to be discussed, which the Hatchery Committees reviewed and addressed. Hatchery Committees representatives present approved the draft October 19, 2016, meeting minutes, as revised.

Action items from the Hatchery Committees meeting on October 19, 2016, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meeting on October 19, 2016)*:

- *Justin Yeager will check when the Yakama Nation (YN) most recently reviewed the Wenatchee steelhead draft Biological Opinion and provide that date to Keely Murdoch (Item I-A).*
  This item is complete.
- *The U.S. Fish and Wildlife Service (USFWS) will send a letter to the HCP Coordinating Committees describing changes in USFWS representation on the Hatchery Committees (Item II-A).*
  This item is complete. Jim Craig (USFWS) emailed a letter to Tracy Hillman describing this change on October 21, 2016.
- *Sarah Montgomery will assist USFWS in acquiring Hatchery Committees cc: email access for Michael Humling (USFWS; Item II-A).*
  This item is complete. Montgomery added Humling to the Hatchery Committees email cc: distribution list on October 20, 2016.
- *A subgroup led by Catherine Willard will convene to prepare a plan to outplant adult spring Chinook salmon in the Chewuch River (Item II-C).*
  Willard said the subgroup met on January 9, 2017, and the plan will be discussed today.
- *Keely Murdoch will research who is leading the Columbia River Inter-Tribal Fish Commission's (CRITFC) parentage-based tagging effort in order to coordinate with Mclain Johnson about genetic sampling (Item II-D).*
  This item is ongoing.

- *Mclain Johnson (Washington Department of Fish and Wildlife [WDFW]) will revise the timeline for conducting genetic analysis for HCP program species and send it to Sarah Montgomery for distribution to the Hatchery Committees (Item II-D).*
  This item will be discussed today.
- *The Hatchery Committees will review the timeline for conducting genetic analysis for HCP program species and provide additional questions to Johnson (Item II-D).*
  This item is ongoing.
- *Mike Tonseth will ask WDFW geneticists about a technical methodology for deciding analysis intervals (Item II-D).*
  This item will be discussed today.
- *Sarah Montgomery and Tracy Hillman will renumber the Hatchery Monitoring and Evaluation (M&E) Plan appendices and append them to the Hatchery M&E Plan (Item II-E).*
  This item is ongoing.
- *Todd Pearsons (Grant PUD) will distribute the paper by Ford et al. (2015) regarding brood year stray rates to the Hatchery Committees for review (Item II-E).*
  This item is complete. Pearsons sent the paper to Montgomery, which she forwarded to the Hatchery Committees on October 20, 2016, and it will be discussed today.
- *Catherine Willard will add a summary table to the draft summary of the 5-Year Hatchery M&E Review process (Item II-F).*
  This item is ongoing. Sarah Montgomery said she is working on it.
- *Craig Busack will discuss proportion of hatchery-origin spawners (pHOS) targets for Methow steelhead with Amilee Wilson (National Marine Fisheries Service [NMFS]), and follow up with the Hatchery Committees by October 21, 2016 (Item III-A).*
  This item is complete. Busack emailed Hatchery Committees representatives on October 21, 2016, stating the consultation has been transferred to Charlene Hurst (NMFS alternate), and Hurst and Busack will further discuss pHOS targets.
- *Sarah Montgomery will provide the WebEx phone number on the agenda for future Hatchery Committees meetings (Item V-B).*
  This item is complete. Montgomery added the WebEx phone number to the January 18, 2017, agenda.

II. Douglas PUD

A. Decision: Twisp Hatchery-origin Steelhead Gametes (Tom Kahler)

Tom Kahler shared a document titled, "Estimating steelhead egg-to-fry survival in the Twisp River: 2017 pilot study," which Sarah Montgomery distributed to the Hatchery Committees on January 6, 2017 (Attachment B). Kahler said Douglas PUD requests gametes from three female and three male Twisp hatchery-origin steelhead, which are surplus to broodstock and escapement needs, that WDFW will collect at the Twisp weir in spring 2017 for use in the egg-to-fry survival study. Mike Tonseth asked when the fish would be collected and where they would be held. Kahler said he does not have a definitive answer because Douglas PUD wants to get approval from the Hatchery Committees before working through logistics, but the tentative plan is to collect fish at the Twisp weir and hold them at Methow Fish Hatchery. Tonseth said WDFW and Chelan PUD are also working on a steelhead egg-to-fry survival study. Because there are no surplus adult steelhead in the Wenatchee River, WDFW and Chelan PUD are interested in sourcing eggs from another location and noted that no surplus adults are available at Wells Dam or other programs due to spawn timing. Tonseth asked what Douglas PUD plans to do with the balance of gametes that are not needed for the study, and said there is potential for WDFW and Chelan PUD to use the extra gametes. Kahler said the extra gametes would be disposed of, or Douglas PUD may consider egg-planting above an anadromous barrier. Tonseth asked to increase the gamete request to include collecting four female and four male Twisp hatchery-origin steelhead, so WDFW and Chelan PUD can utilize the unused gametes from the Douglas PUD study in their own study, which requires gametes from four female and four male steelhead. He said there would be extra gametes from the Douglas PUD study, which only requires 1,500 eggs, and collection of four female and four male steelhead. Doing this would meet requirements for both studies without targeting a separate collection location for the Chelan PUD study. Catherine Willard added that the spawn timing for steelhead in the Chelan River is late March to early April, and Kahler said steelhead spawn around April in the Twisp River. Greg Mackey said that WDFW could collect the two extra fish, assuming there are enough surplus hatchery-origin steelhead present.

Bill Gale asked if there will certainly be enough hatchery-origin steelhead at the Twisp weir to supply this request in addition to broodstock and pHOS needs. Gale also asked how this gamete request relates to the next discussion (Item II-B) regarding Twisp steelhead program broodstock issues. Tonseth said he thinks there will be enough hatchery-origin steelhead at the weir to meet all program needs plus this surplus gamete request. He said part of the discussion regarding Twisp steelhead program broodstock issues involves potentially reducing the pHOS target in the Twisp River from 0.5 to 0.3, which would make more hatchery steelhead available for surplus. Willard said Chelan PUD supports Tonseth's idea of coordinating the studies and adding two additional hatchery-origin steelhead (one female and one male) to the gamete request.

Justin Yeager asked if this gamete request would change any permitting that has been completed to date. Tonseth replied that it would not. Tonseth also clarified that for egg-to-fry survival studies, no progeny are released into the system; the eggs are put into boxes in gravel, and the boxes with fry are later removed.

Gale said a potential impact to bull trout is that the location of the boxes may overlap with bull trout redds. Mackey agreed that there is potential for overlap with bull trout spawning areas, but the chance is low because the boxes will be placed in the gravel in the Twisp River in the spring.

Tracy Hillman summarized that the gamete request is now for four females and four males, and the Wells Hatchery Committee is voting on the collection of gametes for use in Douglas PUD's egg-to-fry survival 2017 pilot study, and WDFW and Chelan PUD's related egg-to-fry survival study. Douglas PUD, WDFW, and the CCT voted yes. Keely Murdoch emphasized that the steelhead collected must be excess fish, and priority must be given to spawning, and YN voted yes. Gale emphasized that any potential issues with bull trout and permitting should be considered before the study is undertaken, and USFWS voted yes. Yeager said he and Brett Farman will discuss this internally and provide NMFS' vote via email. *(Note: Farman communicated NMFS' approval on January 27, 2017.)*

B. Twisp Steelhead Program Broodstock Issues

Mike Tonseth shared a document titled, "Twisp steelhead hatchery broodstock issues," which Sarah Montgomery distributed to the Hatchery Committees on January 18, 2017 (Attachment C). Tonseth said there is increasing concern about negative genetic effects to the Twisp River steelhead population due to continued operation of the Twisp River steelhead program. He said the current target number of Twisp River wild broodstock is small and, according to geneticists (Todd Seamons, WDFW), continued operation of the program will likely decrease the effective population size (Ne), termed a Ryman-Laikre effect, which has unacceptable long-term genetic risks. He said the Hatchery Committees should consider restructuring management of the Twisp River steelhead program and population. Currently, the population is being managed as a separate spawning aggregate, and the Twisp River is being used as a test basin to evaluate steelhead reproductive success, a wild-by-wild conservation approach, and pHOS management (currently 0.50), all possible because of the Twisp Weir and Twisp Acclimation Pond, as well as the intensive M&E performed in this river. He asked the Hatchery Committees to consider continuing to collect natural-origin adult steelhead at the Twisp Weir, which would be utilized in a USFWS Methow basin program (as opposed to a dedicated Twisp program), and the existing Douglas PUD Twisp program (48,000 steelhead) would be converted to a safety net program and targeted for release in the lower Methow River. He said continued releases of juvenile steelhead in the Twisp River are desired, but could come from a composite group from Winthrop National Fish Hatchery (NFH) which would increase and diversify the number of spawners used to produce juveniles for release. He said there are a lot of changes to discuss, but the most immediate issue for spring 2017 is reducing the Twisp hatchery pHOS escapement target from 0.5 to 0.3. He said WDFW has suggestions outlined in Attachment C for real-time genetic analysis that could be implemented in future years in order to increase the number of families represented in the Twisp River, but the focus for 2017 should be on increasing the effective population size by incorporating juveniles from Winthrop NFH's smolt program.

Tonseth said the broodstock collection numbers identified in the 2016 Broodstock Collection Protocols should still be targeted, but the fish would be transferred to Winthop NFH, and juveniles would be released in the lower Methow River. Greg Mackey suggested Tonseth coordinate with Todd Seamons (WDFW), Craig Busack, and Charlene Hurst to determine the potential genetic effects of these proposed changes. Mackey recalled that the Twisp River population is managed as a separate spawning aggregate because it has weak genetic differentiation from other populations. Mackey said the Twisp program may further exacerbate genetic drift by removing hatchery adult steelhead (without being able to know their familial origins), and the Hatchery Committees should consider a better program design and how Douglas PUD's mitigation requirements fit into the program design. He said Douglas PUD is required to provide 8,000 steelhead as No Net Impact (NNI) mitigation, which is the conservation core of the Twisp program, and the rest of the steelhead released satisfy inundation mitigation requirements. He said the inundation mitigation requirement may be more appropriately managed as a safety net or harvest program. Tonseth summarized that changing the Twisp program will require a lot of coordination and discussion over time, but the first items to settle are broodstock collection and 2017 releases, and WDFW proposes to join the Twisp and Winthrop steelhead programs with releases into the Twisp River and the Methow River. Keely Murdoch said truck planting can also be considered for those releases. Tonseth said truck planting is a good idea because it works well for steelhead and because acclimation and release location affect the distribution of fish (i.e., truck planting would result in wider distribution). Tonseth indicated that the JFP were considering release at Buttermilk Bridge, which is upstream of the Twisp Acclimation Pond, in order to encourage spatial distribution of hatchery origin spawners further upstream. Mackey added that evaluating the appropriate release number of steelhead should be a component of these discussions as well, in order to make the best use possible of wild broodstock.

Tonseth said the distribution of steelhead in the Twisp River and Methow River can be evaluated using passive integrated transponder (PIT) tags, and an analysis of releases in the lower Methow River over a 2- to 3-year period could inform the future of releases in the Methow basin, such as if some releases need to be moved out-of-basin. Mackey added that radical shifts in program implementation could affect permitting, and NMFS should definitely be involved in these discussions. Mackey said Douglas PUD will review WDFW's white paper, "Twisp Steelhead Hatchery Broodstock Issues" (Attachment C) and provide feedback to Tonseth.

Tracy Hillman mentioned the results from Mackey's steelhead proportionate natural influence (PNI) modeling work (discussed during the Hatchery Committees October 19, 2016 meeting) which members, especially the YN, questioned regarding the use of a pHOS of 0.3. Murdoch said YN had agreed to a pHOS of 0.5 and does not want to agree to anything more restrictive than they already have. In reference to Mike Tonseth's statement that pHOS would be adjusted from 0.50 to 0.30, Keely Murdoch stated that this was not discussed by the JFP. She said, based on past conversations, YN supports the concept of taking Twisp River natural-origin returns to Winthrop NFH as long as the progeny are released back into the Twisp River. Tonseth clarified that the desire to reduce pHOS from 0.5 to 0.3 starting in 2017 is because there was a collapse of the 1-salt return, and because the population is already small; during the next 2 years they would only be able to collect adults from one age class if the program were not mixed with the Winthrop program. He said WDFW is not advocating for changing pHOS targets for the entire basin, but for a short-term reduction in order to prevent impacts to the Twisp River steelhead effective population size.

Bill Gale said the Winthrop program obligations come from production tables in U.S. v. Oregon[1], and are a sliding goal from 100,000 to 200,000 steelhead. He said USFWS has been able to meet the 200,000 goal when broodstock is available. He said the Winthrop program is also 100% adipose (ad)-clipped, and the Twisp program is not; this may initiate a discussion about steelhead marking in the Methow and Okanogan basins, but is important to consider. Murdoch said it is concerning that the progeny of natural-origin broodstock are ad-clipped in the Winthrop program. Tonseth said there is a lot to consider regarding the Twisp steelhead program, and this can be a topic at the next Hatchery Committees meeting on February 15, 2017.

III.Chelan PUD

A. Chelan Falls Broodstock Collection: Canal Trap Pilot Results

Catherine Willard shared a document titled, "Pilot Concept to Trap Summer-Run Chinook Salmon at the Chelan River Habitat Channel Water Conveyance Canal Outlet: Results," which

---

[1] 2008-2017 *United States v. Oregon* Management Agreement. May 2008. Available: http://www.westcoast.fisheries.noaa.gov/publications/fishery_management/salmon_steelhead/sr--079.2008-2017.usvor.management.agreement_042908.pdf

Sarah Montgomery distributed to the Hatchery Committees on January 18, 2017 (Attachment D). Willard said the Chelan Falls Canal Trap (CFCT) pilot study was successful in collecting 100 summer Chinook salmon for Chelan Falls broodstock. She said trapping occurred from August 4 to August 10, 2016, and during operation of the CFCT, 51 males and 49 females were collected. She said four fish died while being held at Eastbank Hatchery, resulting in 49 males and 47 females being spawned. She said Chelan PUD evaluated the potential effects of high water temperature on gamete quality because the warm water temperatures of the Chelan River have the potential to affect gamete quality of fish collected at the CFCT. She said gametes from CFCT fish were kept separate from Eastbank Outfall (EBO) and Entiat National Fish Hatchery (ENFH) fish, and eye-up rates were similar for the groups of fish, with CFCT fish having a slightly higher eye-up rate (93% compared to 91%). She said no bull trout were encountered, and Chelan PUD plans to continue the pilot study in 2017. She said in 2017, Chelan PUD intends to start collecting broodstock at the CFCT in July, earlier than in 2016, in order to collect fish throughout the summer Chinook salmon run. She said Chelan PUD intends to use ENFH as the backup broodstock collection location, and does not plan to collect summer Chinook salmon broodstock at EBO due to safety issues. Bill Gale said Chelan PUD and USFWS can discuss using ENFH as the backup broodstock collection location closer to collection time.

Mike Tonseth said the CFCT pilot also included assessing disease profiles for collected female summer Chinook salmon using enzyme-linked immunosorbent assays (ELISA). He asked if any females from the CFCT, EBO, or ENFH had high ELISA values. Willard said there were no females with high ELISA values.

B. Chelan PUD 2017 HCP Action Plan (Catherine Willard)

Catherine Willard shared a spreadsheet titled, "Draft 2017 Rock Island and Rocky Reach HCP Action Plan," which Montgomery distributed to the Hatchery Committees on January 18, 2017 (Attachment E). She said the action plan includes typical items such as the annual Hatchery M&E Report, annual Implementation Plan, broodstock collection, and hatchery releases, as well as pilot studies (Chelan Falls Broodstock Collection and Outplanting Adult MetComp in the Chewuch River), ongoing water quality monitoring at Dryden Acclimation Facility, working on coho salmon NNI mitigation, and permitting activities. She said the draft 2017 Rock Island and Rocky Reach HCP Action Plan is available for review, and will be a decision item at the February 15, 2017, Hatchery Committees meeting.

IV. Joint HCP-HC/PRCC HSC

A. USFWS Bull Trout Consultation Update (Bill Gale)

Bill Gale said Karl Halupka (USFWS) sent him an update on USFWS consultations, which he summarized:

- The memorandum describing Halupka's gap analysis and the strategy to rely on the 2012 Wells Relicensing Bull Trout Biological Opinion (BiOp) for coverage for the Methow spring Chinook salmon program has been approved internally and will be transmitted soon.
- Regarding the Okanogan program consultation, USFWS is working on a letter of concurrence for the Tribal Resources Management Plan (TRMP), which will be reviewed internally soon.
- Regarding the draft BiOp covering hatchery programs in the Wenatchee basin, USFWS is waiting for comments on the revised draft from Chelan PUD and WDFW.

B. NMFS Consultation Update (Justin Yeager)

Regarding the Methow spring Chinook salmon consultation, Justin Yeager said Charlene Hurst distributed draft permits to the applicants for final review, and NMFS expects edits and comments by January 19, 2017. He said regarding the Okanogan steelhead TRMP, the TRMP was available for public comment through the end of December 2016, and NMFS is currently reviewing and addressing comments.

C. M&E Report Scheduling (Greg Mackey/Catherine Willard)

Greg Mackey shared a presentation titled, "Hatchery M&E Reporting: Synching to Required Milestones," which Montgomery distributed to the Hatchery Committees on January 13, 2017 (Attachment F). Mackey said the goal of this discussion is to determine a logical reporting schedule that meets Chelan and Douglas PUD's HCP and Grant PUD's Aquatic Settlement Agreement (ASA) requirements. He summarized the HCP requirements for survival studies, recalculation, updating the M&E Plan, performing a Program Review, and Section 10 permitting. He said the proposed timeline (slide 6) includes survival studies (next in 2023), updating the M&E Plan (next in 2018), and Program Review (next in 2020), as well as other milestones. He said performing the Program Review in 2020 makes sense so it is coordinated with recalculation and M&E plan updates and reports. He said the 5-year M&E Report is not an HCP requirement, but is stipulated in the M&E Plan, and the M&E Plan does not stipulate a 10-year Report/Program Review, but the HCPs do. He said the focus/content of the reports may change as well. He said the PUDs are envisioning the annual M&E reports will contain the data collected that year with summary statistics plus cumulative data, and note any exceptions to field methods and the M&E plan. He said the 5-year Report/Statistical Report would include the results of statistical analyses of each M&E objective with an explanation of the assumptions of the analyses, but with limited interpretation of the analyses. This would allow managers to assess the program and identify any red flags but would make the report shorter and more concise. He said the 10-year Report/Program Review would be a much larger report that would include the type of analyses done in the 5-year cycles with additional analyses as warranted, integrated with regional findings for better context. Chapters in the Program Review would be written in scientific manuscript style to provide a high level of scientific rigor and concise writing in order to enhance interpretation of results and promote the possibility of publishing some of the work. He said the Program Review will be used as part of the adaptive management process and would inform recalculation (slide 3 Mackey said the format and function of each report still needs to be determined and finalized, but agreeing on the timeline for the reports is the first step.

Mike Tonseth asked if the PUDs had considered doing 10-year reports for each species, staggered by different years. Mackey said that was considered, and they also considered organizing the report by basins (e.g., Wenatchee, Methow, Okanogan) to put things into regional context, and then by species. Gale asked if a repeating Hatchery Scientific Review Group (HSRG) review should be included in the proposed timeline. Alene Underwood said the purposes of these reports are to answer questions in the M&E plan within the HCP framework. Tonseth said HSRG reports are more holistic compared to M&E reports. Todd Pearsons agreed and said M&E reports have more specificity about programs and data. Mackey said, after this discussion regarding the timeline, the PUDs can write a description of the components of each report. Underwood suggested writing an SOA so the decision to adopt a new reporting schedule is easily accessible. Tom Kahler summarized that the 10-year Program Review is an HCP requirement, the 5-year Statistical Report is an M&E Plan requirement, and the M&E Plan itself is a requirement of permitting, so any SOA regarding this material should speak only to the reporting timeline and not the pieces in the timeline. Gale asked if the HCP and M&E Plan requirements for Chelan PUD and Douglas PUD are similar to Grant PUD's ASA requirements. Pearsons said it is similar. Mackey said he will coordinate with Chelan and Grant PUDs to develop an SOA describing the components in the proposed Hatchery M&E Reporting Timeline.

D. UCSRB Hatchery Report – Review Period Extension (Tracy Hillman)

Tracy Hillman said the UCSRB's Draft Hatchery Report was distributed to members of the Hatchery Committees for review by Greer Maier. He said Maier agreed to extend the review period and requests comments back to her by January 31, 2017, but the deadline may be flexible. Alene Underwood said Chelan PUD has many comments and will try to respond by January 31, but might need more time. Hillman said after the UCSRB reviews the comments from members of the Hatchery Committees, he will invite Maier to a Hatchery Committees meeting to discuss the comments. *(Note that the UCSRB Draft Hatchery Report was not provided to the Hatchery Committees* *as an official document for review and approval; therefore, it is not listed under Review Items and is not posted to the HCP Hatchery Committees Extranet Site.)*

E. Genetic Analysis for HCP Program Species (McLain Johnson)

McLain Johnson shared a document titled, "Draft Genetic Sampling Timeline," which Sarah Montgomery distributed to the Hatchery Committees on January 18, 2017 (Attachment G). He said he revised the timeline to show analysis needs, the projected year of analysis, and requirements for M&E Plan reporting. He said he and Todd Seamons are still trying to find samples for fall Chinook salmon in the Hanford reach so the stock can be added to the timeline. He said he is still working with Keely Murdoch and CRITFC to acquire more samples for analysis from the Priest Rapids stock. He said WDFW and CRITFC have a growing and positive relationship, which will help in coordinating these genetic analyses. He said developing single nucleotide polymorphism (SNP) panels for analysis incurs an upfront cost and exploratory work, but analyzing a sample using SNPs is relatively inexpensive once a panel has been developed. Many SNPs for these stocks are already established. He said CRITFC, for example, has been doing genetic work related to Lake Cle Elum and can differentiate between Okanagan and Wenatchee sockeye salmon. Tom Kahler added that University of British Columbia researchers have also been working on Okanagan sockeye salmon SNP panels, and similarly, researchers at the Department of Fisheries and Oceans (Canada) have a microsatellite panel for Okanagan sockeye salmon.

Johnson said samples for most of these analyses are collected annually, and the WDFW genetics lab recommends performing analyses on 2 years of samples to increase the robustness of the sample dataset. Mike Tonseth added that the Hatchery Committees still need to discuss whether to vary analysis intervals based on listing status or another factor, and whether to synch analysis years for species. Mackey said genetic analyses should be completed for all populations of the same species in the same year. He said, during the last discussion about this, Todd Pearsons mentioned that a power analysis could determine how large of a genetic change could be detected in a population and how rapid it may occur, which could ultimately inform analysis intervals; populations at risk or with genetic structure that could change a lot or change quickly could be analyzed more frequently (e.g., small populations). Tonseth said Twisp steelhead are an example of a population where genetic change was detected after a few years of genetic analysis, and the population is at risk due to a low effective population size. Pearsons said a power analysis could also be based on the size of programs compared to the size of their receiving natural population; one would expect to see genetic differences occur more quickly in small populations.

Johnson said, historically, samples were analyzed using microsatellite panels, and samples can be reanalyzed with SNP panels. Tonseth said a baseline period for each program needs to be determined, because hatchery programs change over time especially in regards to broodstock. For example, he said the Wenatchee steelhead program started in 1989 using stock from Wells Fish Hatchery, and transitioned to locally adapted broodstock in 1998, so the baseline could be set at 1998. This needs to be discussed and agreed to for each program and can determine whether old samples need to be reanalyzed with SNP panels.

Todd Seamons joined the meeting via phone, and asked about the purpose of genetic monitoring for HCP program species. Catherine Willard said the purpose, as described in the M&E Plan for PUD Hatchery Programs, is to determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program. Seamons asked what the consequences are to hatchery operations if genetics are found to be changing. Tonseth said it could change the program, for example, a program might have to be segregated rather than integrated. Seamons said analysis intervals can be determined by how much change is acceptable before the genetics "problem" is identified and addressed. He said, after one generation, changes are unlikely to be identified; after two generations, there may be an identifiable trend; and after three generations (likely longer than 10 years), the problem is likely identifiable but at this point, the problem has been compounding for three generations and will be harder to fix. Pearsons said the acceptable risk of genetic change, and therefore the time between analysis intervals, is partially determined by how at-risk the population is. He said a small program might warrant more frequent analysis than a large program because a small program has greater potential for rapid and substantial genetic change—a power analysis can help determine the potential for effects and level of change for each program. Seamons used the Twisp steelhead program as an example of intensive sampling (due to the relative reproductive success study), where a problem has been identified with analysis intervals capturing only one generation (due to the fact that a parentage study has been underway for eight years), a problem which may not have been detected using the diversity statistics other programs use at broader time intervals. The opportunity to address problems after only one generation comes from a different (more intense) level of analysis.

Bill Gale said the USFWS is interested in synching sampling and analysis intervals with the HCP program species timeline. He said the spring Chinook salmon safety-net program at Winthrop NFH could be synched with the Methow spring Chinook salmon analysis. For steelhead, safety-net releases from the Methow Fish Hatchery could also be included in these analyses. USFWS collects summer Chinook salmon in the Entiat River, which could be coordinated with the HCP program analyses. He said the timeline can be modified to include USFWS sampling and analysis, and USFWS can perform analyses at Abernathy Fish Technology Center, or help fund analyses. Seamons said the WDFW genetics lab and Abernathy Fish Technology Center work together frequently, and coordinating those analyses would not be a problem. Gale said he would send a report about genetic analysis of summer Chinook salmon in the Entiat River to Johnson. (*Note: Montgomery distributed the USFWS report, "Summer Chinook Salmon in the Entiat River: Genetic Analysis of*

Hatchery and Natural Origin Adults Spawning in the Wild" to the Hatchery Committees on January 18, 2017.)

Hillman summarized the Hatchery Committees feedback for Johnson regarding the Draft Genetic Sampling Timeline and discussions regarding genetic sampling intervals for HCP program species: 1) perform genetic analyses for all stocks of spring Chinook salmon in the same year (i.e. 2018); 2) add USFWS programs to the timeline; 3) work with the WDFW genetics lab on a power analysis to determine recommended analysis frequency; and 4) determine a baseline period for each analysis.

Seamons said he and the WDFW genetics lab are very busy, but could likely work with Johnson to perform the power analysis in the next 6 months. Mackey asked if there are any new genetic techniques that might replace using SNP panels. Seamons said he does not imagine that anything would replace the use of SNP panels. He said the way SNP genotypes are obtained or the analysis methods could change, but an entirely different marker type being developed is unlikely at this point. Mackey mentioned Hatchery Committees parties are considering reanalyzing older samples with SNP panels that were initially analyzed with microsatellite panels, but if another technique were on the horizon, it would affect that decision. Seamons said detection power is affected by the number of markers used in the analysis, and more and more markers are being developed. For example, a sample could be reanalyzed with a SNP panel with 296 markers (e.g., CRITFC's steelhead panel), but if more markers are added to the panel for a total of 500 markers, the sample could be reanalyzed again with increased statistical power. He said parties should consider whether the benefit of added statistical power is worth the cost. He said WDFW intends to have SNP panels with many markers, and use the same panels as CRITFC, which also adds loci regularly to their panels.

F. Stray Rate Targets (Todd Pearsons)

Todd Pearsons shared a presentation titled, "Stray Rate Targets," which Sarah Montgomery distributed to the Hatchery Committees on January 18, 2017, following the meeting (Attachment H). He said he also distributed a paper by Ford et al. (2015)[2] after the Hatchery Committees last discussed stray rates in October 2016, which Montgomery distributed to the Hatchery Committees on October 20, 2016. He said this discussion focuses on the 5% brood year stray rate target (Question 6.1.1 in the Hatchery M&E Plan), and he has been trying to determine the origin of the target but has not received an explicit answer about how the 5% target was determined even after

---

[2] Ford, M.J., A. Murdoch, and M. Hughes, 2015. Using parentage analysis to estimate rates of straying and homing in Chinook salmon (*Oncorhynchus tshawytscha*). Molecular Ecology 24, 1109-1121. Doi: 10.1111/mec.13091

querying a number of scientists that were involved in the fundamental development of recovery plan guidelines. Monitoring Question 6.1.1 of the M&E Plan is: "Is the stray rate of hatchery fish less than 5% for the total brood return?" Pearsons said if natural stray rates are determined to be higher than 5%, it would be unexpected for hatchery-origin fish in the same basin to meet the 5% target; hence, natural stray rates can be used to inform targets.

He summarized many factors that can influence straying such as: imprinting quality; origin (hatchery vs. natural); species, stock or tributary; spawning habitat quality; access, including temperature, flow, and barriers; spawning density; dendricity; and geography. He said only some of these factors are affected by or under the control of hatchery programs. He said Ford et al. estimated natural-origin stray rates for the Chiwawa River, Little Wenatchee River, Nason Creek, the White River, and the Upper Wenatchee River, some of which exceeded 5% and approached 100% in one case. He said Ford et al. demonstrated that stray rates of natural origin fish are higher than previously thought (especially in the Little Wenatchee and Upper Wenatchee rivers), stray rates vary by tributary and generation/origin, and non-hatchery factors influence stray rates (e.g. tributary, habitat). Pearsons said, for example, the upper Wenatchee River does not have high-quality habitat, so it would make sense that stray rates are higher in that location.

Pearsons said imprinting is just one of many factors affecting stray rates. He said the hatchery experience appears to affect fish even when they are imprinted in the natural environment, and some factors are outside the purview of programs. He said he thinks the brood-year stray rate target for spring Chinook salmon is unrealistically low. He said data suggesting salmon imprinted in natural environments have varying stray rates that can be above 5% are not unique—an old study in California showed coho stray rates far exceeding 5% (cf. Quinn 2005[3]).

Pearsons identified one possible target refinement as adding together the possible sources of stray rates (i.e., the stray rate of natural origin fish from hatchery parentage + a stray rate addition as a result of the hatchery experience + a stray rate addition from poor habitat, high density, and other non-imprinting factors). He said fish are not controlled in their selection of a spawning site solely by imprinting, so targets related to the distribution of fish spawning should be realistic and consider the other factors affecting where a fish decides to spawn.

---

[3] Quinn, Thomas P. *The Behavior and Ecology of Pacific Salmon and Trout*. American Fisheries Society, Bethesda (Maryland), in association with University of Washington Press, Seattle (Washington), 2005.

Tracy Hillman said he discussed this with Michelle McClure (NMFS) and she provided the following thoughts:

- The Technical Recovery Team (TRT) used some expert opinion in the selection of the 5% and 10% stray rate targets. (Note: the 5% and 10% stray rates apply to the recipient spawning aggregates.) The basic idea was to have the numbers in the flow chart/graph combo be congruent with the previous criterion for genetic integrity. In other words, how much introgression from non-evolutionarily significant unit (ESU) fish would produce impairment to the natural genetic structure of the population? Ultimately, disrupting population structure affects extinction risk, but not quite in the quantifiable way that abundance and productivity can.

She also added the following thoughts:

1. The TRT criteria cannot be formally changed at this point without (probably) a committee forming to review new information.
2. That said, the TRT was very explicit that things should be considered on a case-by-case basis, and the addition of new empirical information would certainly be a factor that should go into that case-by-case consideration. This is part of the reason why guidelines were provided with many disclaimers about making informed judgments based on the situation at hand; the TRT knew that there would be more information, situations would change, and so forth.
3. One word of caution, though, for the Upper Columbia, is that the genetic stock structure of the entire basin is incredibly altered (and basically homogeneous). To the extent that natal fidelity is genetically influenced (and we know that it has some elements of genetic influence and a good deal of environmental), the straying we're seeing empirically might be a result of previous anthropogenic activities (like mixing them all up).
4. It would be important to also include in the review of new empirical information other studies since the TRT guidelines on straying. She recalled one study on the Olympic peninsula, where researchers found that spawners were more closely related to individuals within a 50-yard radius (approximate distance) of their redd than individuals outside that area.

Pearsons said TRT criteria are unlikely to be changed without an entire committee forming to review new information, but empirical information should be a factor in a case-by-case assessment for PUD programs (particularly related to a BY stray target). He said, for the upper Columbia basin, the contemporary genetic stock structure is unnatural, and because natal fidelity is genetically influenced, stray rates could be a result of anthropogenic activities. He said there is flexibility in the case-by-case basis, but that might be decided by the National Oceanic and Atmospheric Administration, especially if the recovery plan needs to be modified or if they need to write a letter describing the different stray rates and supporting data. Casey Baldwin (CCT) pointed out that the spatial aspect of stray rates needs to be considered and identified up-front. He said the initial criteria in the M&E Plan is straying between populations, and Pearsons' example using the Wenatchee basin is a within-population stray, and it is important to consider if strays are from outside the ESU. He said it should be identified whether the stray rate is for within-population strays, between-population strays, or out-of-ESU strays. Hillman asked if the TRT developed criteria for brood year return. Baldwin said the TRT did not have a set criteria for brood-year stray rates (Question 6.1.1). He said what matters more than brood year return is the spawner composition—the sum of strays to a population, not just the sum of strays from one program in the receiving population. Pearsons said he wants to focus this discussion on brood year stray rates. Hillman said brood year stray rate targets and Question 6.1.1 have implications for Questions 6.1.2 and 6.1.3. Pearsons said, if there are many issues in addition to imprinting, a 5% target will probably not be met in some cases no matter how much the program is shifted and tweaked. Baldwin suggested that weighting natural-origin stray rates based on abundance of natural origin fish could decrease stray rates in each spawning aggregate.

Tonseth requested that Pearsons write a white paper about factors affecting the brood year stray rates of hatchery fish, and considerations for revising stray rate targets. Pearsons agreed and asked the representatives present to please contact him if they find any information on the sources of the brood year stray rate targets set in the M&E Plan.

G. Spring Chinook Salmon Outplanting in the Chewuch River (Catherine Willard/All)

Catherine Willard said a subgroup of Hatchery Committees members met on January 9, 2017, and made progress on a plan for outplanting adult spring Chinook salmon (MetComp) in the Chewuch River. She said several data gaps were identified, and participants are working on follow-up tasks. Willard said this will be discussed in more detail at the February 15, 2017, Hatchery Committees meeting.

H. Expanded Sampling at the OLAFT (Mike Tonseth)

Mike Tonseth said he plans to discuss expanded sampling at the OLAFT at Priest Rapids Dam with the Hatchery Committees at the February 15, 2017, meeting, and will follow up with an email describing the sampling before the next meeting.

V. HCP Administration

A. Representative Changes and Distribution Lists (Tracy Hillman)

Tracy Hillman welcomed Brett Farman (NMFS representative) and Casey Baldwin (CCT alternate) to the Hatchery Committees, and said Charlene Hurst has also been designated as the NMFS alternate.

Hillman said these changes in representation are described in letters distributed by Sarah Montgomery on December 23, 2016 (for Baldwin), and January 6, 2017 (for Farman and Hurst).

Hillman reminded the Hatchery Committees that HCP Parties designate representatives and alternates as they see fit, with no approval required from the Coordinating or Hatchery Committees. Representatives and alternates are automatically provided access to email distribution lists and the HCP Extranet Site. Hillman reminded the Hatchery Committees that Coordinating Committees review and approval is, however, required to provide non-HCP representatives/alternates access to HCP Extranet Sites and email distribution lists.

B. Letters to HCP Non-Signatories (Tracy Hillman)

Tracy Hillman said the HCP Coordinating Committees Chairperson (currently John Ferguson) sends a letter each year on behalf of the Parties to the Wells, Rocky Reach, and Rock Island HCPs to the HCP Non-signatory parties (American Rivers and the Confederated Tribes of the Umatilla Indian Reservation) offering to meet, discuss progress, and answer questions. Hillman said Ferguson sent the letters on January 4, 2017, and if a positive response is received, Hillman and Ferguson will set up a workshop that includes representatives from the Coordinating, Hatchery, and Tributary committees.

C. Back-to-back Meetings with the PRCC HSC (Sarah Montgomery)

Sarah Montgomery summarized that the Hatchery Committees discussed back-to-back meetings with the PRCC HSC as a joint item during the PRCC HSC November 17, 2016, meeting. Hatchery Committees representatives present agreed that they will hold back-to-back meetings with the PRCC HSC at Grant PUD's Wenatchee, Washington, office, with the HCP Hatchery Committees meeting from 9 a.m. to as late as 12:30 p.m., unless prevented by lengthy agenda items or logistical constraints. Montgomery said that agreement is summarized in these meeting minutes for clarity.

D. Next Meetings

The next Hatchery Committees meetings are February 15, 2017 (Grant PUD), March 15, 2017 (Grant PUD), and April 19, 2017 (Grant PUD).

Summary

We propose to monitor in-situ steelhead egg-to-fry survival at 12 locations in the Twisp River using gametes from hatchery steelhead and using methods similar to what have been used for spring Chinook salmon in the Twisp and other rivers. The overall goal is to provide estimates of egg-to-fry survival within the Twisp River throughout the range of steelhead spawning, complementing studies being done on other steelhead life stages. In addition, we will examine how survival varies across habitat conditions (location, fine sediment, scour, substrate size) at different locations. The methods will include the construction of three artificial redds at each location, constructing redds of uniform size and dimension, collection of gametes from hatchery fish, placing 100 fertilized eggs in modified Whitlock-Vibert boxes with native spawning gravel (from site), placing egg boxes in constructed redds, burying them, and recovering the boxes and fry after predicted hatching and emergence. The modified Whitlock-Vibert boxes prevent fry from escaping and all alevins of fry will be destroyed on completion of the study. **To conduct the study, we are requesting gametes from three female and three male Twisp River hatchery steelhead from the Methow Hatchery.**

Background

Survival from spawning to parr-stage is thought to limit many salmon (*Oncorhynchus sp*p.) and steelhead (*O. mykiss*) populations particularly those in the interior Columbia River basin (Johnson et al. 2012; Roni et al. 2016). Unfortunately, most of the modeling efforts that point to egg-to-fry survival as limiting factor have used data from laboratory studies or data from a handful of natural redds (e.g., Karieva et al.

2000; Honea et al. 2009; Roni et al. 2016). Egg-to-fry survival in particular is thought to be a critical life stage and only recently have large-studies been conducted to examine the variation in survival in the natural environment for Chinook and coho (e.g. Johnson et al. 2012; De Boer et al. unpublished). In addition, egg-to-fry survival is particularly sensitive to changes in habitat conditions such as fine sediment, scour and temperature (Chapman et a. 1988; Devries 1997). Beginning in 2009, we studied egg-to-fry survival for Chinook salmon in the Yakima (2009 to 2013), Wenatchee (2010 to 2017) and Twisp (2014 to 2015) rivers. We developed efficient and effective techniques for estimating egg-to-fry survival at multiple locations throughout a watershed that can be applied to other species. While we have considerable data on Chinook salmon and some data on coho salmon, almost no data exist on egg-to-fry survival in the natural environment for steelhead. Thus, using methods similar to those we developed for Chinook salmon, we propose to conduct a pilot study to estimate egg-to-fry survival for Steelhead in the Twisp River.

Goals and Objectives

The overall goal of this study is to provide reasonable estimates of egg-to-fry survival for Twisp River steelhead and complement ongoing fall-parr abundance and smolt-production estimates, spawning ground surveys, and companion studies of relative reproductive success, to identify factors limiting the reproductive success of Twisp River steelhead. Successful implementation of this study, in combination with those other ongoing investigations in the Twisp River, will leave only the fry-to-parr stage of the steelhead life-cycle without a survival estimate.

More specifically our objectives are to:

1) Provide reliable estimates of Twisp River steelhead egg-to-fry survival using modified methods used for Chinook and coho2) Estimate Twisp River steelhead egg-to-fry survival under a variety of habitat conditions by sampling twelve sites throughout the known spawning distribution of Twisp River steelhead

3) Examine relationship between key habitat variables (fines, substrate size, and temperature) and steelhead survival

4) Estimate egg-to-fry survival at existing Columbia Habitat Monitoring Program (CHaMP) sites to examine effects of meso and micro habitat conditions on survival

Methods

Steelhead egg-to-fry survival would be measured at twelve sites throughout the range of spawning steelhead in the Twisp River drainage. Specific locations of sites will be determined based on existing spawning, access, and known locations of CHaMP sites (Figure 1). We will also examine whether sampling can occur at any of the 12 locations used previously for spring Chinook salmon egg-to-fry study; many of these locations are also used by steelhead, and we have existing agreements with land owners for access.

A total of three redds would be constructed at each site, using the gametes from three unique male-female pairs**.** Tracking survival of individual crosses is important as previous studies on Chinook have shown a strong parentage effect (Johnson et al. 2012; Roni et al. 2016). The detailed methods would follow those of Johnson et al. (2012), which include constructing redds of uniform size and dimension, collection of gametes from hatchery fish, placing 100 fertilized eggs in modified Whitlock-Vibert boxes with native spawning gravel (from site), placing egg boxes in constructed redds and burying them. Whitlock-Vibert boxes have a long history of use in incubation and fine sediment intrusion studies (Wesche et al. 1989; Johnson et al. 2012; Roni et al. 2016). Modification of Whitlock-Vibert boxes includes placing fine mesh screen to prevent alevins and fry from escaping, removal of the top tray, addition of native gravels (from sites) and addition of a PIT tag in the box to assist in locating redds for recovery.

Egg boxes will then be recovered at the stage where 50% of the fry would be expected to swim up from gravel (typically 700 to 900 temperature units depending upon the species). Temperature loggers will be deployed at each of 12 study sites to monitor the accumulation of thermal units and determine exact date of recovery. **Because we will place 100 eggs in each egg box, approximately 1500 eggs would be needed from each of three females and approximately 4 ml of milt would be needed from each of three males.** Artificial redd locations will be identified by triangulation from the bank and through the use of a hand held PIT tag detector. The redds will then be excavated, the egg box delicately removed to minimize loss of fine sediment and transported to the bank in a small tub of water to enumerate survivors and dead eggs or fry and the total number of days between stocking of eggs and redd excavation recorded (see Johnson et al. 2012 for detailed description of methods). Surviving fry will be transported live to the lab where length to the nearest millimeter and wet-weight to the nearest milligram will be measured on each individual. Developmental indices (kD) will be calculated for each of the surviving fry based on Bams (1970).

Microhabitat data assessed at each site will include substrate size (D16, D50, D84, % fines) based on Wolman pebble counts (Wolman 1954), scour based on chains at each redd (Nawa and Frisell 1993; Johnson et al. 2012), and fine sediment infiltration. Fine sediment infiltration (percent fines) into artificial redds will be estimated from the egg boxes following excavation of artificial redds (Johnson et al. 2012). In addition, where possible, sites will be located within reaches currently monitored as part of CHaMP, which will provide additional information about meso habitat conditions within study sites/reaches.

Data analysis

To demonstrate the range of steelhead egg-to-fry survival in the Twisp, initial analysis will include basic *summary* statistics (mean, standard error of mean) by sites and cross (male-female pair). To specifically examine the influence of site and mating on survival and developmental stage, we will use an Analysis of variance (ANOVA) with both site and cross (male-female pairs or parentage) as fixed factors in the model. Tukey multiple comparisons will be used to determine differences between pairs of reaches and crosses. An ANOVA will also be used to compare physical variables (percent fines, D_{50}, D_{84},

D_{16}, days in gravel, scour) among reaches. We will use regression to examine relationships between physical variables and egg-to-fry survival. Because we will have survival data from twelve sites spread across the basin, we can also use spatial statistical and analysis tools developed by Ver Hoef et al. (2014) and Peterson et al. (2014) to interpolate and map steelhead egg-to-fry survival throughout the study area.

Expected Results and Potential Challenges

Based on results of previous studies we've conducted on Chinook in the Twisp, Yakima and Wenatchee as well as with coho in the Yakima, we expect to find differences in both egg-to-fry survival, fry developmental indices, and condition among locations in the Twisp as well as among crosses (male-female pairs). Depending upon the differences in fine sediment, scour, and spawning substrate among sites there may be correlations between survival and fine sediment, scour, and other physical variables.

We have used this method at nearly 100 redds per year for more than 5 years particularly for Chinook salmon, but this will be the first time for steelhead. Thus the first year of this study is a pilot to confirm the feasibility of the methods for steelhead and make any necessary modifications to protocols used for Chinook and coho. Most of challenges faced with Chinook and coho were related to unusual weather conditions and recovery egg boxes during spring flows. Thus one potential challenge could be high flows during either redd construction or recovery as steelhead spawn in the spring rather than fall. However, most steelhead appear to spawn near the channel margins and the Twisp is smaller than some other rivers we have worked in. We have had some minor vandalism (most likely curious fisherman) at a few sites on the Yakima and Wenatchee, but these were largely restricted to summer or early fall when there was heavy recreation use; we don't expect this to be a problem on the Twisp given the land ownership and time of year.

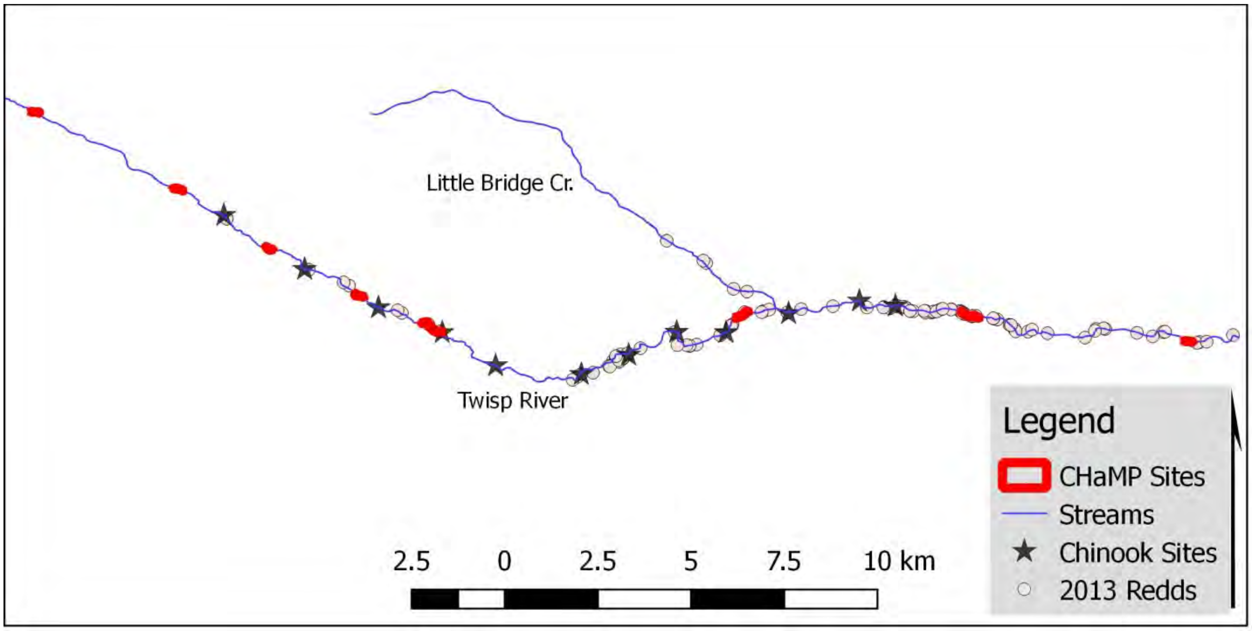

Figure 1. Map of Twisp River showing 2013 Steelhead redd, current CHaMP sites, and location of Chinook egg-to-fry study sites (2013/2014). Note that several years of spawner data are available. 2013 is presented simply for demonstration purposes and multiple years of spawning data will be used to determine final locations.

Problem statement: The current target number of Twisp River wild broodstock is low (26 fish), and variation in family survival results in few families represented as returning adults. Life history diversity also appears to be lower for the hatchery population leading to hatchery adults having fewer age classes and less overlap among cohorts. These issues combined with a pHOS target of 0.5 results in a large fraction of natural spawners originating from only a few families. The continued operation of the Twisp program using current protocols will likely result in a severe reduction of Ne (i.e., Ryman-Laikre effect), posing unacceptable long-term genetic risks.

WDFW has developed a suite of actions for consideration which range from the immediate concerns in 2017 to more long term programmatic issues associated with meeting future Section 10 Permit conditions while minimizing genetic risks and continuing to support recovery (see Tables 1 and 2 for current and proposed program structure). In addition, we have provided new and more precise estimates of run escapement into the Methow (before fishery impacts; Table 3) and spawning escapement estimates for all major tributaries (Table 4). Current redd survey data suggest mainstem spawning has been much lower than historical due to shifts in hatchery release locations. Based on PIT tag data, the majority of natural fish are spawning in tributaries. Hence, a majority of fish spawning in the mainstem are likely of hatchery origin.

In general, actions considered that could be taken to reduce the impacts of current hatchery management on Ne are:

1. Increasing the number of families produced in the hatchery and released in the Twisp River, which can be achieved by:
   a. Using Twisp NOR broodstock, but increasing the number of NOR broodstock taken at the Twisp weir
   b. Changing the source of broodstock for producing fish to be released in the Twisp River by:
      i. Combining Twisp and Winthrop NOR broodstock to create a larger composite broodstock
      ii. Releasing a mix of Twisp and Winthrop produced smolts without mixing spawners of each program
      iii. Switching to Winthrop NOR broodstock
      iv. Switching to Wells safety net broodstock
2. Reducing releases of adult hatchery fish upstream of the Twisp weir (i.e, reducing pHOS)
3. Increasing the number of families of adult hatchery fish released upstream of the Twisp weir, which can be achieved
   a. Indirectly by increasing the diversity of age at maturity of adult hatchery fish released upstream (better cohort diversity
   b. Directly by measuring relatedness among hatchery fish returning to the weir and releasing fish based on their estimated relatedness to balance familial representation

The Joint Fisheries Parties (JFP) met recently to discuss how these actions may or may not meet management objectives for the Methow sub-basin and the potential implications/benefits thereof. There is still strong interest in maintaining releases of WxW smolts into the Twisp River.

Given the genetic risks of associated with low Ne under the current program, there are both juvenile and adult actions the JFP is recommending to be implemented beginning this spring.

Immediate actions for Twisp hatchery adults returning in 2017:

Reduce Twisp hatchery escapement (pHOS) to 0.3 plus, prior to release, hold and tag hatchery fish, perform in-season near real-time genetic analysis for relationship status in order to distribute released fish among as many families and cohorts as possible.

Immediate actions for Twisp smolt releases in 2017:

Alternative 1: Release Twisp stock and an additional 13,000 WNFH smolts (this number was identified as what was available at WNFH with a unique coded wire tag that could be PIT tagged prior to release) following a volitional release at Buttermilk Bridge. *This is currently the preferred alternative.*

Alternative 2: Mix Twisp juveniles with WNFH progeny and release 48,000 mixed progeny (production target) from Buttermilk Bridge. Releases into the Twisp River and those from WNFH would both include some proportion of Twisp and WNFH-origin progeny. This alternative may not be feasible based on how the USFWS operates the two year smolt program (the Twisp is only a yearling program).

Immediate actions for broodstock collection in 2017:

- Collect the requisite 26 NO broodstock from the Twisp weir (consistent with the 2016 Broodstock Collection Protocols) and transfer to WNFH to support meeting the 110 NO broodstock requirement for the USFWS conservation program.

- Collect additional hatchery origin returns from the Twisp weir and WNFH (through hatchery returns and/or through the USFWSs hook and line broodstock collection) to produce 48K safety net fish which would be subsequently released into the lower Methow (2018 release).

Future actions for broodstock collection and smolt production and release in 2018 and beyond:

- Shift the DPUD Twisp release goal to a lower Methow safety net program. Fish would be released at the lower Burma Road bridge. Juveniles would be adequately PIT tagged to evaluate to determine distribution within the Methow sub-basin (i.e., do fish stay within the lower Methow where they can be targeted in a conservation fishery with minimal impacts to NO fish or are we likely to see these fish distribute themselves significantly upstream and in particular the tributaries). Information from this evaluation will help inform future decisions for the upper Methow safety net program, should pHOS/PNI objectives under the new permits fail to be reached under the current program structure and permit requirements).

- Release 50,000 WNFH smolts (post volitional release) upstream of the Twisp Weir (Buttermilk Bridge and other sites). Excess hatchery fish collected at the weir will be used for broodstock at MSH for safety net program.

- Reduce pHOS in the Twisp to <0.3 and Methow (< 0.5). The distribution of safety net fish could be monitoring using PIT tags and adjustments to release numbers and locations adaptively managed through time.

- In subsequent years, a mix of Twisp and WNFH adults will be allowed to spawn naturally. Excess hatchery fish would be culled or used for safety net program.

Under the new program structure, the size of the aggregate conservation program (USFWS and DPUD) would change from 248,000 to 200,000 (WNFH would house the full conservation program) with adult requirements reducing from 136 to 110. The total number of NO adults removed at the Twisp weir would go from 26 to 22 (to ensure the Twisp is not over represented, adult collection would be consistent with the proportion of NO fish spawning in the Twisp (about 20%) relative to the rest of the basin.

Table 1. 2017 brood year Steelhead Program Structure at Wells Hatchery and the Methow River sub-basin.

Program	Hatchery	Owner	Release Location	Release Target	Broodstock Collection Locations
Twisp Conservation	Methow Hatchery (incubation); Wells Hatchery (rearing)	Douglas PUD	Twisp Acclimation Pond	48,000	Twisp WxW
Methow Safety-Net	Wells Hatchery	Douglas PUD	Methow Hatchery	100,000	HxH: Twisp Weir (up to 25%) + WNFH Hatchery (75%) or WNFH 1st, MFH 2nd to make up balance

Pilot Concept to Trap Summer-Run Chinook Salmon at the Chelan River Habitat Channel Water Conveyance Canal Outlet-Results

Summary

- In an effort to identify a new summer Chinook broodstock collection site, Chelan PUD implemented a pilot in 2016 to trap adult summer Chinook salmon at the outlet structure of the water conveyance canal for the Chelan Tailrace Pump Station.
- Trapping at the Chelan Falls Canal Trap (CFCT) began August 4th, 2016 and concluded on August 10th, 2016. The trap was open for broodstock collection for four days.
- During operation of the CFCT, 51 males and 49 females were collected for broodstock. The broodstock experienced four mortalities while being held at Eastbank Hatchery resulting in 49 males and 47 females being spawned.
- Gamete Evaluation: The warm water temperatures of the Chelan River have the potential to affect the gamete quality of fish collected at the CFCT. In order to evaluate gamete quality, broodstock and subsequent gametes collected at this site were held separate at Eastbank Hatchery from broodstock collected from the Eastbank Outfall (EBO) and Entiat National Fish Hatchery (ENFH). The eye-up rate between gametes from broodstock collected at the CFCT and the EBO/ENFH were compared (Table 1).
- Zero bull trout were encountered at the trap.

Table 1. Eye-up rates for the Chelan Falls Canal Trap (CFCT), Eastbank Outfall (EBO) and Entiat National Fish Hatchery (ENFH).

Type	Eye-up rate
CFCT	93.33%
EBO/ENFH	91.05%

Hatchery M&E Reporting

Synching to Required Milestones

Todd Pearsons
Greg Mackey
Peter Graf
Catherine Willard

January 18, 2017

HCP Requirements

Element	Section	Frequency	Previous	Next
Survival Studies	8.4.4	Every 10 years	2010	2020
Recalculation	8.4.5	Every 10 years	2013	2023
M&E Plan Update	8.5	Every 5 years	2013	2018
Program Review	8.8	Every 10 years	2012	2020
Section 10 Permit	10.2.5	Every 10 years	2004	2017

Program Review

- Review hatchery evaluation program
- Review population/hatchery interaction studies
- Review if hatchery program is operating according to goals in M&E Plan
- Hatchery production
- Adult-to-smolt (in-hatchery survival standards)
- Smolt-to-adult (not actually a standard, but covered by HRR)
- Section 10 Permits

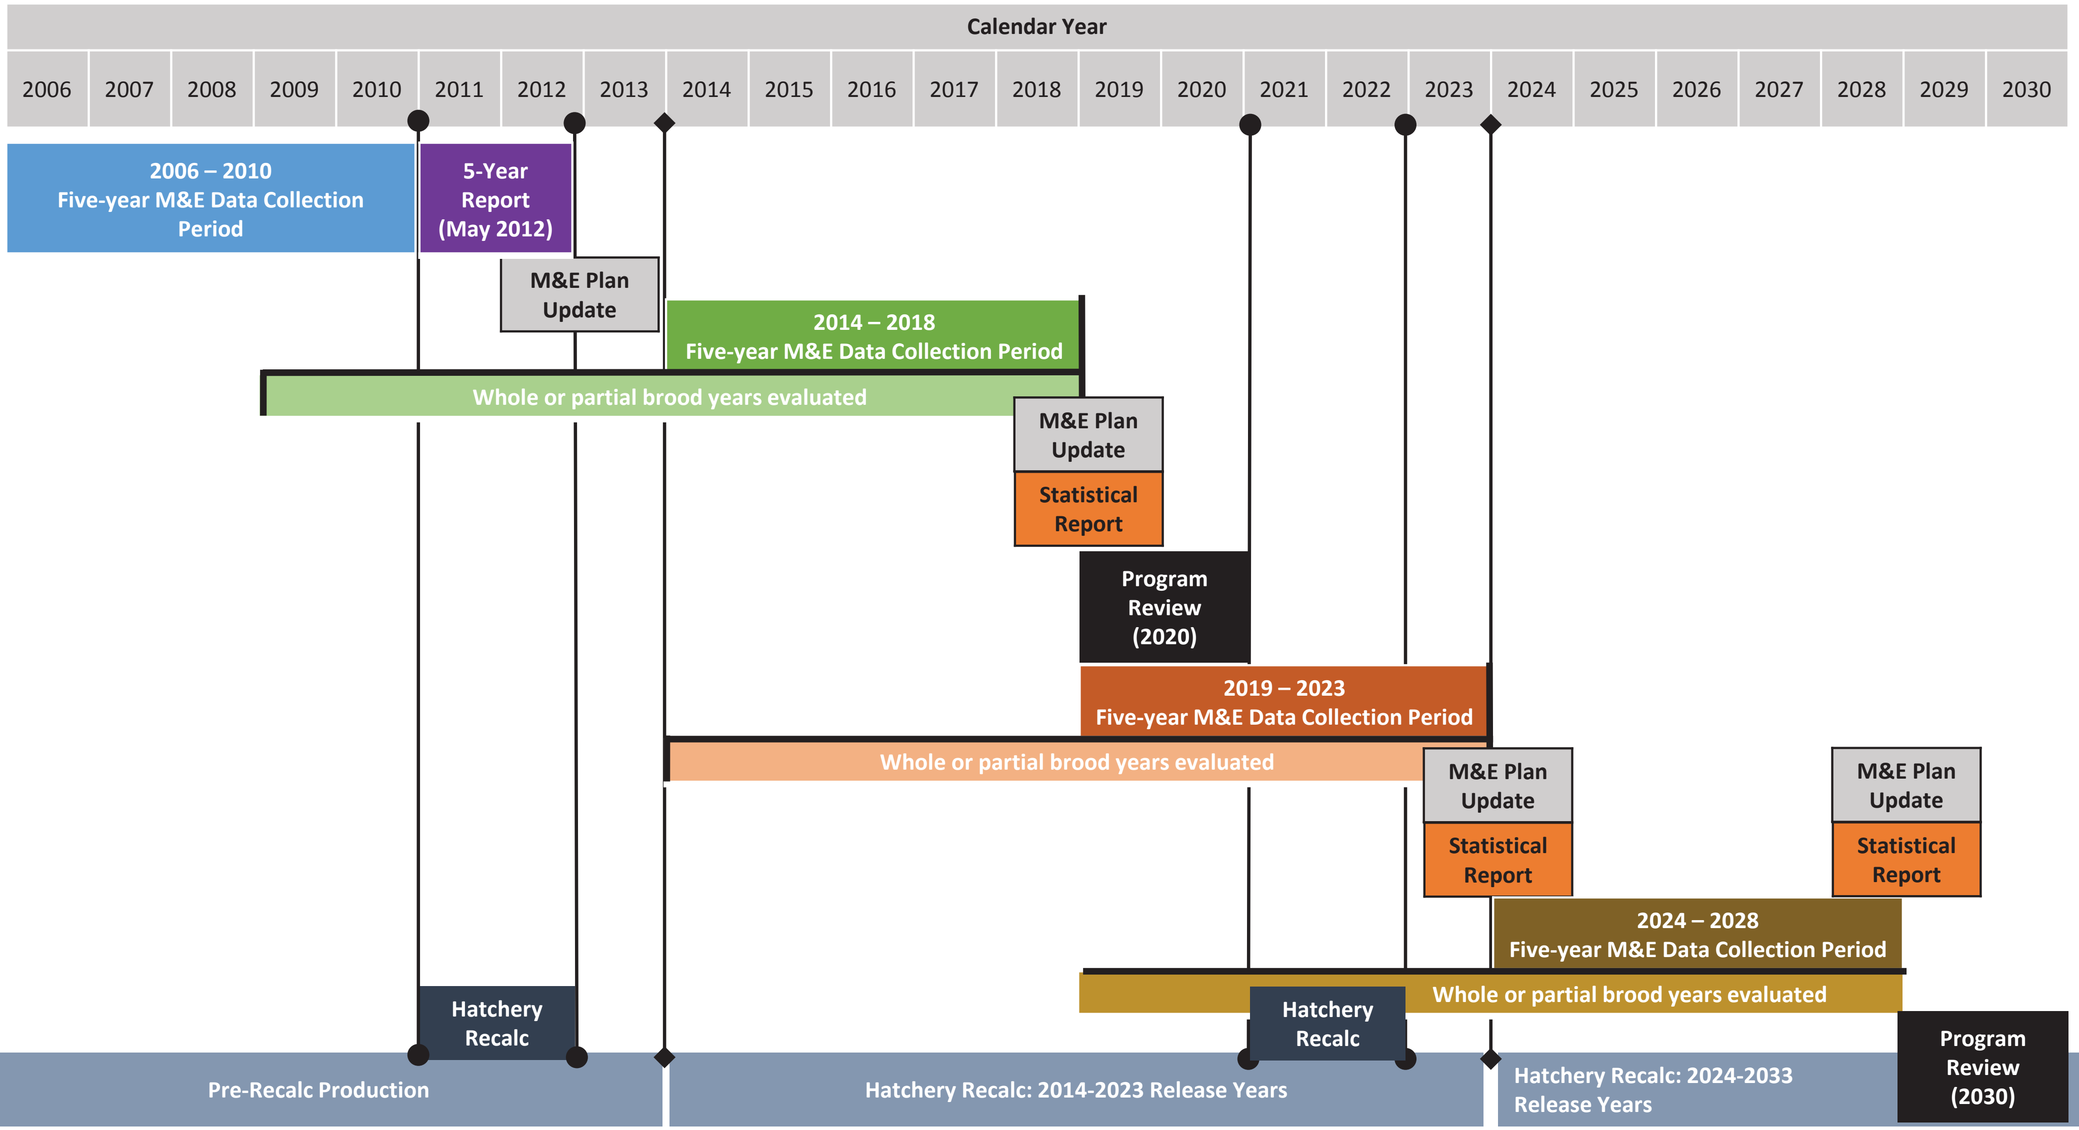
Hatchery M&E Reports

Report type	Frequency	Content	Function
Data	Annual	Cumulative description of data (raw and derived) and field methods	Informs annual M&E implementation plans
Statistical	5 year	Presentation of statistical analyses and description of statistical methods	Informs 5 year M&E plan
Program Review	10 year	Integrates and interprets information from data and statistical reports and also includes integration from other programs and studies. Written in scientific manuscript format. Fulfill "Program Review" requirements	Informs recalculation and adaptive management

Report Schedule (anchors from recalculation)

Year	Activity	Data years
2023	Hatchery recalculation	2011-2019
2022	First brood collection for hatchery recalculation (2024 release)	--
2021	Hatchery recalculation process and agreement	--
2020	Program Review	Adds 2011-2019
2018 2019	Statistical report and 5 year M&E plan review, contracting	Adds 2011-2018
2013	Statistical report, 5 year M&E plan review	Thru 2010

PUD Hatchery Monitoring and Evaluation Reporting Timeline



Species	Stock	Life Stage	Location	Last Analyses	Samples Needed	Analyses Year	Reporting
Fall Chinook	Hanford	Adult	brood, spawning ground	2010?	2019, 2020	2020	2021
Spring Chinook	Wenatchee	Adult	brood, Tumwater	2004	(in hand) 2016, 2017	2017	2018
	Entiat	Adult	brood, spawning grounds	2006	2017, 2018	2018	2019
	Methow	Adult	brood, spawning grounds	2006	2017, 2018	2018	2019
	Okanogan	Adult	none for now, spawning grounds	none	2017, 2018	2018	2019
Steelhead	Wenatchee	Adult	brood, Tumwater	2010	2017, 2018	2018	2019
	Entiat	Adult/Smolt	brood, screw trap	2010	2017, 2018	2018	2019
	Methow	Adult	brood, weir	2008	2017, 2018	2018	2019
	Okanogan	Adult/Smolt	brood, weir	none	2017, 2018	2018	2019
Sockeye	Wenatchee	Adult	spawning grounds	2007	2018, 2019	2019	2020
	Okanogan	Adult	brood, spawning grounds	none	2018, 2019	2019	2020
Summer Chinook	Wenatchee	Adult	brood, spawning grounds	2010	2019, 2020	2020	2021
	Methow	Adult	brood, spawning grounds	2010	2019, 2020	2020	2021
	Okanogan	Adult	brood, spawning grounds, weir	2010	2019, 2020	2020	2021

Stray Rate Targets

Presented to HSC/HC, 1/18/2017

Stray rates (Hillman et al. 2013)

- **Q6.1.1:** Is the stray rate of hatchery fish less than 5% for the total brood return?
- **Q6.2.1:** Do hatchery strays make up less than 5% of the spawning escapement within other non-target independent populations?
- **Q6.3.1:** Do hatchery strays make up less than 10% of the spawning aggregate within non-target spawning areas within the target population?

- *Does anyone know the origin of the 5% BY stray?*

Expectations and standards (Hillman et al. 2013)

- "When populations are not independent, straying among them does not pose a risk of genetic homogenization. In addition, stray rates of hatchery-origin fish cannot be expected to be lower than for natural-origin fish. When estimates of stray rates for natural-origin fish are available and if they exceed the 5% or 10% thresholds identified in this plan, analysis and interpretation of stray rates must take into account the concept that hatchery programs may be held to unattainable standards based on the natural stray rate."

Factors that influence straying

- Imprinting quality (Dittman et al. 2015)
- Origin (e.g., hatchery or natural, Ford et al. 2015)
- Species, stock or tributary (Shapovalov and Taft 1954, Keefer and Caudill 2012, Ford et al. 2015)
- Spawning habitat quality (Cram et al. 2013, Ford et al. 2015)
- Access (water temperature, flow, barriers) (Bugert 1998, Dittman et al. 2010, Cram et al. 2013)
- Spawning Density (e.g., competition, pheromones; Keefer and Caudill 2012, Quinn 2005)
- Dendricity (e.g., choices, opportunities)
- Geography (e.g., distance, configuration)

Data from Tables 2 and 4, Ford et al. (2015) (*small differences in results from tables 2 and 4)

Origin	Stray rate (%, 2 and 4)
Chiwawa	4%, 3%
Little Wenatchee	18%, 17%
Nason	9%, 9%
White	1%, 5%
Upper Wenatchee	100%

Relevant points from Ford et al. 2015

- Stray rates of natural origin fish are higher than previously thought (up to 100%)
- Stray rates varied by tributary (LW>N>W>C) and generation/origin (H1>H2>NW)
- Non-hatchery factors can influence stray rates (e.g., tributary, habitat)

Considerations

1. Imprinting is one of many factors that influence straying
2. The hatchery experience appears to do something to increase straying, even when fish are imprinted in the natural environment
3. Some factors that influence straying are outside the purview of hatchery programs
4. Stray rates of spring Chinook that were produced in the natural environment (i.e., correct imprinting) ranged from 1-100%
5. BY stray rate target is unrealistically low (5%) and other stray targets may not always be achievable if program size is sufficiently high
6. The stray rate target should be revised to incorporate new information

Possible BY stray target refinement

- Target = (stray rate of natural origin fish from hatchery parentage) + (stray rate addition as a result of hatchery experience) + (stray rate addition from poor habitat, high density, and other non-imprinting factors)

FINAL

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Hatchery Committees

Date: March 13, 2017

From: Tracy Hillman, HCP Hatchery Committees Chairman

cc: Sarah Montgomery, Anchor QEA, LLC

Re: Final Minutes of the February 15, 2017, HCP Hatchery Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Hatchery Committees meeting was held at the Grant PUD office in Wenatchee, Washington, on Wednesday, February 15, 2017, from 9:00 a.m. to 12:30 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- McLain Johnson (Washington State Department of Fish and Wildlife [WDFW]) will revise the timeline for conducting genetic analysis for HCP program species by incorporating suggestions provided during the Hatchery Committees January 18, 2017, meeting (Item I-A). *(Note: This item is ongoing.)*
- McLain Johnson and WDFW geneticists will perform a power analysis to inform genetic analysis intervals and intensity for HCP program species (Item I-A). *(Note: this item is ongoing.)*
- Sarah Montgomery and Tracy Hillman will renumber the Hatchery Monitoring and Evaluation (M&E) Plan appendices and append them to the Hatchery M&E Plan (Item I-A). *(Note: this item is ongoing.)*
- Sarah Montgomery will add a summary table to the draft summary of the 5-Year Hatchery M&E Review process (Item I-A). *(Note: this item is complete.)*
- Greg Mackey will distribute a link to Scott Blankenship's (Cramer Fish Sciences) blog (Item III-B). *(Note: Mackey sent a paper and tool by Blankenship on the Ryman-Laikre effect to Montgomery on March 3, 2017, which she distributed to the Hatchery Committees that same day.)*
- Brett Farman will check on the status of Methow spring Chinook salmon permits and the timeline for Methow steelhead consultation (Item IV-B).
- Catherine Willard will look into other potential release locations in the Chewuch River, particularly upstream, for the spring Chinook salmon outplanting study (Item IV-D).
- The Hatchery Committees will review the draft study plan, "Outplanting Surplus Methow Composite Spring Chinook Salmon Adults to Increase Natural Production in the Chewuch River," and provide comments to Catherine Willard by March 8, 2017. Sarah Montgomery

distributed the draft outplanting plan to the Hatchery Committees on February 14, 2017 (Item IV-D). *(Note: This item is complete.)*

- Greg Mackey will coordinate with Chelan and Grant PUDs to revise the proposed Hatchery M&E Reporting Timeline, which Sarah Montgomery distributed to the Hatchery Committees on February 13, 2017 (Item IV-E). *(Note: Mackey sent a revised M&E Reporting Timeline to Montgomery on March 2, 2017, which Montgomery distributed to the Hatchery Committees for review that same day.)*
- Tracy Hillman will discuss with WDFW and Yakama Nation (YN) the level of effort involved in adding statistical analyses to the annual M&E reports for PUD programs (Item IV-E).
- Andrew Murdoch (WDFW) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item IV-F).

Decision Summary

- The Rock Island and Rocky Reach Hatchery Committees representatives present approved the hatchery portion of Chelan PUD's 2017 HCP Action Plan as follows: Chelan PUD, U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NMFS), WDFW, Colville Confederated Tribes (CCT), and YN approved on February 15, 2017 (Item II-A). *(Note: this is also a decision item at the HCP Coordinating Committees meeting on February 22, 2017.)*

Agreements

- The Hatchery Committees agreed to reschedule the March 15, 2017, meeting to March 13, 2017, starting at 1 p.m. (Item V-A).

Review Items

- Sarah Montgomery sent an email to the Hatchery Committees on February 23, 2017, notifying them that Douglas PUD's draft 2017 Wells HCP Action Plan is available for review, with approval requested at the March 13, 2017, Hatchery Committees meeting.
- Sarah Montgomery sent an email to the Hatchery Committees on March 3, 2017, notifying them that the draft 2017 Broodstock Collection Protocols are available for review and discussion at the March 13, 2017, Hatchery Committees meeting. Mike Tonseth requests comments by March 16, 2017.
- Sarah Montgomery sent an email to the Hatchery Committees on March 3, 2017, notifying them that Chelan PUD's draft 2017 Steelhead Release Plan is available for review and discussion at the March 13, 2017, Hatchery Committees meeting, with approval requested by March 16, 2017. *(Note: a revised version of the draft plan was distributed on March 6, 2017.)*

- Sarah Montgomery sent an email to the Hatchery Committees on March 3, 2017, notifying them that Douglas PUD's draft Wells HCP SOA, "Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs" is available for review and discussion at the March 13, 2017, Hatchery Committees meeting, with approval requested by March 17, 2017. *(Note: the SOA and the M&E Reporting Timeline are separate documents; the draft timeline was distributed by Montgomery on March 2, 2017.)*
- Sarah Montgomery sent an email to the Hatchery Committees on March 8, 2017, notifying them that Chelan PUD's draft Rocky Reach and Rock Island HCP SOA, "Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD, and Chelan PUD Hatchery Programs" is available for review and discussion at the March 13, 2017, Hatchery Committees meeting, with approval requested by March 21, 2017. *(Note: the SOA and the M&E Reporting Timeline are separate documents; the draft timeline was distributed by Montgomery on March 2, 2017. Also note the Rocky Reach and Rock Island HCP SOA is a separate SOA from the Wells HCP SOA, though the content is similar.)*

Finalized Documents

- No documents have been finalized recently.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the January 18, 2017, Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the Hatchery Committees and asked for any additions or changes to the agenda. The following revisions were requested:

- Sarah Montgomery added the draft Hatchery M&E Reporting Schedule and draft statement of agreement (SOA).
- Greg Mackey added an update on the Twisp River steelhead egg-to-fry survival study.
- Mackey also added a discussion on Twisp River steelhead broodstock.
- Casey Baldwin removed the Similkameen summer Chinook salmon stray rates discussion.

The Hatchery Committees reviewed the revised draft January 18, 2017, meeting minutes. Sarah Montgomery said there are several outstanding comments to be discussed, which the Hatchery Committees reviewed and addressed. Hatchery Committees representatives present approved the draft January 18, 2017, meeting minutes, as revised.

Action items from the Hatchery Committees meeting on January 18, 2017, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meeting on January 18, 2017)*:

- *Sarah Montgomery and Tracy Hillman will renumber the Hatchery Monitoring and Evaluation (M&E) Plan appendices and append them to the Hatchery M&E Plan (Item I-A).*
  This item is ongoing.
- *Sarah Montgomery will add a summary table to the draft summary of the 5-Year Hatchery M&E Review process (Item I-A).*
  This item is ongoing.
- *Keely Murdoch will research who is leading the Columbia River Inter-Tribal Fish Commission's (CRITFC's) parentage-based tagging effort in order to coordinate with Mclain Johnson (Washington Department of Fish and Wildlife [WDFW]) about genetic sampling (Item IV-E).*
  Murdoch said this item is complete.
- *Justin Yeager and Brett Farman will discuss internally the Douglas PUD Twisp gamete request and provide National Marine Fisheries Services' (NMFS') vote to the Hatchery Committees (Item II-A).*
  Tracy Hillman said Farman provided NMFS approval on January 27, 2017.
- *Douglas PUD will review WDFW's white paper, "Twisp Steelhead Hatchery Broodstock Issues," which Sarah Montgomery distributed to the Hatchery Committees on January 18, 2017, and provide comments to Mike Tonseth (Item II-B).*
  Greg Mackey said he provided comments to Tonseth.
- *Greg Mackey will coordinate with Chelan and Grant PUDs to develop a SOA describing the components in the proposed Hatchery M&E Reporting Timeline, which Sarah Montgomery distributed to the Hatchery Committees on January 13, 2017 (Item IV-C).*
  The revised draft Hatchery M&E Reporting Timeline and SOA were distributed to the Hatchery Committees on February 13, 2017, and both will be discussed today.
- *Hatchery Committees members will review the Upper Columbia Salmon Recovery Board (UCSRB) Draft Hatchery Report and provide edits and comments to Greer Maier (UCSRB) by January 31, 2017, and invite Maier to discuss comments in person at an upcoming Hatchery Committees meeting (Item IV-D).*
  Tracy Hillman said various members of the Hatchery Committees have provided comments to Maier and this item is complete.
- *McLain Johnson will revise the timeline for conducting genetic analysis for HCP program species incorporating suggestions provided during the Hatchery Committees January 18, 2017, meeting (Item IV-E).*
  This item is ongoing.

- *McLain Johnson and WDFW geneticists will perform a power analysis to inform genetic analysis intervals and intensity for HCP program species (Item IV-E).*
  This item is ongoing.
- *Todd Pearsons (Grant PUD) will write a white paper about factors affecting the brood year stray rates of hatchery fish and considerations for revising stray rate targets (Item IV-F).*
  Pearsons sent his paper, "Stray Rate Targets for Hatchery Programs," to Sarah Montgomery on February 6, 2017, which she distributed to the Hatchery Committees. This will be discussed today.

II. Chelan PUD

A. Decision: Chelan PUD 2017 HCP Action Plan (Catherine Willard)

Catherine Willard shared a spreadsheet titled, "Draft 2017 Rock Island and Rocky Reach HCP Action Plan," which Sarah Montgomery distributed to the Hatchery Committees on January 18, 2017 (Attachment E of January 18, 2017, meeting minutes). Willard asked if anyone had questions about the plan. She said it includes typical items such as the annual Hatchery M&E Report, annual Implementation Plan, broodstock collection, and hatchery releases, as well as pilot studies (Chelan Falls Broodstock Collection and Outplanting Adult MetComp in the Chewuch River), ongoing water quality monitoring at Dryden Acclimation Facility, working on coho salmon No Net Impact (NNI) mitigation, and permitting activities. Casey Baldwin asked if anyone raised concerns about the plan at the January 18, 2017, Hatchery Committees meeting. Tracy Hillman said there were none, and this is the same version as the one presented in January. He reminded everyone that the Hatchery Committees vote on the hatchery portion of their respective committee's draft HCP Action Plans, and the Coordinating Committees vote on approving the whole plan. The Rock Island and Rocky Reach Hatchery Committees representatives present approved the hatchery portion of Chelan PUD's 2017 HCP Action Plan as follows: Chelan PUD, USFWS, NMFS, WDFW, CCT, and YN approved on February 15, 2017.

Greg Mackey said Douglas PUD will distribute their draft 2017 HCP Action Plan for review soon.

III. Douglas PUD

A. Egg-to-Fry Survival Study in the Twisp River (Greg Mackey)

Greg Mackey said, after discussing the Twisp River Steelhead egg-to-fry survival study initially planned for 2017 with Phil Roni (Cramer Fish Sciences), Douglas PUD has decided to do an egg-to-fry survival study with spring Chinook salmon instead of steelhead. He said Douglas PUD will request approval for spring Chinook salmon gametes later in spring 2017. He said spring Chinook salmon are more of a concern for conservation and Douglas PUD still intends to work with Chelan PUD to acquire the surplus steelhead gametes they need from the Twisp River for their study. Hillman said the document that supported a steelhead egg-to-fry survival study (which Sarah Montgomery distributed to the Hatchery Committees on January 6, 2017, and was reviewed last month) noted that egg-to-fry survival for spring Chinook salmon has been extensively studied, and he asked why Douglas PUD is choosing to switch to spring Chinook salmon. Mackey said Douglas PUD will develop a more in-depth study design to get better estimates of spring Chinook salmon egg-to-fry survival than previously attained. Mike Tonseth asked if Douglas PUD would consider expanding the egg-to-fry survival study into the Methow and Chewuch rivers. Mackey said Douglas PUD is interested in expanding the study to those rivers, but they have not reached that level of detail in discussions yet.

B. Twisp Steelhead Program Broodstock Issues (Greg Mackey)

Greg Mackey said Douglas PUD reviewed WDFW's memorandum, "Twisp Steelhead Broodstock Issues" (which Sarah Montgomery distributed to the Hatchery Committees on January 18, 2017), and provided comments to WDFW. Mackey said the memorandum states that continued operation of the Twisp program would likely result in severe reduction of effective population size (i.e., Ryman-Laikre effect), and he asked that WDFW and Todd Seamons (WDFW geneticist) write up the methods and results of the analysis. Mike Tonseth said WDFW is still addressing Douglas PUD's comments on the memorandum, and will bring a more detailed document and plan back to the Hatchery Committees. Mackey said programmatic shifts are not straightforward, so the Hatchery Committees should keep in mind that any changes to the PUD or USFWS programs would result in changes to agreements about broodstock collection and adult management. Tonseth said no decisions regarding programmatic changes have been made yet, so the 2016 Broodstock Collection Protocols are still being followed. He said the draft 2017 Broodstock Collection Protocols (not yet distributed) may change in early 2017, depending on agreements within the Hatchery Committees.

Mackey said the Ryman-Laikre effect is detectable in Twisp River steelhead because parentage analyses are being performed every year, so data are available for assessing effective population size (N_e) with a sensitivity that normally would not be possible. He said other programs are likely experiencing the same effect, but it is not detectable or being investigated as intensively, and this could result in a severe reduction in effective population size because the issues continue for a longer period without detection. Tonseth said relative reproductive success studies are designed to detect changes such as effective population size, and the results and discussion of this analysis might necessitate taking a closer look at other programs. He said, for now, issues with the Twisp steelhead program are a parallel conversation with developing the draft 2017 Broodstock Collection Protocols, but if the Hatchery Committees agree to Twisp steelhead program changes, the draft 2017

Broodstock Collection Protocols will change as well. Mackey added that Scott Blankenship wrote a blog post about how hatcheries have the potential to reduce effective population size, and said he will distribute a link to the blog.

IV. Joint HCP-HC/PRCC HSC

A. USFWS Bull Trout Consultation Update (Matt Cooper)

Matt Cooper said Karl Halupka (USFWS) sent him an update on USFWS consultations, which he summarized as follows:

- The USFWS letter of concurrence regarding the Tribal Resource Management Plan developed by the CCT was signed on January 31, 2017.
- Regarding the draft Biological Opinion (BiOp) covering hatchery programs in the Wenatchee basin, Halupka plans to distribute a schedule soon for finalizing the BiOp and requests input on the draft from parties (Chelan PUD and WDFW) who have not provided comments yet.

Greg Mackey asked if the memorandum describing Halupka's gap analysis and the strategy to rely on the 2012 Wells Relicensing Bull Trout BiOp for coverage for the Methow spring Chinook salmon program was sent to NMFS. Bill Gale confirmed the memorandum was distributed to NMFS.

B. NMFS Consultation Update (Brett Farman)

Regarding the Methow spring Chinook salmon consultation, Brett Farman said the permits are in queue for signature at NMFS. After that, the permits will be distributed to the applicants for their signature and will then be finalized and distributed by email. Mike Tonseth said the applicants were expecting the permits in January 2017 and asked for a more detailed update on the timeline for permits being signed. Farman said, if NMFS does not sign the permits by February 17, 2017, he will send an email to the applicants with an updated timeline.

Regarding the Okanogan steelhead Tribal Resources Management Plan (TRMP), Farman said NMFS received public comments and will be reviewing and addressing the comments. He said Charlene Hurst can answer questions about that consultation.

Greg Mackey asked if Farman had an update from Hurst or Craig Busack (NMFS) on the Methow steelhead consultation. Mackey said Douglas PUD's last discussion with NMFS on the Methow steelhead consultation was regarding gene flow. He said, because the Methow spring Chinook salmon consultation is almost complete, Douglas PUD is wondering about the timeline for the Methow steelhead consultation. Farman said he would check on the timeline.

C. Draft 2017 Broodstock Collection Protocols (Mike Tonseth)

Mike Tonseth said the draft 2017 Broodstock Collection Protocols will be distributed for review soon. WDFW is waiting on spring Chinook salmon forecasts and predictions on ocean conditions. He said the Hatchery Committees will have approximately 2 weeks to review the protocols so Tonseth can revise them prior to further discussion at the March 13, 2017, Hatchery Committees meeting. He suggested the Hatchery Committees review the appendix about marking, because passive integrated transponder (PIT)-tagging levels tend to vary between years. Todd Pearsons said the Hatchery Committees and Priest Rapids Coordinating Committee Hatchery Sub-Committee (PRCC HSC) recently discussed steelhead marking and tagging and asked if anything related to that discussion has been incorporated into the draft protocols. Tonseth said only agreed-to changes are incorporated into the protocols. Pearsons asked if changes proposed now (e.g., differential steelhead marking) would be incorporated into the 2017 protocols or if they would have to wait until 2018. Tonseth said anything proposed can be discussed and incorporated, because the protocols are a living document and can be added to or changed. Casey Baldwin mentioned that if the Okanogan steelhead TRMP is approved, CCT might seek changes to the protocols this year. Tonseth added that the spring Chinook salmon forecasts are uncertain and the thermal blob might also affect the size of the return in 2017. He said models are currently predicting low returns, which might also change the protocols. Baldwin said run forecasts for spring Chinook salmon from the Columbia River Technical Advisory Committee (TAC) are not too bad for 2017. Tonseth said WDFW considers the TAC forecasts for other species, but does not rely on them for spring Chinook salmon.

Tonseth reminded the Hatchery Committees that in 2016, they discussed trapping constraints at Wells Dam related to broodstock collection, and the Coordinating Committees agreed trap operators at Wells Dam have the flexibility to trap spring Chinook salmon outside the protocols used to date (16 hours per day, 3 days per week) in order to achieve broodstock collection targets as prescribed in the annual Broodstock Collection Protocols. He said the new spring Chinook salmon permits will not limit the trapping days available for spring Chinook salmon at Wells Dam. He said part of the discussion at the Coordinating Committees meetings (including an SOA that was never approved) regarded potentially evaluating the size of the conservation program in the Methow basin. He said appropriate program levels for safety-net and conservation programs were previously determined for the Wenatchee basin, but not for the Methow basin, and the conservation program may not currently be the appropriate size. He said WDFW proposes an increase in trapping at Wells Dam as part of the Broodstock Collection Protocols in 2017 in order to meet the current size of the program, but he asked the Hatchery Committees to commit to determining whether the conservation program in the Methow basin is the right size. Bill Gale said the distribution of the program between conservation and safety-net is better suited to discussion by the Joint Fisheries Parties (JFP) than the Hatchery Committees, because the JFP also discuss federal programs like the Winthrop National Fish

Hatchery (NFH). He suggested the JFP make a commitment to discussing this in 2017. Tonseth said he does expect the JFP to discuss this, but the outcome of the program size discussions affect PUD programs, so it will also need to be discussed by the Hatchery Committees. Gale agreed and said it should be clarified that the JFP will perform the program size analysis and the overall program obligation will not change, but it might be proportioned into conservation and safety-net differently. Greg Mackey said although the Hatchery Committees do not have jurisdiction over federal programs, the Hatchery Committees do need to make the determination of the PUD programs size and type.. Tonseth summarized that WDFW is okay with increased trapping efforts at Wells Dam in 2017, and the level of effort for trapping in the future will be based on the outcome of the JFP and Hatchery Committees discussions about the size of the Methow spring Chinook salmon program.

Mackey said an additional concern with permit conditions under the Wells Bull Trout BiOp and increased trapping effort is that the timing for spring Chinook salmon trapping at Wells Dam is also the time of year most bull trout pass Wells Dam, so increased trapping could result in increased bull trout encounters. Gale said new spring Chinook salmon permits for the Methow program do not have detailed stipulations about trapping constraints because permit conditions default to the 2012 Wells Relicensing Bull Trout BiOp. Mackey said the 2012 Bull Trout BiOp might not have detailed stipulations about trapping periods. Gale said trapping constraints likely depend on how bull trout take is calculated. Mackey said take is calculated for different activities at Wells Dam, so it is not very straightforward. Tonseth summarized that there is still a lot of uncertainty about how the 2017 spring Chinook salmon run will form for hatchery and natural-origin fish, and the draft 2017 Broodstock Collection Protocols include a change in proposed trap operations at Wells Dam due to a shortage in collection in 2016.

Tonseth said, for the 2017 steelhead return, WDFW expects a collapse of the 2-salt return, because there was a collapse of the 1-salt return in 2016. He said, as the run develops, WDFW will be able to determine how many steelhead may be collected for broodstock and this number may need to be adjusted based on the age structure of the return. Catherine Willard asked Tonseth if the Chelan Falls broodstock collection site is included in the draft protocols, and Tonseth replied yes.

Gale said, in 2016 and previous years, USFWS has raised concerns regarding Pacific lamprey passage at Tumwater Dam. He said USFWS approved the 2016 Broodstock Collection Protocols contingent on further discussions and studies of Pacific lamprey. Willard said Chelan PUD plans to provide an update on Pacific lamprey and Tumwater Dam at the Rocky Reach Fish Forum (RRFF) March 2017 meeting. Gale asked that an update also be provided to the Hatchery Committees. Tracy Hillman asked if questions about Pacific lamprey pertain to the Hatchery Committees and said the RRFF typically addresses Pacific lamprey discussions. Gale said, from the USFWS' perspective, they are being asked to approve activities in the protocols that potentially affect Pacific lamprey passage. He said it is unclear whether the dam itself or the activities at the dam are affecting Pacific lamprey passage. Hillman said it is still not clear to him how Pacific lamprey relate to Hatchery Committees discussions, because they are not an HCP plan species. Gale said bull trout are not an HCP plan species, but they pertain to Hatchery Committees discussions. Tonseth said bull trout are unique in that they are a listed species. Gale said bull trout and Pacific lamprey are similar in that they are not plan species, and he said there is an issue with Pacific lamprey passage at Tumwater Dam and he wants to continue discussing it and working on it.

D. Spring Chinook Salmon Outplanting in the Chewuch River (Catherine Willard/All)

Catherine Willard said a subgroup of Hatchery Committees members met on January 9, 2017, and made progress on a plan for outplanting surplus adult spring Chinook salmon (MetComp) in the Chewuch River. She said several data gaps were identified and participants are working on follow-up tasks. She shared the draft plan titled, "Out-planting Surplus Methow Composite Spring Chinook Salmon Adults to Increase Natural Production in the Chewuch River – Draft," which Sarah Montgomery distributed to the Hatchery Committees on February 14, 2017 (Attachment B). She said the goal of the draft plan is to determine if outplanted surplus Chinook salmon in the Chewuch River stay in the Chewuch River and, if they do, determine their spawner success. She said Cameron Sharpe (Oregon Department of Fish and Wildlife [ODFW]) provided some advice based on ODFW outplanting in the Willamette River, namely to place fish as close to the peak spawning time as possible and put fish as high in the watershed as possible. Willard said the draft plan includes PIT tagging fish and releasing them at two locations: 1) above the upper Chewuch River PIT array, where there is easy access through the campground and good spawning habitat; and 2) at Memorial Bridge, between the PIT arrays in the Chewuch River, so travel outside of the PIT-array zone can be determined. The study will also document any outplanted fish returning to the Methow Fish Hatchery and PIT-tag detections at the Chewuch River arrays. Willard said they do not intend to place fish on occupied spawning grounds and would release them upstream or downstream in that case. She said the plan will be a decision item at the March Hatchery Committees meeting.

Greg Mackey said skewed sex ratios tend to reduce effective population size and asked why the female to male ratio is 80:20. Todd Pearsons said he recommended the 80 female to 20 male ratio as a way to maximize the number of eggs put into spawning gravel, knowing that males may mate with multiple females. He said the proposed ratio was a compromise and noted that the ratio can be adjusted depending on the sex ratio of the run-at-large. Mike Tonseth said sampling at Wells Dam will inform the expected sex ratio of the run, and if it is 75 females to 25 males or greater, the ratio can be managed. Pearsons added that literature on salmon reproduction suggests males are less successful than females in producing surviving progeny, so for a first-year investigation the risk in an 80:20 sex ratio is relatively low.

Willard asked Tonseth what the permitting approval process would be for this study. Tonseth said permits limit the number of adults and juveniles that can be released and permits determine the pHOS and proportionate natural influence (PNI) levels for programs. He said current permits acknowledge that pHOS and PNI targets in the Methow basin are difficult to meet. He said, in 2017, anticipating an overall low abundance of spring Chinook salmon in the Methow basin means that WDFW will likely be more concerned with meeting escapement objectives than PNI and pHOS objectives. Keely Murdoch said 2017 might turn out to be a good year to try this outplanting study because overall abundance is predicted to be low.

Bill Gale said the priority of actions for surplus hatchery fish returning to the Methow basin should be discussed. He said he sees the priorities as: 1) escapement; 2) broodstock for the Methow program; and 3) broodstock for the Winthrop program. Tonseth said he sees the priorities as: 1) broodstock for the conservation program; 2) WNFH safety-net production; and 3) outplanting in the Chewuch River. Pearsons challenged those priorities and said the fish targeted for use in this study are conservation program fish; therefore, this study, which contributes to natural production, should be prioritized over the safety-net program. Tonseth said the Hatchery Committees will need to consider the permits and structure of the programs before deciding how to assign surplus fish in 2017. He said counts at Wells Dam will inform the number of wild fish returning to the Methow basin. From that, they can calculate escapement, pHOS, and PNI. Mackey said there can also be a balance of priorities, with some fish used for this outplanting study and others used for broodstock for WNFH. Pearsons said the safety-net program can still be met without using surplus fish as would be used in this study. Gale said not including these fish in the safety-net program would affect the 3-population PNI value. Casey Baldwin asked where the Okanogan spring Chinook salmon program is on the priority list for surplus fish and if those fish come from Winthrop NFH. Gale said the Okanogan program uses safety-net fish that return to Winthrop NFH, so the Okanogan program would not be affected.

Baldwin said it would be helpful for Figure 1 in the proposed outplanting study to show relative spawner abundance and habitat quality in reaches of the Chewuch River and it might make sense to move the upstream release site even farther upstream because there might be even more unpopulated habitat above the most upstream release site. Willard said she will look into other potential release locations in the Chewuch River, particularly upstream, for the spring Chinook salmon outplanting study. Pearsons said ease of release is a major consideration for this study; truck access is very important at release locations so fish can go straight from the truck into the river using a tube. Baldwin said the CCT have a Whooshh system to aid with truck releases, which might be useful for this study. Willard summarized that the subgroup will revise the study and provide it to the Hatchery Committees for review prior to the March Hatchery Committees meeting.

E. M&E Report Scheduling (Greg Mackey/Catherine Willard)

Greg Mackey shared two documents, the draft "Wells HCP Hatchery Committees SOA: Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD, and Chelan PUD Hatchery Programs" (Attachment C), and the draft "Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs" (Attachment D; Sarah Montgomery distributed both documents to the Hatchery Committees on February 13, 2017). Mackey said the SOA provides background and purpose for the schedule, and the schedule itself is a separate document that describes the reporting timeline and content and function of each report. Mackey said M&E report types are summarized in Table 1. The content for the annual data report will be a cumulative presentation of data and concise description of field methods, plus any deviations in methods (though the methods themselves are in the M&E Plan). ESA permit reporting requirements will also be covered in this report. The 5-year statistical report will present statistical analyses for each M&E plan objective, descriptions of statistical methods, and explanation of violations of assumptions of statistical procedures. The 10-year Program Review will be a bigger, in-depth report written in scientific manuscript format, which integrates and interprets information, including integration of findings from other populations, programs, and studies. It will fulfill the HCP's "Program Review" requirements. Mackey said Table 2 describes the major elements of HCP processes and their time intervals. He said, among the PUDs, survival studies have the most variation in time intervals. He said Table 3 is a proposed schedule through 2024. Mackey said the purpose of the SOA is to accept this document and state that altering the timeline would require Hatchery Committees approval, and a similar SOA could be used for Grant PUD and the PRCC HSC [note: each PUD plans to present their own SOA that is specific to their agreement(s)].

Casey Baldwin noted that the statistical report is scheduled to be completed 2 years before the 10-year Program Review and asked if data from the 2 years between the reports would be analyzed in the 10-year Program Review. Tracy Hillman said, in order to complete a Program Review, the statistical analyses would have to be completed again, including those 2 years of data. Baldwin asked why the statistical report and Program Review are offset, because it seems redundant to do statistical analyses again 2 years after the statistical report. Mackey said one option would be to skip every other 5-year report and instead include the statistical analyses in the Program Review. When the schedule was developed all the reporting requirements were trying to be met explicitly, hence the redundant reporting of the 5-year and Program Review. Hillman suggested that most of the statistical analyses could actually be done in the annual report, but the productivity and abundance comparisons to reference or control populations take more time and should probably only be included in the statistical report or Program Review. Peter Graf said recalculation begins next in 2023 and the document authors tried to fit the timeline around doing a Program Review in 2020 just before recalculation. Graf suggested the statistical report and Program Review could be collapsed into one report, because they are currently only 18 months apart in the timeline. Mike Tonseth agreed and said duplication of effort is unnecessary. Hillman said he will coordinate with WDFW and YN, as M&E operators, to determine if most of the statistical analyses can be completed in each annual report. He said it might be beneficial to present the statistical analyses each year so the Hatchery Committees can make informed decisions, and every 5 years include statistical analyses on reference populations, population dynamics, and productivity. Hillman said the timeline could be set up so the 5-year statistical report falls on years when the 10-year Program Review is done. Todd Pearsons said the purpose of the 5-year report is to inform the M&E Plan review and update. Tonseth replied having statistical analyses in the annual report provides sufficient information to review and update the M&E Plan, so the timeline and purpose of the 5-year report could be shifted to align with Program Review. Todd Pearsons suggested that the PUDs discuss the timeline further and distribute a revised version for review. Greg Mackey said he will coordinate with Chelan and Grant PUDs to revise the proposed Hatchery M&E Reporting Timeline.

F. Expanded Sampling at the Off-ladder Fish Trap (Mike Tonseth)

Mike Tonseth said the OLAFT at Priest Rapids Dam is currently operating from about July 1 to early or mid-November, primarily for steelhead viable salmon population (VSP) monitoring. He said this monitoring (8 hours a day, 3 days a week) plus supplemental PIT tagging provides adult return estimates of hatchery and wild steelhead with high precision. Tonseth said he thinks it would also be a good approach for monitoring spring Chinook salmon. He said monitoring for spring Chinook salmon under the same operation (8 hours a day, 3 days a week) beginning in mid-April would provide sufficient sample size and precision to assess populations of spring Chinook salmon. He said unbiased estimates for prespawn mortality are lacking for spring Chinook salmon and this sampling could inform those estimates, as well as providing data for managing pHOS and PNI objectives. He said operating the OLAFT from mid-April to mid-November would encompass many species' runs, though sockeye would not be included in sampling because their abundances are so high. He said the JFP met and discussed this, and thinks there is utility in pursuing this sampling scheme. He said, if it works, sampling at Wells and Tumwater dams for spring Chinook salmon could be decreased and the OLAFT approach could answer more detailed questions about entire distinct population segments or non-evolutionarily significant units. He said the state does not want to invest time and money into developing a plan and proposal for expanded OLAFT sampling unless the Hatchery Committees parties support pursuing it.

Greg Mackey said the population estimate for steelhead uses PIT-tag detection data and it would be helpful to fully understand the model and ensure it is a statistically rigorous approach to estimating populations before shifting M&E programs. He said expanded sampling at OLAFT is probably a better way to acquire data for estimating populations, practical limitations notwithstanding. Tonseth said the expanded sampling may not change how broodstock is collected, but it would decrease ancillary handing and delay.

Tracy Hillman asked if the population estimates come from the mark-recapture model developed by Kevin See (Quantitative Consultants, Inc.). Tonseth replied yes; the model works well for steelhead and is being considered for other stocks and runs. Hillman said the model is described in Appendix D to the Chelan and Grant PUDs Annual Hatchery M&E Report. Pearsons said it would be helpful to understand how the model will be used, how run composite sampling would be performed, and what would change relative to existing M&E efforts. He asked, for example, would it increase or decrease the handling events of fish? And, what is proposed to change at every location compared to what is proposed to change at the OLAFT? Tonseth said he will work with Andrew Murdoch (WDFW) to write an overview of proposed sampling and program changes to address these discussion items.

G. Stray Rate Targets (Todd Pearsons)

Todd Pearsons said the Hatchery Committees and PRCC HSC discussed stray rates in January 2017 and he was asked to expand his presentation in January into a paper, "Stray Rate Target for Hatchery Programs," which Sarah Montgomery distributed to the Hatchery Committees on February 2, 2017 (Attachment E). Pearsons summarized recent scientific literature that for natural-origin fish, stray rates vary between 0 and nearly 100%, and there are a variety of factors influencing stray rates. He said this implies that it is difficult to set a standardized stray rate target, and Keefer and Caudill (2014)[1] state the following:

> There are certainly no universally 'appropriate' straying rates that can be used as management targets…Fisheries managers must balance the potential demographic and genetic risks of straying on both donor and recipient populations with the benefits of proposed management actions. This will require consideration of how strays are identified and enumerated, the size and spatial distribution of donor and recipient populations, and agreement

[1] Keefer, M. L., and C. C. Caudill. 2014. Homing and straying by anadromous salmonids: a review of mechanisms and rates. *Rev Fish Biol Fisheries* (2014) 24:333–368. DOI 10.1007/s11160-013-9334-6.

> about what stray rates are desirable or ''natural''. Costs, benefits, and target rates are likely to differ widely among study systems."

Pearsons said his paper focuses on the first type of stray rate target from Hillman et al. 2013[2], brood-year stray rates, and the paper summarizes and includes quotes from existing literature so everyone can interpret the material for themselves. He asked for questions and said he would like to discuss the stray rate target itself, whether it should be eliminated, or if there is a scientifically supported target to which the Hatchery Committees and PRCC HSC can agree. He said the origin of the 5% brood-year stray rate target is also interesting, because it was unclear where it originated from and experts in straying mainly focus on targets related to the origin of the stray in regard to the recipient population, instead of brood-year stray rates. Hatchery Committees representatives' questions and comments are summarized in the following paragraphs.

Purpose of the brood-year stray rate target

Bill Gale said question (Q)1 (regarding brood-year stray rates) of the M&E Plan is a measure of hatchery performance, whereas Q2 and Q3 are related to natural-origin populations and permit conditions. Mike Tonseth said Q1 is more of an indicator objective or management index than a target and exceeding Q1 means a higher likelihood of exceeding the Q2 and Q3 targets. Pearsons said the recipient population targets (Q2 and Q3) are more important targets because not meeting them requires program changes. He said he is uneasy about having management implications tied to a target where the target is not achievable and scientifically supported. Casey Baldwin said eliminating Q1 would decrease the ability to understand or take management actions for programs that do have a stray problem and the problem with relying on Q2 is that it is program-specific [note: does not account for the strays from other sources than the program that is evaluated]. Pearsons also questioned whether hatchery fish should be expected to have stray rate targets close to those of natural-origin fish?

Baldwin said it would be helpful to know what proportion of programs are not meeting the 5% brood-year stray rate target. Greg Mackey said fish transported to acclimation sites never meet the target and fish released directly from a fish hatchery usually do meet the target, but it varies a lot.

---

[2] Hillman, T., T. Kahler, G. Mackey, J. Murauskas, A. Murdoch, K. Murdoch, T. Pearsons, and M. Tonseth, 2013. *Monitoring and evaluation plan for PUD hatchery programs*. Chelan PUD, Wenatchee, Washington.

Keely Murdoch said the Chewuch and Twisp rivers have pronounced stray rates because fish have a strong connection to the Methow Fish Hatchery.

Gale said, from a program performance view, the stray rate should be as low as possible and 5% is just a benchmark. Not meeting that target does not mean the program is not meeting its permit conditions. Pearsons said management actions should be based on scientifically derived targets and, for things that are beyond the control of the hatchery, targets should not be set. Murdoch countered that if there was no target for brood-year stray rates, needed changes to programs might not occur. Pearsons said brood-year stray rates should be reported whether there is a target or not, and targets are not necessary to make program changes.

Hatchery versus wild stray rates

Tonseth said results from the Ford et al. 2015[3] paper suggest that straying is largely habitat related. He said wild fish do not tend to stray, but hatchery-origin fish do. He said descendants from natural-origin fish spawning in one location return to that location, whereas progeny of hatchery-origin fish seek out higher quality habitat. He said imprinting, and the location of fish hatcheries are therefore important pieces to understanding hatchery-origin fish and straying.

Mackey said the rate of straying is not as important as the result of straying. He said, in the Methow basin, the population is homogenized (there is no genetic differentiation among the fish in the Twisp, Methow and Chewuch rivers), so it does not matter where hatchery fish go from a population genetic standpoint, but it does matter from an escapement goal and pHOS standpoint. He said the adult spring Chinook outplanting plan in the Chewuch River will also help inform stray rates in the Methow basin.

Potential changes to the target

Pearsons said that the approved M&E plan says that the committees will incorporate new information about natural stray rates when they become available so that hatchery programs are not held to unrealistic standards. He said that new information is now available and should be used to inform the broodyear stray target. He asked what the role of science was in the committees if we were not willing to use recent compelling science on a topic that was specifically identified in the

[3] Ford, M. J., A. Murdoch, and M. Hughes, 2015. Using parentage analysis to estimate rates of straying and homing in Chinook salmon (*Oncorhynchus tshawytscha*). *Molecular Ecology* 24:1109–1121.

monitoring plan? He asked what level of science would be necessary to change the broodyear stray target?

Baldwin said information from the Wenatchee basin (high stray rates) suggests that a one-size-fits-all approach to stray rate targets may not be appropriate. He suggested adding subsections to Q1; 1a) would address within-basin brood-year stray rates and 1b) would address out-of-basin brood-year stray rates.

Tracy Hillman asked if the stray rates identified in Ford et al. (e.g., 1.3 to 17.5%) would be appropriate for spring Chinook salmon within the Wenatchee River basin. That is, Ford et al. indicates that the natural-origin stray rate for Chiwawa spring Chinook salmon is 4.1%. Should that be the target for this program? Pearsons said peer-reviewed scientific literature suggests there is not a single appropriate brood-year stray rate target to set. Baldwin summarized that the Hatchery Committees appear to be uncomfortable with eliminating Q1 altogether, but would rather come up with a revised stray rate target based on information in Ford et al. or other sources. Hillman said this discussion will continue at the March 13, 2017, Hatchery Committees meeting.

V. HCP Administration

A. Next Meetings

Mike Tonseth said he and Jeff Korth are unavailable from March 14 to 16, 2017, and asked the Hatchery Committees if they would like to reschedule the in-person March meeting to a time when WDFW is available to discuss the draft 2017 Broodstock Collection Protocols or if they would prefer to schedule a conference call in addition to the scheduled meeting to discuss the protocols and other items requiring WDFW input in March. Hillman summarized that the protocols and the Twisp Steelhead program are both items requiring WDFW input. Hatchery Committees representatives present discussed alternate dates and times, and agreed to meet on Monday, March 13, 2017, starting at 1 p.m. They plan to meet at the Grant PUD conference room.

The next Hatchery Committees meetings are on Monday, March 13, 2017, at 1 p.m. (Grant PUD), April 19, 2017, (Grant PUD), and May 17, 2017 (Grant PUD).

Out-planting Surplus Methow Composite Spring Chinook Salmon Adults to Increase Natural Production In the Chewuch River - DRAFT

Background

During the recent review of the “Evaluation of Hatchery Programs Funded by Douglas County PUD 5-year Report 2006-2010”, Objective 6, Monitoring Question Q6.1.1: “Is the stray rate of hatchery fish less than 5% for the total brood year return?” was identified as not meeting the target for the Chewuch River final acclimated fish. The Hatchery Committees (HCs) determined that methods to improve homing would have uncertain success, be difficult to implement, and challenging to statistically evaluate. In an effort to achieve the goal of increased hatchery-origin spawner abundance in identified reaches that a higher rate of homing would convey, the HCs agreed to pilot adult out-planting of surplused Methow Composite spring Chinook into the Chewuch River.

The goal of this pilot evaluation is to determine if surplused Methow Composite spring Chinook adults collected and held at the Methow Hatchery, and subsequently out-planted into the Chewuch River, spawn in the Chewuch River. This pilot evaluation will be conducted in an effort to increase spawner abundance, spawner distribution, and natural production in the Chewuch River. It is a low-risk management tool that has been used in many locations such as the Wenatchee and Willamette watersheds.

2017 Out-planting Surplused Methow Composite Spring Chinook Salmon Adults Objectives

- Document the number of female hatchery-origin spring Chinook salmon adults that are trapped and held at the Methow Hatchery and out-planted in the Chewuch River that exhibit spawning behavior and ultimately spawn in the Chewuch River.
- Assess the percentage of hatchery origin spring Chinook salmon adults that are trapped and held at the Methow Hatchery and out-planted in the Chewuch River leave the Chewuch River.

Methods

Hatchery-origin spring Chinook salmon adults returning to the Methow Hatchery, in excess of broodstock needs for the Methow Hatchery, will be candidates for transporting into targeted spawning reaches of the Chewuch River.
We will collect, hold and out-plant a maximum of 200 surplused adults at a sex ratio of 80% females and 20% males (excluding jacks and adjustable depending upon the sex ratio of the run at large). The specific number of fish to be held and out-planted will be based upon permit requirements, availability of fish, and pHOS constraints in the sub-basin.

Holding and Out-planting

Surplus hatchery-origin adults returning to the Methow Hatchery will be held and out-planted one week before estimated peak spawning (i.e., during the latter part of August/early September). All fish that are out-planted will be PIT-tagged and marked with a visible mark. Up to 100 adults will be released into one of two sites. One of the sites will be above the upper Chewuch PIT tag instream PIT tag antenna array (CRU) and the other below CRU and above the Winthrop (CRW) PIT tag antenna array (Figure 1). Release locations will be determined based on vehicle access, suitable spawning habitat, distance from the hatchery, distance from PIT tag arrays, and areas that are not being utilized by spawners already in the system.

Evaluation

The association of the transported adults with redds will be documented during spawner surveys (e.g., identification of transported adults on redds). Potential spawning success of females will be documented by estimating the proportion of eggs that are retained within female carcasses sampled during carcass recovery surveys. Carcass location will be documented using a GPS device.

The CRW PIT tag antenna array will be used to determine the percentage of PIT-tagged hatchery origin spring Chinook salmon adults that are out-planted in the Chewuch River that leave the Chewuch River. Additionally, any adults that are out-planted and last detected outside of the Chewuch River will be considered to have left the Chewuch River. Fish returning to the Methow Hatchery will also be documented.

The results of the 2017 out-planting effort will be used to adjust the methods in 2018.

Wells HCP Hatchery Committees
Statement of Agreement

Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 15, 2017

Statement

The Wells HCP Hatchery Committees approves the Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 15, 2017. Any future alterations of the schedule will require HCP Hatchery Committee approval.

Background

The Douglas and Chelan HCPs and Grant Settlement Agreement and 2008 NMFS Biological Opinion for Grant PUD (hereafter referred to collectively as the Agreements) specify certain reporting dates or intervals for hatchery monitoring and evaluation (M&E). The Endangered Species Act incidental take permits and the PUD hatchery M&E Plan also have reporting requirements. These reporting time requirements were designed to provide timely information to operators and managers, fulfill permitting requirements, inform other activities such as updating M&E plans, recalculation of hatchery production, evaluation of meeting objectives, status of meeting permit requirements, and adaptive management actions. To date, the reporting timing that has been implemented has not necessarily met the intent of the Agreements, and has not been orchestrated to work with the various actions that the Hatchery Committees and NMFS require. This document, Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 15, 2017, is the new reporting schedule that is consistent with the Agreements, meets reporting requirements under the M&E Plan, meets ESA Section 10 permit requirements, and optimizes the sequence of reporting and the actions that rely on M&E information.

Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs

March 15, 2017

Introduction

The Douglas and Chelan PUDs' HCPs, Grant PUD's Settlement Agreement, and the 2008 NMFS Biological Opinion (Biop) for Grant PUD (hereafter referred to collectively as the Agreements) specify certain reporting dates or intervals for hatchery monitoring and evaluation (M&E). The Endangered Species Act (ESA) incidental take permits and the Monitoring and Evaluation Plan for PUD Hatchery Programs (Hillman et al. 2013) also have reporting requirements. These reporting date requirements were designed to provide timely information to operators and managers and fulfill permitting requirements. Additionally, the reports are used to inform other activities such as updating M&E plans, recalculation of hatchery production, evaluation of meeting M&E objectives, status of meeting permit requirements, and adaptive management actions. To date, the past reporting timing has not necessarily met the intent of the Agreements, and has not been orchestrated to align with the various actions that the Hatchery Committees and NMFS require. Subsequently, we have designed a reporting schedule that is consistent with the Agreements, meets reporting requirements under the M&E Plan, meets ESA Section 10 permit requirements, and optimizes the sequence of reporting and the actions that rely on M&E information.

Section 1: Monitoring and Evaluation Reports

Three levels of M&E reporting will be implemented (Table 1). These reports are consistent with past reporting and the M&E Plan, but have been restructured to streamline transfer of information and meet the Agreements requirements.

Table 1. M&E Report Types

Report type	Frequency	Content	Function
Data	Annual	Cumulative description of data (raw and derived) and field methods	Informs annual M&E implementation plans
Statistical	5 year	Presentation of statistical analyses and description of statistical methods	Informs 5 year M&E plan and provides in depth data analysis
Program Review	10 year	Integrates and interprets information from data and statistical reports and also includes integration from other programs and studies. Written in scientific manuscript format. Fulfills HCP "Program Review" requirements	Informs recalculation and adaptive management. Determines if programs are meeting objectives.

The Data report will be produced annually and will provide data collected in the most recent field year. The report will provide tables of cumulative data, including the most recently collected, and provide summary statistics where appropriate (e.g., mean, standard deviation, etc.). The report will provide a concise description of the field methods that could be used in a scientific publication and describe deviations from previous sampling, standard field practices or sampling plans. This report will provide up to date information for managers and operators, fulfill incidental take reporting requirements, and inform annual adjustments to the implementation of the M&E plan.

The Statistical report will be produced every five years. The report will provide a concise description of the analytical methods used (e.g., similar to a scientific journal article) and the results of the statistical analyses for each objective as described in the M&E plan. The report will also provide the assumptions of the statistical analyses and note any deviations in expected performance of a given analysis (e.g., issues related to normality, dependency, non-constant variance; etc.). The report is not intended to provide interpretation of the results, but will provide the outcomes of the statistical tests. This will provide managers and operators a periodic update of the performance of the hatchery programs.

The Program Review will be produced every ten years and will meet the Program Review as described in the HCPs (Section 8.8 of the Wells HCP, Section 8.7 of the Rocky Reach/Rock Island HCPs). The report will provide the results of any natural population/hatchery interaction studies (as needed), and determine if the hatchery programs are operating consistent with the goals as outlined in the relevant M&E Plan. The review will determine if hatchery program goals and objectives, as defined in the Hatchery Plan (HCPs Section 8), Section 10 permits, as further defined in the HCPs, have been met or sufficient progress is being made toward their achievement; and determine if hatchery production objectives are being achieved.

Section 2: Required Reports and Actions

The HCPs list required reports or actions. The M&E reporting is either directly described or closely tied to these milestones (Table 2).

Table 2. Required Elements in the Agreements

Element	Document	Section	Frequency	Previous	Next
Survival Studies	HCP	8.4.4	Every 10 years	2010	2020
Recalculation	HCP SSSA/BiOp	8.4.5	Every 10 years Every 10 years	2013	2023
M&E Plan Update	HCP SSSA	8.5 13.1.4	Every 5 years Every 5 years	2013	2018
Program Review	HCP	8.8	Every 10 years	2012	2020
Section 10 Permit	HCP	10.2.5	Every 10 years	2004	2017

Section 3: Schedule

The M&E reporting schedule is designed to be consistent with the Agreements. However, it also has been designed to provide a logical sequence of information based on significant milestones in the HCPs as well as consistency with Grant PUDs settlement agreement and NMFS BiOp. Reporting was designed to provide the Program Review prior to recalculation in order to have the most up to date data vetted and organized prior to recalculation. The Statistical Report will be produced every five years, including years when the program Review is due. The Data Report will be produced annually (see Table 3 and Figure 1). The PUDs also require advanced knowledge of M&E and reporting requirements to facilitate timely contracting.

Table 3: Schedule of M&E Reporting and Significant Actions under the Agreements

Year	Activity	Data Years
2024	5-year M&E plan review	--
2023	Hatchery Recalculation finalized	2011-2019
2023	Data Report	Adds 2022
2022	First brood collection for hatchery recalculation (2024 release)	--
2022	Data Report	Adds 2021
2021	Hatchery recalculation process and agreement	--
2021	Data Report	Adds 2020
2020	Program Review	Adds 2011-2019
2020	Data Report	Adds 2019
2019	Data Report	Adds 2018
2019	Statistical Report	Through 2018
2019	5-year M&E plan review	--
2018	Data Report	Adds 2017
2017	Data Report	Adds 2016
2016	Data Report	Adds 2015
2015	Data Report	Adds 2014
2014	Data Report	Adds 2013
2013	5 year M&E plan review	--
2013	Statistical Report (i.e. 5-Year Report)	Through 2010

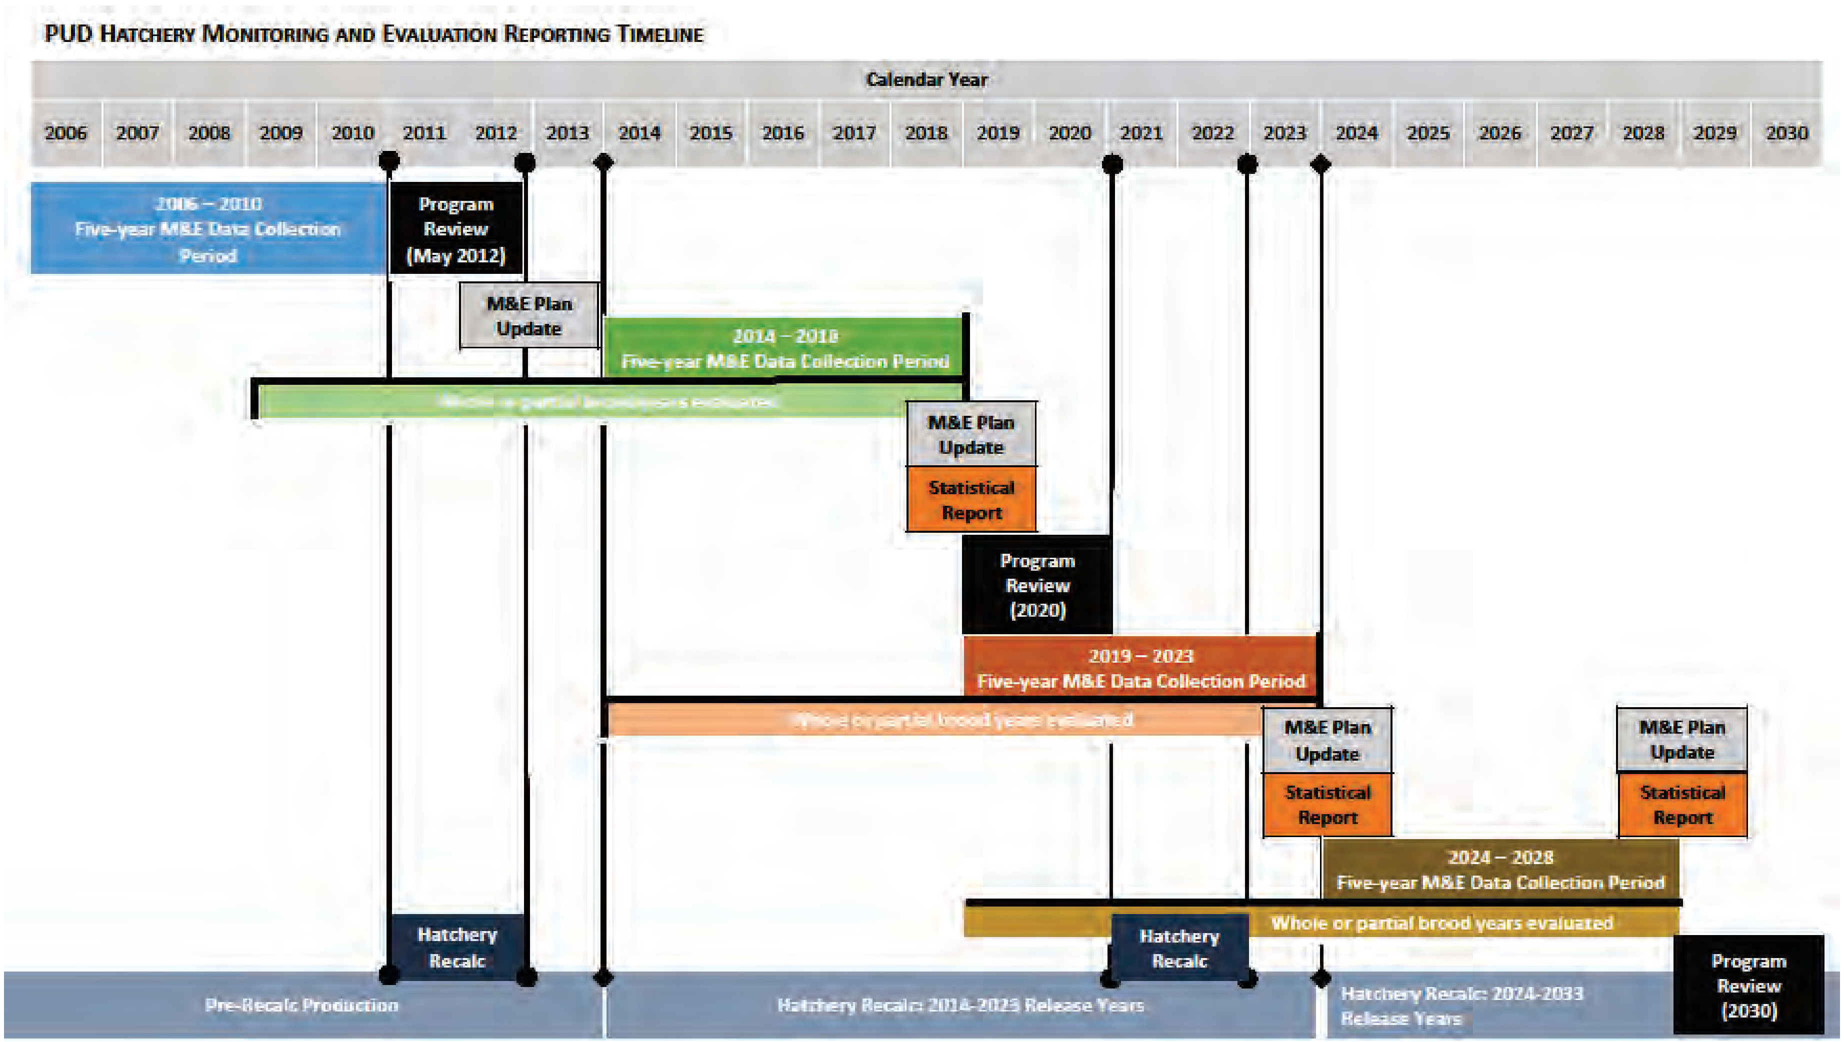

Figure 1. Timeline of requirements and reporting under the Agreements.

Stray Rate Target for Hatchery Programs

Todd Pearsons, Grant PUD

Stray rates of hatchery fish are used to evaluate the risk hatchery programs may pose to non-target populations and to estimate the potential benefits to a target population. As such, targets or guidelines have been developed to set standards for maximum stray rates. For example, the following stray rate targets have been identified in the Middle Columbia Public Utility Districts hatchery Monitoring and Evaluation plan (Hillman et al. 2013):

1) stray rate of hatchery fish less than 5% for the total brood return,

2) hatchery strays make up less than 5% of the spawning escapement within other non-target independent populations, and

3) hatchery strays make up less than 10% of the spawning aggregate within non-target spawning areas within the target population.

This paper focusses on the first target above, which is the percent of adult returns that fail to return to the tributary of release (e.g., tributary such as Nason Creek or Chewuch River). Although there are implications of the first target on targets 2 and 3, those implications will not be the focus of this paper. In Keefer and Caudill's (2014) nomenclature of straying, this paper will focus on donor straying and not recipient population straying.

Origin of the 5% Brood year Target

Murdoch and Peven (2005) defined the original brood year stray target for Chelan PUD hatchery programs as 5% but provided no background for this number. As such, it is difficult to know how this number was generated. In contrast, the targets for recipient populations was "suggested based on a literature review and recommendations by the ICTRT. It can be re-evaluated as more information on naturally-produced Upper Columbia salmonids becomes available. This will be evaluated on a species and program specific basis and decisions made by the HCP HC." (Murdoch and Peven, 2005, page 11).

Stray rate targets for hatchery fish were developed prior to much empirical information on straying of natural origin fish. The belief was that straying of natural origin fish was less than 5%. Even as recent as 2005, Quinn (2005; page 104) reported "Homing to the natal site is the characteristic behavior pattern in all salmonids; about 95-99% of the fish that survive to adulthood do so." This statement supports the idea of a 5% stray target. However, in the same publication stray rates of natural origin fish were presented that exceeded 5% and reached 26.8%.

An informal survey of experts on straying suggests that the original brood year stray target was based upon expert opinion because there was limited information about stray rates of natural origin fish.

Stray rates of natural origin fish

Rates of straying of natural origin fish have ranged between 0% and 100%. Shapovalov and Taft (1954) performed one of the earliest studies of stray rates of natural origin fish involving more than one species. They studied stray rates of coho salmon and steelhead in two coastal California creeks that were less than 8 km apart. They didn't evaluate other creeks for strays beyond the two nearby creeks so their stray rates should be considered minimums. The minimum stray rate of coho salmon was 14.9% for coho originating from Waddell Creek and 26.8% from coho originating from Scott Creek. The minimum stray rate for steelhead was 1.9% for steelhead originating from Waddell Creek and 2.9% from steelhead originating from Scott Creek.

More recently, Ford et al. (2015) estimated stray rates of natural origin spring Chinook salmon in the upper Wenatchee watershed using genetic techniques. Based upon tables 2 and 4 of Ford et al. (2015); stray rates were 4% or 3% for fish originating from the Chiwawa River, 18% or 17% for fish originating from the Little Wenatchee River, 9% for fish originating from Nason Creek, 1% or 5% for fish originating from the White River, and 100% for fish originating from the upper Wenatchee River. It is not clear why the numbers differ slightly between the tables.

Their continues to be a paucity of studies that have evaluated stray rates of natural origin fish, but the few studies that are available indicate that stray rates can be quite high and variable between locations.

Factors that influence stray rates

A variety of factors have the potential to influence stray rates of hatchery origin fish. Keefer and Caudill (2014, page 333) identified a number of factors that influence straying: "Research in several disciplines indicates that adult straying is affected by endocrine physiology and neurological processes in juveniles, incomplete or interrupted imprinting during rearing and emigration, and by complex interactions among adult maturation processes, reproductive behaviors, olfactory memory, environmental conditions during migration, and senescence physiology. Reported salmonid stray rates indicate that the behavior varies among species, among life-history types, and among populations within species." Furthermore they state on page 339, "In the wild, changing environmental conditions and stress promote frequent hormonal fluctuations, which in turn generate olfactory receptor neurons and imprinting opportunities. In contrast, juveniles reared in relatively stable hatchery environments show fewer and lower amplitude hormone surges. These differences likely explain the reduced imprinting and a greater propensity for straying in hatchery versus wild salmonids."

Ford et al. (2015) found variation in spring Chinook salmon stray rates that were related to origin (hatchery vs. natural) and location (e.g., tributary such as Nason Creek). Fish released from the Chiwawa acclimation facility had higher stray rates than natural origin fish that originated from the Chiwawa River. Progeny of hatchery origin fish that spawned in nature had higher rates of straying than progeny of natural origin fish that spawned in nature. They suggested that the difference in stray rates between origins could be a genetic effect. They further speculated that variation in location such as the upper Wenatchee River may be partially explained by the quality of spawning habitat; poor spawning habitat was related to high stray rates.

Dittman et al. (2010) evaluated homing of spring Chinook salmon that were released from three different acclimation sites in the upper Yakima River watershed. They found that, “While homing was clearly evident, the majority (55.1%) of the hatchery fish were recovered more than 25 km from their release sites, often in spawning areas used by wild conspecifics.” They further concluded that, “These results suggest that genetics, environmental and social factors, or requirements for specific spawning habitat may ultimately override the instinct to home to the site of rearing or release.” Cram et al. (2012) also showed evidence of multiple factors influencing homing of hatchery origin spring Chinook salmon in the Yakima River; “Environmental conditions near each acclimation facility were markedly different and contributed to varying fidelity among spawning groups to their release areas.” “Acclimation facilities characterized by marginal habitat could be expected to have higher stray rates than those in more productive areas”. “Salmon released from the two sites that were located in areas of marginal spawning habitat quality (Clark Flat and Jack Creek) showed low fidelity to their acclimation areas, but their distribution was affected by homing. Females that strayed from these acclimation sites may be the most likely to colonize other reaches in the watershed, as they are unable to spawn near their release site.” Dittman et al. (2010) estimated a stray rate of 97% for fish released from the Jack Creek acclimation site and spawned in 2005. It was highly unlikely that the high stray rate was the result of poor imprinting and more likely to have been due to access and spawning habitat (Cram et al. 2012); “social or imprinting factors are unlikely to be the primary drivers of straying behavior, given the frequency with which the Cle Elum River was used for spawning by hatchery-origin females. Females that spawned in the Cle Elum River were almost exclusively wild- or Jack Creek-origin salmon.”

Westley et al. (2013) concluded that there are differences among different taxonomic groupings of fish: “Our results revealed large and generally consistent differences in the propensity to stray among species, life history types within species, and populations. Paired releases indicated that (i) Chinook salmon (*Oncorhynchus tshawytscha*) strayed more (mean population range 0.11%–34.6%) than coho salmon (*Oncorhynchus kisutch*) (0.08%–0.94%); (ii) ocean-type Chinook (5.2%–18.6%) strayed more than stream-type Chinook (0.11%–10%); and Chinook salmon (0.90%–54.9%) strayed more than steelhead (0.30%–2.3%). We conclude these patterns are largely the result of species-specific behavioral and endocrine factors during the juvenile life stages, but analyses also suggest that environmental factors can influence straying during the adult upstream migration.” The magnitude of straying presented by Westley et al. (2013) was influenced by the spatial scale that was considered a stray; “each recovery we defined individuals as strays if they were recaptured outside the river basin of their release, a spatial scale that generally conforms to the local population level and scale for conservation.” This spatial scale is generally larger than what is targeted in the upper Columbia Basin and so the relatively low magnitudes of straying are likely the result of the spatial scale evaluated.

Westley et al. (2015) found that multiple factors influenced straying including migration distance and density dependence: “We used two decades of tagging and recapture data from 19 hatchery populations of *Oncorhynchus tshawytscha* (Chinook salmon) in the Columbia River, USA, to quantify the effects of regional and local climate conditions, density dependence, watershed features such as area and position on the landscape, and direct anthropogenic influence on dispersal rates by adult salmon during the breeding season. We found that the probability of dispersal, termed ‘‘straying’’ in salmon, is plastic in response to multiple factors and that populations showed varied responses that were largely idiosyncratic. A regional climate index (Pacific Decadal Oscillation), water temperatures in the mainstem Columbia River that was commonly experience by populations during migration, water temperatures in local subbasins unique to each population during the breeding season, migration distance, and density dependence had the strongest effects on dispersal." They further stated: "Ultimately, our results provide evidence that analyses that examine the response of dispersal to single factors may be misleading."

There are likely a variety of other factors that influence straying that have not been discovered yet, but published work indicates a variety of factors influence stray rates including those outside the control of hatchery imprinting.

Implications of stray data on stray rate target

The stray rate of adult fish that were born in nature is likely to be the best that could be expected for hatchery programs (i.e., optimal imprinting for the given environmental conditions) and it may not be possible to duplicate similar rates of straying in hatchery programs. Hatchery fish may have higher stray rates than natural origin fish because of: 1) imperfect water sources for rearing and acclimation, 2) moving fish resulting in less than optimal imprinting circumstances (e.g., to acclimation sites, Dittman et al. 2015), 3) low stress resulting in low hormone triggers to promote imprinting in juveniles (Keefer and Caudill 2014), 4) altering a natural life-history pattern (e.g., subyearling to yearling; Westley et al. 2013), 5) the timing and method of release (Keefer and Caudill 2014), as well as 6) the possible genetic phenomenon that offspring of hatchery origin fish stray more than offspring of natural origin fish (Ford et al. 2015). The genetic effect may be stronger in the first generation than the second generation so the hatchery effects reported by Ford et al. (2015) for naturally spawned progeny may be even larger in first generation hatchery fish. It is possible to control some of the factors that contribute to higher stray rates of hatchery fish, but others are likely to be an inherent cost of achieving other hatchery related benefits (i.e., a tradeoff).

The PUD M&E plan says that the stray targets will be revised as new information becomes available:

> "When populations are not independent, straying among them does not pose a risk of genetic homogenization. In addition, stray rates of hatchery-origin fish cannot be expected to be lower than for natural-origin fish. When estimates of stray rates for natural-origin fish are available and if they exceed the 5% or 10% thresholds identified in this plan, analysis and interpretation of stray rates must take into account the concept that hatchery programs may be held to unattainable standards based on the natural stray rate." (Hillman et al. 2013).

There is new published information about the stray rate of naturally spawning fish that indicates that the 5% brood year stray target should be revised because stray rates of offspring of naturally spawning fish can exceed 5% and that stray rate is influenced by a number of factors outside the control of hatchery programs.

In their review of straying, Keefer and Caudill 2014 (page 359) concluded: "There are certainly no universally 'appropriate' straying rates that can be used as management targets." Furthermore, they wrote, "Fisheries managers must balance the potential demographic and genetic risks of straying on both donor and recipient populations with the benefits of proposed management actions. This will require consideration of how strays are identified and enumerated, the size and spatial distribution of donor and recipient populations, and agreement about what stray rates are desirable or ‘‘natural’’. Costs, benefits, and target rates are likely to differ widely among study systems.”

Furthermore, changing the normal life-history of fish in hatcheries can result in trade-offs describe by Westley et al. (2013; page 744) “the release of ocean-type Chinook salmon as yearlings rather than subyearlings was associated with increased straying. Presumably, this reflects a disruption of the normal seasonal patterns of growth, endocrine events, imprinting, and migration for the yearling releases. Though the mechanisms underpinning this finding are unclear, the patterns suggest that attempts to rear ocean-type Chinook salmon an extra year in fresh water to increase the size of smolts may come at a cost of extra straying.” In short, the benefit of higher survival must be assessed relative to benefits of homing: both cannot be maximized in all hatchery programs.

Consistent with the finding from Keefer and Caudill (2014) that there is not a universally appropriate stray rate target, it is recommended that the brood year stray rate target in Hillman et al. (2013) be eliminated or revised using the best available information. If sufficient information is available, then location and stock specific brood year stray targets could be approximated using the following equation: Target = (stray rate of natural origin fish from hatchery parentage) + (stray rate addition as a result of hatchery experience) + (stray rate addition from poor habitat, high density, and other non-imprinting factors). In most cases, sufficient information will not be available to populate such an equation and case-by-case management choices will have to be made to balance the benefits and costs of artificial propagation (Keefer and Caudill 2014).

It is important to note that imprinting is one of many factors that influence straying. As such, hatchery programs do not have full control over the stray rate of hatchery fish. For example, if habitat conditions or access are poor or become worse, then it is possible that stray rates may be high or could increase (e.g., Jack Creek and Clark Flats acclimation sites in the Yakima Basin; Cram et al. 2012). Furthermore, the density of spawners or juveniles, amount of pesticide exposure, or other habitat conditions can influence stray rates (Keefer and Caudill 2014, Brett and Hinch 2015).

Use of acclimation sites are a trade-off that generally result in increased number of fish back to a target location but at the cost of increased stray rates (relative to on-station release such as Methow Hatchery). As such, a balanced approach might include determining the desired number of fish to return to a target location, adjusting program size by factoring in the stray rate, and then determining whether the system can absorb the number of strays. If the number of strays is too high, then one option is to reduce the number of fish released into a target area until acceptable numbers of strays are achieved. Alternatively, if straying is caused by poor habitat conditions, then efforts to improve spawning habitat could be pursued.

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Hatchery Committees

Date: April 20, 2017

From: Tracy Hillman, HCP Hatchery Committees Chairman

cc: Sarah Montgomery, Anchor QEA, LLC

Re: Final Minutes of the March 13, 2017, HCP Hatchery Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Hatchery Committees meeting was held at the Grant PUD office in Wenatchee, Washington, on Monday, March 13, 2017, from 1:00 p.m. to 4:30 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- McLain Johnson (Washington State Department of Fish and Wildlife [WDFW]) will revise the timeline for conducting genetic analysis for HCP program species incorporating suggestions provided during the Hatchery Committees January 18, 2017, meeting (Item I-A). *(Johnson sent the revised timeline to the Hatchery Committees on April 6, 2017.)*
- McLain Johnson and WDFW geneticists will perform a power analysis to inform genetic analysis intervals and intensity for HCP program species (Item I-A). *(Johnson sent a memo regarding genetic analysis intervals to the Hatchery Committees on April 6, 2017.)*
- Andrew Murdoch (WDFW) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A). *(Note: this item is ongoing.)*
- Hatchery Committees representatives will review the Hatchery Monitoring and Evaluation (M&E) Plan Objectives before the Hatchery Committees April 19, 2017, meeting (Item IV-A).
- Casey Baldwin will discuss internally the steelhead marking strategy in the draft 2017 Broodstock Collection Protocols and provide feedback to Mike Tonseth (Item IV-D).
- Keely Murdoch will discuss internally the Yakama Nation (YN)'s egg requests for their summer Chinook salmon program (Item IV-D).
- Hatchery Committees representatives will discuss internally WDFW's proposal for collection and rearing for the Twisp Steelhead program in 2017 and provide a vote by March 30, 2017 (note: this includes adult collection at the Twisp Weir, transfer to Winthrop National Fish Hatchery (NFH), spawning as part of aggregate composite population. and incubation to eyed-egg or fry stage at Winthrop NFH, then transfer to Methow Fish Hatchery (FH); Item IV-E). *(See "Agreements".)*

- Catherine Willard will revise the draft study plan, "Outplanting Surplus Methow Composite Spring Chinook Salmon Adults to Increase Natural Production in the Chewuch River," and distribute it to the Hatchery Committees for approval at the April 19, 2017, meeting (Item IV-F). *(Note: Willard sent a revised draft plan to Sarah Montgomery on March 24, 2017, which she distributed to the Hatchery Committees that same day.)*
- Tracy Hillman will preliminarily revise the brood-year (BY) stray rate target language in the Hatchery M&E Plan for further discussion at the Hatchery Committees April 19, 2017, meeting (Item IV-G).
- Tracy Hillman will assess the relationship over the last 10 years between exceeding BY stray rate targets and exceeding recipient stray rate targets (Item IV-G).

Decision Summary

- The Wells Hatchery Committee representatives present approved Douglas PUD's Wells HCP 2017 Action Plan as follows: Douglas PUD, U.S. Fish and Wildlife Service (USFWS), WDFW, National Marine Fisheries Service (NMFS), YN, and Colville Confederated Tribes (CCT) approved on March 13, 2017 (Item II-A). *(Note: the Wells HCP Coordinating Committee will also discuss the Action Plan on March 28, 2017.)*
- The Wells Hatchery Committee representatives present approved Douglas PUD's Statement of Agreement (SOA), M&E Reporting Schedule for the Douglas PUD, Grant PUD, and Chelan PUD Hatchery Programs, as follows: Douglas PUD, USFWS, WDFW, NMFS, YN, and CCT approved on March 13, 2017 (Item II-B).
- The Rock Island and Rocky Reach Hatchery Committees representatives present approved Chelan PUD's SOA, M&E Reporting Schedule for the Douglas PUD, Grant PUD, and Chelan PUD Hatchery Programs, as follows: Chelan PUD, USFWS, WDFW, NMFS, YN, and CCT approved on March 13, 2017 (Item III-A).
- The Rock Island and Rocky Reach Hatchery Committees representatives approved Chelan PUD's draft 2017 Steelhead Release Plan as follows: Chelan PUD approved on March 13, 2017, and USFWS, WDFW, NMFS, YN, and CCT approved via email on March 16, 2017 (Item III-B).
- The Hatchery Committees representatives approved WDFW's draft (v3) 2017 Broodstock Collection Protocols as follows: WDFW, Chelan PUD, Douglas PUD, NMFS, USFWS, YN, and CCT approved via email on April 7, 2017 (Item IV-D). *(Note: the Wells HCP Coordinating Committee also approved the protocols via email on April 11, 2017.)*

Agreements

- The Wells Hatchery Committee agreed that the approximately 48,000 BY 2016 Twisp River steelhead smolts will be truck-released from Buttermilk Bridge instead of acclimated at the Twisp Acclimation Pond (Item IV-E).
- The Rock Island Hatchery Committee agreed that Chelan PUD and USFWS can perform maturation sampling for 300 Chiwawa spring Chinook salmon (Item IV-H).
- The Wells Hatchery Committee agreed that Douglas PUD may perform maturation sampling for 300 Methow spring Chinook salmon (Item IV-H).
- The Wells Hatchery Committee approved the following items related to the Twisp Steelhead Program: 1) For the 2017 BY, the HC agrees to use composited broodstock (in coordination with the USFWS program at WNFH) to support the Douglas PUD S1 conservation program currently in the Twisp River, and 2) Broodstock sufficient to meet Douglas PUD's Twisp S1 conservation program will be collected via hook-and-line in the mainstem Methow River concurrent with broodstock collection for the USFWS and utilize the Twisp Weir as a backup location if mainstem collections fall short. Adults will be transferred to, held, spawned, and incubated to the eyed egg stage at Winthrop NFH. Eyed eggs proportionally representative from each spawn take necessary to meet DPUD's 48K S1 conservation production will be transferred to Wells hatchery for final incubation and rearing before release. These items were approved via email as follows: WDFW and YN approved on March 30, USFWS and CCT approved on March 31, NMFS approved on April 4, and Douglas PUD approved on April 5, 2017, and concurred with 3) For the 2017 juvenile releases, 13,000 Winthrop NFH S2 conservation fish will be direct planted at Buttermilk Bridge (Item IV-E).

Review Items

- Sarah Montgomery sent an email to the Hatchery Committees on March 24, 2017, notifying them that a revised version of the Draft Outplanting Surplus Methow Spring Chinook Salmon Plan is available for review, with comments due to Catherine Willard by April 12, 2017 (Item IV-F).

Finalized Documents

- Sarah Montgomery sent an email to the Hatchery Committees on March 13, 2017, notifying them that the Final Douglas PUD SOA, M&E Reporting Schedule for the Douglas PUD, Grant PUD, and Chelan PUD Hatchery Programs, is now available for download from the Hatchery Committees Extranet site.

- Sarah Montgomery sent an email to the Hatchery Committees on March 13, 2017, notifying them that the Final Chelan PUD SOA, M&E Reporting Schedule for the Douglas PUD, Grant PUD, and Chelan PUD Hatchery Programs, is now available for download from the Hatchery Committees Extranet site.
- Sarah Montgomery sent an email to the Hatchery Committees on March 13, 2017, notifying them that the Final M&E Reporting Schedule for the Douglas PUD, Grant PUD, and Chelan PUD Hatchery Programs is now available for download from the Hatchery Committees Extranet site.
- Sarah Montgomery sent an email to the Hatchery Committees on March 24, 2017, notifying them that the 2016 Wells HCP Annual Report was finalized following a 30-day review period, which ended on March 10, 2017. Comments received on the draft report were incorporated into the final report.
- Sarah Montgomery sent an email to the Hatchery Committees on April 6, 2017, notifying them that the 2016 Rock Island and Rocky Reach HCP Annual Reports were finalized following a 30-day review period, which ended on March 20, 2017. Comments received on the draft report were incorporated into the final report.
- Sarah Montgomery sent an email to the Hatchery Committees on April 14, 2017, notifying them that the Final 2017 Broodstock Collection Protocols were finalized and submitted to NMFS, and are now available for download from the Hatchery Committees Extranet site.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the February 15, 2017, Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the Hatchery Committees and asked for any additions or changes to the agenda. The following revisions were requested:

- Greg Mackey added a discussion regarding Methow Hatchery Pond 13 Predation

Sarah Montgomery said the revised draft February 15, 2017, meeting minutes are available for review until March 15, 2017 (seven days after they were distributed), but the Hatchery Committees can still discuss the minutes today and elect to approve them early. The Hatchery Committees reviewed the revised draft February 15, 2017, meeting minutes. Montgomery said there are several outstanding comments to be discussed, which the Hatchery Committees reviewed and addressed. Hatchery Committees representatives present approved the draft February 15, 2017, meeting minutes, as revised.

Action items from the Hatchery Committees meeting on February 15, 2017, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meeting on February 15, 2017)*:

- *Sarah Montgomery and Tracy Hillman will renumber the Hatchery Monitoring and Evaluation (M&E) Plan appendices and append them to the Hatchery M&E Plan (Item I-A).*
  This item is complete.
- *Sarah Montgomery will add a summary table to the draft summary of the 5-Year Hatchery M&E Review process (Item I-A).*
  This item is complete.
- *McLain Johnson (Washington State Department of Fish and Wildlife [WDFW]) will revise the timeline for conducting genetic analysis for HCP program species by incorporating suggestions provided during the Hatchery Committees January 18, 2017, meeting (Item I-A).*
  This item is ongoing. Mike Tonseth said he expects a revised timeline will be distributed to the Hatchery Committees soon.
- *McLain Johnson and WDFW geneticists will perform a power analysis to inform genetic analysis intervals and intensity for HCP program species (Item I-A).*
  This item is ongoing.
- *Greg Mackey will distribute a link to Scott Blankenship's (Cramer Fish Sciences) blog (Item III-B).*
  Mackey sent a paper and tool by Blankenship on the Ryman-Laikre effect to Montgomery on March 3, 2017, which she distributed to the Hatchery Committees that same day. Mackey said the blog was not working when he searched for the link.
- *Brett Farman will check on the status of Methow spring Chinook salmon permits and the timeline for Methow steelhead consultation (Item IV-B).*
  Farman provided an update on the status of Methow spring Chinook salmon permits, which is included under item IV-C in these meeting minutes.
- *Catherine Willard will look into other potential release locations in the Chewuch River, particularly upstream, for the spring Chinook salmon outplanting study (Item IV-D).*
  Willard said this will be discussed today.

- *The Hatchery Committees will review the draft study plan, "Outplanting Surplus Methow Composite Spring Chinook Salmon Adults to Increase Natural Production in the Chewuch River," and provide comments to Catherine Willard by March 8, 2017. Sarah Montgomery distributed the draft outplanting plan to the Hatchery Committees on February 14, 2017 (Item IV-D).*
  Willard said comments were received and incorporated into the revised draft for discussion today.

- *Greg Mackey will coordinate with Chelan and Grant PUDs to revise the proposed Hatchery M&E Reporting Timeline, which Sarah Montgomery distributed to the Hatchery Committees on February 13, 2017 (Item IV-E).*
  This item is complete and will be discussed today; a revised version was distributed on March 2, 2017.
- *Tracy Hillman will discuss with WDFW and Yakama Nation (YN) the level of effort involved in adding statistical analyses to the annual M&E reports for PUD programs (Item IV-E).*
  Hillman said he discussed this with Andrew Murdoch (WDFW) and Brian Ishida (YN); however, the PUDs decided not to include statistical analyses in the annual M&E Reports.
- *Andrew Murdoch will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item IV-F).*
  Mike Tonseth said this is ongoing.

II. Douglas PUD

A. Decision: Draft 2017 Wells HCP Action Plan (Greg Mackey)

Greg Mackey shared a document titled "Draft 2017 Wells HCP Action Plan" (Attachment B), which Sarah Montgomery distributed to the Hatchery Committees on February 23, 2017. Mackey said the plan is similar to previous years. He said the Wells Hatchery Modernization will be completed in August, so he can arrange a tour or meeting at the facility at that time. The Wells Hatchery Committee representatives present approved the hatchery portion of Douglas PUD's Wells HCP 2017 Action Plan as follows: Douglas PUD, USFWS, WDFW, NMFS, YN, and CCT approved on March 13, 2017.

B. Decision: Wells HCP SOA M&E Report Scheduling (Greg Mackey)

Greg Mackey said the Wells Hatchery Committee is voting on an SOA specific to the Wells HCP, even though the topic of the SOA is a joint HCP-HC and Priest Rapids Coordinating Committee Hatchery Sub-Committee (PRCC HSC) discussion (under item IV-A). The Wells Hatchery Committee representatives present approved Douglas PUD's SOA M&E Reporting Schedule for the Douglas PUD, Grant PUD, and Chelan PUD Hatchery Programs, as follows: Douglas PUD, USFWS, WDFW, NMFS, YN, and CCT approved on March 13, 2017. Sarah Montgomery distributed a final version of the SOA, which is included in these minutes as Attachment C.

C. Methow Pond 13 Predation (Greg Mackey)

Greg Mackey said there have been high levels of predation at Pond 13 at the Methow FH this winter. He said Pond 13 is a rectangular outdoor pond, where approximately 80,000 spring Chinook salmon were placed during the summer and held throughout the winter. He said despite using wires, netting, and daytime hazing to deter predators, many of the salmon were consumed by birds, especially by mergansers, cormorants, and herons. He said one potential cause for the higher than usual predation is that it was a cold winter and more bodies of water than usual froze over. He said Pond 13 was one of the only open water areas nearby, so it attracted birds.

Hatchery managers seined and weighed fish in the pond to determine how many salmon survived. They estimated about 35,306 salmon remain. He said current plans to further deter predators include installing a 12-foot chain-link fence with a higher density of bird wires (but not so dense as to trap or kill birds).

Bill Gale asked how this level of predation affects overall release goals. Mackey said the Twisp Program has extra spring Chinook salmon smolts (approximately 11,000 extra smolts). He said the Methow spring Chinook salmon program has approximately 191,200 smolts remaining, which is about 15% lower than the release goal. Jayson Wahls (WDFW) said this was an abnormal year for temperature and predation. He said the primary predators were mergansers, cormorants, and herons, and he noticed more birds than usual accessing Pond 13. He said Pond 13 is susceptible to predation because its netting must be removed in the winter (otherwise it freezes into the pond during snow loads).Douglas PUD and Methow FH staff are planning to install more bird wires to decrease future predation.

III.Chelan PUD

A. Decision: Rocky Reach/Rock Island HCP SOA M&E Report Scheduling (Catherine Willard)

Catherine Willard said the Rocky Reach and Rock Island Hatchery Committees are voting on an SOA specific to the Rocky Reach and Rock Island HCPs, even though the topic of the SOA is a joint HCP-HC and PRCC HSC discussion (under item IV-A). Mike Tonseth suggested one change to language in the SOA related to Endangered Species Act (ESA) permits, which Willard edited in the document. The Rocky Reach and Rock Island Hatchery Committees representatives present approved Chelan PUD's SOA M&E Reporting Schedule for the Douglas PUD, Grant PUD, and Chelan PUD Hatchery Programs, as follows: Chelan PUD, USFWS, WDFW, NMFS, YN, and CCT approved on March 13, 2017. Sarah Montgomery distributed a final version of the SOA, which is included in these minutes as Attachment D.

B. Decision: Draft 2017 Steelhead Release Plan and Preliminary 2016 Results (Catherine Willard)

Catherine Willard shared a presentation titled, "Release Year 2016 Preliminary Results" (Attachment F). Willard described the program and variables at Chiwawa Acclimation Facility, then summarized the preliminary results for survival to McNary Dam for screened (which includes movers vs. non-movers) vs. non-screened, brood origin (HxH vs. WxW) and release locations (Chiwawa River, Nason Creek, and upper Wenatchee River). Fork length, smolt index, and residualism were also evaluated. Questions and comments are summarized in the following sections.

Bill Gale asked if the survival for Blackbird Island Pond is evaluated based on only fish that leave the pond, or the survival of all the fish that are were stocked in the pond. Willard replied that Chelan PUD uses passive integrated transponder (PIT) tags to track the survival of fish stocked in Blackbird Island Pond and fish that stay in the pond are not removed from the analysis.

Tracy Hillman asked where flow (cubic feet per second [cfs]) is measured for the Chiwawa River releases. Willard said flow is measured at the gauge in Plain, Washington.

Regarding the expanded numbers for potential residuals by BY, Hillman asked if any of the steelhead migrated downstream after holding for one year. Willard said there is evidence that at least one PIT-tagged fish did this and Chelan PUD is working with John Skalski (Columbia Basin Research) to determine if residualism can be estimated from historic data and if additional PIT tags and/or PIT antenna arrays are needed in the Wenatchee sub-basin to provide a more robust estimate of residualism for future releases.

Regarding the BY 2015 screened movers and screened non-movers, Casey Baldwin asked if there is a significant difference in release timing between the two groups. Willard said yes ($P<0.01$); there were significantly more non-movers detected after July 1 than movers. She said the multiple cohort analysis will provide a better assessment of PIT-tagged fish that stay longer than 1 year before migrating, which will supplement information gained from studying movement before and after July 1.

Willard shared a document titled "Draft 2017 Steelhead Release Plan" (Attachment G), which Montgomery distributed to the Hatchery Committees on March 6, 2017. Willard summarized the differences between the draft 2017 plan and the 2016 plan. Willard said Chelan PUD will only perform screened (a.k.a. volitional) releases in 2017 and will implement more intensive length-weight sampling on fish held indoors to increase the dataset for non-moving fish. She said Chelan PUD plans to PIT-tag a group of non-moving fish (held in the raceway) to assess the movements of non-moving fish. She said one potential change for 2017 that is not included in this document is an evening release and Chelan PUD and WDFW are working together to determine its feasibility.

Willard said Chelan PUD requests a vote on the draft release plan either today, or before March 16, 2017 (10 days after the plan was distributed). Hillman asked the Rocky Reach and Rock Island Hatchery Committees if they approve the plan or if they would like more time. The Chelan PUD representatives present approved the 2017 Steelhead release plan during the meeting on March 13, 2017, and other parties said they would provide a vote by March 16, 2017. (Note: The 2017 Steelhead Release Plan was approved by USFWS, WDFW, NMFS, YN, and CCT via email on March 16, 2017.)

IV. Joint HCP-HC/PRCC HSC

A. Decision: M&E Report Scheduling (Greg Mackey/Catherine Willard)

Greg Mackey shared a document titled, "Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD, and Chelan PUD Hatchery Programs," which Sarah Montgomery distributed to the Hatchery Committees on March 2, 2017 (Attachment E). Mackey said Douglas PUD and Chelan PUD also have SOAs related to this document (Items II-B and III-A). The SOAs provide background and purpose for the schedule, and the schedule itself is a separate document that describes the reporting timeline and content and function of each report. Mackey said this document details the required M&E reports and actions, the content of the M&E reports, and the reporting schedule through 2052. He said Table 3 summarizes the schedule and data to be used in each report. He said 2017 to 2019 is a transition period, after which the schedule falls into regular reporting cycles. Todd Pearsons asked if the Statistical Report would be produced every 5 years except in years where the Program Review is also produced (i.e., every 10 years, with statistical information included in the Program Review document instead of a separate Statistical Report). Keely Murdoch said yes, statistical analyses will be performed every 5 years and will be included in the Statistical Report or Program Review, which alternate every 5 years. Mackey said the last report including statistical analyses was completed in 2012, so analyses were initially planned for 2017 in the schedule (5 years later), but have been moved to 2019 (7 years later) to coincide with the Program Review. He said if there are any statistical questions about certain datasets in the interim, specific analyses can be performed.

Mackey said there is currently an M&E Plan update scheduled for 2017 or 2018, then one again in 2021. Mike Tonseth recalled the level of effort involved in updating the M&E Plan and appendices, and suggested the Hatchery Committees review the M&E Plan and write amendments to the existing plan as necessary in 2017 or 2018, with the expectation that the 2021 update incorporates these amendments into the M&E Plan itself. Regarding contracting, Bill Gale asked if there is an ideal time of year to complete the M&E Plan update. Mackey said Douglas PUD begins their M&E contract year on January 1, so September would be a good target to finish the update in order to draft related items, such as budgets and scopes of work for contracting. Willard agreed for Chelan PUD. Pearsons said Grant PUD would prefer to finalize updates in August. Murdoch said she does not anticipate updating the M&E Plan will take much effort and it could even be completed by August 2017. Tonseth said the Hatchery Committees should focus the next update (in 2017 or 2018) on items that need to be fast-tracked for implementation. Mackey suggested the Hatchery Committees representatives review the Hatchery M&E Plan prior to the April 19, 2017, meeting and bring forth any objectives for discussion. Representatives present agreed to update the M&E Plan in 2018. The Wells, Rocky Reach, and Rock Island Hatchery Committees voted on the SOAs approving the schedule as described under Items II-B and III-A.

B. USFWS Bull Trout Consultation Update (Matt Cooper)

Matt Cooper said Karl Halupka (USFWS) sent him an update on USFWS consultations, which he summarized as follows:

- The USFWS is moving forward with finalizing the biological opinion (BiOp) for the batch of Wenatchee hatchery programs. USFWS requests comments by Friday, March 31, 2017, and will respond to comments, review the BiOp internally, then finalize it, with a target date of mid-May.

- Natasha Meyers-Cherry (NMFS) has been coordinating with Halupka about the next hatchery program consultation in the upper Columbia River basin. There are two candidates; Methow steelhead and a batch for Columbia River mainstem unlisted programs. Which of these will go first is currently unclear, but NMFS will coordinate with committee members on the decision. Either candidate will likely result in information requests from the USFWS to committee members about specific aspects of these programs as they are currently implemented.

Mike Tonseth asked if Halupka would like feedback on prioritization for the next hatchery program consultation and said he believes Methow steelhead are the priority. Cooper said NMFS will coordinate that prioritization. Bill Gale said some of the steelhead programs in the Methow basin already have bull trout coverage—similarly to the Methow spring Chinook salmon programs, the steelhead program at Winthrop NFH has bull trout coverage (the USFWS is currently reviewing the adequancy of coverage for the PUD programs). Greg Mackey said the Wells BiOp should provide bull trout coverage for the new steelhead consultation. Gale said that would be a good question for Halupka, and said he is not sure whether the steelhead program has fishery effects; the spring Chinook salmon program does not, so the aspects of coverage may be different. Gale said a gap analysis will probably occur.

C. NMFS Consultation Update (Brett Farman)

Regarding the Methow spring Chinook salmon consultation, Brett Farman said the last signatures are being obtained and the permits should be distributed this week by Charlene Hurst.

Regarding the Methow steelhead consultation, Farman said Hurst may have time in May and June to work further on finalizing this consultation. He said the proposed action needs to be finalized, which will include genetics and fisheries information. He said for some of the programs, Section 7 consultations will be complete, but National Environmental Policy Act (NEPA) will not be complete, and permits will not be issued. He said NMFS is trying to finish the Section 7 consultations, then follow up with NEPA and permit processes. Gale asked if that means it would be approximately 12 months until permits are issued for the Methow steelhead consultation. Farman said it depends on other timelines and there is not a defined sequence or timeline at this time. Mackey said if Hurst needs anything else for the next steps for this consultation to please let the PUDs know. Farman said he is not aware of any specific needs, but that communication can happen with Hurst.

D. Draft 2017 Broodstock Collection Protocols (Mike Tonseth)

Mike Tonseth shared a document titled, "Draft 2017 Broodstock Collection Protocols v1" (Attachment H), which Sarah Montgomery distributed to the Hatchery Committees on March 3, 2017. Tonseth said he requested feedback on the protocols and changes from 2016 and comments will be discussed today.

Tonseth said one item that should be discussed is external marking for Okanogan steelhead program wild-by-wild fish. He said there is currently a "TBD" label for this program in Appendix B. Tonseth said in 2016, Kirk Truscott had incorporated language in the protocols for external marking to include an alternate fin clip to distinguish from other program fish, which was never resolved during the year. He said now would be a good time to discuss and resolve this. Todd Pearsons said there is concern about doing a ventral clip on descendants of wild-by-wild Omak steelhead and marking should be consistent with the conservation value of the fish. Casey Baldwin agreed and said he would discuss this with Truscott. Tonseth said Truscott had brought up potentially differentiating between Omak wild-by-wild and Twisp wild-by-wild steelhead. Baldwin asked if the differential marking is related to a Methow management objective. Tonseth said the Methow steelhead program may be bound by proportionate natural influence and proportion of hatchery-origin spawners objectives and fish may need to be intercepted earlier in the system, so distinguishing between Methow and Omak steelhead may be desired. Baldwin asked why Omak fish should be marked instead of Twisp fish, since it is a Methow management objective. Greg Mackey said the Twisp Weir is being used to target Twisp wild-by-wild fish, so they are no longer collecting wild broodstock at Wells Dam. He said it would not be desirable to take steelhead bound for the Okanogan River and put them into a Wells FH program, since the CCT are trying to get an Okanogan basin steelhead stock going. He said he and Truscott had discussed how it is difficult to differentially mark all the different groups of steelhead coming through Wells Dam. Baldwin said he and Truscott will discuss this and provide clarification on the steelhead marking strategy for Omak steelhead.

Tonseth said another question in the protocols regards summer Chinook salmon eggs for the YN program. He said each year, the protocols state an egg allocation for the YN program, and he asked Keely Murdoch to discuss whether the request in the protocols is still consistent with YN's expectations. Murdoch said she will discuss this internally.

Tonseth said one change from the 2016 protocols is the Methow spring Chinook salmon trapping schedule. He said the Wells HCP Coordinating Committee has oversight for the trapping schedule because it is related to fish passage and hydropower operations. The 2017 protocols include additional trapping days (5 total days per week, not to exceed 3 days in a row) to increase the probability of meeting the broodstock collection targets for the program and a decrease in the total trapping hours per day to 12 hours. He said this schedule provides more availability and flexibility in broodstock collection without a significant increase in trapping hours.

Tonseth said the ongoing discussion about the Twisp steelhead conservation program also factors into the draft 2017 Broodstock Collection Protocols. He said the 2017 protocols include a near-term plan for the direction of the Methow steelhead program: compositing the existing programs with a Winthrop NFH component and a PUD component and mixed releases of S1 and S2 smolts in the Twisp River and other locations. He said the Joint Fisheries Parties (JFP) identified a necessity to develop a steelhead management plan (similar to that proposed for spring Chinook salmon), so there is better direction on steelhead recovery in the Methow basin. He said the current proposal is to composite the Twisp and Winthrop NFH programs. The one-year smolt program (48,000 fish) would be a combined USFWS-and Twisp broodstock, then sufficient eggs would be transferred to Methow or Wells FH for rearing, and fish would be released into the Twisp River (at Buttermilk Bridge), from Winthrop NFH on station, or released elsewhere in the basin as part of a study. He said studies could be set up on a rotational basis, such as 5 years of supplementation in the Chewuch River, then 5 years of supplementation at another location. Tonseth summarized that compositing the programs is the near-term plan while a comprehensive management plan is being developed.

Bill Gale said compositing the program would help with steelhead gene flow in the Methow basin, because each year would have multiple BYs returning. He said the steelhead currently released from Methow FH should be PIT-tagged [they already are] so their return locations can be evaluated. This would inform the longer-term plan and whether shifting to releases lower in the basin would help with management objectives. Mackey said Douglas PUD's No Net Impact commitment is 8,000 fish and they were releasing 48,000 to maintain constant release numbers for the reproductive success study, for which 2016 was the last adult cohort. He said the 48,000 number can change and Douglas PUD should contribute in whatever way makes the most sense for safety-net or conservation fishery numbers. Tonseth said the JFP thinks the conservation numbers (i.e., 48,000) should be maintained until the longer-term management plan is developed. Tonseth and Gale both emphasized the value in releasing S1 and S2 smolts in 2017 for comparison and age class diversity reasons. Mackey said he, Tom Kahler, and Todd Seamons (WDFW) discussed the Twisp steelhead program, and Seamons stated that steelhead are naturally a multi-age emigrant, but hatcheries force steelhead into one age class, which limits the age structure of the returning adults. This further emphasizes the benefit in having two age groups for 2017 releases. Tonseth summarized that the biggest change in the 2017 protocols is compositing the steelhead conservation programs in the Methow basin.

Gale said during the February 15, 2017, Hatchery Committees meeting, he requested an update from Chelan PUD on the feasibility study for Pacific lamprey at Tumwater Dam. Willard said Chelan PUD received the draft feasibility study on March 2, 2017, and it is currently undergoing internal review, after which it will be distributed to the Rocky Reach Fish Forum (RRFF) where anyone can receive updates. Gale said Pacific lamprey at Tumwater Dam are an issue for both the RRFF and the Hatchery Committees. Willard said Chelan PUD requests that Gale receive updates from Steve Lewis, the USFWS representative on the RRFF, or the HCP Coordinating Committees if it relates to passage, because it is not an issue for the Hatchery Committees to discuss. She said Chelan PUD understands that there are conflicting concerns regarding Pacific lamprey at Tumwater Dam, but Hatchery Committees representatives are responsible for implementing the hatchery programs, and that does not include Pacific lamprey at Tumwater Dam. Gale said the draft 2016 Rocky Reach HCP Annual Report states that Pacific lamprey are an issue for discussion in the HCP Coordinating Committees and HCP Hatchery Committees meetings. Willard said Chelan PUD does not intend to discuss Pacific lamprey during Hatchery Committees meetings; though they understand the concern for Pacific lamprey and implementing hatchery programs requires using Tumwater Dam. Tracy Hillman asked Gale about the level of detail of discussions about Pacific lamprey he is requesting, and whether he is asking for a broad overview of Chelan PUD’s current actions, or whether he is asking the Hatchery Committees to be involved in decision-making regarding Pacific lamprey. Gale said he is requesting a brief update on current actions and study results and that the USFWS vote on the draft 2017 Broodstock Collection Protocols depends on meeting the Upper Columbia Non-Target Taxa of Concern objectives for Pacific lamprey. Willard said Chelan PUD can provide a brief update, but not a presentation as previously requested. Tonseth suggested that the Hatchery Committees request an update from the RRFF on the status of Pacific lamprey-related activities occurring at Tumwater Dam that could affect actions that the Hatchery Committees are involved in. He said that would provide information about plans and actions and would not compromise the proposed broodstock collection protocols. He said while the RRFF is the appropriate venue for discussing Pacific lamprey, the Hatchery Committees should be aware of any actions that might affect meeting the goals and objectives of hatchery programs involving Tumwater Dam. Hillman said he is the chair of the RRFF and he can provide Pacific lamprey as they relate to Tumwater Dam updates to the Hatchery Committees.

Pearsons said another topic of discussion under broodstock collection protocols is the size of conservation programs. He said he noticed the large number of fish that would be managed at Tumwater Dam and if natural fish are being used in a way where their returning offspring are killed, it should be discussed in 2017. Pearsons clarified that he is specifically talking about Nason Creek spring Chinook salmon. He said Grant PUD's Nason Creek spring Chinook salmon came from tangle-net fishery broodstock collection, and he said he wants to discuss whether programs are the right mix of conservation and safety-net fish. Tonseth said this would not involve changing production levels, just the ratio of conservation to safety-net fish.

Tonseth said Pearsons' concern about the size of the conservation and safety-net programs also relates to potential M&E Plan updates. He said the Twisp steelhead program is experiencing a Ryman-Laikre effect and has a low effective population size. He said the genetic effects were detected because analyses were in place and sampling was relatively intensive. This begs the question of whether similar effects are occurring elsewhere in conservation programs, but are not being detected. He said smaller programs and populations are more at risk of negative genetic effects, so as the Hatchery Committees discuss new management plans with conservation elements, they should consider program sizes and potential genetic effects, which may also result in changes to the M&E Plan and objectives. He said the timeline and scope for M&E for conservation programs may need to be more intensive. Gale asked if the Wenatchee management plan has a timeline for being updated. Tonseth said that plan can be updated any time and developing Methow basin spring Chinook salmon and steelhead management plans will provide guidance for updating the Wenatchee management plan, too. He said effective population size is one extra consideration for management plans that may not have been originally considered.

Pearsons mentioned that the protocols can be discussed further on Thursday, March 16, 2017, during the joint portion of the PRCC HSC meeting, if Chelan and Douglas PUDs are available. Tonseth said he requests any further comments on the draft 2017 Broodstock Collection Protocols by March 16, 2017, and if edits are straightforward he will send a revised version to vote on via email. (Note: if further discussions are warranted, he and Montgomery will coordinate to set up a conference call.)

E. Brood Year 2017 Twisp Steelhead (Mike Tonseth)

Mike Tonseth said the draft 2017 Broodstock Collection Protocols previously discussed today include information for the BY 2018 Twisp River steelhead. He said because the Twisp program has spring collection targeted, adults are not yet in hand for the BY 2017. He said there are two components of the BY 2017 Twisp steelhead that need to be discussed.

The first component is the schedule and location for release of the BY 2016 Twisp steelhead. He said there are approximately 48,000 S1 smolts on hand for release. He said rather than acclimating and releasing them from the Twisp Acclimation Pond, WDFW would like to truck plant those fish at Buttermilk Bridge. He said plans for moving fish need to be decided quickly. Keely Murdoch asked if the smolts are PIT-tagged, and Tonseth replied yes. He said the total number that would be truck-planted at Buttermilk Bridge would be approximately 48,000 smolts, plus Winthrop NFH will also release an additional 13,000 smolts that have coded wire tags. The Wells Hatchery Committees representatives present agreed that the approximately 48,000 BY 2016 Twisp River steelhead smolts should be truck-released from Buttermilk Bridge, instead of acclimated at the Twisp Acclimation Pond as follows: Douglas PUD, WDFW, YN, CCT, USFWS, and NMFS agreed on March 13, 2017.

Tonseth said the second component is BY 2017 steelhead collection. He said WDFW wants to collect BY 2017 fish at the Twisp Weir in the spring, then transfer them to Winthrop NFH, where they would be spawned as part of the aggregate composite population there. Wells FH or Methow FH would then receive eggs or fry, and WDFW and Douglas PUD would rear the fish as S1s. He said the BY 2017 could be the start of what is proposed for BY 2018 and beyond. Some questions and concerns in deciding how to handle BY 2017 fish include fish health, temperature, live-spawning, sampling schemes, tagging, and hatchery space. Bill Gale said Chris Pasley (USFWS) and Jayson Wahls (WDFW) should discuss temperature concerns. Greg Mackey said one consideration for fish health is if Twisp wild brood are brought to Winthrop NFH and are live-spawned, then kelts will be on station, simplifying the kelt program, but possibly creating fish health transfer concerns for the juveniles. Murdoch said the Winthrop NFH brood is already live-spawned, so that would not be a difference from current methods. She said the difference in fish health protocols between the two programs is in their lethal sampling of fish. She said the Winthrop NFH program is big enough that a sufficient fish health sample is achieved without lethally sampling progeny from all wild females that are live-spawned (males and hatchery-origin fish are lethally sampled). She said WDFW's Twisp steelhead program lethally samples fry from 100% of live-spawned fish, so a question for WDFW's fish health program is whether subsampling of adults instead of sampling progeny of live-spawned females is sufficient. Tonseth said there might be enough background and sampling at a high enough rate that subsampling could be sufficient, but the fish health experts will need to talk about it. He said WDFW's preference is to transfer eyed eggs, not fry. Wahls said more feedback is needed, but he does not think WDFW will allow transferring non-tested fish. Mackey said keeping the fish until they are juveniles creates a lot more effort to transfer. Mackey said in 2017, Douglas PUD would incubate eyed eggs at Methow FH (Wells FH is not ready to receive eggs in spring 2017), and if eyed egg transfer is allowable, they can use the room at the hatchery dedicated to the Twisp program. Gale asked if early rearing for the composite steelhead program could be separated from other programs during early rearing. Mackey said the Twisp room is an isolated incubation room but the start room is not bio-isolated, and the fish would eventually be placed into circular tanks at Well FH.

Tonseth asked if representatives present are comfortable with compositing the Twisp and Winthrop programs for BY 2017. This would include fish collection at the Twisp Weir, held, spawned, incubated to eyed egg stage or held to fry stage at Winthrop NFH, then transferred to Methow or Wells FH. He asked if decisions should wait on fish health conversations, hatchery space, and the possibility of raising fish to an S1 stage at Methow FH. Wahls said the Twisp Weir will begin operating at the end of March, so a decision is needed by the end of the month at the latest. WDFW voted yes on this agreement during the meeting on March 13, 2017, and other representatives requested more time. Tonseth requested a vote by March 30, 2017.

Michael Humling (USFWS) said the Winthrop S2 program broodstock collection has typically avoided collection below the Twisp River, but since compositing the programs is an ongoing discussion and trending towards a positive vote, he asked if USFWS should extend their collection area below the Twisp River. Tonseth said if that were to happen, fish collected in the area between Carlton Acclimation Pond and the Twisp River should be subtracted from the total number targeted from the Twisp Weir. He said it would not be desirable to exceed the proportion of Twisp-origin fish in the collection. Humling said at the moment, he thinks steelhead are stacked up in the lower Methow River, but with warmer temperatures, fish will start moving very soon. Mackey suggested collecting as Humling proposed, up to the number identified as the Twisp broodstock collection target. Humling said he will have USFWS avoid collecting in the area where fish are currently stacked up and will expand broodstock collection below the Twisp River.

F. Spring Chinook Salmon Outplanting in the Chewuch River (Catherine Willard/All)

Catherine Willard shared a document titled, "Revised Draft Outplanting Surplus Methow Composite Spring Chinook Salmon Adults" (Attachment I) and a related spreadsheet, "Adult Outplanting Calculator" (Attachment J), which Sarah Montgomery distributed to the Hatchery Committees on March 13, 2017. Willard said she received comments on the previous version of this draft and inserted any substantial changes in track-changes. She summarized the changes to the document and questions and comments followed.

Casey Baldwin asked how long fish are retained in the system. Willard said there are likely differences between males and females and translocation of females may be more successful because males are more transient. She said male maturation is difficult to ascertain compared to females.

Greg Mackey introduced the spreadsheet and said it can be used to ensure the study stays within permit conditions (the gene flow sliding scale). He said some of the inputs to this equation could be estimated in-season at the 50% passage point at Wells Dam. He said there should be sufficient fish on hand as they are captured at Methow FH during brood collection and gene flow management, and the size of release at that point would be a management decision. Matt Cooper asked if there is a minimum number at which point the study would not be undertaken. Mackey replied that the study intends to augment returns to the Chewuch program, up to the point that is defined by the ESA permit conditions.

Bill Gale asked if there is enough space at Methow FH to accommodate this study. Mackey said yes and because there are prescription restrictions forfish that may be released, they will be held separately. Tonseth said these fish can be treated with Formalin but not antibiotics or other substances. Tonseth suggested adding a caveat that if fish are being held for the study and there is a significant bacterial outbreak, the fish will not be released.

Regarding release sites, Keely Murdoch said YN requested that the workgroup consider out-planting higher up in the basin. Willard said she discussed this with Charlie Snow (WDFW), who said there is not abundant spawning habitat above the areas identified in this draft; it is more "pocket spawning" Willard said she will add text about if there is available spawning habitat that is not occupied by spawners, crews can be flexible about planting upstream of the currently designated locations.

Gale asked what the reporting strategy for this would be. Willard said she will add language about reporting and she will revise the draft plan and distribute it for approval in April 2017.

Murdoch said contingency language should be added for higher release sites and a preference should be stated for upper sites. Todd Pearsons pointed out that this will be a multi-year study, so the release location can be changed.

G. Brood Year Stray Rate Targets (Todd Pearsons)

Tracy Hillman introduced the BY stray rates topic by emphasizing the potential implications of failing to meet a target, even if the target does not link to extinction risk. He said some objectives are more important than others and the BY stray rate target is linked to the other two stray rates, even if it is not linked directly to extinction risk. He said BY stray rates may be better suited as informing other targets, which appears more in line with how the Hatchery Committees consider BY stray rates—it is useful information to describe what is happening within programs, and can also inform Q2 and Q3. Mike Tonseth said if there is an issue with recipient population strays, looking at the BY stray rate for example could determine if a specific BY, culture, handling difference, or broodstock origin is correlated with the issue. He said in this way, BY stray rates could be considered a management objective. Bill Gale said one issue with this approach might be programs with really high BY stray rate targets, but are still within the target for recipient populations because these programs stray a little bit to many locations. Another potential issue would be spikes of recipient stray rate problems because of low natural-origin returns. He said examining the differences or causative factors is most important. Tonseth said it is difficult to set a BY stray rate target for all programs, because facilities and limitations affect programs in different ways. Tonseth said it is important to maintain the perspective of examining BY stray rates without tying the rates to a target. Gale said he is not opposed to changing the language of stray rate targets, but he sees a potential issue if the target is removed and a program has a very high BY stray rate but is still meeting Q2 and Q3 targets. He said folks might argue at that point that change is not warranted, because the targets are met.

Hillman said that most hatchery fish stray to only a few locations. He suggested performing an analysis to determine if the situation Gale describes often occurs. That is, did programs with high BY stray rates also exceed within and among recipient population stray rate targets.

Gale said the language about BY stray rates is important and should state that the BY stray rates should be used as an indicator of program performance. Keely Murdoch said she will need to discuss this internally before making a decision about eliminating the target altogether or changing the language behind it and said she supports performing the analysis. Greg Mackey said another option is rewriting Q1 so that it is contingent on Q2 and Q3. Tonseth said because the Hatchery Committees are already committed to reviewing the M&E Plan before the next meeting, they can also begin to flag objectives for review. He said it will be important to provide plenty of background as to why the target is changing. Todd Pearsons said the M&E Plan clearly states that new information should be used to update the plan, so as long as the new information is detailed in the review process, it is okay to change or eliminate the target. Hillman agreed and said there appears to be justification for removing or modifying the BY stray rate target. Casey Baldwin said from the perspective of the receiving population, strays should be assessed as the total stray rate rather than a program by program rate, and how the objective is worded should take this into consideration. Hillman said he will preliminarily revise the BY stray rate target language in the Hatchery M&E Plan for further discussion at the Hatchery Committees April 17, 2017, meeting and will analyze the relationship over the last 10 complete BYs between exceeding BY stray rate targets and exceeding recipient stray rate targets.

H. Maturation Sampling for Methow and Chiwawa Spring Chinook Salmon 2017 Releases (Willard/Mackey)

Catherine Willard said Chelan PUD proposes to perform maturation sampling in partnership with USFWS and WDFW on 300 spring Chinook salmon for the third year in a row. The Rock Island Hatchery Committee agreed that Chelan PUD,USFWS, and WDFW can perform maturation sampling on 300 Chiwawa spring Chinook salmon as follows: YN, WDFW, USFWS, NMFS, Chelan PUD, and CCT agreed March 13, 2017.

Greg Mackey said Douglas PUD proposes to sample 300 spring Chinook salmon for maturation sampling as part of their new permit conditions. The Wells Hatchery Committee agreed that Douglas PUD can perform maturation sampling on 300 Methow spring Chinook salmon as follows: Douglas PUD, YN, WDFW, USFWS, NMFS, and CCT agreed March 13, 2017.

V. HCP Administration

A. Next Meetings

The next Hatchery Committees meetings are on April 19, 2017 (Grant PUD), May 17, 2017 (Grant PUD), and June 21, 2017 (Grant PUD).

Draft 2017 ACTION PLAN
WELLS HCP

WELLS HCP COORDINATING COMMITTEE

1. **Juvenile Fish Bypass**
   a. Gas Abatement Plan (GAP) and Bypass Operating Plan (BOP) to CC........ 5 January 2017
   b. CC comments on GAP/BOP to DCPUD .... 6 February 2017
   c. CC approval of GAP/BOP .... 14 February 2017
   d. Submit final GAP/BOP to FERC for approval .... 28 February 2017
   e. 2017 Bypass operations at Wells .... 9 April 2017 – 19 August 2017

2. **Annual Monitoring of Juvenile Migration Run Timing**
   a. 2017 Skalski passage-dates analysis to DCPUD .... September 2017
   b. 2017 draft passage-dates analysis and post-season bypass report to CC.........October 2017
   c. CC approval of 2017 final report .... December 2017

3. **Expand PIT-tag Detection in Spillway # 2 of the Wells Bypass System**
   a. Biomark installation and testing of expanded system....................................... March 2017
   b. Operation and performance monitoring.............................. 9 April 2017 – 19 August 2017
   c. Technical Advisory Memorandum to CC...November 2017

4. **Fishway Outage Schedule for Fishway Inspection, Maintenance, and Fishway Projects**
   a. West Fishway.. 15 November – 14 December 2017
   b. East Fishway ....19 December 2017 – January 2018
   c. Adult Fishway Trap Coordination Meeting.. April 2017

5. **Multi-Year Sub-yearling Chinook Life-history Study**
   a. Monitor fish tagged in 2011-2013 study years through adult returns.......... December 2018
   b. Draft juvenile life-history report to CC .... June 2017
   c. Final juvenile life-history report .... September 2017
   d. Draft and Final Life-History Report 2019

6. **Review and Approval of 2017 Hatchery Broodstock Collection Protocol**
   a. Draft protocol to CC for review.. February 17, 2017
   b. CC approval of draft protocol .... March 28, 2017
   c. Deadline for submission of protocol to NMFS... April 15, 2017

7. **Pikeminnow Control Program**
   a. Draft 2016 pikeminnow report to HCP CC .... April 2017
   b. Final 2016 pikeminnow report.. June 2017
   c. Pikeminnow removal – Wells Project.. March – November 2017

8. **2020 Survival Verification Study**
   a. Study Plan to HCP CC... September 2017
   b. Approval of Study Plan... December 2017

9. HCP Annual Report

a. Draft 2016 annual report to DCPUD for review..January 12, 2017
b. Draft 2016 annual report to CC for 30-day review....................................February 8, 2017
c. CC comments on draft 2016 report due to Anchor QEA...............................March 7, 2017
d. Final 2016 annual report to DCPUD ....March 23, 2017
e. Final 2016 annual report due to FERC ....March 31, 2017

WELLS HCP HATCHERY COMMITTEE

1. **Implement 5-year Hatchery Monitoring and Evaluation (M&E) Plan**
   a. Ongoing implementation .... January – December 2017
   b. Draft annual report for 2016 to Douglas PUD .... June 2017
   c. Draft annual report to Hatchery Committee (HC) .... August 2017
   d. Final annual report to HC .... September 2017
   e. Draft 2018 implementation plan to HC .... July 2017
   f. HC approval of final 2018 implementation plan .... September 2017
   g. Develop new draft schedule for M&E Reporting .... February 15, 2017
   h. Final new schedule for M&E Reporting .... March 15, 2017

2. **Twisp Population Study**
   a. Implementation .... September – October 2017
   b. 2014, 2015, 2016 Reports .... October 2017

3. **Spring Chinook Egg-to-Fry Study**
   a. Develop study design .... June 2017
   b. Implement study .... August 2017
   c. Draft report .... July 2018

4. **2017 Broodstock Collection Protocol**
   a. Draft to HC for review .... February 9, 2017
   b. HC approval of draft protocols .... March 15, 2017
   c. CC approval of Wells Dam trapping operations .... March 28, 2017
   d. Deadline for submission to NMFS .... April 15, 2017
   e. Implementation .... May 2017 to April 2018

5. **Annual Implementation – Okanagan Sockeye Fish/Water Management Tools**
   a. Water Year 2016-2017 .... October 2016 – September 2017
   b. Record of management decisions .... December 2017

6. **Modernization of the Okanagan Sockeye Fish/Water Management Tools**
   a. Phase 2 .... October 2016 – August 2017
   b. Phase 3 (Final) .... September 2017 – August 2018

7. **Methow Steelhead Relative Reproductive Success Study**
   a. Implementation .... March 2010 – December 2021
   b. Annual report on genetic analysis .... September/October 2017
   c. Biological data in Annual M&E Report (above) .... September 2017
   d. Final report 2021/2022

8. **Hatchery Genetic Management Plans**
   a. Receive new Methow spring Chinook hatchery permit .... February 2017
   b. Implement new spring Chinook permit 2017
   c. Receive new Wells steelhead hatchery permit .... *to be determined*
   d. Receive new Wells summer Chinook hatchery permit .... *to be determined*

9. Wells Hatchery Modernization

a. Construction complete .... August 31, 2017

10. Coho Hatchery Program

a. Develop plans for dividing Twisp Acclimation Pond to accommodate coho 2017

11. Chief Joseph Hatchery Production

a. Hatchery Production (spring/summer Chinook)..2017
b. Monitoring and Evaluation 2017

WELLS HCP TRIBUTARY COMMITTEE

1. **Plan Species Account Annual Contribution**
   a. $176,178 in 1998 dollars ($267,771.65 in 2017 dollars) .... January 2017

2. **Annual Report - Plan Species Account Status**
   a. Submittal of 2016 account-status report to Tributary Committee (TC): .... February 2017
   b. Integration into 2016 HCP Annual Report: .... February 2017

3. **General Salmon Habitat Program**
   a. Project review and funding .... January-December 2017

4. **Small Project Program**
   a. Project review and funding Decision .... January-December 2017

Wells HCP Hatchery Committee
Statement of Agreement

Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 13, 2017

(Douglas PUD, NMFS, USFWS, WDFW, YN, and CCT approved on March 13, 2017)

Statement

The Wells HCP Hatchery Committee approves the Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 13, 2017. Any future alterations of the schedule will require HCP Hatchery Committee approval.

Background

The Douglas and Chelan HCPs and Grant Settlement Agreement and 2008 NMFS Biological Opinion for Grant PUD specify certain reporting dates or intervals for hatchery monitoring and evaluation (M&E). The Endangered Species Act incidental take permits and the PUD hatchery M&E Plan also have reporting requirements. These reporting time requirements were designed to provide timely information to operators and managers, fulfill permitting requirements, inform other activities such as updating M&E plans, recalculation of hatchery production, evaluation of meeting objectives, status of meeting permit requirements, and adaptive management actions. To date, the reporting timing that has been implemented has not necessarily met the intent of the Wells HCP, and has not been orchestrated to work with the various actions that the Hatchery Committee and NMFS require. This document, Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 13, 2017, is the new reporting schedule that is consistent with the Wells HCP, meets reporting requirements under the M&E Plan, meets ESA Section 10 permit requirements, and optimizes the sequence of reporting and the actions that rely on M&E information.

Rocky Reach and Rock Island HCP Hatchery Committees
Statement of Agreement

Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 13, 2017

(Chelan PUD, NMFS, USFWS, WDFW, YN, and CCT approved on March 13, 2017)

Statement

The Rocky Reach and Rock Island Habitat Conservation Plans (HCP) Hatchery Committees (HC) approve the Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 13, 2017. Any future alterations of the schedule will require HCP Hatchery Committees approval.

Background

Chelan PUD's HCPs specify the need to update the hatchery monitoring and evaluation (M&E) plan every five years and to comprehensively review the hatchery program every 10 years utilizing new information from the M&E program. The National Marine Fisheries Service Section 10(A)(1)(a) and 10(A)(1)(b) Endangered Species Act permits for Chelan PUD's hatchery programs and the *Monitoring and Evaluation Plan for PUD Hatchery Programs* also contain reporting requirements for hatchery M&E information. To date, these reporting requirements have not aligned, which has resulted in a disjointed review and input cycle to inform updates to M&E plans, recalculation of hatchery production, evaluation of M&E objectives, status of meeting permit requirements, and adaptive management actions. The document, Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 13, 2017, optimizes the sequence of hatchery M&E reporting and is the new reporting schedule for hatchery M&E information.

Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs

March 13, 2017

Introduction

The Douglas and Chelan PUDs' HCPs, Grant PUD's Settlement Agreement, and the 2008 NMFS Biological Opinion (Biop) for Grant PUD (hereafter referred to collectively as the Agreements) specify certain reporting dates or intervals for hatchery monitoring and evaluation (M&E). The Endangered Species Act (ESA) incidental take permits and the Monitoring and Evaluation Plan for PUD Hatchery Programs (Hillman et al. 2013) also have reporting requirements. These reporting date requirements were designed to provide timely information to operators and managers and fulfill permitting requirements. Additionally, the reports are used to inform other activities such as updating M&E plans, recalculation of hatchery production, evaluation of meeting M&E objectives, status of meeting permit requirements, and adaptive management actions. To date, the past reporting timing has not necessarily met the intent of the Agreements, and has not been orchestrated to align with the various actions that the Hatchery Committees and NMFS require. Subsequently, we have designed a reporting schedule that is consistent with the Agreements, meets reporting requirements under the M&E Plan, meets ESA Section 10 permit requirements, and optimizes the sequence of reporting and the actions that rely on M&E information.

Section 1: Monitoring and Evaluation Reports

Three levels of M&E reporting will be implemented (Table 1). These reports are consistent with past reporting and the M&E Plan, but have been restructured to streamline transfer of information and meet the requirements of the Agreements.

Table 1. M&E Report Types

Report type	Frequency	Content	Function
Data	Annual	Cumulative description of data (raw and derived) and field methods. Basic statics reported.	Informs annual M&E implementation plans
Statistical	5 year	Presentation of statistical analyses and description of statistical methods. Addressed in the Program Review when the two would occur in the same year.	Informs 5 year M&E plan and provides in depth data analysis
Program Review	10 year	Integrates and interprets information from data and statistical reports and also includes integration from other programs and studies. Written in scientific manuscript format. Fulfills HCP "Program Review" requirements. Addresses Statistical Report requirements.	Informs recalculation and adaptive management. Determines if programs are meeting objectives.

The Data Report will be produced annually and will provide data collected in the most recent field year. The report will provide tables of cumulative data, including the most recently collected, and provide summary statistics where appropriate (e.g., mean, standard deviation, etc.). The report will provide a concise description of the field methods that could be used in a scientific publication and describe deviations from previous sampling, standard field practices or sampling plans. This report will provide up to date information for managers and operators, fulfill incidental take reporting requirements, and inform annual adjustments to the implementation of the M&E plan.

The Statistical Report will be produced every ten years on the five year intervals between the Program Review (see below). The report will provide a concise description of the analytical methods used (e.g., similar to a scientific journal article) and the results of the statistical analyses for each objective as described in the M&E plan. The report will also provide the assumptions of the statistical analyses and note any deviations in expected performance of a given analysis (e.g., issues related to normality, dependency, non-constant variance; etc.). The report is not intended to provide interpretation of the results, but will provide the outcomes of the statistical tests. This will provide managers and operators a periodic update of the performance of the hatchery programs.

The Program Review will be produced every ten years and will meet the Program Review as described in the HCPs (Section 8.8 of the Wells HCP, Section 8.7 of the Rocky Reach/Rock Island HCPs) and will address the information reported in the Statistical Report. The report will provide the results of any natural population/hatchery interaction studies (as needed), and determine if the hatchery programs are operating consistent with the goals as outlined in the relevant M&E Plan. The review will determine if hatchery program goals and objectives, as defined in the Hatchery Plan (HCPs Section 8), Section 10 permits, as further defined in the HCPs, have been met or sufficient progress is being made toward their achievement; and determine if hatchery production objectives are being achieved.

Section 2: Required Reports and Actions

The HCPs list required reports or actions. The M&E reporting is either directly described or closely tied to these milestones (Table 2).

Table 2. Required Elements in the Agreements

Element	Document	Section	Frequency	Previous	Next
Survival Studies	HCP	8.4.4	Every 10 years	2010	2020
Recalculation	HCP SSSA/BiOp	8.4.5	Every 10 years Every 10 years	2013	2023
M&E Plan Update	HCP SSSA	8.5 13.1.4	Every 5 years Every 5 years	2013	2018
Program Review	HCP	8.8	Every 10 years	2012	2020
Section 10 Permits	HCP	10.2.5	Every 10 years	2004	2017

Section 3: Schedule

The M&E reporting schedule (Table 3) is designed to be consistent with the Agreements. However, it also has been designed to provide a logical sequence of information based on significant milestones in the HCPs as well as consistency with Grant PUDs settlement agreement and NMFS BiOp. Reporting was designed to provide the Program Review (ten year interval) prior to recalculation in order to have the most up to date data vetted and organized prior to recalculation. The Statistical Report will be produced every ten years. On the five year intervals between the ten year intervals, the Statistical Report material will be addressed in the Program Review. The Data Report will be produced annually (see Table 3). The PUDs also require advanced knowledge of M&E and reporting requirements to facilitate timely contracting. The Agreements terminate in 2052.

Table 3: Schedule of M&E Reporting and Significant Actions under the Agreements

	Year	Recalculation	M&E Review	Program Review	Statistical Report	Data Report	Annual Data	Statistical/Program Review Data

DRAFT Memorandum

Date: March 3, 2017

To: Rock Island and Rocky Reach HCP Hatchery Committees

From: Catherine Willard (CPUD), Scott Hopkins (CPUD), Chris Moran (WDFW), and Mclain Johnson (WDFW)

Re: 2017 Wenatchee Steelhead Release Plan (Brood Year 2016)

Background

Chelan PUD is required to produce 247,300 steelhead smolts for release into the Wenatchee River Basin in 2017 as part of the Rock Island and Rocky Reach HCP requirements. As of February approximately 267,035 Wenatchee summer steelhead (142,224 HxH and 124,811 WxW) are on station at the Facility.

Beginning in winter 2011 the Chelan PUD Wenatchee River steelhead program was relocated to the Chiwawa Acclimation Facility ("Facility") (Figure 1) following significant upgrades to accommodate tributary based overwinter acclimation for the Wenatchee steelhead program. Steelhead are transferred from Eastbank Hatchery to the Facility in November and released in April through May. The Facility consists of three, in line circular, dual-drain tanks within an enclosed building and are operated on a partial water reuse system (RAS). The two outer tanks hold steelhead during rearing and the center tank is used solely for receiving fish that are allowed to move from the outer tanks to the center tank during release. Fish are not provided the opportunity to move to the center tank until gates are removed (typically April 20th). When the center tank contains a pre-determined number of fish for a release, fish are loaded into a hatchery truck and truck-planted at one of five release locations. This "screening" method has been used to differentiate between apparent active migrants (fish that move from the outer tanks to the center tank) from apparent non-active migrants (fish that do not move from the outer tank to the center tank).

In addition to the circular vessels, there are three traditional flow-through raceways (RCY) located outside. The smaller of the three, Raceway Three (RCY3), is used to rear steelhead when it is not needed for rearing "high ELISA" spring Chinook juveniles. Raceways One (RCY1) and Two (RCY2) are located adjacent to each other. The wall between the two raceways contains a gated opening that when removed, allows fish to move between the raceways. In addition to removing the gate, the water is lowered in the receiving pond (typically April 20th) to establish a directional flow that apparent active migrant fish may cue to. Similar to the RAS vessels, this set-up allows for a screening method that attempts to differentiate between apparent active- and apparent non-active migrants. When RCY1 contains the pre-determined number of fish suitable for release, fish are loaded into a transport truck and truck-planted at one of five release locations. Historically, this screening method has been termed a volitional release but is currently termed a screening method as this more accurately describes the end result of the action.

2017 Release Strategy Objectives

- Evaluate best hatchery management practices for hatchery releases to optimize homing fidelity, minimize residualism, maximize out-migration survival, and minimize negative ecological interactions (Draft NMFS Wenatchee River Steelhead Section 10 Permit).
- Assess hatchery release practices to inform development of a residualism baseline for the Wenatchee steelhead program consistent with the Draft NMFS Wenatchee River Steelhead Section 10 Permit DRAFT Steelhead Residual Management Plan.
- Utilize data collected from the 2017 Wenatchee River Steelhead release to assess applicable monitoring and evaluation objectives (i.e., Objectives 4 and 6) for the Wenatchee River summer steelhead hatchery program (Hillman et al. 2013).

Methods

The 2017 release strategy will evaluate the effectiveness of the screening method, and the role of rearing vessel (RAS versus RCY) and brood origin on fish performance (e.g., juvenile survival and adult returns). The 2017 release plan methodology will consist only of screened releases; release years 2015 and 2016 evaluated screened and non-screened releases. Additionally, 2,500 PIT tags will be applied to non-movers remaining in RCY2 at the end of the screened release period to increase the PIT sample size of non-movers to better understand their post release performance. As with previous years, the release numbers and locations identified in Table 1 are proportionally based on the spawning distributions in the respective streams.

- Cormack-Jolly–Seber survival probabilities to MCN will be calculated for each release group using recaptures of PIT-tagged fish.
- The percentage of PIT-tagged fish detected in the Wenatchee sub-basin after July 1 of the year of release will be calculated to estimate potential residualism for each release group.

Release Timing

In an effort to more closely align hatchery steelhead releases with the peak outmigration period for wild steelhead and potentially increase smolt to smolt survival, all fish located at the Facility will be released by May 8th; fish acclimated at Blackbird Island Pond will be allowed to volitionally move out of the pond through the end of June (after which time the pond outlet will be closed as in years past).

Release Location

Release locations in 2017 will be the same as the previous two years.

Pre-release Monitoring and Evaluation

Throughout acclimation and release, established sampling, transfer and release protocols will be followed (Hillman et al. 2013). Additionally, to gain another year of data on screened RAS reared steelhead, non-lethal precocial maturation sampling will be conducted and smolt index will be evaluated for steelhead reared in the two RAS vessels (n=200 movers; n= 200 non-movers).

Table 1. Steelhead release numbers and locations, 2017.

Vessel	Origin[1]	Estimated Number Released[2]	Estimated # PIT-tagged	Destination	rkm	Movers or Non-movers
RAS3	WxW	11,971[3]	2,375	Nason	7.0	Movers
RCY1	Mixed	38,210	2,181	Nason	7.0	Movers
RAS1	WxW	11,720[3]	2,375	Nason	7.0	Movers
RAS1	WxW	Unknown	Unknown	Nason	7.0	Non-Movers
RAS3	WxW	Unknown	Unknown	Nason	7.0	Non-Movers
		61,901		**Total**		
RCY1	Mixed	78,299	4,469	U. Wenatchee	79.2	Movers
		78,299		**Total**		
RCY1	Mixed	73,379	4,188	Chiwawa	11.4	Movers
		73,379		**Total**		
RCY1	Mixed	Unknown	Unknown	L. Wenatchee	40.2	Non-movers
RAS1	WxW	Unknown	Unknown	L. Wenatchee	40.2	Non-movers
RAS3	WxW	Unknown	Unknown	L. Wenatchee	40.2	Non-movers
ELISA	HxH	24,952	2,500	Blackbird	40.5	Movers

[1]Mixed = HxH and WxW.
[2]Releases will occur April 20 - May 8; any remaining non-movers will be released by May 8th.
[3]Maximum estimated number of fish to be released; non-movers have not been subtracted from these totals.

Figure 1. Chiwawa Acclimation Facility site description.

Subject: **DRAFT UPPER COLUMBIA RIVER 2017 BY SALMON AND 2018 BY STEELHEAD HATCHERY PROGRAM MANAGEMENT PLAN AND ASSOCIATED PROTOCOLS FOR BROODSTOCK COLLECTION, REARING/RELEASE, AND MANAGEMENT OF ADULT RETURNS**

The attached protocol was developed for hatchery programs rearing spring Chinook salmon, summer Chinook salmon and summer steelhead associated with the mid-Columbia HCPs; spring Chinook salmon, summer Chinook salmon and steelhead programs associated with the 2008 Biological Opinion for the Priest Rapids Hydroelectric Project (FERC No. 2114); and fall Chinook salmon consistent with Grant County Public Utility District and Federal mitigation obligations associated with Priest Rapids and John Day dams (ACOE funded), respectively. These programs are funded by Chelan, Douglas, Grant County Public Utility Districts (PUDs), and ACOE and are operated by the Washington Department of Fish and Wildlife (WDFW), with the exception of the Omak Creek/Okanogan Basin steelhead Broodstock collection, and acclimation/release of Omak Creek steelhead which is implemented by the Confederated Tribes of the Colville Reservation (CTCR).

This protocol is intended to be a guide for 2017 collection of salmon (2017BY) and steelhead (2018BY) broodstocks in the Methow, Okanogan, Wenatchee, and Columbia River basins. It is consistent with previously defined program objectives such as program operational intent (i.e., conservation and/or harvest augmentation), mitigation production levels (e.g., HCPs and Priest Rapids Salmon and Steelhead Settlement Agreement), changes to programs as approved by the HCP-HC and PRCC-HSC, and to comply with ESA permit provisions, USFWS consultation requirements.

Notable in this year's protocols are:

- Continuing for 2017, no age-2 or 3 males will be incorporated into spring or summer Chinook programs unless necessary to maintain effective population size (minimum female to male ratio of 1:0.75; conservation programs only).

- Use of ultrasonography to determine the sex of each fish retained for brood to ensure achieving the appropriate number of females for program production (does not include Priest Rapids Hatchery).

- Utilization of genetic sampling/assessment to differentiate Twisp River and Methow River Basin natural-origin spring Chinook adults collected at Wells Dam, and CWT interrogation during spawning of hatchery spring Chinook collected at the Twisp Weir and Methow FH to differentiate Twisp and Methow Composite hatchery fish for discrete management of Twisp and Methow Composite production components for the GPUD, CPUD and DPUD programs.

- Collection of only hatchery adult steelhead at Wells Dam/Hatchery for the Lower Methow safety-net (WFH/MFH), and Wells Hatchery Okanogan and mainstem Columbia safety-net programs.

- Collection of spring Chinook for the Nason Creek and Chiwawa programs using combination of Tumwater Dam and the Chiwawa Weir.

- Targeted collection of 100% of the Wenatchee summer Chinook and Wenatchee hatchery origin steelhead broodstock at Dryden Dam to reduce the number of activities that may contribute to delays in fish passage at Tumwater Dam (some adult collections at Tumwater may be necessary if sufficient adults cannot be acquired at Dryden Dam).

- Targeted collection of 100% of the natural origin steelhead broodstock at Tumwater Dam.

- Collection of summer Chinook broodstock from the Chelan Falls Canal Trap (CFCT), sufficient to meet a 576K yearling juvenile Chelan Falls program. Summer Chinook collections at Entiat Hatchery may be used to support the Chelan Falls program if broodstock collection efforts at the CFCT fall short.

- Collection of surplus hatchery origin steelhead from the Twisp Weir (up to 25% of the required broodstock) to produce the 100K Methow safety-net on-station-released smolts (up to 17 adults). The remainder of the broodstock (51) will be WNFH returns collected at WNFH (or by angling/trapping/tangle netting for WNFH program) and/or Methow Hatchery and surplus to the WNFH program needs. Collection of Wells stock may be used if WNFH and Twisp returns are insufficient. The collection of adults will occur in spring of 2018.

- Summer Chinook collections at Wells Dam to support the CJH program may occur if CCT broodstock collection efforts fail to achieve broodstock collection objectives.

- Collection from the Wells Hatchery volunteer channel of Wells summer Chinook to support the YN, Yakima River summer Chinook program.

- Targeted collection of 1,000 adipose present, non-coded wire tagged fall Chinook from the PRD OLAFT.

- Targeted collection of about 400 adipose present, non-coded wire tagged fall Chinook using hook and line efforts in the Hanford Reach.

- Juvenile releases, unless otherwise noted in this document, will follow past conventional practices for each of the respective programs.

- Compositing of the Twisp steelhead conservation program with the WNFH conservation program. Releases into the Twisp and other locations in the basin will be mixture of S_1 and S_2 smolts.

- Release of 50K Methow safety net steelhead smolts into the lower Methow River (Effy's Bridge).

These protocols may be adjusted in-season, based on actual run monitoring at mainstem dams and/or other sampling locations. Additional adaptive management actions as they relate to broodstock objectives may be implemented as determined by the HCP-HC or PRCC-HSC and within the boundaries of applicable permits.

Also included in the 2017 Broodstock Collection Protocols are:

Appendix A: 2017 BY Biological Assumptions for UCR Spring, Summer, and Fall Chinook and 2018 BY Summer Steelhead Hatchery Programs
Appendix B: Current Brood Year Juvenile Production Targets, Marking Methods, Release Locations
Appendix C: Return Year Adult Management Plans
Appendix D: Site Specific Trapping Operation Plans
Appendix E: Columbia River TAC Forecast
Appendix F: Annual Chelan, Douglas, and Grant County PUD RM&E Implementation Plans
Appendix G: DRAFT Hatchery Production Management Plan

Methow River Basin

Spring Chinook

Inclusion of natural-origin fish in the broodstock will be prioritized for the aggregate conservation program in the Methow Basin. Collections of natural-origin fish will not exceed 33% of the Methow Composite (i.e., non-Twisp) and Twisp natural-origin run escapement consistent with take provisions in Section 10 (a)(1)(A) Permits 18925 and 20533.

Hatchery-origin spring Chinook, if needed, will be collected in numbers excess to program production requirements to facilitate BKD management, comply with ESA Section 10 permit take provisions, and to meet programmed production shortfalls with natural origin fish. Based on historical Methow FH spring Chinook ELISA levels above 0.12, any hatchery origin spring Chinook broodstock collection will include hatchery origin spring Chinook in excess to broodstock requirements by approximately 33.3% (based upon the most recent 5-year mean

ELISA results for the Methow/Chewuch program; 11.8% for the Twisp program). For purposes of BKD management and to comply with maximum production levels and other take provisions specified in ESA Section 10 permits 18925 and 20533, culling will include the destruction of eggs from hatchery-origin females with ELISA levels greater than 0.12 and/or that number of hatchery origin eggs required to maintain production at 223,765 yearling smolts. Culling of eggs from natural-origin females will not occur unless their ELISA levels are determined by WDFW Fish Health to be a substantial risk to the program. Progeny of natural-origin females, with ELISA levels greater than 0.12, may be differentially tagged for evaluation purposes. Annual monitoring and evaluation of the prevalence and level of BKD and the efficacy of culling returning hatchery- and natural-origin spring Chinook will continue and will be reported in the annual monitoring and evaluation report for this program.

WDFW genetic assessment of natural-origin Methow spring Chinook (Small et al. 2007) indicated that Twisp natural-origin spring Chinook can be distinguished, via genetic analysis, from non-Twisp spring Chinook with a high degree of certainty. The Wells HCP Hatchery Committee accepted that Twisp-origin fish could be genetically assigned with sufficient confidence and that natural origin collections can occur at Wells Dam. Scale samples and non-lethal tissue samples (fin clips) for genetic/stock analysis will be obtained from adipose-present, non-CWT, non-ventral-clipped spring Chinook (suspected natural-origin spring Chinook) collected at Wells Dam, and origins assigned based on genetic analysis. Natural-origin fish retained for broodstock will be PIT tagged (pelvic girdle) for cross-referencing tissue samples/genetic analyses. Tissue samples will be preserved and sent to the WDFW genetics lab in Olympia Washington for genetic/stock analysis. Spring Chinook collected from Wells will be held until genetic analysis results are received (unless adult holding is not yet available due to the Wells modernization project, in which case fish will be held at Methow FH pending results), then transferred to and retained at Methow Hatchery and spawned for each program depending on results of DNA analysis. Brood collection of NORs at Wells will be based upon assignment of Twisp NORs to the Twisp program and non-Twisp NORs being used to support Methow and Chewuch River releases. Spring Chinook collected at Methow Hatchery will be held at MFH until genetic analysis results are received and then handled accordingly.

The number of natural-origin Twisp and Methow Composite (non-Twisp) spring Chinook retained will be dependent upon the number of natural-origin adults returning and the collection objective limiting extraction to no greater than 33% of the natural-origin spring Chinook return to the Methow Basin. Natural origin fish not assigning to the Twisp or Methow Composite (combined, these make up the entire Methow Basin spring Chinook population) will be released back into the Columbia River.

Weekly estimates of the passage of Wells Dam by natural-origin spring Chinook will be provided through stock-assessment and broodstock-collection activities. This information will facilitate in-season adjustments to collection composition so that extraction of natural-origin spring Chinook remains no more than 33%. Trapping at the Winthrop NFH will be included, if needed, as a result of broodstock shortfalls.

Pre-season run-escapement of Methow-origin spring Chinook to Wells Dam during 2017 is estimated at 3,265 spring Chinook, including 2,292 hatchery and 973 natural origin spring

Chinook (Table 1 and Table 2). In-season estimates of natural-origin spring Chinook will be adjusted proportional to the estimated returns to Wells Dam at weekly intervals and may result in adjustments to the broodstock collection targets presented in this document.
The following broodstock collection protocol was developed based on BKD management strategies, projected return for BY 2017 Methow Basin spring Chinook at Wells Dam (Table 1 and Table 2), and assumptions listed in Appendix A.

The 2017 aggregate Methow spring Chinook broodstock collection will target up to 122 adult spring Chinook (18 Twisp, 104 Methow; Table 3). Based on the pre-season run forecast, Twisp fish are expected to represent about 5% of the CWT tagged hatchery adults and 18% of the natural origin spring Chinook passing above Wells Dam (Tables 1 and 2). Based on this proportional contribution and a collection objective to limit extraction to no greater than 33% of the age-4 and age-5 natural-origin spawning escapement to the Twisp, the 2017 Twisp origin broodstock collection will total 18 wild fish, representing 100% of the broodstock necessary to meet Twisp program production of 30,000 smolts. Methow Composite fish are expected to represent about 42% of the CWT tagged hatchery adults and 82% of the natural origin spring Chinook passing above Wells Dam (Tables 1 and 2). Based on this proportional contribution and a collection objective to limit extraction to no greater than 33% of the age-4 and age-5 natural-origin recruits, the 2017 aggregate Methow broodstock collection will total 104 natural origin spring Chinook. Broodstock collected for the aggregate Methow programs represents 100% of the broodstock necessary to meet the Methow programs production of 223,765 smolts. The Twisp River releases will be limited to releasing progeny of broodstock identified as wild Twisp and or known Twisp hatchery origin fish, per ESA Permit 18925. The Grant/Douglas/Chelan PUD releases will include progeny of broodstock identified as wild non-Twisp origin (or known Methow Composite hatchery origin if needed to meet shortfalls in the production goal) fish. Age-3 males ("jacks") will not be collected for broodstock.

Table 1. Brood year 2012-2014 age class-at-return projection for wild spring Chinook above Wells Dam, 2017.

Brood year	**Smolt Estimate**		**Age-at-return**									
			Twisp Basin					**Methow Basin**				
	Twisp[1]	Methow Basin[2]	Age-3	Age-4	Age-5	Total	SAR[3]	Age-3	Age-4	Age-5	Total	SAR[4]
2012	12,277	35,976	9	71	**11**	91	0.0074	47	615	**126**	788	0.0219
2013	24,605	36,242	19	**142**	21	182	0.0074	48	**619**	127	794	0.0219
2014	28,380	41,353	**21**	164	25	210	0.0074	**54**	707	145	906	0.0219
Estimated 2017 Return			**21**	**142**	**11**	**174**		**54**	**619**	**126**	**799**	

[1] Smolt estimate is based on sub-yearling and yearling emigration (Charlie Snow, personal communication).

[2] Estimated Methow Basin smolt emigration based on Twisp Basin smolt emigration, proportional redd deposition in the Twisp River and Twisp Basin smolt production estimate.

[3] Geometric mean Twisp NOR spring Chinook SAR to Wells Dam estimated using natural origin PIT tag returns (BY 2003-2009; David Grundy, personal communication).

4 Geometric mean Methow NOR spring Chinook SAR to Wells Dam estimated using natural origin PIT tag returns (BY 2003-2009; David Grundy, personal communication).

By program		Number of Adults: Hatchery	Number of Adults: Wild	Total	Collection location	Mating protocol
Twisp	**30,000**		**9F/9M**	**18**	Wells Dam/Twisp Weir	2x2 factorial
MetComp	**193,765**		**52F/52M**	**104**	Wells Dam/Methow Hatchery	2x2 factorial
Total	**223,765**		**61F/61M**	**122**		

Trapping at Wells Dam will occur at the East and West ladder traps beginning on May 1, or at such time as the first spring Chinook are observed passing Wells Dam, and continue through June 20, 2017. Spring Chinook broodstock collection and stock assessment sampling activities authorized through the 2017 Douglas PUD Hatchery M&E Implementation Plan will utilize a combination of trapping on the East and West ladders as per the detailed descriptions of the modified trapping operations for spring Chinook collection in Appendix D (pages 38 and 39).

Natural origin spring Chinook will be retained from the run, consistent with spring Chinook run timing at Wells Dam (weekly collection quota). Collection goals will be developed by Wells M&E staff to identify the most appropriate spatial and temporal approach to achieving the overall brood target. All natural origin spring Chinook collected at Wells Dam for broodstock will initially be held at Well FH (or immediately transferred to Methow FH taking into account the status of adult holding during the modernization project) pending genetic results and then transferred to Methow FH. Fish collected at MFH will remain at MFH or transferred to WNFH.

Trapping at the Twisp Weir for spring Chinook may begin May 1 or at such time as spring Chinook are observed passing Wells Dam and may continue through August 23. The trap may be operated up to five days per week/24 hours per day (provided it is manned during active trapping).

Trapping at the Methow Outfall trap and Winthrop NFH ladder operations will run concurrent with the Twisp Weir. Pending development of an adult management plan for spring Chinook in the Methow basin, hatchery-origin adults captured at the Methow Outfall (surplus to the Methow Hatchery program) will be transferred to the WNFH for incorporation into WNFH brood as supported by the HGMP's of both facilities.

Steelhead

Douglas PUD and Grant PUD steelhead mitigation programs above Wells Dam utilize adult broodstock collections from multiple sources and locations such as at Wells Dam, Twisp Weir, Methow Hatchery volunteer trap, WNFH volunteer trap, Okanogan River Basin and angling in Methow River (Table 5). Generally incubation/rearing occur for the Methow safety net, Okanogan, and Columbia River release at Wells Fish Hatchery (FH) with incubation/early rearing at Methow Hatchery for the DPUD conservation program. Broodstock for the composited conservation programs (DPUD and USFWS) is achieved via hook-and-line in the Methow Basin and the Twisp Weir. Broodstock for the Methow safety net program is achieved primarily through returns to WNFH and surplus fish removed at Methow Hatchery and the Twisp Weir.

Specific program brood sources are structured as follows:

Wells Hatchery – Conservation Releases

The Wells Hatchery conservation releases are a composite of locally collected Twisp wild broodstock and adults collected by the USFWS in the mainstem Methow River. Adults are collected in the spring of the current spawn year.

Wells Hatchery – Methow River Release

The Wells Hatchery Methow River release (Methow safety net program) uses locally collected hatchery origin broodstock representative of the Twisp and WNFH conservation programs and as needed, the Methow safety-net program. Adults are collected in concert with adult management activities at the Twisp Weir, Methow Hatchery, WNFH, and through hatchery fish intercepted during natural origin brood hook and line collection for the USWFS Winthrop conservation program. As a backup to potential collection shortfalls in the Methow safety net program as a result of uncertainties in spring collection efficiencies, a portion of the Methow program will be augmented with collection of hatchery origin adults (30) occurring in the fall at Wells Dam. These fall-collected Wells stock fish will be considered surplus to any spring-collected Methow and Okanogan broodstock, and eggs and/or fry from these surplus broodstock may be utilized for other programs in the upper Columbia.

Wells Hatchery-Columbia River Release

The Wells Hatchery Columbia River releases will use returns to Wells Hatchery and may be augmented with adult returns to the Methow Hatchery and Winthrop FH if needed to fulfill the program. To ensure the safety-net programs (Methow and Okanogan) have broodstock, a portion of the broodstock requirement (60 adults) will be collected at Wells Dam in the fall of 2017, and held at Wells Hatchery (Table 5). These fall-collected Wells stock fish will be considered surplus to the spring-collected Methow and Okanogan broodstock, and eggs and/or fry from these surplus broodstock may be utilized for other programs in the upper Columbia.

Winthrop NFH – Methow River Release

The USFWS Methow River release will primarily use natural origin fish collected through hook and line collection efforts in the Methow River each spring and adults collected at the Twisp Weir. In the event NO collection falls short of the target, hatchery origin returns to WNFH will be prioritized, followed by excess hatchery returns to Methow Hatchery. Transfer of adult and/or gametes/eggs between program will be carefully choreographed to ensure fish are being utilized in the most efficient and effective manner.

Okanogan River releases

The Okanogan River uses a combination of natural origin adults collected in Omak Creek and hatchery origin adults collected in Omak Creek or elsewhere in the Okanogan Basin through CCT collection efforts. As a backup to potential collection shortfalls in the Okanogan, a portion of the Okanogan program will be augmented with collection of hatchery origin adults (30) occurring in the fall at Wells Dam. These fall-collected Wells stock fish will be considered surplus to any spring-collected Methow and Okanogan broodstock, and eggs and/or fry from these surplus broodstock may be utilized for other programs in the upper Columbia.

Steelhead programs located upstream of Wells Dam and at Wells Hatchery are presented in Table 4.

Table 4. 2018 brood year Steelhead Programs at Wells Hatchery and Upstream of Wells Dam

Program	Hatchery	Owner	Release Location	Release Target	Broodstock Collection Locations
DPUD Conservation	Methow Hatchery (incubation); Wells Hatchery (rearing)	Douglas PUD	Twisp River @ Buttermilk Bridge	24,000 (S_1)	MetComp WxW
DPUD Conservation	Methow Hatchery (incubation); Wells Hatchery (rearing)	Douglas PUD	WNFH on-station or as part of a rotational release plan to be developed by the JFP	24,000 (S_1)	MetComp WxW
Methow Safety-Net	Wells Hatchery	Douglas PUD	Methow Hatchery	50,000	HxH: Twisp Weir (up to 25%) + WNFH Hatchery (75%) or WNFH 1st, MFH 2nd to make up balance
Methow Safety-Net	Wells Hatchery	Douglas PUD	Methow River @ Effy's Bridge	50,000	HxH: Twisp Weir (up to 25%) + WNFH Hatchery (75%) or WNFH 1st, MFH 2nd to make up balance
Mainstem Columbia Safety-Net	Wells Hatchery	Douglas PUD	Wells Hatchery	160,000	HxH: Wells FH/Dam returns (1st option); Methow FH/WNFH (2nd option)
WNFH Conservation Program	WNFH	USFWS	WNFH (up to 176K), Twisp River @ Buttermilk Bridge (24K), other locations as determined by the JFP	Up to 200,000 (S_2)	Maximize use of NOR, up to 55 pair captured by hook and line in the Methow River above Twisp, up to 12 pair from the Twisp Weir, volunteers to WNFH, and tangle netting in Spring Creek.
Omak Creek	Wells Hatchery	Grant PUD	Omak Creek	Up to 40,000[1]	Okanogan Basin/Omak Creek (up to 16 wild or hatchery)
Okanogan	Wells Hatchery	Grant PUD	Okanogan Basin	Up to 90,000[1]	42 Wells Stock collected at Wells Dam/Hatchery or at tributary locations in the Okanogan Basin operated by the CCT

[1] The Grant PUD programs will total 100,000 smolts, +-10% (58 broodstock). Broodstock collection number, origin, location, and smolt numbers will be consistent with those detailed in National Marine Fisheries Service (NMFS) letter to Randall Friedlander (CCT) and Jeff Grizzel (GPUD) dated February 27, 2014 and detailed in Table 4 and Table 5 herein.

The following broodstock collection protocol was developed based on mitigation program production objectives (Table 6), biological assumptions (Appendix A), and the probability that sufficient adult steelhead will return in 2017/2018 to meet production objectives absent a preseason forecast at the present time.

For the 2018 brood steelhead programs operating above Wells Dam, a total of 350 adults (152 natural origin and 198 hatchery origin adults) are estimated to be needed to fulfill the respective mitigation obligations (Table 6). To support these obligations and to ensure sufficient backup adults are on hand in the event tributary based collection efforts fall short of targets, trapping at Wells Dam and/or Wells FH will selectively retain up to 257 hatchery origin steelhead (west [and east, as necessary] ladder and volunteer trap collection; Table 5). As a note, all potential broodstock will be scanned for PIT tags at collection. Any adult determined to have been part of the Yakama Nations kelt reconditioning program will be released in the vicinity it was collected.

Methow Conservation Program (DPUD)

In the spring of 2018, 24 wild steelhead will be targeted at the Twisp Weir and transferred to the Winthrop Hatchery for spawning, incubation, and possibly early rearing (to facilitate viral testing of progeny resulting from live spawning females for the YN kelt reconditioning program), after which they will be moved to Wells Hatchery for the balance of rearing (Table 5).

Methow Safety Net Program

Up to 14 surplus hatchery-origin Twisp-stock steelhead (to meet up to 25% of the 100K Methow Safety-Net release) will be targeted at the Twisp Weir and moved to Wells Hatchery for spawning. No less than 46 hatchery adults will be targeted at WNFH and if needed/available, Methow Hatchery volunteer traps to meet the balance of the program needs (Table 6). Up to 30 hatchery origin Wells stock collected and held at the Wells Hatchery will be used as a final option if broodstock collection at the Twisp Weir, and WNFH and MH traps are unsuccessful (Table 5). If needed, WNFH HO fish identified through PIT tag detections, collected at the MFH outfall may be transferred to WNFH for use in the Spawning Channel Evaluation Project rather than retained for broodstock. Coordination between USFWS and WDFW hatchery staff will occur during the season to determine prioritization.

Methow Conservation Program (USFWS)

Approximately 110 natural origin adults (55 pair) will targeted for retention through hook and line collection efforts in the Methow River (Table 6). In the event of a shortage, excess hatchery steelhead from the Twisp Weir and volunteer returns to the WNFH will be utilized as needed to augment WNFH broodstock. Should there be inadequate surplus steelhead from these sources, excess hatchery steelhead (presumed Methow Safety-Net origin) captured at the Methow Hatchery volunteer trap will be used to fulfill the program. Up to 24 additional NO adults from the Twisp Weir will be transferred to WNFH and combined to form a pooled composite conservation program that will support both DPUD and USFWS conservation programs.

Okanogan Hatchery/Endemic Program

Fifty-eight (58) adult steelhead will be targeted in the Okanogan Basin, including up to 16 natural-origin adults collected from Omak Creek for a 40K endemic program operated by the CCT and funded by GCPUD as part of their 100K UCR steelhead mitigation obligation (Table 5). Additionally, up to 30 hatchery adult steelhead will be targeted at Wells Dam/Hatchery as a back-up collection contingency due to unknown broodstock collection efficiencies in the Okanogan River Basin (Table 5).

Table 5. Broodstock collection locations, number, and origin by program.

Program	Number of Adults[1]		Primary collection location	Number of backup adults[2]	Backup collection location(s)	Total adult collection[1]	
	Hatchery	Wild				Hatchery	Wild
DPUD Columbia R.	108		Wells FH/Dam Wells Dam		Methow FH	108	
DPUD Methow R.	68		Twisp weir (14) Methow FH (46)	Up to 30	WNFH[3] Wells Dam	98	
DPUD Met. Conservation		24	Twisp weir	NA	NA		24
GPUD Okanogan R.	0-58[6]	0-58[7]	Omak Cr. Okanogan R. Wells FH[5]	30	Wells Dam	0-88	0-58
USFWS Methow R.		110	Methow R. WNFH[4]	NA	Methow FH		110
Total (PUD programs)	**176-234**	**24-82**		**60**		**206-294**	**24-82**
Total (All programs)	**176-234**	**134-192**		**60**		**206-294**	**134-192**

[1] Assumes a 1:1 sex ration (see table 6).
[2] All backup broodstock are hatchery origin adults.
[3] May include hatchery origin adults collected via the USFWS hook and line efforts for natural origin fish in the Methow River and adult returns to WNFH.
[4] May also include excess hatchery origin adults collected at Methow FH and the Twisp Weir.
[5] Spring collection of hatchery origin steelhead as needed to meet program shortfall for the Okanogan Program.
[6] Dependent upon number of NOR broodstock collected in the Okanogan Basin to achieve 58 total broodstock for the Okanogan program.
[7] Depending upon NOR abundance, trapping efficiency, and issuance of a new Section 10 Permit for the Okanogan steelhead program to allow, up to 100% wild collected in the Okanogan Basin to achieve program broodstock target.

Table 6. Number of broodstock needed to produce approximately 608,000 smolts for the above Wells Dam 2018 brood summer steelhead programs. Includes primary collection location(s) and mating strategy. *Broodstock totals do not include additional fish that may be collected at other locations as a backup for shortfalls from primary collection sources.*

Program	Production target/request	Number of Adults		Total	Collection location	Mating protocol
		Hatchery	Wild			
DPUD[1] Columbia R.	160,000	54F/54M		**108**	Wells Dam/Twisp Weir/	1:1
DPUD[2] Methow R.	100,000	34F/34M		**68[4]**	Twisp Weir, MFH, WNFH, Wells Dam	1:1
DPUD Methow Conservation	48,000		12F/12M	**24**	Twisp Weir/USFWS	2x2 Factorial
GPUD Okanogan R.[3]	100,000	21F/21M	8F/8M	**58[5]**	Okanogan R./Omak Creek	1:1/2x2[7]
USFWS	200,000		55F/55M	**110[6]**		2X2 Factorial

Total[4]	**608,000**	**109F/109M**	**75F/75M**	**368**

[1] Mainstem Columbia releases at Wells Dam. Target HxH parental adults as the hatchery component.
[2] Methow hatchery release of HxH fish produced from either adults returning from the Winthrop conservation program, adults trapped at MFH, and/or surplus hatchery adults from the Twisp weir.
[3]Okanogan Basin releases, including Omak Creek is100,000 smolts as part of GCPUD's 100K summer steelhead obligation and targets 58 adults in the Okanogan Basin, including up to 16 natural origin adults to fulfill the Okanogan Basin Production of 100,000 smolts comprised of natural origin and locally-adapted steelhead returning to the Okanogan River. Upon issuance of a new Section 10 permit for the Okanogan Steelhead program, up to 58 natural origin steelhead may be collected in the Okanogan Basin to fulfill the broodstock target, consistent with the Section 10 Permit provisions. Retention of progeny from these fish will be dependent upon success of CCT trapping efforts in Okanogan Basin tributaries.
[4] Up to an additional 30 hatchery adults will be collected at Well FH as a fall back to shortfalls in collections for the Methow safety net.
[5] Up to an additional 30 hatchery origin adults will be collected at Wells Dam as backup to potential shortfalls in Okanogan Basin collection efforts.
[6] Collection priority: 1) hook and line, 2) adult returns to WNFH, 3) excess adult returns to Methow Hatchery.
[7] A 1:1 mating protocol will be used for all HxH crosses within the Okanogan. The Okanogan endemic program (WxW) will utilize a minimum 2x2 factorial mating to minimize potential negative effects associated with a small effective population size.

Overall collection for the PUD programs will be 294 fish (a combination of program specific and back-up adults; Table 5) and limited to no more than 33% of the entire run and/or 33% of the natural origin return. Hatchery and natural origin collections will be consistent with run-timing of hatchery and natural origin steelhead at Wells Dam and the Twisp Weir. Trapping at the Wells Dam ladders will occur between 01 August and 31 October, up to three days per week, and up to 16 hours per day, as required to meet broodstock objectives. Trapping will be concurrent with summer Chinook broodstocking efforts through 15 September on the west ladder (Appendix D). Operational criteria and dates for the Twisp Weir are still under construction.

Adult return composition including number, origin, age structure, and sex ratio will be assessed in-season at Priest Rapids and Wells dams. Broodstock collection adjustments may be made based on in-season monitoring and evaluation. If collection of adults from the east ladder trap is necessary, access will be coordinated with staff at Wells Dam due to the rotor rewind project.

Adult Collection – DPUD and USFWS Conservation Programs – All adults collected as part of the DPUD (formerly Twisp) and USFWS conservation programs will be transferred, held, and spawned at WNFH.
Rearing - At either the eyed egg stage or early ponded fry stage (to be determined after discussions with fish health), a sufficient number of progeny will be transferred to DPUD facilities for rearing to a yearling smolt stage (S_1). WNFH will rear the balance of the production to a two year smolt (S_2).

Release – At release, 24K S1 smolts and 24K S_2 smolts from the conservation program will be direct planted into the Twisp River at the Buttermilk Bridge.

The remaining S_1 smolts will either be transferred to WNFH for release concurrent with the S_2 release or combined with a comparable number of S_2's for release elsewhere in the Methow Basin.

The Methow safety net program will be split into two release components, the first of which will occur directly from MFH consistent with past practices. The second 50K group will be adequately PIT tagged and direct released in the lower Methow at Effy's Bridge.

Surplus UCR Juvenile Steelhead Management

In the event excess juvenile are produced from the over-collection efforts to support the Methow safety net and /or Okanogan safety net programs which rely on spring adult collections, the parties agree that distribution of juveniles will follow the following priority matrix:

1. Used to support shortfalls in the WNFH production obligation provided fish health and/or marking requirements for the program can be met.

2. Used to support any shortfalls in the Wells Columbia River release provided fish health and/or marking requirements for the program can be met.

3. Used to support shortfalls in the Ringold SHD program provided fish health and/or marking requirements for the program can be met.

4. Out-planted to landlocked lakes within Okanogan County and/or Colville Reservation provided fish health requirements can be met or provided stocking allotments are not exceeded (as determined by WDFW and/or CCT fishery managers).

In addition, surplus fish, including broodstock, will be distributed at the earliest possible life-stage (e.g., prespawn adults, eyed-egg, fry) per WDFW policy.

Summer/fall Chinook

The summer/fall Chinook mitigation program in the Methow River utilizes adult broodstock collections at Wells Dam and incubation/rearing at Eastbank Fish Hatchery. The total production level target is 200,000 summer/fall Chinook smolts for acclimation and release from the Carlton Acclimation Facility.

The TAC 2017 Columbia River UCR summer Chinook return projection to the Columbia River (Appendix D) and BY 2012, 2013, and 2014 spawn escapement to tributaries above Wells Dam indicate sufficient summer Chinook will return past Wells Dam to achieve full broodstock collection for supplementation programs above Wells Dam. The following broodstock collection protocol for the Methow summer Chinook program was developed based on initial run expectations of summer Chinook to the Columbia River, program objectives, and program assumptions (Appendix A).

For 2017, up to 118 natural-origin summer Chinook at Wells Dam west (and east, if necessary) ladder(s), including 59 females for the Methow summer Chinook program (Table 7). Collection will be proportional to return timing between 01 July and 15 September. Summer Chinook stock assessment will run concurrent with summer Chinook broodstock collection at the west ladder trap. Trapping may occur up to 3-days/week, 16 hours/day (48 cumulative hours per week). Age-3 males ("jacks") will not be collected for broodstock.

Should use of Wells Dam be needed to meet any shortfalls in broodstock for summer/fall Chinook programs occurring in the Okanogan Basin, the CCT will notify the HCP-HC and Wells

HCP Coordinating Committee/PRCC-HSC and coordinate with Douglas PUD, Grant PUD, and WDFW to facilitate additional broodstock collection effort. Summer Chinook broodstock collection efforts at Wells Dam, should they be required to meet CJH program objectives, will be conducted concurrent with broodstock collection efforts for the Methow summer Chinook program and or steelhead collection efforts for steelhead programs above Wells Dam.
If the probability of achieving the broodstock goal is reduced based on passage at the west ladder or actual natural-origin escapement levels, broodstock collections may be expanded to the east ladder trap and/or origin composition will be adjusted to meet the broodstock collection objective. If collection of adults from the east ladder trap is necessary, access will be coordinated with staff at Wells Dam due to the rotor rewind project.

Table 7. Number of broodstock needed for Grant PUDs Methow summer Chinook production obligation of 200,000 smolts, collection location, and mating strategy.

Program	Production target	Number of Adults		**Total**	Collection location	Mating protocol
		Hatchery	Wild			
Methow	200,000		59F/59M	**118**	Wells Dam	1:1
Total	**200,000**		**118**	**118**		

Rearing – Early rearing growth will be modulated for a targeted size at release of approximately 18 fpp. Beginning on or about February 1, fish will be fed to satiation to maximize spring growth regardless of end size.

Release - The summer Chinook salmon acclimated at the Carlton Acclimation Facility will be forced released using the following criteria.

- all fish will be released during darkness (e.g., 9:00 PM or later),
- all fish will be released when Columbia River and Methow River flows are predicted to be satisfactory,
- all fish will be released no later than May 7 regardless of flow conditions,
- attempts will be made to have a steady release of fish to reduce collisions on the PIT antenna array.

Satisfactory flows in the Columbia occur when spilling flows are started and flows in the Methow River are satisfactory when flows are high and turbid. Releases will not occur until satisfactory flows in the Columbia occur, but could occur if Methow River flows are not satisfactory due to insufficient snow pack.

Columbia River Mainstem below Wells Dam

Summer/fall Chinook

Collection at the Wells FH volunteer channel will be used to collect the broodstock necessary for the Wells FH yearling (320,000) and sub-yearling (484,000) programs.
Because of CCT concerns about sufficient natural origin fish reaching spawning grounds and to ensure sufficient NOR's being available to meet the CCT summer Chinook program, incorporation of natural origin fish for the Wells program or programs with broodstock originating from the Wells volunteer channel, will be limited to fish collected in the Wells volunteer channel. The following broodstock collection protocol was developed based on mitigation objectives and program assumptions (Appendix A).

WDFW will target 494 run-at-large summer Chinook from the volunteer ladder trap at Wells Fish Hatchery outfall for the Wells sub-yearling and yearling programs, and up to 178 for the YN 275K-350K green egg request for the Yakima summer Chinook program (Table 8). Due to fish health concerns associated with the volunteer collection site (warming Columbia River water during late August), the volunteer collection will begin July 11 and terminate by August 31.

Summer/fall Chinook mitigation programs that release juveniles directly into the Columbia River between Wells and Rocky Reach dams have traditionally been supported through adult broodstock collections at the Wells Hatchery volunteer channel. For 2017, broodstock collection for the Chelan Falls summer Chinook program will be prioritized at the Chelan Falls Canal Trap (CFCT) which was successfully piloted in 2016, beginning July 1 through September 15. Collection efforts in the EBO in 2015 and 2016 were insufficient to meet the adult requirements for the Chelan Falls program necessitating development of alternate collection locations/strategies. If shortfalls in adult needs are expected and the number of females needed to meet program has not been reached by August 15^{th}, the HCP HC will discuss whether broodstock collection may default to surplus summer Chinook from the Entiat NFH or other HCP approved location to make up the difference. The 2017 broodstock target for the Chelan Falls program is 358 adults (Table 8). The total production level supported by this collection is up to 576,000 yearlings for the Chelan Falls program.

Table 8. Number of broodstock needed for the combined Chelan and Douglas PUD Columbia River below Wells summer Chinook production obligations of 1,380,000 smolts, collection location, and mating strategy. Also includes broodstock necessary for outside programs that rely on adult collection at Well Hatchery in 2017.

Program	Production target	Number of Adults[2]		**Total**	Collection location	Mating protocol
		Hatchery	Wild			
Wells 1+	320,000	94F/94M		**188**	Wells VC[3]	1:1
Wells 0+	484,000	153F/153M		**306**	Wells VC[3]	1:1
Chelan Falls 1+	576,000	179F/179M		**358**	EB outfall	1:1
Yakama Nation	350,000[1]	89F/89M		**178**	Wells VC[3]	NA

Total	1,730,000	515F/515M		1,030	

[1] The YN request is for between 275K and 350K green eggs to support the Yakima River summer Chinook program.
[2] The number of adults collected for these programs may indirectly incorporate natural origin fish; however, because they are volunteers, the number is likely to be less than 10% of the total.
[3] Wells Hatchery volunteer channel trap.

Wenatchee River Basin

In 2016 the Eastbank Fish Hatchery (FH) is expecting to rear spring Chinook salmon for the Chiwawa River and Nason Creek acclimation facilities located on the Chiwawa River and Nason Creek. The program production level target for the Chiwawa program (Chelan PUD obligation) in 2016 is 144,026 smolts, and based upon the biological assumptions (Appendix A) will require a total broodstock collection of about 80 natural origin spring Chinook (Table 10). The spring Chinook production obligation for Grant PUD in the Wenatchee Basin is 223,670 smolts (125,000 conservation and 98,670 safety net) and based upon the biological assumptions (Appendix A) will require a total broodstock collection of 142 adults (70 natural origin and 72 hatchery origin; Table 10).

Pre-season run-escapement of Wenatchee spring Chinook to Tumwater Dam during 2016 is estimated at 2,101 spring Chinook, including 1,359 hatchery and 752 natural origin spring Chinook (does not include age-3 males; Table 9). In-season estimates of natural-origin spring Chinook to Tumwater Dam will be provided through stock-assessment and broodstock-collection activities. This information will facilitate in-season adjustments to collection composition so that extraction of natural-origin spring Chinook remains no more than 33%.

Table 9. Age-4 and age-5 class return projection for wild and hatchery spring Chinook to Tumwater Dam during 2017.

	Chiwawa Basin			Nason Cr. Basin			Wenatchee Basin to Tumwater Dam		
	Age-4	Age-5	Total	Age-4	Age-5	Total	Age-4	Age-5	Total
Estimated wild return	418	108	**526**	123	32	**155**	614	159	**773**
Estimated hatchery return	3,238	63	**3,301**	1,336	0	**1,336**	4,574	63	**4,637**
Total	3,656	171	**3,827**	1,459	32	**1,491**	**5,188**	**222**	**5,410**

Table 10. Number of broodstock needed for the combined Wenatchee spring Chinook production obligation of 367,969 smolts, collection location, and mating strategy.

Program	Production target	Number of Adults		**Total**	Collection location	Mating protocol
		Hatchery	Wild			
Chiwawa Conservation	144,026	18F/18M	37F/37M	**74[1]**	Chiwawa Weir and Tumwater Dam[4]	2x2 factorial
Nason	125,000	0	35F/35M	**77[2]**	Tumwater	2x2 factorial

Conservation					Dam[4]	
Nason Safety net	98,670	34F/34M[3]	0	**68**	Tumwater Dam	1:1
Total	**367,969**	**104**	**144**	**255[2]**		

[1] Includes 36 hatchery origin adults (represents ~50% of the adult target) to ensure the Chiwawa production goal is met if insufficient NO adults are collected).
[2] Includes ~10% additional NO fish for the Nason program to account for fish that may assign back to the White River spawning aggregate. No more than 70 NO fish will be retained for spawning.
[3] Due to the lack of returning hatchery fish from the Nason program (first age-4 returns are expected in 2017), Chiwawa hatchery fish will only be collected to satisfy the Nason Cr. safety net program if in-season estimates of returning conservation fish fall short of expectations.
[4] Collection of NO fish at Tumwater for the Chiwawa program will include previously PIT tagged adults (NO juveniles PIT tagged at the Chiwawa smolt trap).

Chiwawa River Conservation Program Broodstocking:

- Based upon estimates of returning previously PIT tagged NO fish to Tumwater Dam (Table 11), approximately 30 previously PIT-tagged NO spring Chinook from the Chiwawa River could be collected at TWD between June 1 and July 15, concurrent with Nason Creek brood stocking, adult management, RM&E, and the RRS Study.
- The balance of adults needed to meet the Chiwawa Conservation program (up to ~74 total or ~37 females) would be collected at the Chiwawa Weir.
    - Weir operations would be on a 24 hour up/24 hour down schedule from about June 15 through August 1 (not to exceed 15 cumulative trapping days). Timing of trap operation would be based on NO fish passage at TWD and would use estimated travel times (derived from PIT tags) to the lower Chiwawa PIT tag antenna array.
    - In the absence of adequate redd count data (i.e. until 2018) to calculate the 10% threshold, if after 15-days of weir operation, 67 bull trout encounters, or 15 August, the NO broodstock target is not reached, the balance of the mitigation obligation will be met through hatchery fish already retained for the Chiwawa program at TWD.
    - Additionally, no more than 10 percent of the estimated mean number of adult bull trout in the Chiwawa Basin (using a rolling five year average derived from expanded redd counts) may be encountered during broodstock collection without concurrence from the USFWS. Sufficient redd data to calculate a five year average is expected to be available as early as 2018.
    - To ensure the production target is met for the Chiwawa program, in the event that insufficient NO adults are collected for the conservation program, HO adults (presently estimated at 50% of the total broodstock requirement, however may be adjusted up or down depending on the run) would be collected at TWD to make up the shortfall (see Table 10) between June 1 and July 15.
    - Historic and in-season data for NO spring Chinook timing to the lower Chiwawa array from TWD will be used to determine optimal dates for collection.

- Any bull trout that are caught at the Chiwawa trap will be immediately removed and released at a site ~10KM upstream of the weir to prevent fallback/impingement and to mitigate for potential delay. Handling and transport will be conducted by WDFW hatchery staff.
- If a bull trout is killed during trapping, despite implementing conservation measures, trapping activities will cease and not continue until additional measures to minimize risks to bull trout can be discussed with the USFWS.

Table 11. PIT tagged natural origin adults to Tumwater Dam for the most recent 5-years (2012-2016) with conversion rates from Bonneville Dam.

	Detections at Bonneville Dam		Detections at Tumwater Dam			
Return year	Nason	Chiwawa	Nason	Conversion rate	Chiwawa	Conversion rate

2015	9	42	6	0.667	28	0.667
2016	8	34	8	1.000	24	0.706
Mean	6.4	46.2	4.4	0.710	31.0	0.688
Geomean	5.7	44.0	3.4	0.603	29.5	0.671

Nason Creek Conservation Program Broodstocking:

- Up to ~77 NO spring Chinook (to allow for up to 10 percent of White River NO fish estimated to be encountered at Tumwater Dam MSA; Table 10) would be collected at TWD between June 1 and July 15.
  - Only 70 NO adults (35 females) will be retained to produce the 125K Nason Conservation program.
  - Collection of additional HO fish may occur in the event NO collection/retention falls short of expectation.
  - Brood stock collection would run concurrent with adult management, RM&E, and the Spring Chinook Relative Reproductive Success Study. The GAPS microsatellite panel and existing GAPS plus WDFW spring Chinook Wenatchee baseline will be used for genotyping and GSI analyses similar to methods used in 2013.

- Decision Rules:
  - Any fish that assigns to the White River with greater than 90% surety will be released in the White River.

  - Unassigned fish (individuals that can't be assigned to the Wenatchee Population or Leavenworth NFH), will be released upstream of Tumwater Dam.
  - In the event more fish assign to Nason or Chiwawa than are needed to meet the conservation program, the excess with the lowest assignment probabilities will be returned to the river upstream of Tumwater Dam.

Nason Creek Safety Net Program Broodstocking:

- Up to ~68 HO spring Chinook adults (from safety net program – identified by snout wire + body wire) would be targeted at TWD (Table 10) between June 1 and July 15, concurrent with NO brood stock collection, adult management, RM&E, and the Spring Chinook Relative Reproductive Success (RRS) Study.

Nason Creek spring Chinook Rearing/Release Strategy:

Rearing – Early rearing growth will be modulated for a targeted size at release of approximately 18 fpp. Beginning on or about February 1, fish will be fed to satiation to maximize spring growth regardless of end size.

Release - Spring Chinook salmon acclimated at the Nason Creek Acclimation Facility will be forced released using the following criteria.

- all fish will be released during darkness (e.g., 9:00 PM or later),
- all fish will be released when Columbia River and Nason Creek flows/condtions are predicted to be satisfactory,
- all fish will be released no later than May 7 regardless of flow conditions,
- attempts will be made to have a steady release of fish to reduce collisions on the PIT antenna array.

Satisfactory flows in the Columbia occur when spilling flows are started and flows in Nason Creek are satisfactory when flows are high and turbid. Releases will not occur until satisfactory flows in the Columbia occur, but could occur if Nason Creek flows are not satisfactory due to insufficient snow pack.

**NOTE: Due to the uncertainty of having a reliable surface water intake structure (compromised by heavy bedload movement during fall [2015] and winter [2016] freshets) at the Nason Creek Acclimation Facility in time for acclimation of this brood year, alternate rearing strategies and/or locations may need to be considered by the HSC.

Steelhead

The steelhead mitigation program in the Wenatchee Basin uses broodstock collected at Dryden and Tumwater dams located on the Wenatchee River. Per ESA section 10 Permit 1395 provisions, broodstock collection will target adults necessary to meet a natural origin – conservation (WxW) oriented program, not to exceed 33% of the natural origin steelhead return to the Wenatchee Basin and a hatchery origin (HxH) – safety net program. The conservation and safety net programs each make up approximately half of the 247,300 production obligation. Based on these limitations and the assumptions listed in Appendix A, the following broodstock collection protocol was developed:

WDFW will retain a total of 140 mixed origin steelhead for broodstock for a smolt release objective of 247,300 smolts (Table 12). The 70 hatchery origin adults will be targeted at Dryden Dam and if necessary Tumwater dam. The 70 natural origin adults will be targeted for collection at Tumwater Dam. Collection will be proportional to return timing between 01 July and 14 November. Collection may also occur between 15 November and 5 December at both traps, concurrent with the Yakama Nation coho broodstock collection activities. Only adipose present coded wire tagged hatchery fish (or previously PIT tagged WxW hatchery progeny) will be retained for the safety net program. Adult return composition including number, origin, age structure, and sex ratio will be assessed in-season at Priest Rapids and at Dryden Dam. In-season broodstock collection adjustments may be made based on this monitoring and evaluation. To better ensure achieving the appropriate females equivalents for program production, the collection will include the use of ultrasonography to determine the sex of each fish retained for broodstock.

In the event steelhead collections fall substantially behind schedule, WDFW may initiate/coordinate adult steelhead collection in the mainstem Wenatchee River by hook and line. In addition to trapping and hook and line collection efforts, Tumwater and Dryden dams may be operated between February and early April the subsequent spring to supplement broodstock numbers if the fall trapping effort provides fewer than the required number of adults.

Table 12. Number of broodstock needed for the combined 2018 BY Wenatchee summer steelhead production obligation of 247,300 smolts, collection location, and mating strategy.

Program	Production target	Number of Adults		Total	Collection location	Mating protocol
		Hatchery	Wild			
Wenatchee Conservation[1]	123,650	0	35F/35M	**70**	TWD[3]/Dryden LBT-RBT[4]	2x2 factorial
Wenatchee Safety net[2]	123,650	35F/35M	0	**70**	Dryden LBT-RBT[4] /TWD[4]	1:1
Total	**247,300**	**70**	**70**	**140**		

[1] Broodstock collection for the conservation program will occur primarily at Tumwater Dam and will only fall back to Dryden Dam trapping facilities if a shortfall is expected.
[2] Broodstock collection for the safety net program will occur primarily at the Dryden Dam trapping facilities to minimize activities at TWD that could increase unintended delays on non-target fish. Collection at Tumwater Dam will only occur if shortfalls in broodstock are expected at Dryden Dam.
[3] TWD=Tumwater Dam.
[4] Dryden LBT-RBT= Dryden Dam left and right bank trapping facilities.

Summer/fall Chinook

Summer/fall Chinook mitigation programs in the Wenatchee River Basin utilize adult broodstock collections at Dryden and Tumwater dams, incubation/rearing at Eastbank Fish Hatchery (FH) and acclimation/release from the Dryden Acclimation Pond. The total production level target for BY 2016 is 500,001 smolts (181,816 GCPUD mitigation and 318,185 CCPUD mitigation).

The TAC 2017 Columbia River UCR summer Chinook return projection to the Columbia River (Appendix D) and BY 2012, 2013 and 2014 spawner escapement to the Wenatchee River indicate sufficient summer Chinook will return to the Wenatchee River to achieve full broodstock collection for the Wenatchee River summer Chinook supplementation program. Review of recent summer/fall Chinook run-timing past Dryden and Tumwater dam indicates that previous broodstock collection activities have omitted the early returning summer/fall Chinook, primarily due to limitations imposed by ESA Section 10 Permit 1347 to minimize impacts to listed spring Chinook. In an effort to incorporate broodstock that better represent the summer/fall Chinook run timing in the Wenatchee Basin, the broodstock collection will front-load the collection to account for the disproportionate collection timing. Approximately 43% of the summer/fall Chinook destined for the upper Basin (above Tumwater Dam) occurs prior to the end of the first week of July; therefore, the collection will provide 43% of the objective by the end of the first week of July. Weekly collection after the first week of July will be consistent with run timing of summer/fall Chinook during the remainder of the trapping period. With concurrence from NMFS, summer Chinook collections at Dryden Dam may begin up to one week earlier. Based on these limitations and the assumptions listed in Appendix A, the following broodstock collection protocol was developed:

WDFW will retain up to 262 natural-origin, summer Chinook at Dryden and/or Tumwater dams, including 131 females (Table 13). To better ensure achieving the appropriate females for program production, the collection will implement the draft Production Management Plan, including ultrasonography to determine the sex of each fish retained for broodstock. Trapping at Dryden Dam may begin 27 June and terminate no later than 15 September and operate up to 7-days/week, 24-hours/day. Trapping at Tumwater Dam if needed may begin 15 July and terminate no later than 15 September and operate up to 48 hours per week for broodstock related activities.

Table 13. Number of broodstock needed for the combined 2017 BY Chelan and Grant PUD Wenatchee summer Chinook production obligations of 500,001 smolts, collection location, and mating strategy.

Program	Production target	Number of Adults		Total	Collection location	Mating protocol
		Hatchery	Wild			
Chelan PUD	318,185		83F/83M	**172**		
Grant PUD	181,816		48F/48M	**98**		
Total	**500,001**		**131F/131M**	**262**	Dryden LBT-RBT[1] /TWD[2]	1:1

[1] Dryden LBT-RBT= Dryden Dam left and right bank trapping facilities.
[2] TWD=Tumwater Dam.

Priest Rapids Fall Chinook

Collection of fall Chinook broodstock at Priest Rapids Hatchery (PRH) will generally begin in early September and continue through about mid-November. Juvenile release objectives specific to Grant PUD (5,599,504 sub-yearlings), and Federal (1,700,000 sub-yearlings at PRH + 3,500,000 smolts at Ringold Springs Hatchery – collection of broodstock for the federal programs are conditional upon having contracts in place with the ACOE), mitigation commitments. Biological assumptions are detailed in Appendix A. For the Ringold Springs production, adult collection, holding, spawning and incubation occurs at PRH until the eyed-egg stage. Eyed eggs are transferred to Bonneville Hatchery until they are transferred for spring acclimation and release at Ringold Springs.

For 2017 up to 1,000 adipose present, non-coded wire tagged (high proportion of natural origin) fall Chinook adults will be targeted at the OLAFT). Additional NO adults targeted as a continued pilot evaluation through hook-and-line angling efforts in the Hanford Reach to increase the proportion of natural origin adults in the broodstock to meet integration of the hatchery program will also be incorporated into the program. It is estimated that approximately 400 adults may be collected through the hook-and-line efforts. Close coordination between broodstock collections at the volunteer channel, the OLAFT and through hook-and-line efforts in the Hanford Reach will need to occur so over collection is minimized. Fish surplus to production needs will be culled at the earliest possible life-stage (e.g, brood collected, brood spawned, eggs). Presumed NOR's collected and spawned from either hook-and-line caught broodstock or OLAFT collections will be prioritized for PRH programs (i.e. OLAFT and Hanford Reach angler caught fish will be externally marked, held in a separate pond from volunteer collected fish, spawned first each week, and to the extent possible segregated and reserved for the GPUD program).

Grant PUD staff will work closely with WDFW hatchery and M&E staff to maintain separation of gametes/progeny of OLAFT and angling collected adults at spawning and through incubation/early rearing.

Based upon the biological assumptions in Appendix A, an estimated 4,219 females will need to be collected (3,536 spawned) to meet the 10,799,054 smolts required to meet the current three up-river bright (URB) programs which rely on adults collected at the Priest Rapids Hatchery volunteer channel trap, hook-and-line efforts on the Hanford Reach, and/or the Priest Rapids Dam off ladder trap (OLAFT; Table 14).

To increase the probability of incorporating a higher percentage of NOR's from the volunteer channel, adipose present, non-CWT males and females will be prioritized for retention and males older than 3 will be prioritized. In addition, preliminary information suggests that the pNORs is higher in the later part of the trapping period than the earlier period. As data become available, the PRCC-HSC may choose, in-season, to retain a disproportionately high number of broodstock from the latter half of the returns to the volunteer trap.

Implementation Assumptions

1) Broodstock may be collected at any or all of the following locations/means: the PRD off ladder trap (OLAFT – operated 4-days per week/8 hrs/day to collect up to 1,000 presumed NOR's), hook-and-line angling (ABC) in the Hanford Reach (actual numbers collected are uncertain but will contribute to the overall brood program and pNOB), and the Priest Rapids Hatchery volunteer channel trap.

2) Assumptions used to determine egg/adult needs is based upon current program performance metrics.

3) Broodstock retained from the volunteer channel will exclude to the degree possible, age-2 and 3 males (using length at age; i.e. retain males ≥ 75 cm) to address genetic risks/concerns of younger age-at-maturity males producing offspring which return at a younger age (decreased age-at-maturity) and also decrease the probability of using hatchery origin fish in the broodstock that are skewed towards earlier ages at maturity.

4) Only adipose present, non-CWT males and females will be retained for broodstock from volunteer channel collected broodstock unless a shortage is expected.

5) Only progeny of adipose present, non-wired fish encountered through hook-and-line angling and at the OLAFT will be prioritized for retention into the program.

6) Broodstock collected from the OLAFT and by hook-and-line will exclude age-2 and to the degree possible age-3 fish (<75 cm) to minimize genetic risks/concerns of younger age-at-maturity males producing offspring which return at a younger age (decreased age-at-maturity) and to ensure the highest proportion of NOR's in the collection (e.g. collection of 1 in 5 age-3 fish for broodstock from the OLAFT).

7) All gametes of fish spawned from hook-and-line broodstocking efforts and/or OLAFT collections will be incorporated into the PRH based programs.

8) Real time otolith reading and an alternative mating strategy will be implemented in 2017 similar to 2015 and 2016 unless the PRCC-HSC agrees that the PNI objective in 2017 can be met without implementing 1x4 matings. Otoliths from males from the OLAFT and ABC collections will be collected during the peak spawning week and read prior to spawning. If the male is natural origin, then it will be spawned with 4 females, otherwise it will be spawned with two.

9) All eggs or juveniles leaving PRH (including surplus) will have a unique otolith mark so that returning adults can be identified.

10) Natural origin broodstock collection at the volunteer trap will be prioritized for the GPUD program by collecting fish when the probability of encountering natural origin fish is highest and balancing run-time representation.

Table 14. Number of broodstock needed for the combined Grant PUD and ACOE fall Chinook production obligations of 10,799,504 sub-yearling smolts at Priest Rapids and Ringold Springs hatcheries, collection location, and mating strategy.

Program	Production target	Number of Adults	**Total**
Grant PUD	5,599,504	2,234F/1,145M	**3,379**
ACOE-PRH	1,700,000	681F/350M	**1,031**
ACOE – Ringold[1]	3,500,000	1,397F/716M	**2,113**
Total	**10,799,504**	**4,312F/2,211M**	**6,523**

Collection location	Estimated number of adults		Total	Collection location	Mating protocol
	Hatchery	Wild			
Priest Rapids Hatchery	**3,266F/1,683M**	**119F/55M**	**5,123**	PRH volunteer trap	1:2
OLAFT[2]	**307F/153M**	**360F/180M**	**1,000**	PRD off-ladder trap	1:2, 1:4
ABC[3]	**23F/45M**	**113F/219M**	**400**	Hanford Reach	1:2, 1:4
Total	**3,596F/1,881M** (5,477; 84.0%)	**592F/454M** (1,046; 16.0%)	**6,523**		

[1] As of brood year 2009, Priest Rapids Hatchery is taking sufficient eggs to meet the 3,500,000 sub-yearling smolt release at Ringold-Meseberg Hatchery funded by the ACOE – late incubation of this program occurs at Bonneville.
[2] Estimated number of fall Chinook females and males to be acquired from the OLAFT in 2017. F/M ratios were derived through run at large data. Estimates of H/W were derived through otolith results.
[3] ABC fish are adults collected from hook and line collection efforts on the Hanford Reach. Estimates of F/M were derived through 2012-2014 spawn numbers. Estimates of and H/W were derived through otolith results from 2012 and 2014.

2018	Okanogan WxW (CCT/GPUD)	Up to 100K [6]	Body/snout CWT/Alternate fin clip (TBD)[7]	Up to 20,000 PIT [8]	Okanogan/Similkameen Omak, Salmon, Antoine, other tribs. (TBD)	2019	5-8	Volitional

[1] Release of fish at the Goat Wall Pond remote acclimation site operated by the YN is conditional upon HC and HSC approval.
[2] Externally marking of this group is presently funded by WDFW. Marking of this 1M fish is contingent on *US v. Oregon* Policy Committee approval for 2017.
[3] Presently all CWT's are applied to the snout.
[4] The Okanogan SPC program derives its juveniles from a 200K transfer of Methow SPC from WNFH as part of a reintroduction effort. Fish are released into the Okanogan Basin.
[5] The Chief Joe Hatchery SPC program presently receives surplus adults from the Leavenworth NFH. Juveniles are released on station from CJH.
[6] Total Okanogan release not to exceed 100K + 10%.
[7] PIT number s to each release site are estimated and not actual.
[8] Dependent upon conditions in pending Section 10 Permit.
[9] Total PIT tag release in the Okanogan 20,000
[10] Beginning with the 2017 brood, adult returns from the Nason conservation program will be utilized to meet the Nason safety net program and will receive a supplemental body tag (blank wire either at the base of the adipose or the caudal peduncle) in addition to the adipose clip and snout CWT so that they can be differentiated and prioritized at TWD.

Appendix C

Return Year Adult Management Plans

At a gross scale, adult management plans will include all actions that <u>may</u> be taken within the current run year to address surplus hatchery fish (if any). At the time of submission for this document, spring Chinook will probably be the only group where a reasonable pre-season forecast may be available to lay out what the expected surplus is, how many can be expected to be removed through each action, etc. Preseason forecasts for steelhead will be available in September

Wenatchee Spring Chinook

Pre-season estimates for age-4 and age-5 adults project a total of 5,410 (773 natural origin [14.3%] and 4,637 hatchery origin [85.7%]) spring Chinook back to Tumwater Dam in the Wenatchee Basin. Approximately 3,827 Chiwawa and 1,491 Nason spring Chinook are to reach Tumwater Dam in 2017, of which about 681 (12.8%) and 4,637 fish (87.2%) are expected to be natural and hatchery origin spring Chinook, respectively. The balance of about 92 natural origin spring Chinook expected back are destined to the remaining spawning aggregates (Table 1). In-season assessment of the magnitude and origin composition of the spring Chinook return above Tumwater Dam will be used to provide in-season adjustments to hatchery/wild composition and total broodstock collection, consistent with ESA Section 10 Permits 18118 and 18121.

Table 1. Age-4 and age-5 class return projection for wild and hatchery spring Chinook to Tumwater Dam during 2017.

	Chiwawa Basin[1]			Nason Cr. Basin[1]			Wenatchee Basin to Tumwater Dam[2]		
	Age-4	Age-5	Total	Age-4	Age-5	Total	Age-4	Age-5	Total
Estimated wild return	418	108	**526**	123	32	**155**	614	159	**773**
Estimated hatchery return	3,238	63	**3,301**	1,336	0	**1,336**	4,574	63	**4,637**
Total	3,656	171	**3,827**	1,459	32	**1,491**	**5,188**	**222**	**5,410**

[1] Reflects NOR estimates to Tumwater Dam and has not been adjusted for pre-spawn mortality.
[2] Wenatchee Basin to Tumwater Dam total includes NORs to the White, Little Wenatchee, and Chiwawa rivers and Nason Creek.

Absent conservation fisheries or adult removal at Tumwater Dam (TWD), the expected number of age-4 and age-5 Hatchery Origin Returns (HOR) for the upper Wenatchee River Basin as a whole is estimated to be approximately six times the expected number of Natural Origin Returns (NORs; 6.3 times the number of NOR's in the Chiwawa River and 8.6 times the number of NOR's in Nason Creek). The combined HO and NO returns will represent about 4.2 times the number of adults needed to meet the interim Chiwawa run escapement to TWD of 900 fish indicating a disproportionate number of hatchery origin spring Chinook will be on the spawning grounds in the fall of 2017 (Table 2). The combined HO and NO returns will represent about 3 times the number of adults needed to meet the interim Nason run escapement to TWD of 500 fish indicating a disproportionate number of hatchery origin spring Chinook will be on the spawning grounds in the fall of 2017 (Table 3).

Additional Adult Management

2017 adult management actions are intended to provide for near 100% removal of age-3 hatchery males (jacks), and unknown hatchery origin adults (ad-/cwt-) and up to about 93% of the age-4 and age-5 hatchery origin adults (about 1,717 males and 1,288 females according to current models, Table 2). In addition, approximately 68 HO and 144 NO adults will be removed between TWD and the Chiwawa Weir and retained for broodstock to support meeting the combined Grant and Chelan PUD Wenatchee spring Chinook obligation, the balance will be surplused at TWD and used for tribal and/or food bank disbursements or nutrient enhancement projects.

Table 2. Run escapement and spawning escapement of Chiwawa River hatchery and natural origin fish to Tumwater Dam and the Chiwawa River in 2017.

	To Tumwater Dam		To Chiwawa River		Adults surplused at TWD[3]	Total Chiwawa spawners
	Wild	Hatchery	Wild[1,2]	Hatchery[2]		
Females[4]	305	1,850	228	73	1,717	**301**
Males[4]	221	1,388	156	55	1,288	**211**
Sub-total	526	3,238	384	128	3,005	**512**
Pre-spawn survival[6]			0.85	0.55		
Expected PNI						**0.80**
Expected pHOS						**0.25**

[1] Wild broodstock needs of 74 wild NO fish (37 females/37 males) for the Chiwawa conservation program have already been accounted for in this total as well as pre-spawn mortality.
[2] Adjusted for pre-spawn mortality.
[3] Does not include age-3 hatchery males "jacks" removed during adult management activities at TWD or through a conservation fishery.
[4] Age-4 and age-5 fish only. Gender proportions were made based upon a 5-year average sex ratio for hatchery and wild fish of the same age class.
[5] This should result in approximately 301 redds in the Chiwawa Basin under the assumption that each female produces only one redd.
[6] Estimated survival from Tumwater to spawn.

Table 3. Run escapement and spawning escapement of Nason Creek hatchery and natural origin fish to Tumwater Dam and Nason Creek in 2017.

	To Tumwater Dam		To Nason Creek		Adults surplused at TWD[3]	Total Nason spawners
	Wild	Hatchery	Wild[1,2]	Hatchery[2]		
Females[4]	90	763	47	159	440	**206**
Males[4]	65	573	26	120	321	**146**
Sub-total	155	1,336	73	279	761	**352**
Pre-spawn survival[6]			0.85	0.55		
Expected PNI						**0.56**
Expected pHOS						**0.79**

[1] Wild broodstock needs of 70 wild NO fish (35 females/35 males) for the Nason conservation program have already been accounted for in this total as well as pre-spawn mortality.
[2] Adjusted for pre-spawn mortality and HO broodstock needs of 68 fish (34 females/34 males).
[3] Does not include age-3 hatchery males "jacks" removed during adult management activities at TWD or through a conservation fishery.
[4] Age-4 and age-5 fish only. Gender proportions were made based upon a 5-year average sex ratio for hatchery and wild fish of the same age class.
[5] This should result in approximately 206 redds in Nason Creek under the assumption that each female produces only one redd.
[6] Estimated survival from Tumwater to spawn.

Wenatchee Summer Steelhead

Depending on the outcome of preseason and in-season estimates of hatchery and natural origin steelhead to the Wenatchee Basin during the annual run cycle monitoring at the Priest Rapids Dam Off Ladder Trap (OLAFT), removal of surplus adult steelhead may occur at Tumwater Dam or in combination with a conservation fishery.

A more detailed run forecast will be available in September 2017. Adult management plans will be finalized then and appended to this document.

Methow Spring Chinook

Pre-season estimates project a total of 3,265 (973 natural origin [29.8%] and 2,292 hatchery origin [70.2%]) spring Chinook back to Methow Basin. Of the 2,292 hatchery returns, about 748 are estimated to be from the conservation program with the balance of 1,544 from the WNFH safety net program (Table 5).

Table 5. Brood year 2012-2014 age class and origin run escapement projection for UCR spring Chinook at Wells Dam, 2017.

	Projected Escapement											
	Origin								**Total**			
	Hatchery				**Wild**				**Methow Basin**			
Stock	**Age-3**	**Age-4**	**Age-5**	**Total**	**Age-3**	**Age-4**	**Age-5**	**Total**	**Age-3**	**Age-4**	**Age-5**	**Total**
MetComp	188	473	12	**673**	54	619	126	**799**	242	1,092	138	**1,472**
%Total				41.5%				82.1%				56.7%
Twisp	16	47	12	**75**	21	142	11	**174**	37	189	23	**249**
%Total				4.6%				17.9%				9.6%
Winthrop (MetComp)	324	1,189	31	**1,544**					324	1,189	31	**1,544**
%Total				53.9%								33.7%
Total	528	1,709	55	**2,292**	75	761	137	**973**	603	2,470	192	**3,265**

Some level of adult management will be required to limit the number of hatchery spring Chinook on the spawning grounds. Because a conservation fishery is not yet possible under current permit limitations, adult management will need to occur through operation of the volunteer channel traps located at both the Methow Hatchery (MH) and Winthrop NFH (WNFH).

Presently hatchery fish from MH are prioritized to: a) contribute to the supplementation of the natural populations (up to either the escapement objectives or PNI/pHOS goal), b) make up shortfalls in natural origin brood for the MH conservation program, and c) to support the 400K safety net program at WNFH. As such WNFH will operate their return channel to support removal of excess safety net fish. MH will operate its volunteer trap and will provide surplus hatchery adults (in excess to the MH needs) to WNFH to support the safety net program, to support removal of excess safety net and conservation fish, or retain adults to facilitate testing translocation of conservation fish to under-seeded spawning areas as approved by the HCP HC and PRCC HSC.

Specific actions are as follows:

Twisp River Spring Chinook: spring Chinook in the Twisp River will be managed separately from the rest of the basin.

a. Adipose-clipped fish encountered at the Twisp Weir will be removed (putative WNFH returns or strays from outside of the basin).
b. Age-3 hatchery males will be removed and euthanized or transported to WNFH.
c. Adult management will be performed to maintain pHOS ≤0.50. pNOB will be >0.50 and may be allowed to fluctuate between 0.50 and 1.0 in order to achieve a pHOS ≤0.50.
d. Wild fish will be collected as broodstock – up to ~18 individuals, but not to exceed 33% of the wild run. Hatchery fish may be collected as broodstock dependent on collection success of wild fish and provided that Twisp-program pNOB may not be less than 0.50.
e. The Twisp Weir will be fished for the duration of the broodstock collection, only, in 2017. Adult management activities will be incidental to broodstock collection. Once broodstock collection is completed, the weir will be opened to fish passage to limit delay/trapping effects on bull trout. Tentatively, during broodstock collection, the weir will be fished from 6:00 AM to 9:00 PM on a daily basis. Deviation from this schedule may be implemented based on the run size and catch efficiency for broodstock.

Methow River (MFH and WNFH) and Chewuch River Spring Chinook (MetComp):

a. Stock assessment will be performed at Wells Dam during the spring Chinook broodstock collection. This information on stock, hatchery:wild, and male:female composition coupled with fish counts, will be used in conjunction with fish counts at Wells Dam to adjust in-season adult management targets.
b. MetComp returns will be managed by removing volunteers at WNFH and Methow Hatchery using the outfall traps at these facilities.
    i. All hatchery-origin age-3 males will be removed
        1. Gender identified by ultrasound.
    ii. The Methow and Winthrop FH volunteer traps will be fished continuously (24 h per day/7 d per week) throughout the run and fish removed at least once daily (depending on specific facility limitations), or as often as needed when fish are

present. Adjustments to the operation of the trapping facilities will be made based upon capture/extraction rates as well as bull trout encounters and take limitations.

iii. Trapping will cease at Methow Hatchery if:
   1. Removal of MFH and WNFH origin adults meets the targets established (in this document and as adjusted in-season), or
   2. If overall hatchery bull trout take is likely to be exceeded. However, in-season adjustment may be made to reduce the likelihood of bull trout encounters including, but not limited to: limiting 1) the time of day trap is fished, 2) hours per day fished, 3) days per week fished.

iv. Trapping will cease at Winthrop Hatchery if:
   1. Removal of WNFH and MFH origin adults meets the targets established (in this document and as adjusted in-season), or
   2. If overall hatchery bull trout take is likely to be exceeded. However, in-season adjustment may be made to reduce the likelihood of bull trout encounters including, but not limited to: limiting 1) the time of day trap is fished, 2) hours per day fished, 3) days per week fished.

v. All adipose clipped returns encountered at WNFH and MFH volunteer traps will be removed.
   1. Returns to WNFH will be retained at WNFH for broodstock or surplusing.
   2. Returns to MFH will be transferred to WNFH for broodstock (WNFH safety net and Okanogan 10(j) programs) or surplusing.

vi. Conservation program returns may also be transported to specific reaches of the Methow and/or Chewuch Rivers to meet the minimum spawning escapement objective or to experimentally augment spawner distribution (such an action will require an approved study or implementation plan by the HCP HC and PRCC HSC, and be permissible under current ESA permits.

Based on the preseason forecast for wild and hatchery spring Chinook to the Methow Basin, once NO broodstock requirements are fulfilled and accounting for an estimated prespawn mortality for NO fish of 50% (42% for HO fish), there will be approximately 426 NO spawners. Based upon the sliding PNI scale for NO run sizes >300 fish, the initial goal for 2017 will be to manage for a minimum spawning escapement of 548 spawners; to achieve this, an estimated 67.4% of the hatchery returns (1,862 HO fish) will need to be removed (Table 6). This will result in approximately 122 hatchery origin spawners on the spawning grounds after accounting for prespawn mortality.

Table 6. Calculated targets and projected adult management results for Methow spring Chinook in 2017.

Wild Spawning Escapement	pNOB[2]	pHOS	PNI Target[3]	Allowable Hatchery Spawners	Hatchery surplus	Hatchery Broodstock (WNFH + 10j)	Proportion of Hatchery Fish to Remove	Total spawning escapement
426[1]	1.00	0.223	0.82	122	0 MH	472	0.674[4]	548
					1,544 WNFH			
				Adjusted for Pre-spawn loss	Total Surplus			
				290	1,390			

[1] Adjusted for prespawn mortality. Includes about 78 NO fish expected to go into the Twisp River basin.
[2] pNOB of conservation program only.
[3] Based on 3-pop model and assumes a minimum of 75% conservation program adults for WNFH broodstock.

[4] Assumes a 90% conversion of hatchery fish to hatchery outfalls. Value includes hatchery adults needed to meet WNFH and Okanogan 10(j) production components.

In-season assessment of the magnitude and origin composition of the spring Chinook return above Wells Dam will be used to provide in-season adjustments to hatchery/wild composition and total broodstock collection, consistent with ESA Section 10 Permits 18925, 18927, and 20533.

Methow Summer Steelhead

Depending on the outcome of preseason and in-season estimates of hatchery and natural origin steelhead to the Methow Basin during the annual run cycle monitoring at the Priest Rapids Dam Off Ladder Trap (OLAFT), removal of surplus adult steelhead may occur at the Twisp Weir (primarily as an action related to the steelhead RSS to meet a 1:1 hatchery:wild spawning composition upstream of the weir), the Wells Hatchery Volunteer Channel, volunteer returns to the Methow Hatchery and Winthrop NFH, or in combination with a conservation fishery.

A more detailed run forecast will be available in September 2017. Adult management plans will be finalized then and appended to this document.

Okanogan Summer Steelhead

Depending on the outcome of preseason and in-season estimates of hatchery and natural origin steelhead to the Okanogan Basin during the annual run cycle monitoring at the Priest Rapids Dam Off Ladder Trap (OLAFT), removal of surplus adult steelhead may utilize a conservation fishery or in combination with removal through spring Okanogan tributary weir operations.

A more detailed run forecast will be available in September 2017. Adult management plans will be finalized then and appended to this document.

Appendix D

Site Specific Trapping Operation Plans

Tumwater Dam

For 2017, WDFW and Chelan PUD are proposing the following plan (a summary of activities by month for Tumwater Dam is summarized in Table 1):

1) **Real-time monitoring and trap operations:** Throughout all trapping activities described in this plan, the two PIT tag antennae arrays within the Tumwater Dam ladder (weir 15 and 18, see Appendix 2), will be monitored by WDFW and Chelan PUD and detections of previously PIT tagged fish will be evaluated to determine the median passage time of fish between first detection at weir 15 and last detection at weir 15 or weir 18. Median passage estimates will be updated with every 10 PIT-tagged fish encountering weir 15. If the median passage time is greater than 48 hours, trapping will cease and fish will be allowed to exit via the ladder (i.e., bypass the trap). If trapping has been stopped, PIT tag passage monitoring will continue and trapping will resume if and when the median passage time is less than 24 hours. In summary, real-time PIT tag monitoring will occur both when the trap is operational and when fish are bypassed. This will provide an opportunity to evaluate trapping effects versus baseline passage rates through the ladder for future operations.

2) **Improved Fish Handling Efficiency**: Several infrastructure improvements at Tumwater allow WDFW and other operators to cycle through sampled fish more quickly. These improvements consist of an additional holding tank and an improved conveyance system between the trap and holding tank. The facility improvements and additional staffing by WDFW (3 operators instead of 2) during peak spring Chinook and sockeye passage (i.e. June 1 and July 15), will ensure that the trapping denil is operated constantly allowing unimpeded passage through the trap. Historically, the trapping denil has been periodically shut down while fish were being processed.

3) **Enhanced effort for Tumwater trapping operations from June 1 and July 15**: The Tumwater trap will be operated in an active-manned trapping condition (the ladder bypass will not be used however, fish may still ascend the denil [steep pass] unimpeded). The trap will be checked a minimum of 1x per day. More frequent trap checks will be made as fish numbers increase. Between June 16 and July 15 the Tumwater trap will be actively manned 24 hours/day 7 days/week utilizing two- three person crews (two people will sample fish and the third will maintain operation of the steep pass so that it will not be closed to passage). This represents an additional person to keep the denil operating constantly. If during this period staff are not available (due to logistical, funding, or other issues) to keep the denil operating continuously, the trap will be opened to allow for nighttime passage (this is in addition to passage required under a detected delay event).

4) **Enhanced effort and limited Tumwater trapping operations from July 16 to August 31**: The trap will be operated 3 days/week for up to 16 hours/day (not to exceed 48 hours per week) to support broodstock collection activities for summer Chinook and sockeye run composition sampling (CRITFC) and sockeye spawner escapement PIT tagging. Video enumeration and full passage will occur when trapping is not occurring.

5) **Planned Tumwater trapping operations from September 1 until mid-December:** The trap will return to a 24 hours/7day/week manned or unmanned active trapping for steelhead and Coho broodstock collection and adult steelhead management. During this time period bull trout are rare and spring Chinook are not present at Tumwater. For this trapping period, real-time monitoring will continue to be implemented.

6) **Operations at Tumwater from mid-December until about mid-February:** During this period the trapping facility is not operated due to having been winterized. Only video enumeration and full passage are available during this period.

7) **Planned Tumwater trapping operations from mid-February through May:** The trap will return to a 24 hours/7day/week manned or unmanned active trapping for adult steelhead management and spawner escapement tagging. Beginning on or about May 1, limited spring Chinook broodstocking, run comp sampling, etc. may also occur. For this trapping period, real-time monitoring will continue to be implemented.

8) **Limitation in staffing or other unforeseen problems**: If WDFW staff are not available to operate the trapping facility (according to this plan) for any reason, then full passage will be allowed (fish will be allowed to bypass the trap and exit the ladder directly), until staff are able to return.

9) **Unforeseen scenarios and in season observations**: If during the trapping period, observations from field staff warrant reconsideration of any part of the plan as described above, WDFW and Chelan PUD will alert the Hatchery Committee and work cooperatively with the Services to determine whether changes are needed to further minimize incidental take or otherwise ensure that take is maintained at the manner and extent previously approved by the Services

Table 1. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and reproductive success activities anticipated to be conducted at Tumwater Dam in 2017. Blue denotes steelhead, brown spring Chinook, orange sockeye, pink summer Chinook, and green Coho.

Activity	Month											
	Jan	Feb	Mar	Apr	May	June	Jul	Aug	Sep	Oct	Nov	Dec
SHD pHOS mgt[1]		15 Feb				15 June			1 Sep			15 Dec
Su. SHD BS collection[2]									1 Sep		15 Nov	
Su. SHD Spawner Esc. tagging[3]		15 Feb				15 June			1 Sep			15 Dec
Spring Chinook RSS[4]					1 May		15 Jul					
Sp Chinook run comp[5]					1 May		15 Jul					
Sp Chinook pHOS mgt[6]					1 May		15 Jul					
Sp Chin stray mgt[7]					1 May		15 Jul					
Sockeye run comp[8]							15 Jul	15 Aug				
Sockeye spawner esc tagging[9]							15 Jul	15 Aug				
Su. Chin BS collection[10]							1 Jul		15 Sep			
Coho BS collection[11]									1 Sep		30 Nov	

[1] Adult management of the 2017 brood will end in June 2017. However it is anticipated that adult management will occur for the 2018 brood beginning 1 September or earlier if conducted in conjunction with broodstock collection activities at Tumwater Dam for other species.
[2] Summer steelhead broodstock collection will be prioritized at Dryden Dam traps. However if broodstock objectives cannot be met at Dryden then trapping may occur at Tumwater concurrent with other activities.
[3] SHD spawner composition tagging at Tumwater Dam will run concurrent with SHD adult management and other (broodstock) activities at Tumwater Dam.
[4] The spring Chinook RSS will run from 1 May through about 15 July or at such time or at such time the sockeye return develops at Tumwater Dam.
[5] Spring Chinook run composition sampling will run concurrent with the RSS.
[6] Spring Chinook pHOS management will end in July consistent with the arrival of the sockeye return and run concurrent with RSS activities.
[7] Removal of unknown hatchery origin spring Chinook strays at Tumwater Dam will run concurrent with the RSS.
[8] Sockeye run composition sampling will occur at Tumwater Dam beginning no earlier than 15 July. Trapping at Tumwater Dam for run composition sampling will follow a 3d/week, 16hrs/d (48 hrs/week) trapping schedule consistent with permit 1347.
[9] Sockeye spawner escapement sampling will occur at Tumwater Dam beginning no earlier than 15 July. Trapping at Tumwater Dam for spawner escapement tagging will follow a 3d/week, 16hrs/d (48 hrs/week) trapping schedule consistent with permit 1347.
[10] Summer Chinook broodstock collection will be prioritized at Dryden Dam. However if broodstock objectives cannot be met at Dryden Dam then trapping may occur at Tumwater Dam. Trapping at Tumwater Dam for summer Chinook broodstock will follow a 3d/week 16hr/day (48 hrs/week) trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities.
[11] Coho trapping will be conducted at both Dryden and Tumwater Dams. Trapping at Tumwater Dam for Coho broodstock will follow a 3d/week 16hr/day (48 hrs/week) trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities. Collection is permitted through December 7 of each year but typically ceases by the end of November.

Dryden Dam

For 2017, WDFW and Chelan PUD are proposing the following plan (a summary of activities by month for the right and left bank Dryden Dam traps is summarized in Table 2):

The Dryden Dam left and right bank trapping facilities will operate up to five days per week, 24 hours per day beginning July 1 and continue until as late as November 15. Both traps, if operated, will do so on concurrent days and will be checked and cleared every 24 hours, or sooner if it appears that run contribution to the facilities exceeds reasonable limits for adult holding.

If daily river temperatures meet or exceed 21° C (69.8° F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

Table 2. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and/or reproductive success activities anticipated to be conducted at Dryden Dam trapping facilities in 2017. Blue denotes steelhead, brown spring Chinook, orange sockeye, pink summer Chinook, and green Coho.

Activity	Month											
	Jan	Feb	Mar	Apr	May	June	Jul	Aug	Sep	Oct	Nov	Dec

Su. SHD Run Comp.							1 Jul					
Su. SHD spawner esc. Tagging2							1 Jul				15 Nov	
Su. Chinook run comp							1 Jul		15 Sep			
Su. Chin BS collection[3]							1 Jul		15 Sep			
Coho BS collection[4]									1 Sep		30No v	

[1] Summer steelhead broodstock collection will be prioritized at Dryden Dam traps. However if broodstock objectives cannot be met at Dryden then trapping may occur at Tumwater concurrent with other activities.
[2] SHD spawner composition tagging at Dryden Dam will run concurrent with other (broodstock or M&E) activities at Dryden Dam.
[3] Summer Chinook broodstock collection will be prioritized at Dryden Dam. However if broodstock objectives cannot be met at Dryden Dam then trapping may occur at Tumwater Dam. Trapping at Dryden Dam for summer Chinook broodstock will follow an up to 5d/week 24hr/day trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities.
[4] Coho trapping will be conducted at both Dryden and Tumwater Dams. Trapping at Dryden Dam for Coho broodstock will follow an up to 5d/week 24hr/day trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities. Collection is permitted through December 7 of each year but typically ceases by the end of November.

Wells Dam Ladder and Hatchery Volunteer Traps

For 2017, WDFW and Douglas PUD are proposing the following plan (A summary of activities by month for the Wells Dam East/West ladder and Wells FH volunteer traps is summarized in Table 3):

1). **East Ladder Trap:**

The East ladder trap will only be operated as needed to meet broodstock collection objectives and other management activities if they cannot be adequately fulfilled through the West ladder and Wells FH volunteer trap operations or if construction activities on the hatchery modernization preclude use of either the West ladder or volunteer traps.

If the East ladder trap is used, it may begin as early as May 1 and will operate under a maximum 5-days per (operation will be limited to no more than three consecutive days)/12 hours per day or 60 cumulative hours per week and will run concurrent with any trapping activities occurring at the West ladder trap. Anticipated trap operation is not expected to go beyond November 15.

For all species except coho after September 26, when the West ladder trap is operational, and the East ladder trap is used, it may begin as early as May 1 and will operate under a maximum 3-day per week/16 hours per day or 48 cumulative hours per week and will run concurrent with any trapping activities occurring at the West ladder trap. For coho trapping, the East ladder trap may be operated, concurrent with the West ladder trap, 5 days per week/ 9 hours per day September 27 through October 9, and 7 days per week/16 hours per day beginning October 10. Trap operators will bypass Chinook, steelhead, and sockeye during coho trapping. Anticipated trap operation is not expected to go beyond November 15.

If daily river temperatures meet or exceed 21º C (69.8º F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

2). **West Ladder Trap:**

The West ladder may begin as early as May 1 for spring Chinook broodstock collection and will operate under a maximum 5-days per week (operation will be limited to no more than three consecutive days)/12 hours per day or 60 cumulative hours per week and will run concurrent with any trapping activities occurring at the East ladder trap. Anticipated trap operation is not expected to go beyond November 15.

If daily river temperatures meet or exceed 21º C (69.8º F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

3). **Wells FH Volunteer Trap:** The Wells FH volunteer trap may begin as early as July 1 for summer Chinook broodstock collection and operate through mid-June of the following year for steelhead broodstock collection and adult management if needed. The trap may operate up to seven days per week/24 hours per day to facilitate broodstock collection and adult management actions.

If daily river temperatures meet or exceed 21º C (69.8º F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

Table 3. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and/or reproductive success activities anticipated to be conducted at Wells Dam in 2017. Blue denotes steelhead, brown spring Chinook, pink summer Chinook, and green Coho.

Activity	Month											
	Jan	Feb	Mar	Apr	May	June	Jul	Aug	Sep	Oct	Nov	Dec
East/West Ladders												
Su. SHD BS collection[1]									1 Sep		15 Nov	
Su. SHD run comp.									1 Sep		15 Nov	
Su. SHD Spawner Esc. Tagging[2]									1 Sep		15 Nov	
Sp Chinook BS collection					1 May		15 Jul					
Sp Chinook run comp					1 May		15 Jul					
Su. Chin BS collection[3]							1 Jul		15 Sep			
Coho BS collection[5]									15 Sep		15 Nov	
Wells Volunteer Trap												
Su. SHD BS collection[1]									1 Sep		15 Nov	
SHD pHOS mgt.[6]		15 Feb				15 June			1 Sep			15 Dec
Su. Chin BS collection[4]							1 Jul		15 Sep			
Su. Chin Surplussing							1 Jul			30 Oct		

[1] Summer steelhead broodstock collection will be prioritized at West ladder and volunteer traps. However if broodstock objectives cannot be met at either of those two locations then trapping may occur at the East ladder concurrent with other activities.
[2] SHD spawner composition tagging at Wells Dam will run concurrent with other (broodstock or M&E) activities at Wells Dam.
[3] Summer Chinook broodstock collection for the Methow (Carlton) program will be prioritized at the West ladder trap. However if broodstock objectives cannot be met at the West ladder then trapping may occur at the East ladder. Trapping at the west and/or East ladders for summer Chinook broodstock will follow an up to 3d/week 16hr/day (48 cumulative hours) trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities.
[4] Summer Chinook broodstock collection for the Wells Hatchery programs will be prioritized at the Wells Hatchery volunteer trap. Trapping at the volunteer channel may occur up to 7 days per week, 24 hours per day and may include broodstock collection and/or adult management.
[5] Coho trapping may be conducted at both East and/or West ladders. Trapping at Wells Dam ladder traps for Coho broodstock will follow an up to 3d/week 16hr/day trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities. Trapping at the Wells Dam ladder will cease no later than November 15.
[6] Adult management of the 2017 brood will end in June 2017. However it is anticipated that adult management will occur for the 2018 brood beginning 1 September or earlier if conducted in conjunction with broodstock collection activities at the Wells Hatchery volunteer channel for other species.

Methow Hatchery Volunteer and Twisp Weir Traps

For 2017, WDFW and Douglas PUD are proposing the following plan (A summary of activities by month for Methow Hatchery volunteer trap and the Twisp Weir is summarized in Table 4):

Specific operation details for the Methow Hatchery volunteer trap and Twisp Weir are still being worked through. Once those details have been fleshed out more thoroughly, this section will be updated.

If daily river temperatures meet or exceed 21° C (69.8° F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

Table 4. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and/or reproductive success activities anticipated to be conducted at Methow Hatchery and the Twisp Weir in 2017. Blue denotes steelhead, brown spring Chinook, and green Coho.

Activity	Month											
	Jan	Feb	Mar	Apr	May	June	Jul	Aug	Sep	Oct	Nov	Dec
Methow Hatchery[1]												
SHD pHOS mgt.			1 Mar			15 Jun			1 Sep		15 Nov	
Sp. Chinook BS collection					1 May			30 Aug				
Sp. Chinook pHOS mgt.[2]					1 May			30 Aug				
Twisp Weir[3]												
Steelhead RSS			1 Mar		30 May							
Su. SHD BS collection				1-30 Apr								
SHD pHOS mgt.			1 Mar		30 May							
Sp. Chinook BS collection						1 June		15 Aug				
Sp. Chinook pHOS mgt.						1 June		22 Aug				

[1] Specific details on how operation of the Methow Hatchery volunteer trap will work for SHD adult management are still being worked out at this time.
[2] Adult management for spring Chinook at the Methow Hatchery volunteer trap will run concurrent with broodstock collection.
[3] Specific details on how operation of the Twisp Weir will work for 2016 to include the steelhead RSS, broodstock collection, and adult management and spring Chinook broodstock collection and adult management is still being worked out at this time.

Priest Rapids Dam Off Ladder Trap (OLAFT)

Table 5. Summary of broodstock collection, VSP monitoring, and/or run composition sampling activities anticipated to be conducted at the Priest Rapids Dam Off Ladder Trap (OLAFT) in 2017. Blue denotes steelhead, purple fall Chinook, and orange sockeye.

Activity	Month											
	Jan	Feb	Mar	Apr	May	June	Jul	Aug	Sep	Oct	Nov	Dec
SHD VSP Monitoring[1]							1 Jul				15 Nov	
Fall Chin. BS collection[2]									1 Sep		15 Nov	
Fall Chinook Run Comp.[3]									1 Sep		15 Nov	
Sockeye BS Collection[4]						22 Jun	10 Jul					

[1] Steelhead VSP monitoring targets up to 15% of the annual return over Priest Rapids Dam. Presently that requires operation of the OLAFT up to 3 days/ week, 8 hours per day. The trap is opened to passage each night.
[2] To acquire the target 1,000 adipose present, non-CWT adult fall Chinook for broodstock, the OLAFT is operated up to 5 days per week, 8 hours per day. Three of the five days are concurrent with the SHD VSP monitoring. The trap is opened to passage each night.
[3] Fall Chinook run composition runs concurrent with SHD VSP monitoring and/or fall Chinook broodstock collection activities.
[4] Sockeye broodstock collection to support YN reintroduction efforts in the Yakima is based upon abundance based sliding scale. Depending on the strength of the return and allowable allocation, the trap may be operated up to 5 days per week, 8 hours per day beginning about 22 June and running through about 10 July. The trap is opened to passage each night.

Appendix G

DRAFT
Hatchery Production Management Plan

The following management plan is intended to provide life-stage-appropriate management options for Upper Columbia River (UCR) PUD salmon and steelhead mitigation programs. Consistent, significant over-production or under-production risks the PUD's not meeting the production objectives required by FERC and overages in excess of 110% of program release goals violates the terms and conditions set forth for the implementation of programs under ESA and poses potentially significant ecological risks to natural origin salmon communities.

Under RCW 77.95.210 (Appendix A) as established by House Bill 1286, the Washington Department of Fish and Wildlife has limited latitude in disposing of salmon and steelhead eggs/fry/fish. While this RCW speaks more specifically to the sale of fish and/or eggs WDFW takes a broader application of this statute to include any surplus fish and/or eggs irrespective of being sold or transferred.

We propose implementing specific measures during the different life-history stages to both improve the accuracy of production levels and make adjustments if over-production occurs. These measures include (1) Improved Fecundity Estimates, (2) Adult Collection Adjustments, (3) Within-Hatchery Program Adjustments, and (4) Culling.

<u>Improved Fecundity Estimates</u>

A) Develop broodstock collection protocols based upon the most recent 5-year mean in-hatchery performance values for female to spawn, fecundity, green egg to eye, and green egg to release.
B) Use portable ultrasound units to confirm gender of broodstock collected (broodstock collection protocols assume a 1:1 male-to-female ratio). Ultrasonography, when used by properly trained staff will ensure the 1:1 assumption is met (or that the female equivalents needed to meet production objective are collected). Spawning matrices can be developed such that if broodstock for any given program are male limited sufficient gametes are available to spawn with the females.

<u>Adult Collection Adjustments</u>

C) Make in-season adjustments to adult collections based upon a fecundity-at-length regression model for each population/program and origin composition need (hatchery/wild). This method is intended to make in-season allowances for the age structure of the return (i.e. age-5 fish are larger and therefore more fecund than age-4 fish), but will also make allowances for age-4 fish that experienced more growth through better ocean conditions compared to an age-5 fish that reared in poorer ocean conditions.

<u>Within-Hatchery Program Adjustments</u>

D) At the eyed egg inventory (first trued inventory), after adjustments have been made for culling to meet BKD management objectives, the over production will be managed in one or more of the following actions as approved by the HCP-HC or PRCC-HSC:

- Voluntary cooperative salmon culture programs under the supervision of the department under chapter 77.100 RCW;
- Regional fisheries enhancement group salmon culture programs under the supervision of the department under this chapter;
- Salmon culture programs requested by lead entities and approved by the salmon funding recovery board under chapter 77.85 RCW;
- Hatcheries of federally approved tribes in Washington to whom eggs are moved, not sold, under the interlocal cooperation act, chapter 39.34 RCW; and
- Governmental hatcheries in Washington, Oregon, and Idaho; or
- Culling for diseases such as BKD and IHN, consistent with the Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State; or
- Distribution to approved organizations/projects for research.

E) At tagging (second inventory correction) fish will be tagged up to 110% of production level at that life stage. If the balance of the population combined with the tagged population amounts to more than 110% of the total release number allowed by Section 10 permits then the excess will be distributed in one or more of the following actions as approved by the HCP-HC or PRCC-HSC:

- Voluntary cooperative salmon culture programs under the supervision of the department under chapter 77.100 RCW;
- Regional fisheries enhancement group salmon culture programs under the supervision of the department under this chapter;
- Salmon culture programs requested by lead entities and approved by the salmon recovery funding board under chapter 77.85 RCW;
- Hatcheries of federally approved tribes in Washington to whom eggs are moved, not sold, under the interlocal cooperation act, chapter 39.34 RCW; and
- Transfer to another resource manager program such as CCT, YN, or USFWS program;
- Governmental hatcheries in Washington, Oregon, and Idaho;
- Placement of fish into a resident fishery (lake) zone, provided disease risks are within acceptable guidelines; or
- Culling for diseases such as BKD and IHN, consistent with the Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State; or
- Distribution to approved organizations/projects for research.

F) In the event that a production overage occurs after the above actions have been implemented or considered, and deemed non-viable for fish health reasons in accordance with agency aquaculture disease control regulations (i.e. either a pathogen is detected in a population that may pose jeopardy to the remaining population or other programs if retained or could introduce a pathogen to a watershed where it had not previously been detected) then culling of those fish may be considered.

All, provisions, distributions, or transfers shall be consistent with the department's egg transfer and aquaculture disease control regulations as now existing or hereafter amended. Prior to department determination that eggs of a salmon stock are surplus and available for sale, the department shall assess the productivity of each watershed that is suitable for receiving eggs.

Out-planting Surplus Methow Composite Spring Chinook Salmon Adults-DRAFT

Background

The Hatchery Committees (HCs) recently reviewed the "Evaluation of Hatchery Programs Funded by Douglas County PUD 5-year Report 2006-2010". As a result, Objective 6 monitoring question Q6.1.1: "Is the stray rate of hatchery fish less than 5% for the total brood year return?" was identified as not meeting the target for the Chewuch River final acclimated fish. The HCs determined that methods to improve homing would have uncertain success, be difficult to implement, and challenging to statistically evaluate. In an effort to achieve the goal of increased hatchery-origin spawner abundance in identified reaches that a higher rate of homing would convey, the HCs agreed to pilot adult out-planting of surplused Methow Composite spring Chinook into the Chewuch River.

The goal of this pilot evaluation is to determine if surplused Methow Composite spring Chinook adults collected and held at the Methow Hatchery, and subsequently out-planted into the Chewuch River, remain in the Chewuch River and subsequently spawn. This pilot evaluation will be conducted in an effort to determine if adult-outplanting can be an effective tool to increase spawner abundance, spawner distribution, and natural production in the Chewuch River in years of low abundance. It is a low-risk management tool that has been used in many locations such as the Wenatchee and Willamette watersheds.

2017 Out-planting of Surplus Methow Composite Spring Chinook Salmon Adults Objectives:

- During spawning surveys, estimate the number of females trapped and out-planted to the Chewuch River that exhibit spawning behavior, construct a redd, and/or spawned (determined by egg voidance).
- Assess the ability of transporting adult spring Chinook to the Chewuch River to provide the overall number of hatchery spawners allowable under ESA permit conditions.
- Assess how many days fish were held from trapping to out-planting and from out-planting to spawner success.
- Estimate spawner distribution of males and females within the Chewuch River post release and compare results to retention time in the Chewuch River and spawner success.
- Assess the proportion of out-planted males and females that remain in the Chewuch River compared to out-planted males and females determined to have left the Chewuch River.

Methods

Up to 200 hatchery-origin spring Chinook salmon adults (jacks will be excluded) returning to the Methow Hatchery, in excess of broodstock needs for the Methow Hatchery and Winthrop National Fish Hatchery (NFH), will be collected, held and out-planted to targeted spawning reaches of the Chewuch River. The specific number of fish to be held and out-planted will be based upon permit limitations, availability of fish, and pHOS level as agreed to by the HC. A female to male ratio of 1.0:0.2 will be implemented unless run composition assessment for the run at large suggests a deviation from this level.

- Out-plant a maximum of 200 hatchery-origin spring Chinook adults (jacks will be excluded) at a female to male ratio of 1.0:0.2 will be implemented unless run composition assessment for the run at large suggests a deviation from this level.

- The number of adults shall be consistent with the terms and conditions of the ESA incidental take permits for the Methow Hatchery (#18925; #18927; #20533) according to the decision tree below:

1. If the natural origin run to the Methow basin is estimated to be <100, then pHOS in the Chewuch will be =-0.002x+0.8 (where x=estimate of the natural origin run size in the Chewuch River), else,
2. If the natural origin run to the Methow sub-basin is estimated to be ≥100 and <300, then pHOS in the Chewuch River will be =-0.0013x+0.8 (where x=estimate of the natural origin run size in the Chewuch), else,
3. If the natural origin run to the Methow sub-basin is estimated to be ≥300, then pHOS in the Chewuch River will be =0.8(1-e^(-0.006x) (where x=estimate natural origin run size in the Chewuch).
4. In each case, the number of hatchery origin fish to be released in the Chewuch will be calculated as
    a. Find the allowable basin pHOS based on estimated natural-origin spawning escapement to the Methow sub-basin and the estimated pHOS for the Methow Hatchery program (Twisp + MetComp).
    b. Use this pHOS to estimate how many hatchery-origin fish can be allowed in the Chewuch River based on the expected natural-origin spawning escapement to the Chewuch River.
    c. Calculate how many additional, surplus hatchery-origin fish shall be transported and released to the Chewuch River to remain within permit limits.
    d. A spreadsheet “Adult Outplanting Calculator.xls” is available to perform these calculations (Attachment A).

Holding and Out-planting

Surplus hatchery-origin adults returning to the Methow Hatchery will be held (duration of holding period will be variable based upon when the individual was collected) and out-planted approximately one week before estimated peak spawning (i.e., during the latter part of August/early September). If the fish being held for subsequent out-planting experience a disease outbreak, the fish will not be out-planted. All out-planted adults will be PIT-tagged and marked with a visible mark. Depending on availability of fish for out-planting, up to 100 adults will be released into each of one of two sites; if fish availability is limited, all fish will be out-planted into the upper release site. One site will be above the upper Chewuch River PIT tag instream PIT tag antenna array (CRU) and the other below CRU and above the Winthrop (CRW) PIT tag antenna array (Figure 1). Release locations will be determined based on accessibility, suitable spawning habitat, distance from the hatchery, distance from PIT tag arrays, and areas that are not being utilized by spawners already in the system.

Evaluation

The association of the out-planted adults with redds will be documented during spawner surveys (e.g., identification of out-planted adults on redds). Potential spawning success of females will be documented by estimating the proportion of eggs that are retained within female carcasses sampled during carcass recovery surveys. Carcass location and redds determined to be constructed by out-planted adults will be documented using a GPS device.

Post release PIT detections at the CRW PIT tag antenna array, non-Chewuch River PIT detections, and out-planted adults returning to the Methow Hatchery and Winthrop NFH will be used to estimate the proportion of out-planted spring Chinook salmon that left the Chewuch River.

The results of this pilot evaluation will be summarized and presented to the HCs during the February 2018 meeting. The results of the 2017 out-planting effort may be used to inform potential future decisions and/or actions regarding out-planting methodology.

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCPs Hatchery Committees

Date: May 19, 2017

From: Tracy Hillman, HCP Hatchery Committees Chairman

cc: Sarah Montgomery, Anchor QEA, LLC

Re: Final Minutes of the April 19, 2017, HCP Hatchery Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans (HCPs) Hatchery Committees meeting was held at the Grant PUD office in Wenatchee, Washington, on Wednesday, April 19, 2017, from 9:00 a.m. to 12:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A). *(Note: this item is ongoing.)*
- Hatchery Committees representatives will review the Hatchery Monitoring and Evaluation (M&E) Plan Objectives before the Hatchery Committees May 17, 2017, meeting (Item I-A). *(Note: this item is ongoing.)*
- Hatchery Committees representatives will review McLain Johnson's (WDFW) Genetic Monitoring Update for discussion at the Hatchery Committees May 17, 2017, meeting (Item I-A). *(Note: Sarah Montgomery distributed the update on April 6, 2017.)*
- Brett Farman and Charlene Hurst will provide an update to the Hatchery Committees on the differences between Endangered Species Act (ESA) Section 7, Section 10, and Section 4(d) coverage in regards to permitting for some HCP programs (Item II-B).
- Mike Tonseth will organize a workgroup to discuss the future of the Twisp Steelhead Program and define its proposed actions for consultation (Item II-D).
- Catherine Willard and Keely Murdoch will provide coho salmon recalculation numbers to the Hatchery Committees for discussion at the Hatchery Committees May 17, 2017, meeting (Item III-A).
- Keely Murdoch will provide the latest Yakama Nation (YN) Coho Salmon Master Plan to Sarah Montgomery for distribution to the Hatchery Committees (Item III-A).
- Hatchery Committees representatives will discuss internally the brood year stray rate target and prepare for further discussion at the Hatchery Committees May 17, 2017, meeting (Item II-E).

- Matt Cooper will invite Penny Swanson (National Oceanic and Atmospheric Administration) to give a presentation about epigenetics at the Hatchery Committees May 17, 2017, meeting (Item IV-B). *(Note: Cooper asked Montgomery to add a talk by Mackenzie Gavery to the May 17, 2017 agenda.)*

Decision Summary

- The Hatchery Committees representatives present approved the Outplanting Adults Plan (for spring Chinook salmon in the Chewuch River) as follows: Chelan PUD, Douglas PUD, U.S. Fish and Wildlife Service (USFWS), WDFW, National Marine Fisheries Service (NMFS), YN, and Colville Confederated Tribes (CCT) approved on April 19, 2017. Grant PUD (Priest Rapids Coordinating Committee Hatchery Sub-Committee [PRCC HSC]) also indicated approval during the joint HCP-HC/PRCC HSC session (Item II-C).

Agreements

- There were no agreements discussed during today's meeting besides the decision listed in the above section.

Review Items

- There are no items currently out for review.

Finalized Documents

- Sarah Montgomery sent an email to the Hatchery Committees on April 20, 2017, notifying them that the Final Outplanting Adults Plan is now available for download from the Hatchery Committees Extranet site.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the March 13, 2017, Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the Hatchery Committees and asked for any additions or changes to the agenda. No revisions were requested.

The Hatchery Committees reviewed the revised draft March 13, 2017, meeting minutes. Sarah Montgomery said there are several outstanding comments to be discussed, which the Hatchery Committees reviewed and addressed. Hatchery Committees representatives present approved the draft March 13, 2017, meeting minutes, as revised.

Action items from the Hatchery Committees meeting on March 13, 2017, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meeting on March 13, 2017)*:

- *McLain Johnson (Washington State Department of Fish and Wildlife [WDFW]) will revise the timeline for conducting genetic analysis for HCP program species incorporating suggestions provided during the Hatchery Committees January 18, 2017, meeting (Item I-A).*
  This item is complete. Johnson sent the revised timeline to the Hatchery Committees on April 6, 2017.
- *McLain Johnson and WDFW geneticists will perform a power analysis to inform genetic analysis intervals and intensity for HCP program species (Item I-A).*
  This item is complete. Johnson sent a memo regarding genetic analysis intervals to the Hatchery Committees on April 6, 2017, and will be discussed at the May 17, 2017, Hatchery Committees meeting.
- *Andrew Murdoch (WDFW) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A).*
  Mike Tonseth said this item is ongoing.
- *Hatchery Committees representatives will review the Hatchery Monitoring and Evaluation (M&E) Plan Objectives before the Hatchery Committees April 19, 2017, meeting (Item IV-A).*
  This is ongoing and will be discussed during the Hatchery Committees May 17, 2017, meeting.
- *Casey Baldwin will discuss internally the steelhead marking strategy in the draft 2017 Broodstock Collection Protocols and provide feedback to Mike Tonseth (Item IV-D).*
  This item is complete.
- *Keely Murdoch will discuss internally the Yakama Nation (YN)'s egg requests for their summer Chinook salmon program (Item IV-D).*
  This item is complete. Murdoch provided input to Mike Tonseth.
- *Hatchery Committees representatives will discuss internally WDFW's proposal for collection and rearing for the Twisp Steelhead program in 2017 and provide a vote by March 30, 2017 (note: this includes adult collection at the Twisp Weir, transfer to Winthrop National Fish Hatchery (NFH), spawning as part of aggregate composite population. and incubation to eyed-egg or fry stage at Winthrop NFH, then transfer to Methow Fish Hatchery [FH]; Item IV-E).*
  This item is complete.
- *Catherine Willard will revise the draft study plan, "Outplanting Surplus Methow Composite Spring Chinook Salmon Adults to Increase Natural Production in the Chewuch River," and distribute it to the Hatchery Committees for approval at the April 19, 2017, meeting (Item IV-F).*
  This item is complete and will be discussed today.

- *Tracy Hillman will preliminarily revise the brood-year (BY) stray rate target language in the Hatchery M&E Plan for further discussion at the Hatchery Committees April 19, 2017, meeting (Item IV-G).*
  Hillman said edits to language in the M&E Plan depend on further discussion of brood year stray rate targets.
- *Tracy Hillman will assess the relationship over the last 10 years between exceeding BY stray rate targets and exceeding recipient stray rate targets (Item IV-G).*
  This item is complete and will be discussed today.

II. Joint HCP-HC/PRCC HSC

A. USFWS Bull Trout Consultation Update (Matt Cooper)

Matt Cooper said Karl Halupka (USFWS) sent him an update on USFWS consultations, which he summarized as follows:

- Halupka received comments on the draft biological opinion (BiOp) for the batch of Wenatchee subbasin programs, and USFWS is working on incorporating the comments into the BiOp. Halupka expects the BiOp will be finalized in May 2017.
- The USFWS discussed the consultation process for mainstem programs with NMFS.

Catherine Willard asked if Halupka plans to send the draft BiOp to the applicants for review once more before it is finalized. Cooper said he does not expect so. Mike Tonseth asked if Halupka has an update for the Hatchery Committees on the consultation process for Methow steelhead. Bill Gale said Halupka is generally following the consultation schedule set by NMFS.

B. NMFS Consultation Update (Brett Farman/Charlene Hurst)

Charlene Hurst said NMFS is prioritizing consultations that need to be finished in 2017 per the United States v. Oregon Management Agreement. Hurst said NMFS is currently drafting proposed actions for the consultations and any proposed actions should be sent to herself or Karl Halupka.

Hurst said Emi Kondo (NMFS) is working on the consultations for unlisted programs. She said the draft BiOp is almost complete, but more programs need to be added. The upper Columbia River unlisted programs will be addressed after the Leavenworth program consultation is finished.

Hurst said she recently requested information regarding consultation for steelhead programs, which she expects to be completed faster than other consultations. She said the proposed action will need to be finished by June 2017 so that the BiOp can be completed by December 2017, and more work is needed on the gene flow model. She said she set up monthly meetings for the steelhead consultation and asked if any other parties would like to be included in those meetings. Bill Gale asked for Hurst to include himself and Matt Cooper. Keely Murdoch asked to be included and said all Hatchery Committees members should be invited to these coordination meetings and discussions to avoid future slowdown of the consultation process. Kirk Truscott asked that he and Casey Baldwin be included and said steelhead for the Okanogan programs are reared at Wells Fish Hatchery (FH). Todd Pearsons also asked to be included and said if steelhead rearing at Wells FH for the Okanogan programs is not covered under the Tribal Resources Management Plan, then it should be included with this consultation. Greg Mackey said gene flow targets are still undetermined and asked for more information from Hurst on proportionate natural influence (PNI) goals. He said non-governmental organizations have been interested in using proportion of hatchery-origin spawners (pHOS) standards to evaluate hatchery programs. Hurst said the Hatchery and Genetic Management Plans (HGMPs) reference a PNI goal of 0.67, which she said would be a reasonable standard to apply to the programs. She said for the pHOS standard, the Hatchery Scientific Review Group (HSRG) guideline is 30% for integrated programs, so 30% would be a reasonable standard to use for these programs. She said a sliding scale or other technique, and a long-term timeline could help programs attain this goal. Gale asked if Hurst is referencing "effective" pHOS or "straight" pHOS. She said NMFS does not typically use effective pHOS, and Gale said the HSRG largely references effective pHOS. Gale noted that HSRG guidelines for integrated programs mention that the guidelines may not be applicable for depressed or threatened populations; rather, the guidelines are for an ideal hatchery-wild population interaction. He said a depressed population with low abundance may not be able to achieve a pHOS of 30%. Hurst said NMFS will consider the HSRG guidelines when discussing sliding scales and pHOS targets.

Pearsons asked Hurst which programs are bundled for this consultation. Hurst said the steelhead consultation bundle includes the Winthrop program, Wells complex programs (Wells FH, Twisp, and Methow FH), and any releases under the Wells Steelhead HGMP. She said the consultation for unlisted programs will result in one BiOp, which includes Wenatchee summer Chinook salmon, Chelan Falls summer Chinook salmon, Wells summer Chinook salmon, Priest Rapids fall Chinook salmon, Methow summer Chinook salmon, and Ringold upriver bright fall Chinook salmon (which is included with the rest for efficiency). The bundle does not include Similkameen summer Chinook salmon, which is bundled with Chief Joseph programs. Hurst said the type of permit under this BiOp is undecided and could be Section 7 coverage with United States v. Oregon as the federal nexus or Section 10 including a National Environmental Policy Act process with permits issued in 2018. Pearsons asked how each permit coverage type would affect the programs. Hurst said she would discuss the program implications of each coverage type with NMFS legal counsel and update the Hatchery Committees.

Gale asked if Entiat summer Chinook salmon are the only unlisted program not included in the bundle besides Okanogan summer Chinook salmon. Hurst confirmed and said the Entiat program already has coverage. Gale said the Entiat summer Chinook salmon program has a BiOp that will expire and he would like to get the expiration modified. Hurst said she would look into this.

C. Spring Chinook Salmon Out-planting in the Chewuch River (Catherine Willard)

Catherine Willard shared a document titled, "Draft Outplanting Adults Plan," which Sarah Montgomery distributed to the Hatchery Committees on March 24, 2017. Willard said she updated the draft based on discussions during the March 13, 2017, Hatchery Committees meeting and summarized the changes as follows:

- Fish will not be outplanted if they have a disease outbreak
- Further clarification of release sites is included
- Results will be summarized in a report and presented to the Hatchery Committees

Mike Tonseth asked why the results will be presented in February 2018 and said it would be helpful to present them before February so the first draft of the 2018 Broodstock Collection Protocols can incorporate any study elements. Willard said the results can be presented in January or sooner and made that revision in the document.

Bill Gale suggested further clarifying language regarding disease outbreaks to "exhibit disease concerns as identified by fish health personnel" and this edit was made. Tonseth mentioned that internal WDFW meetings indicate that the standard practice of inoculating hatchery fish is currently being phased out, while current practices and rates of culling will likely remain. He said this is being studied further.

The Hatchery Committees representatives present approved the Outplanting Adults Plan (for spring Chinook salmon in the Chewuch River) as follows: Chelan PUD, Douglas PUD, USFWS, WDFW, NMFS, YN, and CCT approved on April 19, 2017. Grant PUD (PRCC HSC) also indicated approval. (Montgomery distributed the Final Outplanting Plan on April 20, 2017 [Attachment B].)

Tonseth brought up a related conversation—the Final 2017 Broodstock Collection Protocols, which were recently discussed and approved by the Hatchery Committees. Tonseth said during the second round of revisions to the protocols, the HCP Hatchery Committees approved the protocols, and then the protocols were sent on to the Wells HCP Coordinating Committee for review; however, this occurred before the PRCC HSC had approved the protocols. Grant PUD made a comment in Appendix C in response to edits by Kirk Truscott and Keely Murdoch regarding prioritization of fish in the Methow program that was not addressed and discussed before the protocols were approved. Todd Pearsons added that it is important for parties who are on the HCP Hatchery Committees and the PRCC HSC (i.e., YN, CCT, NMFS, USFWS, WDFW) to designate to all committees when they are voting on an item that pertains to all committees and to include the PRCC HSC facilitators in any email responses to a vote request. Montgomery added that she only tracks approval for HCP Hatchery Committees items, but will make sure to include the PRCC HSC facilitators and Grant PUD in those email discussions.

The unaddressed comment in Appendix C (Adult Management) was about how fish would be used in years of low abundance for meeting the safety net component at Winthrop NFH or a production shortfall at Methow FH, versus being used to meet escapement objectives in tributaries. Pearsons said if escapement objectives are met, the fish should be outplanted for experimental reasons; however, if there is a shortage of fish spawning in the natural environment, outplanting could be prioritized over populating the safety-net program. Gale asked how managers would know if enough fish are present on spawning grounds. Tonseth said WDFW is looking into using passive integrated transponder (PIT)-tag detection data to estimate how many fish will be present on spawning grounds in various locations. Gale said the outplanting experiment may or may not work, so the prioritization discussion should occur after the utility of translocating adults is demonstrated. Pearsons said outplanting adults poses few risks to natural spawners and asked again in the case of few fish on spawning grounds whether managers should outplant adults or populate the safety-net program. Murdoch said Appendix C includes the language, "as long as both programs [Methow conservation and Winthrop safety-net] meet full production," meaning that program targets should be met and then any extra conservation program fish could be outplanted instead of put into the safety-net program.

Tonseth reminded everyone that Appendix C is about adult management and fish discussed in this section are surplus to broodstock needs (i.e., escapement objectives are already met). Tonseth said he agrees that there should be a higher priority for putting conservation fish on spawning grounds if needed to meet escapement objectives. Gale said the outplanting study has not been tested yet, so while these are interesting discussions and concepts, it might make the most sense to perform the study before discussing this in too much detail. He added that the discussion pertains more to the Joint Fisheries Parties (JFP) than the HCP Hatchery Committees. Truscott agreed and said hatchery production should not be shorted until outplanting is tested. Pearsons clarified that the question is about whether conservation fish would be put on spawning grounds instead of used in the safety-net program. Gale added that any escapement numbers should be evaluated using the 3-population PNI model. Truscott said he would not want to reduce broodstock numbers for the Winthrop program to test adult translocation, because the Winthrop program is important for long-term management and gene flow in the basin. He said if the translocation study works, though, a loss to production might be defensible in order to increase natural productivity. Greg Mackey summarized that there are tradeoffs at stake: fish spawning in the wild could contribute directly to conservation, while approximately 90% of the Winthrop program will be taken out when they return to Winthrop NFH, which would be directing conservation fish to adult management. Mackey said by the time the outplanting will occur, managers will understand the general shape and size of the run from counts at Wells Dam. Tonseth said as the JFP develops the Methow spring Chinook salmon management plan, more guidance will be available for prioritizing fish and programs.

D. Twisp Steelhead Program (Mike Tonseth/Todd Seamons)

Mike Tonseth said Todd Seamons wrote a memo "Re: discovery of potential Ryman-Laikre issues in the Twisp River steelhead using Twisp origin broodstock," which Sarah Montgomery distributed to the Hatchery Committees on March 30, 2017 (Attachment C). Tonseth asked Seamons to discuss his memo and the Twisp steelhead program with the Hatchery Committees.

Seamons provided background for the memo and summarized that the relative reproductive success study in the Twisp River included adult to adult-offspring genetic parentage assignments, which provided the data for these analyses. Seamons said the Twisp steelhead program is seeing amplification of a small portion of the steelhead population by the hatchery (see Attachment C for detailed results). Craig Busack (NMFS) said inbreeding depression is occurring in the Twisp steelhead population. He said a Ryman-Laikre effect is to be expected in this situation, because you can expect hatchery fish to be more productive than wild fish. He said a small number of parents depresses the effective population size of the next generation. Busack said to understand how concerning these effects are, one must understand the extent to which the program is closed. Seamons agreed and clarified that his memo is just an explanation of his analysis and another piece to consider is that life history diversity also reduces the genetic diversity of the population. He said the rate of reduction of diversity increases under a Ryman-Laikre effect.

Busack said from the NMFS perspective, the main issue is the effective size of the Methow steelhead population and although the Twisp is an independent subpopulation, the implications for gene flow with the Methow population need to be considered. Seamons agreed and said for recovery purposes, the Methow population is an important unit. He said WDFW proposes purposefully mixing Twisp hatchery fish with Winthrop NFH steelhead to reduce the rate of diversity reduction. Seamons said there is a tradeoff with allowing local adaption to occur or not and purposefully mixing fish reduces local adaptation (which may not matter for recovery purposes). Seamons said the Yakima River has population structure within small creeks with genetic distinction. He said it is plausible that more genetic structure has previously existed in the Methow basin and could exist again if hatchery populations were intermixed. Busack agreed and said the population itself has to prosper, but genetic diversity within the population should also be considered. Busack suggested increasing the size of the Twisp program as a way to foster diversity in the Twisp River and also guard against Ryman-Laikre effects. Seamons responded that there is risk to mining the wild population if the program is expanded and said WDFW's preferred alternative is mixing the hatchery programs (with the tradeoff being the Twisp subpopulation has less of a chance to locally adapt).

Seamons said another consideration is that hatcheries tend to reduce life-history diversity, so incorporating other age classes and life histories in hatchery production could also be considered. For example, rainbow trout, mixed cohorts, coastal parr, or other ideas could be considered. Greg Mackey said there are a lot of rainbow trout in the Twisp River in upstream reaches and in the headwaters. He said he assumes resident and anadromous fish mix to some degree in the Twisp River and bringing resident fish into the hatchery could influence the life histories of hatchery fish. Gale said a USFWS experimental steelhead program at Abernathy Fish Technology Center was sourced from steelhead and resident juveniles that were forced to mature in freshwater. Busack said it would be interesting to examine the genetic profile of rainbow trout in the Twisp River in comparison to steelhead. Todd Seamons said for comparison, there is a lot of genetic diversity between resident and anadromous steelhead.

Tonseth said the current problems with the Twisp steelhead program are low overall abundance and also single age classes, which is why WDFW proposes compositing programs, and incorporating S2s in the release plan in the Twisp River. Mackey said even though the Winthrop contribution in the Twisp River is low (there are few PIT-tag detections), if Winthrop fish return to the Twisp Weir, they should be allowed upstream of the weir to increase gene flow. Regarding gene flow management, Mackey suggested using a smaller brood and removing fewer fish to decrease the representation of hatchery fish in the run at large and also decreasing sampling removal effects.

Busack emphasized that the Twisp steelhead are a subpopulation of the Methow population and there really is not distinction for any tributaries in the upper Columbia River for steelhead. Gale said the genetic focus should be on creating diversity between Methow and Okanogan steelhead first and within the Methow or Okanogan second. Truscott agreed and said fostering local adaptation within the populations will allow them to slowly diverge.

Tonseth said the JFP will be drafting a Methow basin steelhead management plan and Douglas PUD also needs to define the direction of their Twisp hatchery program as part of the consultation process. He said he will organize a workgroup to better define Douglas PUD's program and the role of the USFWS program to give Hurst a more defined action for consultation. Hurst asked for a defined action by the end of June 2017. Murdoch said when the JFP created the Wenatchee spring Chinook salmon management plan, the comanagers initially drafted it, then brought in CCT, NMFS, and the USFWS. She said she envisions the Methow plan also being the purview of the JFP and not necessarily the PUDs. Tonseth said he agrees with Murdoch, but for defining the Twisp program, Douglas PUD needs to be involved, then the JFP can write the plan. Mackey said he would like for

Busack and Seamons to help define the genetic aspects of the Twisp program and added Douglas PUD does have a stake in the management of Methow spring Chinook salmon and will have to agree to the JFP's plan through the HCP processes.

E. Brood Year Stray Rate Targets (Tracy Hillman)

Tracy Hillman said he was asked to analyze brood year stray rates for Chiwawa spring Chinook salmon. He said the Hatchery Committees expected that recipient populations would have high stray rates in years for which brood year stray rates are high and his analysis showed this to be true for Chiwawa spring Chinook salmon. Hillman asked Charlie Snow (WDFW) to perform the same analysis for Twisp spring Chinook salmon and Snow found a different pattern—when the 5% brood year stray rate target was exceeded, the 10% recipient population target was not exceeded. Hillman summarized the patterns in Table 1.

Table 1. Brood Year Stray Rates

Donor Population Size	Brood Year Stray Rate	Small Recipient Population Stray Rate	Large Recipient Population Stray Rate
Large	High	High	?
Small	High	?	Low

Hillman said when the donor population size is large, the recipient population stray rate is more likely to be high if the recipient population is small. In contrast, strays from a small donor population are unlikely to affect large recipient population stray rates. Thus, high brood year stray rates do not necessarily result in high recipient population stray rates. He suggested the Hatchery Committees consider these patterns and discuss brood year stray rates further while discussing M&E objectives during the May 17, 2017, meeting.

Kirk Truscott said the discussion about brood year stray rates also should consider the purpose of the program. If a large portion of the program is straying, the management target is not being met. Mike Tonseth said some straying has management implications, while other straying can have genetic implications. Truscott asked if there is any information on naturalized populations in the Wenatchee basin that should be considered in these discussions about appropriate brood year stray rates. Todd Pearsons said no other hatchery programs in the Columbia River basin have a brood year stray rate target that he is aware of and there is no obvious justification for a 5% brood year stray rate target. Hillman summarized that the Hatchery Committees also considered using stray rates from Ford et al.[1] as targets and are currently discussing whether the brood year stray rate target should be eliminated entirely, or if not, what the target should be. Hillman said representatives might consider reading a recent paper by Bett et al.[2] that focuses on recipient population strays in small populations of Pacific salmon.

III. Chelan PUD

A. Coho Salmon Master Plan and Recalculation Agreements (Keely Murdoch, Cory Kamphaus, Catherine Willard)

Catherine Willard said the Rocky Reach and Rock Island HCP Coordinating Committees approved the Designation of Juvenile Coho Salmon in Phase III (Standard Achieved) at the Rock Island and Rocky Reach Projects Statement of Agreement (SOA) on March 28, 2017, which is an agreement to move juvenile coho salmon at both Projects from Phase III Standard Achieved Interim-Value to designation of Phase III Standard Achieved, with 93% survival at both Projects. She said this agreement is based on a study that adjusted acoustic survival data to PIT-tag data for coho and spring Chinook salmon, and next, survival numbers will inform coho salmon mitigation calculations for agreements. Keely Murdoch said she, Cory Kamphaus (YN), Willard, and Alene Underwood (Chelan PUD) have discussed the next steps for coho salmon mitigation and agree to use the same methods for calculating mitigation numbers as previously used for other species. She said she and Willard will provide the mitigation calculation numbers for review at the May 17, 2017, Hatchery Committees meeting, then Chelan PUD and YN will discuss how Chelan PUD will meet the mitigation requirements.

Murdoch said she is presenting an update on YN's Coho Salmon Master Plan and Kamphaus will discuss the natural production phases and site development parts of the Master Plan. Murdoch shared a presentation titled, "Upper Columbia Coho Restoration Master Plan – 2017 Update" (Attachment D), which Sarah Montgomery distributed to the Hatchery Committees following the meeting on April 19, 2017. A summary of the presentation and questions and comments are included in the following sections.

[2] Bett N.N., S.G. Hinch, N.J. Burnett, M.R. Donaldson, and S.M. Naman, 2017. Causes and Consequences of Straying into Small Populations of Pacific Salmon. *Fisheries* 42 (4), 220-230. Doi: 10.1080/03632415.2017.1276356

Background (Slides 1-3)

The goal of the Coho Master Plan is to re-establish naturally spawning coho salmon populations in upper-Columbia tributaries (Methow and Wenatchee basins) to biologically sustainable levels, which provide significant harvest in most years. Metrics include escapement and harvest rates.

Phased Approaches: Broodstock Development and Natural Production (Slides 4-11)

Broodstock Development Phase I (BDPI) is complete in both the Wenatchee and Methow basins. Phase II is complete in the Methow basin. In the Wenatchee basin, YN found that there were very few coho redds in Nason Creek, and many more males than females were found at Tumwater Dam.
BDP II is ongoing in the Wenatchee basin, and the emphasis is on getting more coho salmon to upstream sites. Murdoch said YN is attempting to trap 50% of the female broodstock at Tumwater Dam for three generations and if reintroduced stock do not sufficiently reach upstream habitat areas, the contingency plan will be implemented. Murdoch said so far, studies indicate coho salmon that come into the system early and green are more likely to ascend Tumwater Dam; however, patterns are not consistent between years, especially drought years.

The Natural Production Phases include decreasing domestication and increasing fitness in the natural environment. YN used EDT and AHA models, to reduce domestication, and phased PNI targets.

In the Methow River, Murdoch said YN may default some of the release numbers to adult outplants instead of juvenile releases due to acclimation space. Murdoch said they have outplanted adults in Nason Creek and subsequently sampled juveniles throughout Nason Creek. Kamphaus said 30% of the juveniles found were related to outplanted adults and in the year YN outplanted adults, there were 95 redds in Nason Creek, which is exceptionally high for that system. Kamphaus said the adults were PIT-tagged and outplanted at a 1:1 ratio; some males moved out of the system and all but one female stayed in the system, likely contributing to the high number of redds for that year.
Mike Tonseth asked when the outplanted adults were collected in relation to peak spawning in Nason Creek. Kamphaus said the adults were collected as natural fish were being detected at the Nason Creek PIT-tag array.

Willard asked how the hatchery release numbers were calculated. Murdoch said models were used to determine capacity estimates, then release numbers were calculated for achieving that capacity estimate. The goal is to create a spawning aggregate based on the capacity estimate.

Monitoring and Evaluation (Slides 12-16)

Monitoring and evaluation for the Coho Master Plan includes Project Performance Indicators, Species Interactions, and Genetic Adaptability.

Regarding Project Performance Indicators, Murdoch noted that the volitional release and tributary residence timing Project Performance Indicators overlap with the species interactions sections that YN reports to NMFS, so these indicators inform more than project performance.

Regarding Species Interactions, Murdoch said YN checks for the status of Non-Target Taxa Of Concern species in response to reintroduction of coho salmon.

Regarding Genetic Adaptability, Murdoch said there are phenotypic differences between Tumwater Dam and Dryden coho salmon. She said YN is bringing up a side-by-side release of coho salmon from Leavenworth NFH to study survival rate advantages that could be repeated in future years. Kamphaus said YN is also doing genetic monitoring and looking for genetic and phenotypic changes. He said the Columbia River Inter-Tribal Fish Commission is working on a manuscript on assigning coho salmon genetic divergence to adaptive or neutral markers.

Site Development (Slides 17-20)

Kamphaus said the Coho Salmon Master Plan includes some existing sites (e.g., natural earthen ponds, constructed ponds, tanks), some proposed sites, plus Natapoc FH, which is being designed to provide adult holding, early incubation, and full-term rearing for juveniles. Kamphaus reviewed the status of sites in both the Methow and Wenatchee basins and the implementation timelines for both basins. He summarized that all sites are expected to be complete and operational by September 2019. There were no further questions or comments.

IV. HCP Administration

A. HCP Representative Changes

Tracy Hillman said Chelan PUD designated Catherine Willard as the Hatchery Committees representative and the alternate position is currently unfilled, effective April 12, 2017.

Mike Tonseth mentioned that he asked the Coordinating Committees to approve email distribution access for Alf Haukenes, who is the hatchery/wild interactions unit lead for WDFW.

B. Next Meetings

Matt Cooper asked the Hatchery Committees if they would be interested in a presentation about epigenetics by Penny Swanson. Representatives present said they would be and Cooper said he would invite Swanson to present at the May 17, 2017, Hatchery Committees meeting.

The next Hatchery Committees meetings are on May 17, 2017 (Grant PUD), June 21, 2017 (Grant PUD), and July 19, 2017 (Grant PUD).

Out-planting Surplus Methow Composite Spring Chinook Salmon Adults

Final approved by the HCP-HC 4-19-2017

Background

The Hatchery Committees (HCs) recently reviewed the "Evaluation of Hatchery Programs Funded by Douglas County PUD 5-year Report 2006-2010". As a result, Objective 6 monitoring question Q6.1.1: "Is the stray rate of hatchery fish less than 5% for the total brood year return?" was identified as not meeting the target for the Chewuch River final acclimated fish. The HCs determined that methods to improve homing would have uncertain success, be difficult to implement, and challenging to statistically evaluate. In an effort to achieve the goal of increased hatchery-origin spawner abundance in identified reaches that a higher rate of homing would convey, the HCs agreed to pilot adult out-planting of surplused Methow Composite spring Chinook into the Chewuch River.

The goal of this pilot evaluation is to determine if surplused Methow Composite spring Chinook adults collected and held at the Methow Hatchery, and subsequently out-planted into the Chewuch River, remain in the Chewuch River and subsequently spawn. This pilot evaluation will be conducted in an effort to determine if adult-outplanting can be an effective tool to increase spawner abundance, spawner distribution, and natural production in the Chewuch River in years of low abundance. It is a low-risk management tool that has been used in many locations such as the Wenatchee and Willamette watersheds.

2017 Out-planting of Surplus Methow Composite Spring Chinook Salmon Adults Objectives:

- During spawning surveys, estimate the number of females trapped and out-planted to the Chewuch River that exhibit spawning behavior, construct a redd, and/or spawned (determined by egg voidance).
- Assess the ability of transporting adult spring Chinook to the Chewuch River to provide the overall number of hatchery spawners allowable under ESA permit conditions.
- Assess how many days fish were held from trapping to out-planting and from out-planting to spawner success.
- Estimate spawner distribution of males and females within the Chewuch River post release and compare results to retention time in the Chewuch River and spawner success.
- Assess the proportion of out-planted males and females that remain in the Chewuch River compared to out-planted males and females determined to have left the Chewuch River.

Methods

Up to 200 hatchery-origin spring Chinook salmon adults (jacks will be excluded) returning to the Methow Hatchery, in excess of broodstock needs for the Methow Hatchery and Winthrop National Fish Hatchery (NFH), will be collected, held and out-planted to targeted spawning reaches of the Chewuch River. The specific number of fish to be held and out-planted will be based upon permit limitations, availability of fish, and pHOS level as agreed to by the HC. A female to male ratio of 1.0:0.2 will be implemented unless run composition assessment for the run at large suggests a deviation from this level.

- Out-plant a maximum of 200 hatchery-origin spring Chinook adults (jacks will be excluded) at a female to male ratio of 1.0:0.2 will be implemented unless run composition assessment for the run at large suggests a deviation from this level.

- The number of adults shall be consistent with the terms and conditions of the ESA incidental take permits for the Methow Hatchery (#18925; #18927; #20533) according to the decision tree below:

1. If the natural origin run to the Methow basin is estimated to be <100, then pHOS in the Chewuch will be =-0.002x+0.8 (where x=estimate of the natural origin run size in the Chewuch River), else,
2. If the natural origin run to the Methow sub-basin is estimated to be ≥100 and <300, then pHOS in the Chewuch River will be =-0.0013x+0.8 (where x=estimate of the natural origin run size in the Chewuch), else,
3. If the natural origin run to the Methow sub-basin is estimated to be ≥300, then pHOS in the Chewuch River will be =0.8(1-e^(-0.006x) (where x=estimate natural origin run size in the Chewuch).
4. In each case, the number of hatchery origin fish to be released in the Chewuch will be calculated as
    a. Find the allowable basin pHOS based on estimated natural-origin spawning escapement to the Methow sub-basin and the estimated pHOS for the Methow Hatchery program (Twisp + MetComp).
    b. Use this pHOS to estimate how many hatchery-origin fish can be allowed in the Chewuch River based on the expected natural-origin spawning escapement to the Chewuch River.
    c. Calculate how many additional, surplus hatchery-origin fish shall be transported and released to the Chewuch River to remain within permit limits.
    d. A spreadsheet "Adult Outplanting Calculator.xls" is available to perform these calculations (Attachment A).

Holding and Out-planting

Surplus hatchery-origin adults returning to the Methow Hatchery will be held (duration of holding period will be variable based upon when the individual was collected) and out-planted approximately one week before estimated peak spawning (i.e., during the latter part of August/early September). If the fish being held for subsequent out-planting exhibit disease concerns as identified by fish health personnel, the fish will not be out-planted. All out-planted adults will be PIT-tagged and marked with a visible mark. Depending on availability of fish for out-planting, up to 100 adults will be released into each of one of two sites; if fish availability is limited, all fish will be out-planted into the upper release site. One site will be above the upper Chewuch River PIT tag instream PIT tag antenna array (CRU) and the other below CRU and above the Winthrop (CRW) PIT tag antenna array (Figure 1). Release locations will be determined based on accessibility, suitable spawning habitat, distance from the hatchery, distance from PIT tag arrays, and areas that are not being utilized by spawners already in the system.

Evaluation

The association of the out-planted adults with redds will be documented during spawner surveys (e.g., identification of out-planted adults on redds). Potential spawning success of females will be documented by estimating the proportion of eggs that are retained within female carcasses sampled during carcass recovery surveys. Carcass location and redds determined to be constructed by out-planted adults will be documented using a GPS device.

Post release PIT detections at the CRW PIT tag antenna array, non-Chewuch River PIT detections, and out-planted adults returning to the Methow Hatchery and Winthrop NFH will be used to estimate the proportion of out-planted spring Chinook salmon that left the Chewuch River.

The results of this pilot evaluation will be summarized and presented to the HCs no later than the January 2018 meeting. The results of the 2017 out-planting effort may be used to inform potential future decisions and/or actions regarding out-planting methodology.

Memorandum

Todd R. Seamons, Ph.D.
Director, Molecular Genetics Laboratory
Washington Dept. of Fish and Wildlife

RE: discovery of potential Ryman-Laikre issues in the Twisp River steelhead using Twisp origin broodstock

Summary: Adult to adult-offspring genetic parentage assignments were performed as part of an ongoing hatchery-wild relative reproductive success study. Returning adult hatchery-produced steelhead were spawned from very few adults, a result of natural variability in reproductive success among the small numbers of Twisp steelhead spawned in the hatchery each year. However, those hatchery fish comprised a quarter and half of naturally spawning adults in 2014 and 2015 (respectively) setting the stage for a reduction in genetic diversity and effective population size (N_e) to occur (i.e., Ryman-Laikre effects, Ryman and Laikre 1991).

Background – A steelhead hatchery/wild relative reproductive success project has been ongoing in the Twisp River since 2009. Relative reproductive success is evaluated by counting offspring of parents of hatchery and natural origin. Returning adult offspring are identified through genetic parentage analysis. For the first two years of the project, hatchery fish released in the Twisp were Wells stock – a hatchery program with relatively large numbers of broodstock each year, ~82 mated pairs. In 2011, the Twisp program was started, which uses as broodstock only natural origin adults captured at the Twisp weir and has a much lower broodstock goal of 26 individuals or 13 mated pairs. The project has now been ongoing long enough for a full cohort of adult offspring from the Twisp program to have returned. The potential for Ryman-Laikre effects to occur was evaluated by quantifying the number of families represented in the hatchery and natural origin spawners and the proportion of hatchery origin spawners.

Methods – Adult hatchery and natural origin steelhead on their spawning migration are trapped and sampled at the Twisp River weir. A small number (~26, roughly half are female) of unmarked (i.e., natural origin) steelhead were taken and used as broodstock for the Twisp River steelhead hatchery program. The remaining natural origin fish were sampled and released upstream to spawn naturally. A fraction of hatchery origin adults were released upstream to spawn; the number released was limited in an attempt to maintain a specific proportion of hatchery fish on the spawning grounds relative to natural origin fish (~0.50). Remaining hatchery origin fish were euthanized.

Fin clips were taken from all adults trapped at the weir and shipped to WDFW MGL for genetic analysis. Fish were genotyped at the panel of 192 SNP loci used for *Oncorhynchus mykiss* studies statewide. Genotypes were used to match parents to offspring using an algorithm that also infers unsampled parents (COLONY).

Results/Discussion – Ryman-Laikre effects are expected to occur when the number of fish taken into the hatchery for spawning is small resulting in the “amplification” of a small segment of the population

(Ryman and Laikre 1991). The number of fish spawned in the hatchery and the number of families produced was very low for the two years for which I have data. Twenty five adults (12 F, 13 M) were spawned in 2011 and 28 (14 F, 14 M) were spawned in 2012. **These natural origin fish taken for broodstock represented ~10% of the fish returning to the weir in those years.**

Effective size can also be affected by the mating design. Mating was performed as 1:1 pairings followed by a secondary "backup" male. Parental pairings were recorded in 2011, but not in 2012. In 2011, only 12 different primary pairings were made, resulting in a possible 24 different full-sib families, if eggs were fertilized by both the backup male and the primary male. Of the 24 possible full-sib families, members from only 18 families were detected among returning hatchery-origin adults. Most (77%) were offspring of the primary pairings. Although pairings were not recorded in 2012, based on spawn date and the parentage results, many pairings were detected, which, based on 2011 results, I assume mainly represent primary pairings. Of 14 known possible pairings, 12 families were detected. (No half-siblings were detected, which I interpret as failure of the backup male to produce adult offspring.) About 50% of the steelhead redds found in the Twisp basin in 2014 and 2015 were downstream of the weir, so it is likely some families were not sampled.

In order to evaluate the possibility of Ryman-Laikre effects, hatchery produced fish data need to be compared to natural origin fish data. Because hatchery produced fish mature at total age 3, 4, and possibly 5, hatchery fish spawned in 2011 and 2012 produced offspring returning in 2014 and 2015. In order to compare hatchery fish to wild fish, results reported from this point forward were summarized by spawn year, 2014 and 2015. It is important to note that in order to control the proportion of hatchery fish on the spawning grounds not all of the adult hatchery offspring that returned to the weir were released upstream. Thus, the actual number of representatives of hatchery families allowed upstream to spawn was less than what was detected in all returning hatchery fish.

In 2014, 181 fish were captured at the weir consisting of Twisp program hatchery fish (51), other hatchery stocks (52), and natural origin fish (79). Of the 51 Twisp program hatchery fish captured at the weir, 29 were allowed upstream to spawn. Twenty-eight of 29 fish were produced in 2011, and just one was produced in 2012. These 29 fish represented just 12 full-sib families and just 20 different hatchery parents. In contrast, the other hatchery stocks and natural origin steelhead that were released upstream the same year represented 85 full-sib families and 144 different naturally spawning parents. **In 2014, 23% of the naturally spawning adults in 2014 were produced by just 20 (12%) of the assigned and inferred parents.**

In 2015, of 154 Twisp program hatchery fish captured at the weir, at least 47 were allowed upstream to spawn and parentage was completed for 45. Nearly half (24) were produced in 2011 and in 2012 (21). These 45 fish represented just 20 full-sib families and just 33 different hatchery parents. In contrast, 48 natural origin steelhead returned in 2015 and were allowed upstream. These fish represented 48 full-sib families and 87 different parents. **In 2015, nearly half (48%) of the naturally spawning adults were produced by just 33 (26%) of the assigned and inferred parents.**

The potential for Ryman-Laikre effects appeared quite high for the Twisp steelhead hatchery program in two recent spawn years. Of the two spawn years, 2015 is more representative of what would happen in future years because two hatchery cohorts are present (BY 2011 and 2012) and all but two hatchery fish were Twisp program fish. The conditions in 2015 were comparable to those modeled in the original Ryman-Laikre paper reproduced below (Figure 1; figure 1b of Ryman and Laikre 1991). They predicted that with 20 of 200 adults used as hatchery broodstock and half of the spawning population composed of hatchery produced individuals, the expected drop in effective population size would be dramatic – roughly half of what it would be if there was no hatchery program. Their model assumed discrete generations, so half is probably an overestimate of the effects that might occur in Twisp steelhead because overlapping generations support higher diversity by reducing drift. However, the data show that roughly 25% of the parents are amplified to be roughly 50% of the spawners in the next generation, so significant reductions in N_e would be expected if this practice continues. This effect will likely be exacerbated in the 2017 brood year because the run is comprised almost entirely of 2-salt fish, suggesting poor survival of the 2014 brood; 1-salt returns represented only ~6% of the run-at-large sample at Wells Dam in 2016.

References

Ryman, N., and Laikre, L. 1991. Effects of supportive breeding on the genetically effective population size. Conserv. Biol. **5**(4): 325-329.

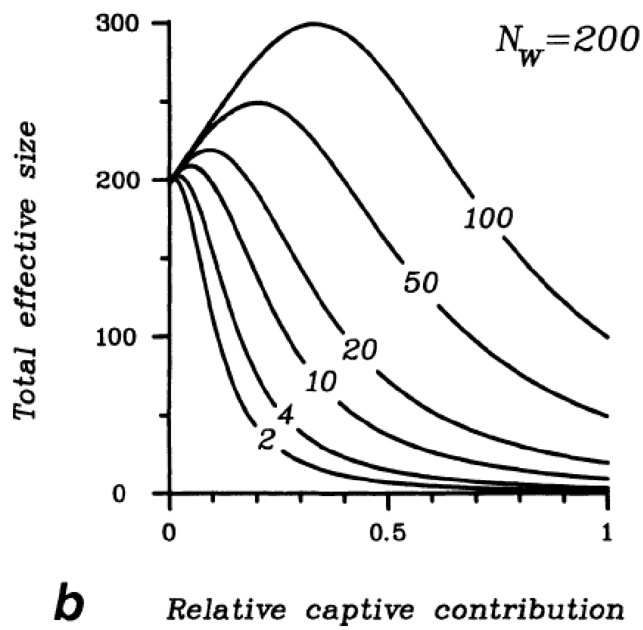

Figure 1. Figure 1b of Ryman and Laikre (1991), which shows the modeled effects on effective population size (N_e) of taking a small number (the different curves) of a small population (in this case 200 individuals) and "amplifying" their genetic representation through artificial propagation. This population size and broodstock size (focus on line = 20) is very similar to the conditions for Twisp steelhead and the Twisp steelhead hatchery program.

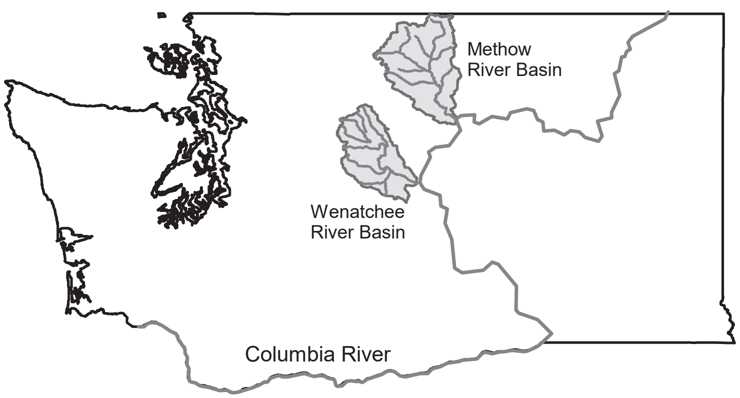
Attachment D

UC Coho Restoration Master Plan – 2017 Update

Keely Murdoch
& Cory Kamphaus

Vision

To re-establish naturally spawning coho populations in mid-Columbia tributaries to biologically sustainable levels which provide significant harvest in most years



Yakama Nation Fisheries

Biological Objectives & Numerical Goals

- Develop a locally adapted, naturally spawning coho stock in the Wenatchee and Methow river basins capable of supporting harvest
  - Metric 1: Mean escapement of NOR returns in the Wenatchee and Methow Rivers of 1500 fish
  - Achieve total harvest rate of 23% which includes a 10% mixed stock harvest, 10% Mainstem harvest, and 5% terminal harvest in most years.

Yakama Nation Fisheries

A Phased Approach

- Broodstock Development Phases
  - Eliminate transfers of lower Columbia broodstock
  - Ensure that coho can reach key habitat
- Natural Production Phases
  - Increase geographical scope
  - Emphasize local adaptation to the natural environment

Broodstock Development Phases

- Broodstock Development Phase I
  - BDPI focused on eliminating reliance on lower Columbia River stocks an transitioning to a local broodstock.
  - Completed in both basins
- Broodstock Development Phase II
  - Encourage continued adaptation of the stock by moving capture sites further upstream
  - Ensure that reintroduced stock is able to reach key habitat areas prior to starting the Natural Production Phases.
  - Completed in the Methow Basin

BDPII Goals

- Wenatchee
  - 50% of female broodstock must be trapped from TWD for one generation (3 years)
  - Implement contingency plan if not achieved in 3 generations
    - Evaluate cause of failure
    - Determine if phenotypic differences between TWD and Dryden
    - Selective broodstock collection
- Methow
  - 100% of broodstock trapped as swim-in to WNFH or MFH (for one generation) with sufficient ‘trappable’ numbers at Wells Dam to expand the program

Natural Production Phases

- Introduce coho to new habitats
- Decrease domestication selection
- Increase fitness in the natural environment
- Modeling
  - EDT to help predict coho habitat and capacity
  - AHA model to reduce domestication selection
  - Phased PNI targets

Natural Production Phases

- Natural Production Implementation Phase (NPIP)
  - Initial introduction into new habitats
  - Create spawning aggregate
  - One generation
  - After three years of release, reduce numbers
- Natural Production Support Phases (NPS 1 & 2)
  - Systematic reduction in releases sizes
  - Increase PNI

Yakama Nation Fisheries

Monitoring and Evaluation

- Project Performance Indicators
- Species Interactions
- Genetic Adaptability

Project Performance Indicators

- Release-to-McNary Survival (PIT tags)
- In-Pond Survival
- Pre-Release Fish Condition
- Volitional Release and Tributary Residence
- Spawning Escapement and Distribution
- Natural Smolt Production
- Egg-to-Emigrant Survival Rates
- Smolt-to-Adult Survival Rate
- Adult-to-Adult Productivity

Yakama Nation Fisheries

Species Interactions

- Status of NTTOC
  - Changes in size, abundance or distribution with reintroduction of coho
  - Natural Production Phases
- NTTOC Risk Assessment
- Mechanisms of Interaction
  - Competition
    - Surrogate Variables
    - Additional Studies
  - Predation
    - Surrogate Variables
    - Additional predation studies

Genetic Adaptability

- Is divergence at neutral and adaptive SNP loci a useful measure of reproductive isolation and phenotypic plasticity?
- Is phenotypic divergence (if observed) a useful proxy for local adaptation?
- Biological significance to perceived local adaptation/naturalization
- Mechanisms leading to adaptation and how quickly can stocks react to alternative natural selection regimes

Genetic Adaptability

- Morphometrics and life history traits.
- Phenotypic traits and Tumwater and Dryden Dams
- Contemporaneous Life-History Traits

Site Development-Overview

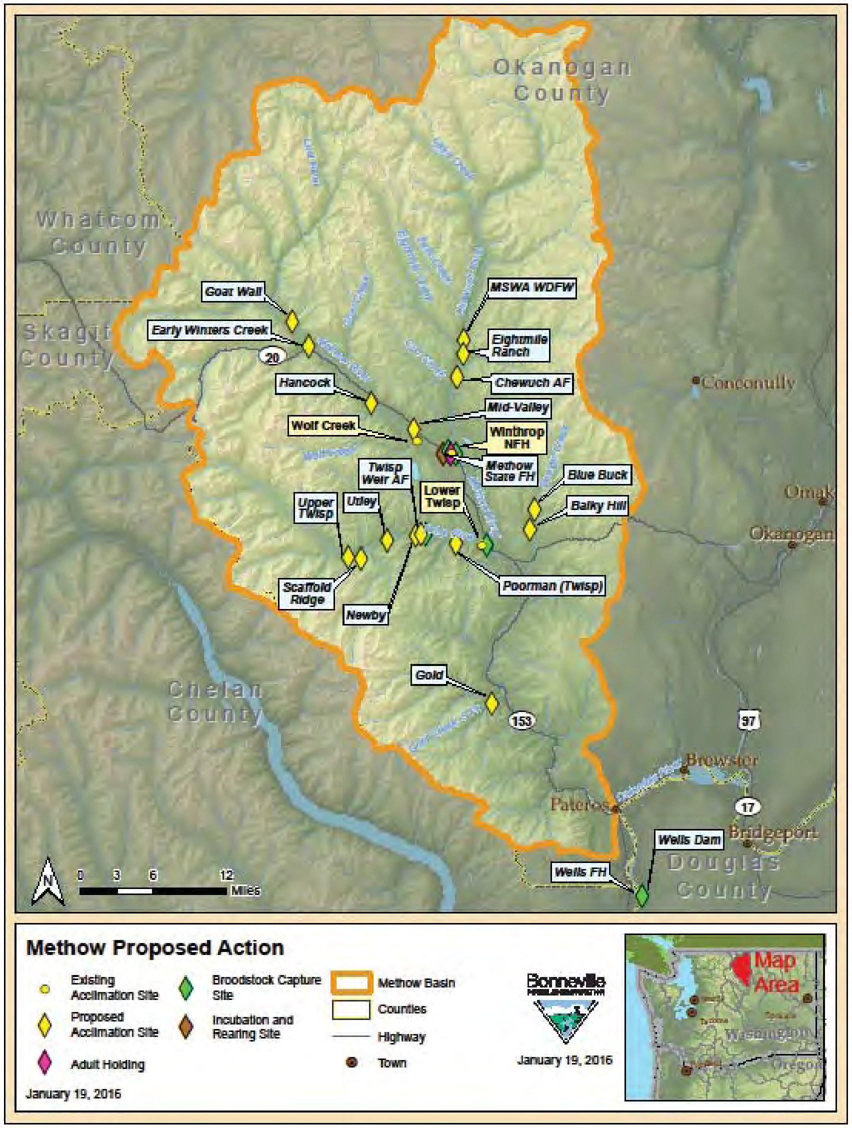
- Proposed Sites-Existing
  - <u>Wenatchee Sites</u>
    - Little Wenatchee River: *Two Rivers*
    - White River: *White River Springs, White River Bridge*
    - Chiwawa River: *Clear Creek Pond*
    - Lower Wenatchee: *Brender Creek*
  - <u>Methow Sites</u>
    - Twisp River: *Twisp Weir Site, Upper Twisp Pond*
    - Chewuch River: *Chewuch Acclimation Facility*
    - Upper Methow River: *Mid-Valley, Goat Wall*
    - Beaver Creek: *Blue Buck*

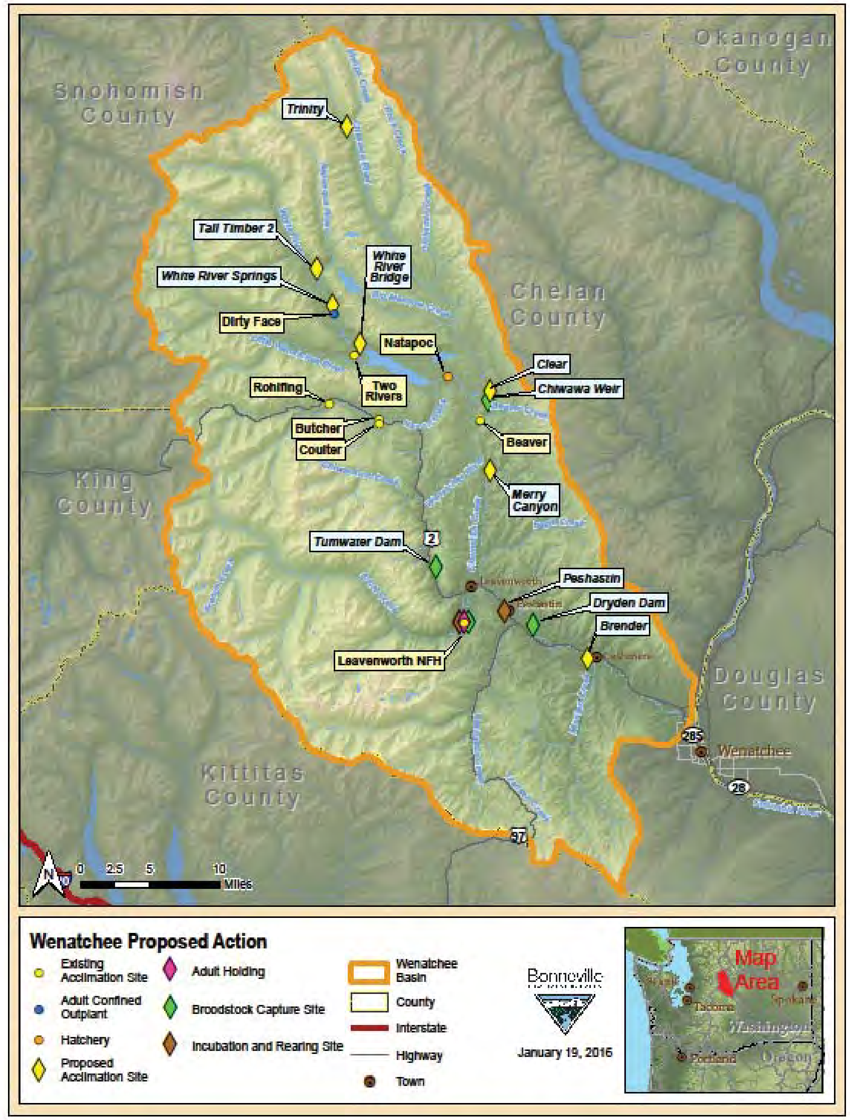
Site Development-Overview

- Proposed Sites: Constructed
- Natapoc FH
  - Being designed to provide adult holding, early incubation for entire WEN program as well as full-term rearing for up to 250,000 juveniles
    - *Transferred as pre-smolts to various acclimation sites*
- Acclimation sites
  - Mostly spring (S) w/ one overwinter (O) location
    - Upper Methow River: *Early Winters (S)*
    - Chewuch River: *Eightmile Ranch (S)*
    - Chiwawa River: *Trinity (O)*
    - White River: *Tall Timber 2 (S)*
    - Chumstick Creek: *Merry Canyon (S)*

Site Development-Overview

Yakama Nation Fisheries





Yakama Nation Fisheries

Site Development-Overview

- Implementation timelines:
  - Varies by project/site but generally:
  - Methow sites
    - Targeted construction of summer/fall 2017 with implementation in spring 2019.
  - Wenatchee acclimation sites
    - Targeted construction most likely summer 2018 & 2019 with implementation once BDP II is completed
  - Wenatchee-Natapoc
    - Bidding process to begin summer/fall 2017 with target of substantial completion of end of August 2019
    - Operational by September 2019

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Hatchery Committees

Date: June 21, 2017

From: Tracy Hillman, HCP Hatchery Committees Chairman

cc: Sarah Montgomery, Anchor QEA, LLC

Re: Final Minutes of the May 17, 2017, HCP Hatchery Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Hatchery Committees meeting was held at the Grant PUD office in Wenatchee, Washington, on Wednesday, May 17, 2017, from 10:30 a.m. to 3:15 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A). *(Note: this item is ongoing.)*
- Hatchery Committees representatives will review McLain Johnson's (WDFW) Genetic Monitoring Update for discussion at the Hatchery Committees June 21, 2017, meeting (Item I-A). *(Note: Sarah Montgomery distributed the update on April 6, 2017; Mike Tonseth postponed the update via email on June 13, 2017.)*
- Tracy Hillman will draft footnotes for Table 1 of the Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs (2013 Update) regarding run timing, redd distribution, and spawn timing (Item II-F).
- Sarah Montgomery will distribute Craig Busack's (National Marine Fisherie Service [NMFS]) 2013 document "Methow Basin Management Frameworks for Spring Chinook and Steelhead" to the Hatchery Committees (Item II-G). *(Note: Montgomery distributed the document following the meeting on May 17, 2017.)*

Decision Summary

- There were no decisions discussed during today's meeting.

Agreements

- There were no agreements discussed during today's meeting.

Review Items

- Sarah Montgomery sent an email to the Hatchery Committees on June 15, 2017, notifying them the Draft 2016 Chelan PUD and Grant PUD Hatchery M&E Annual Report is available for a 30-day review, with comments due to Tracy Hillman by July 15, 2017.

Finalized Documents

- There are no documents that have been recently finalized.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the April 19, 2017, Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the Hatchery Committees and asked for any additions or changes to the agenda. Mike Tonseth postponed the Genetic Monitoring Update to the June 21, 2017, Hatchery Committees meeting. Later in the meeting, Hillman postponed the Brood Year Stray Rate Targets discussion to the June 21, 2017, Hatchery Committees meeting.

The Hatchery Committees reviewed the revised draft April 19, 2017, meeting minutes. Sarah Montgomery said there are no outstanding comments to be discussed. Hatchery Committees representatives present approved the draft April 19, 2017, meeting minutes, as revised.

Action items from the Hatchery Committees meeting on April 19, 2017, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meeting on April 19, 2017)*:

- *Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A).*
  This item is ongoing.
- *Hatchery Committees representatives will review the Hatchery Monitoring and Evaluation (M&E) Plan Objectives before the Hatchery Committees May 17, 2017, meeting (Item I-A).*
  This item will be discussed today.
- *Hatchery Committees representatives will review McLain Johnson's (WDFW) Genetic Monitoring Update for discussion at the Hatchery Committees May 17, 2017, meeting (Item I-A).*
  This item is ongoing and will be discussed during the June 21, 2017 Hatchery Committees meeting.

- *Brett Farman and Charlene Hurst will provide an update to the Hatchery Committees on the differences between Endangered Species Act (ESA) Section 7, Section 10, and Section 4(d) coverage in regard to permitting for some HCP programs (Item II-B).*
  Bill Gale said Farman and Hurst provided information about coverage during a Methow basin workgroup meeting.
- *Mike Tonseth will organize a workgroup to discuss the future of the Twisp Steelhead Program and define its proposed actions for consultation (Item II-D).*
  Tonseth said this item is related to the gene flow discussion occurring today.
- *Catherine Willard and Keely Murdoch will provide coho salmon recalculation numbers to the Hatchery Committees for discussion at the Hatchery Committees May 17, 2017, meeting (Item III-A).*
  This item will be discussed today.
- *Keely Murdoch will provide the latest Yakama Nation (YN) Coho Salmon Master Plan to Sarah Montgomery for distribution to the Hatchery Committees (Item III-A).*
  This item is complete. Murdoch sent the master plan to Montgomery on May 17, 2017, which Montgomery forwarded to the Hatchery Committees on May 19, 2017.
- *Hatchery Committees representatives will discuss internally the brood year stray rate target and prepare for further discussion at the Hatchery Committees May 17, 2017, meeting (Item II-E).*
  This item will be discussed today.
- *Matt Cooper will invite Penny Swanson (National Oceanic and Atmospheric Administration [NOAA]) to give a presentation about epigenetics at the Hatchery Committees May 17, 2017, meeting (Item IV-B).*
  Mackenzie Gavery (*NOAA)* will give a presentation about epigenetics today.

II. Joint HCP-HC/PRCC HSC

A. Epigenetics Presentation (Mackenzie Gavery)

Tracy Hillman welcomed Mackenzie Gavery to the Hatchery Committees meeting. Gavery said she is working on postdoctoral research with Penny Swanson (NOAA) and Krista Nichols (NOAA) and coordinating with Winthrop National Fish Hatchery (NFH) staff to study the influences of hatcheries on DNA methylation in Methow River steelhead. Gavery said her presentation, "Epigenetics: what is it and why is it relevant to hatchery practices?" (Attachment B), will include an overview of epigenetics, discussion of a specific genetic mark called DNA methylation, and its functions and relation to the environment, and then she will present results for the Methow River steelhead DNA methylation study. A summary and questions and comments are included in the following sections.

<u>Background (Slides 1-10)</u>

Epigenetics refers to heritable changes in trait or phenotype caused by a mechanism other than mutation to the DNA sequence. The epigenome of an organism provides the instruction for which genes should be expressed; it regulates the functional aspects of the genome.

An organism's phenotype is influenced by its genes (DNA), its environment, and its epigenome. Unlike DNA, the epigenome can be changed by signals from the environment. In certain cases, epigenetic changes can persist in an organism or be passed to subsequent generations even after the environmental signal is removed.

Of the multiple epigenetic pathways, DNA methylation is the most studied and the focus of Gavery's research.

<u>DNA Methylation (Slides 11-42)</u>

Gavery reviewed the function of DNA methylation, how environmental factors (e.g. toxins, temperature, behavior) have been shown to affect DNA methylation and how DNA methylation state can be inherited. Gavery emphasized environmentally induced epigenetic changes are more likely to be persistent/heritable when exposure occurs during early development.

Todd Pearsons asked what controls which parts of a gene are methylated. Gavery said during mitotic cell division, methylation is on each strand of a Cytosine-Guanine (C-G) base pair, so when the double-helix separates, an enzyme replaces the methyl group on each side of the strand. She said the process for controlling methylation during meiotic cell division is less clear. She said it could be a combination of noncoding RNAs attending certain portions of the genome, but factors determining methylation during meiosis are still being researched. She said there is a clear association between genetics and epigenetics and multiple epigenetic markers work in concert to control gene expression.

Tracy Hillman asked if methylated C-G base pairs anywhere in the codon influence the reading of DNA strands. Gavery said yes, promoter gene sequences play an important regulatory role and methylation in a gene can influence splicing.

Gavery summarized that DNA methylation can be adaptive if the embryonic environment and adult environment match, but can also be maladaptive if they do not match.

<u>Epigenetics: Relevance to Hatchery Programs (Slides 43-68)</u>

Salmon and steelhead reared in a hatchery are phenotypically different than wild fish. Some of the phenotypes, including reduced reproductive success of hatchery fish, are associated with a loss of fitness. Hatchery-induced selection (domestication) or environmentally induced, heritable, epigenetic change could be mechanisms for these fitness losses. Some differences in the environment of wild and hatchery fish that could influence the epigenome include light, temperature, water chemistry, olfactory clues, and available nutrients. Gavery is studying whether there are discernable epigenetic differences between hatchery- and natural-origin steelhead at Winthrop NFH. The project collected returning hatchery- and natural-origin adult steelhead in 2014 and took blood and sperm samples. This research found that hatchery- and natural-origin fish in this system are differentiated by epigenetics. Previous research found that hatchery- and natural-origin fish in this system are not genetically distinct. Larissa Rohrbach (Anchor QEA, guest) asked how other populations of steelhead would compare on the PCA. Gavery said she expects different populations would be distinguishable on the PCA. This project's DNA methylation analysis was performed on red blood cells and sperm cells in order to look at both somatic and germ-line cells (which are passed on to the next generation). Results show steelhead have a heavily methylated genome compared to other species. Comparisons of differentially methylated regions (DMRs) between red blood cells and sperm cells show sperm carry important epigenetic information regarding which genes are going to be turned on in the early embryo. Results also show there are differences in DNA methylation between hatchery- and natural-origin steelhead in both somatic and germline-derived cell types. This research is an important first step in understanding the role of epigenetics in the observed fitness loss of steelhead after a single generation of rearing.

Gavery emphasized that epigenetics can help organisms retain and pass on information about their environment and epigenetics is an emerging field that will help understand how the environment affects phenotype in hatchery fish. Genetic and epigenetic variation can be assessed when considering fitness loss in populations.

Gavery said a second study is underway at the NMFS Manchester facility wherein offspring from natural-origin Methow steelhead families are divided into two groups and reared in a hatchery tank and an artificial stream. Because the fish are siblings and will have similar genomes, differences in epigenetics between the rearing environments will be assessed.

<u>Questions and Comments</u>

Tom Kahler asked if specific genes were identified that were differentially methylated for hatchery- and natural-origin steelhead. Gavery said the research focused on the function of the genes and there are multiple functional classes associated with methylated areas.

Kahler said other research has found differences in wound healing, immunity, and metabolism between groups of study fish. He asked if that persists to a second or further generation. Gavery said her research focuses on a specific cell type, which does not functionally overlap with genes regulating wound healing so it is unclear whether that change would persist.

Greg Mackey asked about the timing and intensity of exposure needed to elicit epigenetic change. Gavery said the timing of exposure appears to be more important than the intensity or length of exposure and early gestational periods are very sensitive to environmental conditions. Rohrbach asked if the most sensitive timeframe is known for fish. Gavery said epigenomes are especially sensitive to change when germlines develop. Rohrbach said when thinking about hatchery rearing affecting phenotypes, this sensitive period could be as short as one day during incubation. Gavery agreed and said epigenetics could be used as a tool, in aquaculture for instance, to effect positive phenotypic changes in a short period without expending as much energy throughout the entire rearing process. Kahler asked if Gavery is familiar with anyone using epigenetics for those kinds of applications. Gavery said she expects epigenetics research is being applied in sole aquaculture and provided an example of an application in plants where high-producing phenotypes are selected for cloning (oil palms).

Bill Gale asked if research so far has shown that reductions in relative reproductive success in hatchery fish carry through more than one generation, and if so, what is the timeline for reversing those epigenetic effects. Gavery said that is currently unknown, but in plants phenotypic changes can persist for 20 generations before reversing; but since the next generation of hatchery fish is being reared in the wild, the impact may or may not erase after just one generation. Kahler said some studies in humans and mouse-models show three to four generations are common, but others have found the persistence of epigenetically induced phenotype persisting for 84 generations. Gavery added teleosts have a high rate of methylation and some fish populations seem to have more environmentally sensitive genotypes than other groups of fish or species. Gale said persistence to a second or further generation in hatchery-origin fish could be a combination of domestication and epigenetic effects, and domestication effects could be longer lived than epigenetic effects. Gale said it would be interesting to see the evolutionary difference in epigenetic effects between different groups of fishes, such as sharks, which are commonly used for biomedical research. Gavery said invertebrates, for example, have much less methylation than teleosts. She said methylation is a tool and different organisms adopt it for different purposes in different evolutionary lines. Kahler added that some species use acetylation and other molecules instead of methylation as tools for epigenetic change.

Catherine Willard asked if methylation in fish species can be reversed by diet, such as high-soy diets. Gavery said in trout, high-methyl diets have been shown to help reverse methylation. She said humans, in contrast to fish, reset methylation regularly although certain regions do not change (imprinted genes are probably more sensitive to transgenerational signals) and diet does appear to affect methylation reversal. She said fish do not reset their methylation in the same way, so they are perhaps more susceptible to transgenerational effects. Gavery emphasized that epigenetic research in fish, especially non-model species, is a really new field and while so much is still unknown, researchers need to be careful when extrapolating results for species in different evolutionary lines.

Hatchery Committees representatives present thanked Gavery for her presentation.

B. USFWS Bull Trout Consultation Update (Matt Cooper)

Matt Cooper said Karl Halupka (U.S. Fish and Wildlife Service [USFWS]) sent him an update on USFWS consultations, which he summarized as follows:

- Halupka said he is still revising the draft Biological Opinion (BiOp) for the batch of Wenatchee subbasin programs and expects it will be finalized in mid-June 2017.
- Halupka has no other progress to report on consultations in the upper Columbia River.

C. NMFS Consultation Update (Brett Farman)

Brett Farman said Emi Kondo (NMFS) has been working on consultation for the unlisted programs in the upper Columbia River. He said the proposed actions will likely be finished in June and any questions regarding that consultation should be directed to Kondo.

Farman said Charlene Hurst is working on the Methow steelhead consultation and coordinating with various people on data requests. He said there is a consultation update meeting schedule for June 1, 2017, and if any additional parties would like to attend, please alert Hurst. He said the Twisp steelhead discussion should be finalized soon, which will also inform this consultation.

D. Wells Hatchery Power/Water Outage (Mike Tonseth/Tom Kahler)

Mike Tonseth said Wells Fish Hatchery experienced a power and water outage on May 2, 2017. He said the power disruption shut down the main well field for the hatchery and even though staff turned on the pumps to the main raceways, there were issues getting enough water to the main incubation building, perhaps due to an airlock that occurred when the well field back up was restarted, preventing the well water from reaching the incubation area.

Tonseth said approximately 20,000-25,000 steelhead fry (of unknown origin) were lost, and a few hundred Chinook fry, but he does not expect this to impact the overall production obligation. Greg Mackey clarified that the fry were sucked into pipe headers and then came out of headers into other tanks (e.g., the sturgeon tank) where hatchery staff attempted to retrieve them but were not entirely successful.

Mackey said the source of the outage was a blown fuse in the dam after power was reestablished after a planned shutdown. The blown fuse knocked out the three-phase power (which the hatchery pumps run on), so dam operators, electricians, and hatchery staff worked to turn on the backup generators, then switch to surface water. Mackey said the surface water was shut off quickly after it was turned on because the water had become stagnant and foul while in the pipe. Mackey said it is not clear whether the well water was prevented from reaching the incubation area by an airlock or not, but there are multiple high points in the pipes of this system where Douglas PUD will be placing air-relief valves. He said this facility will be used for sturgeon, trout, and other species in the future, rather than steelhead or Chinook.

Kirk Truscott asked if the backup plan of switching to surface water worked. Tonseth said it did work; however, the water was determined not to be suitable for fish, so staff switched back to groundwater. Truscott asked which stocks were affected by the fish loss and said the Okanogan program is relatively limited on natural-origin fish. Mackey said he does not think that natural-origin fish were part of the loss, because they would have been in trays instead of start tanks. Tonseth said most of the fish loss was from start tanks and one tray was lost. Kahler said the earliest spawned fish (Wells stock) were more likely killed than other stocks. Tonseth summarized that the fish loss will likely not be detrimental to production obligations; however, it is a fish kill and Douglas PUD has implemented facility improvements to address this.

E. Wells West-ladder Trapping Contingencies (Greg Mackey)

Greg Mackey said the West-ladder Trap at Wells Dam traps fish, which are then transported through an underground pipe to a new adult holding pond. He said Douglas PUD has found that the extension from the old pipe to the new pipe is not designed in a satisfactory way and is being updated. He said a lot of water flows through this 30-inch diameter pipe and there is no dewatering screen before the water enters the pond. He said decreasing the water flow in the pipe could result in fish being trapped and using the desired amount of flow results in too much water in the pond. He said Douglas PUD is working with fabricators to increase the pipe diameter (from 18" to 30" for almost the enire length) and install a dewatering screen. Currently, WDFW is trapping spring Chinook salmon manually at the West-ladder and trapping as usual at the East-ladder. Manual trapping at the West-ladder includes catching fish with a net in a method approved by the Wells HCP Coordinating Committee in 2016. Tom Kahler said so far 12 spring Chinook salmon have passed Wells Dam and the run is later than usual this year. Mackey said that when the West ladder is trapping, the West-ladder is blocked by grating, so fish continue left into a Denil fishway, then into a holding box. He said the operator can use a diverter to pass fish to the holding pond or through the system. He said the improvements to the pipe should be complete very soon.

F. Review Hatchery M&E Plan Objectives (All)

Tracy Hillman said the Hatchery Committees are beginning to review the objectives in the Hatchery M&E Plan[1] in order to update the Plan. He suggested the review of objectives start with Table 1, which includes program objectives, indicators, and goals for conservation hatchery programs including productivity and monitoring indicators.

Hillman said the first objective is to "determine if the program has increased the number of naturally spawning adults" and its indicators are abundance of natural spawners and adult productivity (i.e. natural return rates [NRRs]. There were no issues raised with this objective or its indicators.

Hillman said the second objective is to "determine if the proportion of hatchery fish affects freshwater productivity" and its indicators are residuals vs. proportion of hatchery-origin spawners (pHOS) and juveniles per redd vs. pHOS. Greg Mackey said there are two issues with this objective. He said getting a good estimate of freshwater production is hard, especially in the Methow basin. He said there are also limiting life stages or factors that could influence hatchery operation, which is not considered in this objective and is not captured by using rotary screw smolt traps. He said, for example, if there was no limiting factor in freshwater, programs could confidently boost the hatchery production of smolts. Alternatively, he said if habitat was a limiting factor in freshwater, programs would not want to boost production of smolts because that would result in no increase or possibly decreased natural origin production—the habitat would have to be fixed first. Hillman said for Chiwawa spring Chinook salmon, freshwater production can be estimated. He said there are estimates of total number of migrants, summer parr, and smolts produced within the Chiwawa River basin. No density dependence has been observed with total migrants; however, there is evidence of strong density dependence in parr and smolt production. Comparing the residuals from the stock-recruitment relationships with pHOS indicated no relationship, suggesting that the proportion of hatchery orirgin spawners has not negatively affected productivity of Chiwawa spring Chinook salmon. He said the Nason Creek program could be analyzed in the same way, because total migrants and smolt production within Nason Creek is known. Hillman asked if this objective should be reevaluated, considering the Methow basin data are questionable. Mackey said the key step is to develop a better estimate of freshwater productivity and while the methodology for doing this is being improved in the Methow basin, this objective is okay as it is written. He cautioned that precise estimates do not equate to accurate estimates (using an example where increasing the number of sites reduced confidence intervals, but caused the true number not to be captured within the confidence interval) and emphasized that the methodology for estimating freshwater productivity

---

[1] Hillman, T., T. Kahler, G. Mackey, J. Murauskas, A. Murdoch, K. Murdoch, T. Pearsons, and M. Tonseth, 2013. Monitoring and Evaluation Plan for PUD Hatchery Programs: 2013 Update. Report to the HCP and PRCC Hatchery Committees, Wenatchee, Washington.

can be improved. No changes were requested to this objective because improvements to methodologies are underway.

Hillman said the third objective is to “determine if run timing and distribution meets objectives” and has the indicators of migration timing, spawn timing, and redd distribution. Hillman said in general wild and hatchery fish should have the same migration timing, spawn timing, and redd distribution; however, there are exceptions, e.g., Wenatchee summer Chinook salmon, which the Committees indicated should be segregated. Hillman said the exceptions are outlined in the Appendix to the Plan. Todd Pearsons suggested adding a footnote to this objective and citing the appropriate appendix to review for deviations from the indicator targets. Bill Gale asked how migration timing is quantified. Hillman said it depends on the stock, but usually includes counts at mainstem dams and other locations (such as Bonneville Dam, Priest Rapids Dam, Rock Island Dam, Dryden Dam, Tumwater Dam, and wiers, or for Methow and Okanogan programs, Wells Dam). Tom Kahler said the metric for comparing migration timing is mean Julian date. Hillman said wild and hatchery stocks are compared using cumulative frequency plots and differences in 10%, 50%, 90%, and mean timing.

Regarding all objectives, Pearsons asked if there is a time at which sufficient data could be collected that the committees could say an objective is addressed, and although data could continue to be collected, a difference in result would not be expected (unless the program is changed). In such a case, pehaps the variable no longer merits annual assessment. He suggested considering variables where there is a high degree of correlation year to year, such as spawning distribution. Mackey said he thinks it would not be removed from the list of objectives, but monitoring frequency could be changed. Gale said most of the monitoring pieces are used to make management decisions for hatchery programs anyway, so he does not see how frequency would be changed. Pearsons said some of the variables like spawn timing or spawn distribution answer multiple objectives anyway and emphasized that the M&E Plan is supposed to assess the performance of the hatchery and its effect on natural populations.

Pearsons said the target for spawn timing is “no difference;” however, there should be a difference in spawn timing depending on elevation. He said if hatchery fish are spawning lower in a river, they may spawn later than upper river fish. Kirk Truscott said this indicator could be assessed for fish in the same location at the same time. Gale said the differences in distribution may be subtle enough to not appear in this analysis, because the surveys are weekly. Mike Tonseth said steelhead have protracted spawn timing, which appears to be more related to temperature gradients than elevation. Hillman said his opinion is that differences in spawn timing should focus on biological significance rather than statistical significance. He said he will also add a footnote to this objective for spawn timing.

Hillman said the fourth objective addresses genetic diversity and population structure and suggested the Hatchery Committees review McLain Johnson's genetic monitoring update at the June 21, 2017, Hatchery Committees meeting before discussing this objective. Members present agreed.

Hillman said the fifth objective is to "determine if hatchery survival meets expectations," and its indicators include hatchery return rates (HRRs) being greater than NRRs and greater than goals set for each program. Hillman said the updated appendix includes HRR targets and he will make sure the Plan is consistent with the appendix. No other issues were raised with this objective.

Hillman said the sixth objective is to "determine if stray rates of hatchery fish are acceptable," and its indicators include out-of-basin and in-basin stray rates. Gale suggested editing this to say, "recipient stray rates," and Hillman made that change. Hillman pointed out that the table does not include brood year stray rates. He said this discussion can continue at the June 21, 2017, Hatchery Committees meeting. The seventh and eighth objectives can also be discussed at that time.

G. Methow Steelhead Gene Flow Plan (Greg Mackey)

Greg Mackey shared a spreadsheet titled "Methow Steelhead Gene Flow Analysis," which Sarah Montgomery distributed to the Hatchery Committees on May 16, 2017 (Attachment C). Mackey said Michael Humling (USFWS) and Charlene Hurst also contributed todevelopment of the gene flow management sliding scale.Hurst said she will use whichever plan the Hatchery Committees agree to while writing the Methow steelhead BiOp. Hurst said this plan includes achieving a pHOS of 0.3 for most run sizes. Mackey said that the original plan was to adapt the spring chinook Methow sliding scale to steelhead, but found that this approach did not work very well because of the compressed zone between low run size (300) and recovery target (1,000). He said instead of a sliding scale, this plan is a two-part scale. The plan operates by achieving 500 total spawners at all time at runs below 300 wild fish, regardless of pHOS. Once wild fish number 300 or more, the plan targets pHOS of 0.30. Mackey said he estimates based on the assumption of program performance that a proportion of natural-origin broodstock (pNOB) of 0.9 and a proportionate natural influence (PNI) of 0.75 could be reached.

Keely Murdoch said she is uncomfortable with this gene flow plan. She said in 2013, the Hatchery Committees came to an agreement about pHOS, PNI, and gene flow for the purposes of permitting, which Craig Busack described in a document. (Note: Busack distributed the document, Methow Basin Management Frameworks for Spring Chinook and Steelhead, via email to Hatchery Committees representatives on June 10, 2013, and Montgomery sent it again to the Hatchery Committees distribution list on May 17, 2017, following the meeting). Murdoch said the 0.3 pHOS in the current gene flow plan proposal stems from the Hatchery Scientific Review Group (HSRG) guidelines, which are recommendations, not laws. Hurst said NMFS intends to permit the most scientifically defensible gene flow plan possible, and the one presented today is a proposal for discussion. Hillman asked Murdoch to describe Busack's 2013 gene flow document. Murdoch said the document included a phased approach to reaching a pHOS of 0.5 over the entire basin from October 2013 to October 2020 (phase 1), and to a maximum pHOS of 0.25 in spawning habitat upstream of hatcheries and unrestricted pHOS below hatcheries from October 2020 to October 2023 (phase 2). She said the document also includes a maximum for total steelhead releases, specific information for the Twisp River, and a phased approach to reaching different levels of pHOS in different areas. Hurst asked how that plan would be implemented, because there is no weir in the upper Methow basin. Murdoch guessed that it would be implemented through fisheries and specific release locations for fish with upper basin releases limited. Mike Tonseth recalled that there was uncertainty at the time as to how effective the hatchery can be in attracting hatchery adults back to the facilities. He said there are limited data available now to inform this, and it is still in development. Bill Gale said the other intent of the 2013 plan was to provide a transition period from the old production scheme and levels to the newer production scheme with lower levels, and it would allow for more liberal allowances for pHOS knowing that programs are working through a shift.

Kirk Truscott said the HSRG included qualifications with their pHOS recommendations as well. He said the pHOS level, according to the HSRG, should be based on listing status and populations with low abundance may not be applicable. Mackey said in the Methow, the recommendation at the time was to have a 100,000-steelhead release program. He said Douglas PUD thought at the time that they could achieve a pHOS of 0.25 with some assumptions about adult fish removal at hatchery outfalls. Mackey said the level of scrutiny of the programs has increased and there is the real possibility of a lawsuit concerning the consultation; therefore, Douglas PUD wants to make sure their steelhead program is designed in the most scientifically sound way. He said looking to the future, Douglas PUD is responsible for 8,000 no net impact fish and the 140,000 inundation fish (with 40,000 fish in the Twisp River) that are currently released in the basin, and the steelhead program is further complicated because Winthrop NFH is the driver for the conservation program. Mackey said he did not include the safety-net program in this spreadsheet, but it would need to be included if that program stays in the basin. Mackey emphasized that this spreadsheet is just a first look at the basic shape of the curve for pHOS, pNOB, and PNI and how individual programs contribute to the numbers in this spreadsheet is still to be determined.

Hillman asked Hurst how NMFS would approach an initial pHOS target of 0.5. Hurst said NMFS currently prefers a pHOS target of 0.3, but she understands that it takes time to reach 0.3. Humling said another consideration is that it would take about 85% to 90% removal rates to get to a pHOS of 0.3, which would mean that a PNI of 0.67 would be reached at approximately the same time as a pHOS of 0.3, if not earlier. Tonseth said a phased approach similar to the 2013 approach could be considered. He said since recalculation, steelhead releases in the Methow basin have been capped at

350,000 fish and upper basin releases according to the 2013 approach would be capped at 250,000 fish. He said he likes the idea of a floating pHOS in the lower basin and more stringent pHOS in the upper basin. He said adult removal can also be increased in multiple ways and adult management activities are also being evaluated. Tonseth said capping releases in the upper basin and moving in the direction of trying to reach a pHOS of 0.3 would be a good direction for steelhead in the basin. Hurst agreed that a phased approach might be appropriate to allow for program goals to be realized, but of course it depends on what the phases are and when they start. Hurst asked how many fish the Winthrop program was releasing at the time Busack wrote the 2013 document. Murdoch said Busack's framework document addresses that; it says the Winthrop NFH program will grow during the permit period from 100,000 fish to as high as 200,000 fish as feasible and consistent with a pNOB of 0.5. Gale explained that Winthrop NFH shifted to a 2-year rearing cycle and an increased program and reduced the spring Chinook salmon production on station to save space. He said the Winthrop program maximizes pNOB within the production range of 100,000 to 200,000 fish. Tonseth advocated for combining the 2013 phased approach with the current proposal. Gale said PNI and PNI goals should be calculated using a multi-population model. Murdoch agreed. Hurst said the bulk of the analyses will be completed with the 3- or 4-population model, but the Twisp program will inform these analyses so they are not finished yet.

Mackey said Douglas PUD wishes to release only the fish required to achieve desired purposes in the Methow basin and that might involve changing the proportions of fish in different programs. Tonseth said the ideal program would be appropriately sized so that fewer fish need to be removed as adults. Truscott said the size of the conservation program would ideally maximize recovery efforts, which could be different from the required mitigation level. Hillman summarized that there is more work to be done on the Methow steelhead gene flow plan and the Joint Fishery Parties are also meeting to discuss this. Hurst emphasized that the final gene flow plan should be communicated to her by the end of June so she can write the BiOp.

Truscott asked why the proposed gene flow plan includes meeting a pHOS of 0.3 at 500 fish instead of 750 fish. Mackey said the goal of the plan is to reach 0.3 at the lowest run size possible once 500 total spawners are achieved (and 500 is used because it is a standard, widely-used minimum population size for conservation purposes).

Hurst asked if the future of Twisp broodstock has been decided yet. Gale said 2017 broodstock collection was decided, but parties are still discussing 2018 and future years. Gale said he approves of mixing the smolt age of releases in the conservation program and releasing S2s in the Twisp and S1s in other areas (which would only work if the Twisp and Winthrop programs are composited). He said these elements would maximize diversity of brood years returning and increase the number of age classes and family sizes on spawning grounds. Tonseth said he also advocates using a mainstem collection approach and using the Twisp weir as a back-up collection location. Mackey summarized that the future of the Twisp program will be decided soon and that the gene flow model can be finished by the end of June.

III.Chelan PUD

A. Coho Salmon Recalculation (Catherine Willard/Keely Murdoch)

Catherine Willard said there are two earlier Statements of Agreement (SOAs) relevant to discussions on coho salmon recalculation: the June 20, 2007, Rocky Reach and Rock Island SOA that states the first 10-year check-in on Chelan PUD's coho salmon obligation will occur in 2017, and the August 29, 2007, Rocky Reach and Rock Island SOA that states Chelan PUD enters into agreement with YN to fund 10 years of their coho salmon program in order to meet Chelan PUD's coho salmon obligation. Willard said she and Keely Murdoch have been working together on this item and will jointly discuss the presentation titled "Approach to Determine Chelan PUD Coho Hatchery Mitigation" (Attachment D), which Montgomery will send to the Hatchery Committees once Willard makes a few revisions. (Note: Montgomery distributed the revised presentation on June 9, 2017.)

Willard said Chelan PUD proposes to use the same recalculation methods for coho salmon as were used for other species during the last recalulation. Murdoch said due to variable passive integrated transponder-tag detection efficiencies at Rock Island Dam, SARs were estimated for Wenatchee subbasin program fish from release to Priest Rapids Dam instead of Rock Island Dam. Willard and Murdoch reviewed the approach for determining mitigation, including the Biological Assessment and Management Plan formula outputs for coho salmon returns and smolt-to-adult survival for both Rocky Reach and Rock Island, and the total mitigation (hatchery and natural) for release years 2018 to 2027. Willard said she and Murdoch will finalize the mitigation numbers in an SOA for the Hatchery Committees to review and approve and she anticipates the SOA will also include Chelan PUD and YN's agreement for Chelan PUD to fund YN's coho salmon program for this mitigation.

Mike Tonseth asked if there has been an attempt to align the coho salmon mitigation timeline with other plan species. Willard said that has been discussed; however, Chelan PUD and YN have a contract that ends in October 2017 and a new or extended agreement needs to be in place. Tonseth said it might be efficient to align coho salmon with other plan species, given the uncertainty with plan project releases after 2020. He said the 2021 brood year would be affected by recalculation for release in 2023. Todd Pearsons said he thinks the 2022 brood year would be affected, for release in 2024. Murdoch said YN had a shorter agreement with Douglas PUD to align coho salmon with other plan species. Tom Kahler said YN and Douglas have an agreement for the duration of the HCP, and aligned recalculation for all species, with mitigation for Methow coho natural production beginning in 2023. Willard said there are a few minor errors in the presentation, and she will distribute a revised version.

IV. HCP Administration

A. Update from the Regional Technical Team

Tracy Hillman said the Independent Scientific Advisory Board (ISAB) is working with the Upper Columbia Salmon Recovery Board (UCSRB) to review upper Columbia River spring Chinook salmon recovery analyses and strategies. He said ISAB is visiting the upper Columbia River on July 20-21, 2017, for presentations and site visits. He said ISAB has discussed their review with the UCSRB and may also request information or presentations from the Hatchery Committees.

B. Next Meetings

The next Hatchery Committees meetings are on June 21, 2017 (Grant PUD), July 19, 2017 (Grant PUD), and August 16, 2017 (Grant PUD).

Summary

There are differences in DNA methylation between natural and hatchery-origin steelhead

Summary

There are differences in DNA methylation between natural and hatchery origin steelhead

- How do these DNA methylation changes affect gene expression and ultimately phenotype?

Summary

There are differences in DNA methylation between natural and hatchery origin steelhead

- How do these DNA methylation changes affect gene expression and ultimately phenotype?
- Which environmental parameters are influencing DNA methylation?

Summary

There are differences in DNA methylation between natural and hatchery origin steelhead

- How do these DNA methylation changes affect gene expression and ultimately phenotype?
- Which environmental parameters are influencing DNA methylation?
- How are epigenetic variation and genetic variation interrelated?

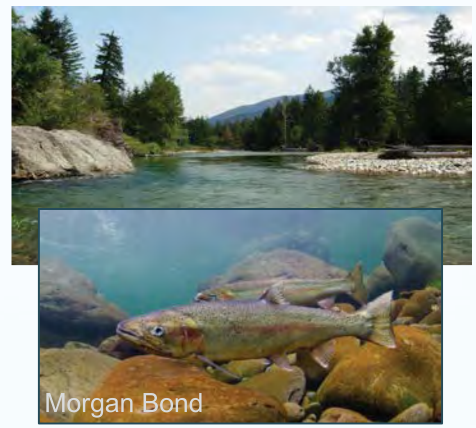
Summary

There are differences in DNA methylation between natural and hatchery origin steelhead

- How do these DNA methylation changes affect gene expression and ultimately phenotype?
- Which environmental parameters are influencing DNA methylation?
- How are epigenetic variation and genetic variation interrelated?
- Are environmentally-induced epigenetic changes transgenerationally inherited?

Concluding Remarks

- Epigenetics can help organisms *retain* (*and potentially pass on*) information about their environment.



- Epigenetics is an emerging tool to help understand how the environment affects phenotype in hatchery-reared fish, which could aid in minimizing heritable fitness loss in these populations.

Approach to Determine Chelan PUD Coho Hatchery Mitigation

- Assume 93% juvenile mortality for Rocky Reach and Rock Island
- Calculate mitigation following the methods in "Recalculation of Mid-Columbia River Public Utility District Hatchery Production, 2014-2023 (January 2012).

  - Compensation for hatchery-origin smolts will be based upon projected hatchery smolt releases.
    - Hatchery coho released x project mortality

  - Compensation for natural-origin smolts will be based upon observed average natural origin adult returns at the individual PUD projects.
    - BAMP formula

Coho Hatchery Mitigation

	Release Years	Projected Annual Release Number	Compensation Rate	Hatchery Mitigation
Methow	2018	500,000	1-(0.93 x 0.93)	67,550
	2019-2021	1,000,000	1-(0.93 x 0.93)	135,100
	2022-2027	700,000	1-(0.93 x 0.93)	94,570

	Release Years	Projected Annual Release Number	Compensation Rate	Hatchery Mitigation
Wenatchee	2018-2020	1,000,000	1-0.93	70,000
	2021-2023	1,160,000	1-0.93	81,200
	2024-2027	810,000	1-0.93	56,700

Coho Natural Mitigation

BAMP formula

- average 10 year NORs/juvenile project survival rate=number of NORs absent unavoidable mortality
- number of NORs absent unavoidable mortality-average 10 year NORs absent unavoidable mortality=adult equivalents to meet NNI
- adult equivalents/mean 10 year SAR of hatchery program=coho natural mitigation number

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Hatchery Committees

Date: July 25, 2017

From: Tracy Hillman, HCP Hatchery Committees Chairman

cc: Sarah Montgomery, Anchor QEA, LLC

Re: Final Minutes of the June 21, 2017, HCP Hatchery Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Hatchery Committees meeting was held at the Grant PUD office in Wenatchee, Washington, on Wednesday, June 21, 2017, from 9:00 a.m. to 12:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A). *(Note: this item is ongoing.)*
- Hatchery Committees representatives will review McLain Johnson's (WDFW) Genetic Monitoring Update (Item I-A). *(Note: Sarah Montgomery distributed the update on April 6, 2017. This item is ongoing, and the update will be discussed at an upcoming Hatchery Committees meeting [date TBD].)*
- Chelan PUD, Douglas PUD, and Grant PUD representatives will discuss internally HCP requirements and coverage options for the unlisted programs in the upper Columbia River basin (Item III-B).
- Charlene Hurst will distribute the draft proposed action for Methow steelhead programs to the Hatchery Committees for a 2-week review (Item IV-A). *(Note: Hurst sent the draft to Sarah Montgomery, which she distributed to the Hatchery Committees on June 22, 2017).*
- Tracy Hillman will make the following revisions to the Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs (2013 Update): 1) draft footnotes for Table 1 regarding run timing, redd distribution, and spawn timing, and 2) revise Objective 6 (Items I-A and III-C).
- Tracy Hillman will revise fish-per-pound (FPP) targets in Appendix 5 of the Hatchery M&E Plan according to the 2017 Broodstock Collection Protocols (Item III-C). *(Note: Hillman made this revision and Sarah Montgomery distributed a revised Appendix 5 and compilation of Appendices 2-5 on June 23, 2017.)*
- Tracy Hillman will invite Jeff Jorgensen (National Oceanic and Atmospheric Administration) to an upcoming Hatchery Committees meeting to present and discuss Wenatchee River spring-

run Chinook salmon life-cycle modeling (Item V-A). *(Note: Jorgensen plans to attend the Hatchery Committees August 16, 2017, meeting.)*

- Tracy Hillman will distribute Jorgensen et al.'s draft chapter, "Wenatchee River spring-run Chinook salmon life-cycle model: hatchery effects, calibration, and sensitivity analyses" to the Hatchery Committees (Item V-A). *(Note: Hillman sent the chapter to Sarah Montgomery, which she distributed to the Hatchery Committees on June 22, 2017.)*

Decision Summary

- There were no decisions discussed during today's meeting.

Agreements

- There were no agreements discussed during today's meeting.

Review Items

- Sarah Montgomery sent an email to the Hatchery Committees on June 15, 2017, notifying them the Draft 2016 Chelan PUD and Grant PUD Hatchery M&E Annual Report is available for a 30-day review, with comments due to Tracy Hillman by July 15, 2017.
- Sarah Montgomery sent an email to the Wells Hatchery Committee on June 22, 2017, notifying them the Draft Proposed Action for the Winthrop National Fish Hatchery and Wells Complex Steelhead Programs is available for review, with comments due to Charlene Hurst by Thursday July 6, 2017.
- Sarah Montgomery sent an email to the Hatchery Committees on June 27, 2017, notifying them that National Marine Fisheries Service's (NMFS') draft proposed action for the upper Columbia River unlisted programs is available for review, with comments due to Emi Kondo (NMFS) by July 17, 2017.

Finalized Documents

- There are no documents that have been recently finalized.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the May 17, 2017, Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the Hatchery Committees and asked for any additions or changes to the agenda. Catherine Willard added a Chelan Falls Broodstock Collection update, and Hillman added updates about the Draft 2016 Chelan PUD and Grant PUD Hatchery M&E Annual Report and the Independent Scientific Advisory Board's planned visit to the upper Columbia River basin.

The Hatchery Committees reviewed the revised draft May 17, 2017, meeting minutes. Sarah Montgomery said there are some outstanding comments to be discussed, which the Hatchery Committees reviewed and revised. Hatchery Committees representatives present approved the draft May 17, 2017, meeting minutes, as revised.

Action items from the Hatchery Committees meeting on May 17, 2017, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meeting on April 19, 2017)*:

- *Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A).*
  This item is ongoing. Mike Tonseth said the overview may be completed in July 2017.
- *Hatchery Committees representatives will review McLain Johnson's (WDFW) Genetic Monitoring Update for discussion at the Hatchery Committees June 21, 2017, meeting (Item I-A).*
  Sarah Montgomery distributed the update on April 6, 2017; Mike Tonseth postponed the update via email on June 13, 2017. Tonseth said this item may be discussed at the August 16, 2017, Hatchery Committees meeting.
  Regarding genetic sampling in the Wenatchee River and broodstocking in the Methow River, Todd Pearsons asked if genetic samples collected and analyzed for that project could also be used as the genetic analyses needed to meet the M&E objective. Tonseth said he believes the same samples and analyses can be used to meet both objectives. Pearsons requested that WDFW also discuss whether samples that have already been collected and samples collected as part of ongoing collection plans can be used in the M&E genetic monitoring scheme. Tonseth said he will provide that information in addition to the broader genetic sampling discussion.
- *Tracy Hillman will draft footnotes for Table 1 of the Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs (2013 Update) regarding run timing, redd distribution, and spawn timing (Item II-F).*
  This item is ongoing.
- *Sarah Montgomery will distribute Craig Busack's (National Marine Fisheries Service [NMFS]) 2013 document "Methow Basin Management Frameworks for Spring Chinook and Steelhead" to the Hatchery Committees (Item II-G).*
  Montgomery distributed the document following the meeting on May 17, 2017.

II. Chelan PUD

A. Chelan Falls Broodstock Collection (Catherine Willard)

Catherine Willard reminded the Hatchery Committees that Chelan PUD is continuing their pilot project to collect summer Chinook salmon broodstock at the Chelan River Habitat Channel Water Conveyance Canal Outlet. She said the pilot project is included in the 2017 Broodstock Collection Protocols, which were approved by the Hatchery Committees. Willard said she wants to ensure that the approval of Broodstock Collection Protocols provides Hatchery Committees approval for the pilot project, and asked if anyone has questions about the project. Mike Tonseth asked if installing the trap and making it operational was delayed this year. Willard responded yes, and broodstock collection is scheduled to begin in the second week of July instead of the first week as planned. Bill Gale said surplus summer Chinook salmon from the U. S. Fish and Wildlife Service (USFWS) Entiat National Fish Hatchery (NFH) are identified as the backup broodstock source in case of a shortfall in collection. He asked if USFWS and Chelan PUD have discussed the logistics of this arrangement for 2017 and when fish would be transferred. Willard said nothing has been discussed in 2017 besides what is included in the Broodstock Collection Protocols. Tonseth said mid-August is the check-in point to decide if surplus fish from Entiat NFH will be needed. Gale said staff at Entiat NFH prefer to surplus summer Chinook salmon early, so it is important to communicate broodstock needs with as much notice as possible. Gale also said that the State and Chelan PUD had some disease concerns with receiving brood late in the return cycle in 2016 and asked if this was still a issue of concern. Willard said the fish Chelan PUD received from Entiat NFH in 2016 were in fine condition for broodstock needs.

B. Tumwater Dam Pacific Lamprey Passage Feasibility Study Update (Alene Underwood)

Tracy Hillman said Chelan PUD has been working on a feasibility study for lamprey passage at Tumwater Dam. Alene Underwood said the report on the feasibility study has been in review by Chelan PUD management. Underwood said one question from management was, "what is Chelan PUD's legal requirement regarding lamprey passage at Tumwater Dam?" Another was, "if a passage structure is constructed, what is the expected biological benefit?" Underwood said staff are currently working to address these questions. Particularly, staff are working on the following three items: 1) distributing the feasibility study as soon as possible, 2) determining regulatory nexus and requirements including off-license mitigation, 3) preparing a biological evaluation to assess lamprey presence in the study area including historical data and potential expected abundance.

Bill Gale said the USFWS has continuing concerns about approving operations at Tumwater Dam through the Broodstock Collection Protocols due to impacts to Lamprey at this facility. Further, he said these impacts are directly related to Chelan PUD's Non-Target Taxa of Concern requirements in M&E plans. Gale urged Chelan PUD to release the feasibility study soon.

III. Joint HCP-HC/PRCC HSC

A. USFWS Bull Trout Consultation Update (Matt Cooper)

Matt Cooper said Karl Halupka (USFWS) has no progress to report on bull trout consultations. Emi Kondo asked who she should coordinate with at USFWS regarding the Methow steelhead consultations. Bill Gale said Kondo should coordinate with Sierra Franks.

B. NMFS Consultation Update (Brett Farman/Emi Kondo)

Unlisted Programs

Emi Kondo said she is providing an update on consultation for the unlisted programs in the upper Columbia River. The programs are Wenatchee summer Chinook salmon, Chelan Falls summer Chinook salmon, Wells summer Chinook salmon, Priest Rapids fall Chinook salmon, Methow summer Chinook salmon, and Ringold upriver bright fall Chinook salmon. She said the Ringold program will likely be a direct consultation with the U.S. Army Corps of Engineers, and her update today focuses on pathways to receive Endangered Species Act (ESA) coverage for the other five programs.

Section 10 vs Section 4(d) Coverage

Kondo said NMFS General Counsel favors using the Section 4(d) process for ESA coverage for these programs. She said the mechanism for receiving 4(d) coverage is that applicants provide NMFS with a detailed program plan and NMFS reviews then approves it. She said NMFS can also help develop the plan and one benefit of 4(d) is that applicants develop and have more control over their own programs. She said the other option for ESA coverage for these programs is a Section 10 incidental take permit. She said a Section 10 direct take permit has been used for the Methow spring Chinook salmon program and the process would be similar for Methow steelhead.

Todd Pearsons asked what the differences are in legal coverage, application material, and timeline between Section 10 and 4(d). Kondo said the legal difference is that Section 4(d) is more protective and provides a wider range of actions a program can operate by (such as a comprehensive plan), whereas Section 10 permits are very specific and operation would have to comply with permit conditions. She said application material is the same (comprehensive Hatchery and Genetic Management Plan [HGMP] for the public to review), and she said timelines for Section 4(d) are more flexible than Section 10, specifically when considering changing program operations, a situation in which Section 10 could result in additional consultation.

Brett Farman said the coverage mechanism for Section 4(d) and Section 10 is different in that Section 10 allows take under permitted actions to be exempt, whereas Section 4(d) allows for categories of actions meeting certain criteria not to be considered take. He said Section 4(d) is more flexible and would have fewer conditions. Kondo added that Section 4(d) is a continuing form of coverage compared to Section 10 which is an expiring form of coverage, and extending Section 10 coverage in lieu of a new permit is a legal vulnerability.

Alene Underwood asked if there is an existing exemption under ESA that would already apply to these unlisted programs. Farman said the exemptions are broad categories of actions (such as forestry, fisheries, and hatchery), and approved actions under these categories do not count as take. Kondo said NMFS can write a letter describing program coverage for 4(d) permit holders, specifying requirements such as monitoring requirements.

Underwood asked if a National Environmental Protection Act process applies to Section 4(d) coverage. Kondo said yes, it applies to both Section 4(d) and Section 10. Underwood asked how consultation with USFWS occurs through these permit pathways. Bill Gale said NMFS is the action agency, so NMFS consults with USFWS regarding bull trout.

Mike Tonseth said although the HCPs specify that NMFS will issue Section 10 coverage, permit applicants should consider using Section 4(d) because it affords the same level of protection and requirements, but is more flexible. He said unlisted programs do not change very much except during recalculation, so only reconsulting when needed (such as during a major program change) would be preferable to reconsulting every 10 years as would occur with Section 10.

Greg Mackey asked if permit applicants for the upper Columbia River unlisted programs could be issued different forms of coverage—some receiving Section 10 and some Section 4(d). Tonseth said the Biological Opinion (BiOp) would consider all six programs, but the permit coverage types can be different. He said the Ringold program, for example, will have Section 7 coverage because the U.S. Army Corps of Engineers is the action agency. Pearsons asked what materials (in addition to HGMPs) NMFS needs from permit applicants for pursuing Section 4(d) or Section 10 coverage. Kondo said she is currently drafting the proposed action section of the unlisted programs BiOp, which will then be reviewed by the permit applicants. Pearsons asked if the HGMPs will need to be revised. Tonseth said all the information necessary for writing the proposed action has been submitted to NMFS and the next step is determining whether any sufficiency letters have been issued by NMFS stating that HGMPs and their supplemental information are sufficient. Pearsons said Grant PUD's unlisted programs have been operating under an extension letter. Underwood said she does not believe Chelan PUD received a sufficiency letter for its programs. Kondo said she will move forward with the BiOp assuming no sufficiency letters have been issued and she will distribute the proposed action for a 2-week review soon. Pearsons said Grant PUD may need more than 2 weeks for review.

Gale asked Kondo to consider, while she is drafting the proposed action, that the USFWS will be using the language in the proposed action to begin considering how the consultation will impact bull trout. Gale said the USFWS will need the HGMPs and proposed action to begin consultation soon, so that programs can receive coverage before December 2017. Tonseth said the Ringold program is the only one requiring coverage by December 2017. Tonseth suggested that Kondo discuss the proposed action with Karl Halupka, as he may have started a gap analysis for this consultation that could be helpful.

Hatchery Committees representatives present generally stated that they prefer pursuing Section 4(d) coverage due to its flexibility, and Chelan PUD, Douglas PUD, and Grant PUD, as permit applicants, indicated they need to discuss coverage options internally and look at language in the HCP and consult legal counsel. Tonseth said if all the HCP signatories are amenable to using Section 4(d) coverage, amendments to the HCPs could be written. Tom Kahler added the Wells HCP states that hatchery programs should have Section 10 coverage; however, the HCP also mentions Section 4(d) coverage, so further assessment and discussion about coverage options is warranted.

C. Review Hatchery M&E Plan Objectives (All)

Tracy Hillman said the first objective to discuss is Objective 6, specifically, brood year stray rates.

Mike Tonseth suggested not assigning a target, but using the brood year stray rates as an indicator and management tool to help guide programs. Greg Mackey agreed and said in some cases, there are a number of actions a program could implement if a brood year stray rate is so high that it is impeding recovery efforts, and in other cases, there are limited actions available to make improvements in homing depending on the circumstances under which fish are released. Tonseth agreed and said he is concerned about setting an arbitrary target that is not actively managed for.

Hillman shared the draft Chelan PUD and Grant PUD Hatchery M&E Annual Report (which Sarah Montgomery distributed to the Hatchery Committees on June 15, 2017), and showed that Tables 5.34, 5.35, and 5.36 address stray rates. Specifically, Table 5.36 includes brood year stray rates, and the only proposed change would be deleting the language about the 5% target—the information about brood year stray rates would still be reported in the annual M&E report and can be viewed and assessed.

Kirk Truscott said without a target, there is potential for one party to believe there is an issue with brood year stray rates, but other parties may disagree. He said not having a target reduces direction and the potential to resolve these issues. Hillman said there is currently a brood year stray rate target of 5%, and some brood year stray rates are vastly over the target; however, this has not been a primary concern for the Hatchery Committees compared to the other stray rate targets. Bill Gale said brood year stray rate targets have been discussed extensively and some program changes have been made to address these high rates. Keely Murdoch said, for example, the intake and other items at the Chiwawa Acclimation Facility have been changed. Tonseth said those discussions and decisions were based mainly on recipient and between-population strays, not brood year stray rates.

Murdoch asked if removing the brood year stray rate target would affect discussions about the differences between homing and straying. Hillman said he does not believe it affects those discussions, because the tables in the annual report still includes both homing and straying rates. Gale said he is concerned that a program could achieve the recipient stray rate targets, but in a way that elevates the number of fish throughout all recipient targets. He said he does not favor a numbered target, but brood year stray rates are important to track. He proposed setting a qualitative target (e.g., "minimization") instead of a quantitative target. Brett Farman said there is still value in having a threshold value for context during discussions. He said removing the target altogether removes action incentives if there are continuing issues.

Mackey suggested thinking about brood year stray rates in a more integrated way, by considering escapement goals, the ratio of hatchery and wild fish on spawning grounds, and homing. He said homing is a tough metric to focus on, and broader management targets should be considered. For example, are the right number of fish in specific spots in the basin at the right ratio? Are released fish posing a risk? Is program size the right size so that not too much adult removal occurs?

Hillman said the current 5% brood year stray rate is not based on literature and is not even included in the text of the M&E Plan. He said it is included in the table and he thinks it was added to make statistical analyses easier. He said language should be added discussing the importance of this metric, minimizing strays, maximizing homing, and how the metric is related to other metrics with which it should be evaluated. He said he will draft this language for the Hatchery Committees to review.

Todd Pearsons advised against using the term "minimization" because it could put managers in a bad position, and suggested instead to integrate the stray rate variables and write new language.

Truscott suggested keeping the 5% brood year stray rate target and explaining in the annual report each year that it is not a management concern. Tonseth said this language can be added to the annual report regardless of whether the target remains. Tom Kahler said one concern for keeping the brood year stray rate target is how parties outside of the Hatchery Committees may interpret brood year stray rates not meeting the target. Truscott said his opinion is that it is preferable to have a target and explain why it was missed and why it is not biologically significant, rather than having no target at all. Catherine Willard added that in discussions about straying in the Methow basin, the questions regarding brood year stray rates were not about whether or not the target was exceeded; there were bigger concerns that were apparent with or without a target for comparison.

Tonseth suggested inserting an expectation that brood year stray rates fall in line with other metrics. He said, for example, in the Chewuch River, brood year stray rates are high and there are also facility limitations. Improvements to homing fidelity have been discussed, and a study design for adult translocation is one potential way to address the homing concerns. Hillman said setting a target for brood year stray rates would be difficult because Ford's work indicates that natural-origin stray rates in the Wenatchee basin range from 0 to 99%, and Chiwawa spring Chinook salmon from 1989 to 2004 had higher than 5% stray rates in all years except years when the program was not operating (Ford et al. 2015[1]). Truscott said he is wary of a situation where discussions about brood year stray rates are not considered because there is no longer a target. Gale said he thinks there is a stray problem in the Chiwawa River, and despite program changes and progress, if the brood year stray rate continues to be as high as 30% and other targets are being met, it should be a concern and should be discussed. Tonseth said brood year stray rates are calculated retrospectively and should be not relied on too heavily as a primary metric. Willard agreed and said return year data are better for assessing stray rates. Hillman summarized that he would draft new language for brood year stray rates under Objective 6 and provide a revised version for Hatchery Committees review.

Hillman said the next monitoring indicator objective in Table 1 of the M&E Plan for discussion is "determine if hatchery fish were released at program targets." He said these data are summarized in Appendix 5; however, k-factor targets are not included in the appendix. Mackey said appropriate k-factors for stocks included in Appendix 5 are unknown (and standard K-factors that have previously been used have been found to be inappropriate for the some stocks in the Upper Columbia). Tonseth agreed and said there are many fish culture differences; however, the expectation that the k-factor of hatchery fish is close to the k-factor for wild fish would be a reasonable target.

Hillman asked if there is anything in the M&E Plan that should be changed regarding this objective. Hillman pointed out that Appendix 5 lists the FPP target for Nason Creek at 18 to 24 FPP; however, in the Nason Creek chapter of the annual report, the program is compared to a target of 24 FPP. Pearsons said the Nason Creek program does not have a typical FPP goal because the growth profile

---

[1] [1] Ford, M., A. Murdoch, and M. Hughes, 2015. Using parentage analysis to estimate rates of straying and homing in Chinook salmon (*Oncorhynchus tshawytcha*). *Molecular Ecology* 24:1109-1121.

is managed to reduce precocious maturation up to February. He said it is more accurate to compare the program to the target range of 18 to 24 FPP.

Hillman asked if the Chelan Falls summer Chinook salmon program has a range target for the same reason. Willard clarified that the target was changed to 13 FPP in the final 2017 Broodstock Collection Protocols and this target should be updated in Appendix 5. Hillman said he will make this update and distribute a revised version to the Hatchery Committees.

Hillman said the last objective in Table 1 for discussion is the monitoring indicator, "provide harvest opportunities when appropriate." Hatchery Committees representatives present voiced no changes or concerns for this objective.

Hillman said Table 2 of the M&E Plan addresses program objectives, indicators, and goals for segregated harvest augmentation hatchery programs including monitoring indicators. The monitoring indicator objectives in this table that have not been previously discussed include "determine if hatchery survival meets expectations," "determine if hatchery fish were released at program targets," and "provide harvest opportunities when appropriate." Hatchery Committees representatives present voiced no changes or concerns for these objectives.

Pearsons asked if this document will replace the 2013 update version. Hillman said yes, this document will be called Hillman et al. 2017.

Tonseth stated there will be no change to the genetic objectives because those updates are still pending.

D. Brood Year Stray Rate Targets (All)

The brood year stray rate targets discussion was covered under the Hatchery M&E Plan Objectives review in section III-C.

IV. Douglas PUD/WDFW/NMFS

A. Methow Steelhead Gene Flow (Greg Mackey/All)

Mike Tonseth said many discussions regarding Methow steelhead gene flow have taken place within the Joint Fishery Parties and in coordination meetings. Greg Mackey said the current plan includes moving the Douglas PUD 100,000 safety net steelhead release to the lower Methow River, where the fish used to be released. Keely Murdoch asked why the release was moved to Methow Fish Hatchery (FH). Tonseth said the release was moved to Methow FH to increase fidelity to the facility for gene flow management; however, steelhead do not reliably enter the volunteer channel and trap at Methow Hatchery nor ascend the ladder and go into the pond at WNFH. Tonseth said the Methow safety-net program is spring-acclimated in contrast to the Winthrop NFH program, which is fully acclimated. He said even the Winthrop NFH steelhead do not reliably return to the fish hatchery. Michael Humling (USFWS) said fine scale analyses of returning fish show that quite a few fish return to Spring Creek (the outlet of Winthrop NFH), but very few fish make it to the hatchery ponds.

Mackey said the latest gene flow plan includes areas for conservation zones and fishery zones. Tonseth said the terms may be revised. Bill Gale suggested the terms "natural production emphasis area" and "Methow mainstem," for referring to the differential gene flow management zones. Tonseth said management activities such as adult removal would occur in the Methow mainstem (previously called the fishery zone). Mackey said another item for discussion includes the proportion of hatchery-origin spawner (pHOS) targets for the two zones. Most recently discussed, the natural production emphasis zone would have a pHOS target of 0.25 and the overall basin target would be 0.5 (so the pHOS in the Methow mainstem zone could be higher than 0.5 as long as the overall basin target is met). Charlene Hurst suggested using a proportion of natural influence (PNI) target of 0.67 for the basin, instead of having a pHOS target. Tonseth said using a PNI instead of pHOS target for the basin makes more sense for meeting basin-wide objectives and in cases of low productivity.

Hurst said the proposed gene flow model includes weighting the fishery (Methow mainstem) zones at 30% of the population and the natural production emphasis zones at 70% of the population, which allows for higher pHOS in the Methow mainstem (such as a pHOS of 0.8 resulting in a basin-wide PNI of 0.71). She said one caveat to this is that the safety net program brood would have to be 100% from the conservation program, and she is not certain how often that is feasible. Mackey said that is not always feasible, and depends on whether broodstock is collected in the spring or in the fall. Tonseth agreed and said there is not enough mark differentiation to identify specific elements of programs. Tonseth said he recently distributed alternatives for marking so that adult returns to the conservation program could be better identified. Gale asked if all conservation program fish are marked with a coded wire tag (CWT). He said the program does not require many fish, so angling in the lower Methow River and transporting fish to Wells FH could work for broodstock collection instead of relying on broodstock collection at Wells Dam. Mackey said he thinks trapping at Wells Dam would achieve the desired number of broodstock, thus reaching a high percentage of safety net program source being from the conservation program. Tonseth said one concern for fall collection at Wells Dam is intercepting Wenatchee basin fish that have the same markings. Gale suggested reading the CWTs when fish are spawned and then backfilling with additional broodstock collection in the spring as needed. Truscott added that the passive integrated transponder (PIT) tag array in the lower Methow River can also be used to determine how many out-of-basin strays are in the area where broodstock is collected.

Gale said it would be reasonable to set the proportion of natural-origin broodstock target for the Winthrop and Twisp conservation programs at 0.9, . Hurst said she will use those pNOB values in consultation. Tonseth said with the current marking scheme, programs can acquire as much conservation hatchery-origin broodstock for the safety-net program as possible (i.e., almost 100%).

Hurst explained the the 25% pHOS in the conservation zone would only apply when the total spawning abundance in the Methow basin exceeds 500 spawners, in which case the pHOS in the conservation zone would be divided between programs such that conservation programs would have a pHOS target of 0.2 and the safety-net program would have a pHOS target of 0.05. Hurst said this would result in a basin-wide PNI of equal to or greater than 0.67 when the number of total spawners is greater than 500 fish, with the pHOS in the “fishery” zone being flexible as long as the basin-wide PNI target is met. Hurst also confirmed that the Methow FH release is being moved to a release location at a lower bridge and those fish will be reared at Wells FH. Gale asked if the 500 total spawners minimum is only natural-origin spawners. Mackey said no, the aggregate of hatchery plus wild spawners should be 500 fish, and when below 500 fish, the basin is managed for an escapement target of 500.

Tonseth summarized that PIT tag detections, viable salmon population (VSP) monitoring at Priest Rapids Dam, and maximizing PIT tags in steelhead will help managers track steelhead throughout the basin and maximize broodstock collection at favorable locations. Matt Cooper asked how the gene flow goals would be assessed. Tonseth said 5-year geometric means would be calculated, similar to the spring Chinook salmon programs. Cooper asked if every facility would perform parental based tagging analyses as part of this plan. Tonseth said yes. He also stated that Charlie Snow (WDFW) performs supplemental PIT tagging at Wells Dam during broodstock collection and run sampling. He summarized that maximizing tags and analyses for steelhead and maximizing steelhead trapping at Wells Dam to increase sample sizes will help inform managers where steelhead are going in the basin. Mackey said the lower Methow River PIT tag array is has low detection efficiency. WDFW is re-locating this array from its current location at Miller Hole. A new array will be installed at the new WDFW access site on the lower Methow.

Hurst said due to different pHOS targets for the conservation and safety-net programs, there is a need to differentiate between Wells FH mainstem releases from the safety-net releases in the Methow River. Tonseth said he is not sure if the juvenile PIT tag rate is high enough to address that question; however, tagging at Priest Rapids Dam and Wells Dam as part of the run composition assessment could improve differentiation. Tonseth said further discussion is warranted about how steelhead are marked in the upper Columbia River and how to maximize flexibility to implement and manage programs.

Hurst said regarding release sites for consultation, please provide the furthest upstream site so it can be factored into evaluating ecological effects, as well as the highest expected release number. Murdoch asked if all release sites need to be identified. Tonseth said no, and this topic and the marking topic can be discussed at the next coordination call.

Hurst said she will draft the proposed action for review and distribute it to the Hatchery Committees. Gale asked if the proposed action will be exclusive to Douglas PUD actions. Hurst said no, the proposed action will include Winthrop NFH actions in preparation for the BiOp. Sarah Montgomery clarified that the Wells Hatchery Committee will review the aspects of Hurst's plan pertaining to Douglas PUD actions.

V. HCP Administration

A. Hatcheries and Life Cycle Modeling (Hillman)

Tracy Hillman said Jeff Jorgensen and others have been working on a life-cycle model for Wenatchee River spring Chinook salmon, which includes a hatchery component. He said he asked Jorgensen if he would be interested in attending a Hatchery Committees meeting and presenting an overview of the model. Hillman said Hatchery Committees representatives could then provide questions and comments about Jorgensen's draft chapter describing the model (and Hillman has already provided some comments to Jorgensen). Hatchery Committees representatives present welcomed the idea of Jorgensen presenting the model, and Hillman said he would invite him to an upcoming meeting. Hillman said he will also distribute Jorgensen and others' draft chapter, "Wenatchee River spring-run Chinook salmon life-cycle model: hatchery effects, calibration, and sensitivity analyses," to the Hatchery Committees as background material.

Todd Pearsons said it would also be helpful for Jorgensen to share the comments he has received from the Independent Scientific Advisory Board (ISAB), and describe how he plans to incorporate those comments.

B. ISAB Visit (Hillman)

Tracy Hillman reminded the Hatchery Committees that the ISAB is visiting the upper Columbia River basin from July 19 to 21, 2017. He said the current plan is that they will take a 1-day field trip to both the Methow basin and the Wenatchee basin, and have 1 day for presentations and meetings.

C. Draft Hatchery M&E Annual Report (Hillman)

Tracy Hillman reminded the Hatchery Committees that the Draft 2016 Chelan PUD and Grant PUD Hatchery M&E Annual Report is available for a 30-day review, with comments due by July 15, 2017. Hillman said some sections of the report currently have placeholders. Specifically, he said 2016 data that rely on scale readings are incomplete because scale readings are not yet complete. He said the sockeye juvenile section is also missing data and there are some issues with Okanogan summer Chinook salmon data in the Regional Mark Information System. WDFW and the Colville Confederated Tribes are working to fix CWT data.

Tonseth added that WDFW will not be able to participate in Hatchery Committees tasks if Washington State does not have an approved budget by July 1, 2017, until the budget is approved.

D. Jeff Korth Retirement (Hillman)

Tracy Hillman reminded the Hatchery Committees that Jeff Korth (WDFW) is retiring at the end of June. Hatchery Committees representatives and alternates present collectively expressed best wishes for Korth in his retirement.

E. Next Meetings

The next Hatchery Committees meetings are on July 19, 2017 (Grant PUD), August 16, 2017 (Grant PUD), and September 20, 2017 (Grant PUD).

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Hatchery Committees

Date: August 21, 2017

From: Tracy Hillman, HCP Hatchery Committees Chairman

cc: Sarah Montgomery, Anchor QEA, LLC

Re: Final Minutes of the July 19, 2017, HCP Hatchery Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Hatchery Committees meeting was via conference call on Wednesday, July 19, 2017, from 9:00 a.m. to 10:30 a.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A). *(Note: this item is ongoing.)*
- Hatchery Committees representatives will review McLain Johnson's Genetic Monitoring Update (Item I-A). *(Note: Sarah Montgomery distributed the update on April 6, 2017. This item is ongoing, and the update will be discussed at the August 16, 2017, Hatchery Committees meeting.)*
- Sarah Montgomery will clarify the review period for the Chelan PUD Draft 2018 Hatchery Monitoring and Evaluation (M&E) Implementation Plan and provide an update to the Hatchery Committees (Item II-A). *(Note: Montgomery sent a summary email with a clarification for the review period to the Hatchery Committees on July 25, 2017.)*
- Tracy Hillman will revise Appendix 4 of the Draft 2017 Update to the Monitoring and Evaluation Plan for PUD Hatchery Programs to include release number targets, and provide it for Hatchery Committees review (Item III-C). *(Note: Hillman revised the appendix and appended it to the Draft M&E Plan,, which Sarah Montgomery distributed to the Hatchery Committees on July 27, 2017.)*
- Tracy Hillman will revise the Draft 2017 Update to the M&E Plan for PUD Hatchery Programs and provide it for Hatchery Committees review (Item III-C). *(Note: Hillman revised the Draft 2017 Update to the M&E Plan for PUD Hatchery Programs for review, which Sarah Montgomery distributed to the Hatchery Committees on July 27, 2017.)*

Decision Summary

- There were no decisions discussed during today's meeting.

Agreements

- There were no agreements discussed during today's meeting.

Review Items

- Sarah Montgomery sent an email to the Rocky Reach and Rock Island Hatchery Committees on July 18, 2017, notifying them that the Chelan PUD Draft 2018 Hatchery M&E Implementation Plan is available for a 30-day review, with comments due to Catherine Willard by August 17, 2017. Chelan PUD indicated they will request approval of the Plan at the Hatchery Committees August 16, 2017, meeting.

Finalized Documents

- There are no documents that have been recently finalized.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the June 21, 2017, Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the Hatchery Committees and asked for any additions or changes to the agenda. Members made no additions or changes to the agenda.

The Hatchery Committees reviewed the revised draft June 21, 2017, meeting minutes. Sarah Montgomery said there are some outstanding comments to be discussed, which the Hatchery Committees reviewed and revised. Montgomery said she would check with Bill Gale about one paragraph before finalizing the minutes. Hatchery Committees representatives present approved the draft June 21, 2017, meeting minutes, as revised, and Montgomery confirmed the finalization via email on July 25, 2017.

Action items from the Hatchery Committees meeting on June 21, 2017, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meeting on June 21, 2017)*:

- *Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A).*
  This item is ongoing.
- *Hatchery Committees representatives will review McLain Johnson's (WDFW) Genetic Monitoring Update (Item I-A). (Note: Sarah Montgomery distributed the update on April 6, 2017.)*

This item is ongoing, and the update will be discussed at the August 16, 2017, Hatchery Committees meeting.

- *Chelan PUD, Douglas PUD, and Grant PUD representatives will discuss internally HCP requirements and coverage options for the unlisted programs in the upper Columbia River basin (Item III-B).*
  This item is complete.
- *Charlene Hurst will distribute the draft proposed action for Methow steelhead programs to the Hatchery Committees for a 2-week review (Item IV-A). (Note: Hurst sent the draft to Sarah Montgomery, which she distributed to the Hatchery Committees on June 22, 2017).*
  This item is complete.
- *Tracy Hillman will make the following revisions to the Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs (2013 Update): 1) draft footnotes for Table 1 regarding run timing, redd distribution, and spawn timing, and 2) revise Objective 6 (Items I-A and III-C).*
  Hillman made these updates and Sarah Montgomery distributed a revised version before the meeting.
- *Tracy Hillman will revise fish-per-pound (FPP) targets in Appendix 5 of the Hatchery M&E Plan according to the 2017 Broodstock Collection Protocols (Item III-C). (Note: Hillman made this revision and Sarah Montgomery distributed a revised Appendix 5 and compilation of Appendices 2-5 on June 23, 2017.)*
  This item is complete.
- *Tracy Hillman will invite Jeff Jorgensen (National Oceanic and Atmospheric Administration) to an upcoming Hatchery Committees meeting to present and discuss Wenatchee River spring-run Chinook salmon life-cycle modeling (Item V-A).*
  Hillman said this item is complete and Jorgensen plans to attend the Hatchery Committees August 16, 2017, meeting.
- *Tracy Hillman will distribute Jorgensen et al.'s draft chapter, "Wenatchee River spring-run Chinook salmon life-cycle model: hatchery effects, calibration, and sensitivity analyses" to the Hatchery Committees (Item V-A). (Note: Hillman sent the chapter to Sarah Montgomery, which she distributed to the Hatchery Committees on June 22, 2017.)*
  This item is complete.

II. Chelan PUD

A. Draft 2018 Hatchery M&E Implementation Plan (Catherine Willard)

Catherine Willard said the Chelan PUD Draft 2018 Hatchery M&E Implementation Plan is currently available for a 30-day review (Attachment B) and any comments or questions should be directed to her. She said the changes between the 2017 and 2018 plans are minor and include only date and authorship changes. Willard said Chelan PUD will request that the Rocky Reach and Rock Island Hatchery Committees approve this plan at the August 16, 2017, Hatchery Committees meeting. Sarah Montgomery said she will clarify the review dates for this document and provide an update to the Hatchery Committees.

III. Joint HCP-HC/PRCC HSC

A. USFWS Bull Trout Consultation Update (Matt Cooper)

Tracy Hillman said Matt Cooper (U.S. Fish and Wildlife Service [USFWS]) sent him an email update for this topic because USFWS staff are unable to attend today's meeting. Hillman summarized the update as follows:

- Karl Halupka is finishing revisions to the Biological Opinion for the batch of Wenatchee subbasin programs and expects it will be finalized by early August 2017.
- The USFWS reviewed a draft proposed action for mainstem unlisted hatchery programs and provided comments to the National Marine Fisheries Service (NMFS). After NMFS responds to comments, the USFWS will decide on a consultation approach for this batch of hatchery programs. Currently the batch does not include Similkameen summer Chinook salmon programs, which USFWS has asked NMFS about. (Note: Emi Kondo [NMFS] stated that she spoke with Halupka regarding this consultation and said the Similkameen summer Chinook salmon program has been analyzed as part of the Okanogan Tribal Resources Management Plan and therefore does not need further consultation or coverage.)
- The USFWS has begun reviewing the proposed action for the Methow summer steelhead program. The primary objective of the review is to inform the USFWS' selection of a pathway to take for completing consultation on this program. A memo similar to the one USFWS completed for the Methow spring Chinook salmon program is one of several options being considered. One key factor in this decision is the degree to which changes in the program since prior consultation may change the program's effects on bull trout and bull trout critical habitat.

Kondo said Charlene Hurst and Halupka have a coordination call on July 24, 2017, to discuss the upper Columbia River (UCR) unlisted programs consultation.

B. NMFS Consultation Update (Brett Farman/Emi Kondo)

Emi Kondo said she has an update on the UCR unlisted programs consultation. She said she received comments on the draft proposed action and expects a few more comments as well. She said the Hatchery Committees discussed the pathway for Endangered Species Act (ESA) coverage for these programs during the June 21, 2017, Hatchery Committees meeting. She said the next step for consulting on this bundle of programs is deciding on the ESA pathway (i.e., Section 10 or Section 4(d) coverage). She said Douglas PUD has indicated that they prefer pursuing Section 10 coverage, while Chelan PUD and Grant PUD have indicated they want to have more discussion with NMFS General Counsel before deciding. She said coordination calls are occurring next week and she can also set up additional calls for anyone interested. She said in addition to deciding on the ESA pathway, another important step is formally initiating consultation. She said the applicants will need to send a letter requesting initiation of consultation, to which NMFS can reply with a submissions letter. Kondo said the letter should describe the consultation process, and once the proposed action is finalized it can be submitted with the letter. Greg Mackey asked Kondo for an example of the letter.

Todd Pearsons said when Grant PUD submitted hatchery and genetic management plan (HGMP) documentation, they submitted a letter requesting coverage, and asked if sending a second letter requesting consultation would be duplicative. Kondo said she will check internally to see if the letter submitted with HGMP documentation is sufficient.

C. M&E Plan for PUD Hatchery Programs 2017 Update (All)

Tracy Hillman said he revised the M&E Plan for PUD Hatchery Programs to reflect changes discussed during the June 21, 2017, Hatchery Committees meeting and also made some editorial edits. Sarah Montgomery distributed the draft revised plan to the Hatchery Committees before the meeting on July 19, 2017 (Attachment C).

Hillman said he added footnotes to Table 1 and Table 2, indicating that more detailed information is included in the appendices. He said he revised the objective in Table 1 "Determine if *recipient* stray rate of hatchery fish is acceptable" (italics are new text) and added a clarifying paragraph to Objective 6 describing the different types of stray rates and stray rate metrics. He added clarifying language to Objective 3 (HRRs), and added references for the appropriate appendices throughout the descriptions of objectives.

Hillman asked the Hatchery Committees why length and weight targets are missing from Appendix 4, which includes fish per pound (FPP), coefficient of variation (CV), and condition factor targets. He said in the M&E Plan, there are targets for size, length, weight, and condition factor. He said Appendix 4 also does not include the number of fish targeted for release (currently in Appendix 2). He asked if Appendix 4 should be revised to include number of fish targeted for release and length and weight targets. Greg Mackey said adding those values to Appendix 4 might make the table unwieldy. Mackey said the statistical test for length was used more to compare the length of hatchery fish to wild fish, and was used less as a true target. Hillman recalled in the last comprehensive report, there were both length and weight targets at release for programs. He said he and Andrew Murdoch (WDFW) performed the analyses for the comprehensive report, and found that size and weight targets often cannot be achieved (i.e., either one can be met, but not both). He said the targets should be revised to better reflect how fish grow, but they have not yet been revised. He suggested adding these targets to Appendix 4. This will place all within-hatchery targets in one appendix. Hearing no objections, Hillman said he would make these revisions for the Hatchery Committees to review.

Hillman said he added clarifications to Objectives 4, 5, and 6 to redirect readers to related appendices. In Objective 5, he said he edited the language about spawn timing to be consistent with Appendix 4 and added an additional hypothesis, "$Ho_{5.2.1.3}$: The relationship between elevation and spawn timing of hatchery-origin fish = the relationship between elevation and spawn timing of natural-origin fish." Mackey asked if the term elevation is accurate or if the hypothesis should address river kilometer. Hillman said the analysis uses elevation, at least in the Chiwawa River; however, river kilometer can be used as a surrogate for elevation.

Todd Pearsons asked about Hillman's edits to the possible statistical analyses for Objective 5. Hillman said he changed the use of an analysis of covariance (ANCOVA) to "Graphic and regression analysis to assess relationships between elevation and spawn timing" because ANCOVAs use discrete variables and elevation is not a discrete variable. He said using continuous variables retains the most information in the data and this regression analysis would be similar to analyses for productivity. He said using an ANCOVA would not be wrong, but it is cleaner to perform regressions for spawn timing and elevation for both wild and hatchery fish, then compare the regressions.

Hillman said he added a paragraph to Objective 6 that the Hatchery Committees should review in detail and clarified percent stray rates throughout the section. Mackey said the paragraph is a good synopsis and asked if annual stray rates and brood-year stray rates would converge to approximately the same rate over a long period, for example 25 years. Hillman said that would typically be the case and was true for the Chiwawa River analysis. However, he said in the Twisp River the rates did not converge and depend on the size of the hatchery program and the size of the recipient population. He said all three stray rates should be examined, but brood-year stray rate targets are not included in the Recovery Plan or Technical Recovery Team documents.

Hillman said he also revised the title of section 6.1.1 to be "Brood-Year Stray Rates" instead of "Stray Rates among Populations by Brood Return," to match the statistical analyses being performed. Mackey agreed and said the title now reflects the analyses being performed and originally stray rates analyses may have been intended to be limited to populations.

Hillman said he also made edits to Objective 9. He asked whether length and weight targets (Q9.1.1) should be added to Appendix 5 and if the targets are going to be revised. Pearsons suggested using the broodstock collection protocol targets (FPP and CV), because they directly represent management guidance given to hatchery staff. Hillman agreed and said using FPP targets is easier and should be considered as a target instead of length and weight. Mackey agreed and said FPP can be extrapolated to determine length or weight per fish if those metrics are needed. Hillman said he will make this edit in the next revised version of the plan for review. Hillman said regarding Q9.3.1, that program K (condition factor) targets are listed as "TBD" in Appendix 5. Hillman said regarding Q9.4.1, the release targets currently identified in Appendix 2 could be moved to Appendix 5 for ease of finding information quickly.

Hillman said he is still working on Appendix 1, which discusses carrying capacity, and expects it will be finished in September 2017.

Pearsons asked about the timeline for finalizing the 2016 Hatchery M&E Annual Report. Hillman said he has received comments on the draft and is incorporating comments and revising the document. He said the report is due on September 15, 2017, but will likely be completed before that date. Pearsons said it would be good to provide the annual report and the revised Hatchery M&E Plan for PUD Hatchery Programs (2017 Update) to the Independent Scientific Advisory Board in early fall so they can incorporate the most recent documents in their review and said he has no problems with the current timelines for finalizing these documents.

IV. HCP Administration

A. Next Meetings

The next Hatchery Committees meetings are on August 16, 2017 (Grant PUD), September 20, 2017 (Grant PUD), and October 18, 2017 (Grant PUD).

1. Introduction

The Habitat Conservation Plan (HCP) specifies that a monitoring and evaluation plan will be developed for the hatchery program. The approach to monitoring the hatchery programs was guided by the "*Monitoring and Evaluation Plan for PUD Hatchery Programs: 2013 Update"* (Hillman et al. 2013) and the "*Conceptual Approach to Monitoring and Evaluating the Chelan County Public Utility District Programs*" (Murdoch and Peven 2005).

The purpose of this document is to define the tasks associated with the approved scope of work to implement Chelan PUD's (CPUD's) hatchery monitoring and evaluation (M&E) plan for 2018. Additionally, monitoring and evaluation activities for Lake Wenatchee sockeye in 2018 are included in this document. As monitoring tasks are completed in 2017 and are evaluated for their efficacy, methodologies to accomplish the tasks defined in the 2018 Implementation Plan may be modified [with Habitat Conservation Plan's Hatchery Committee (HCP-HC) approval].

Deleted: 2017

The work described in this plan has Endangered Species Act (ESA) coverage provided by NFMS Section 10(a)(1)(A) permits 18121 and 1395 and Section 10(a)(1)(B) permit 1347. All activities conducted under this Implementation Plan shall adhere to all terms and conditions as specified in the referenced permits. These permits allow for changes to monitoring or research protocols with the caveat that such modifications are approved by NMFS prior to implementing those changes. Terms and conditions relevant to monitoring and evaluating the hatchery programs have been used to inform the various measurements below and associated scopes of work with entities performing the work. A report summarizing compliance with the terms and conditions set forth under the above-references permits is required for submittal to NMFS; a copy of this completed report will be provided to the HCP HC.

The Implementation Plan includes all four components of the hatchery M&E Program including: (1) aquaculture monitoring; (2) juvenile monitoring; (3) adult monitoring; and (4) data, analysis and reporting. Under each component are study design elements that will be used to inform the overarching program components. Figure 1 illustrates the relationship of the components and study design elements used to address each component. Table 1 depicts which study design element is being performed by entity, and the associated objectives for each study design element as referred to in Hillman et al. 2013. For Lake Wenatchee sockeye salmon, the proposed M&E activities cover juvenile and adult life history stages and provide the data necessary to track or estimate viable salmonid population parameters (VSP) and is described in Section 6.0.

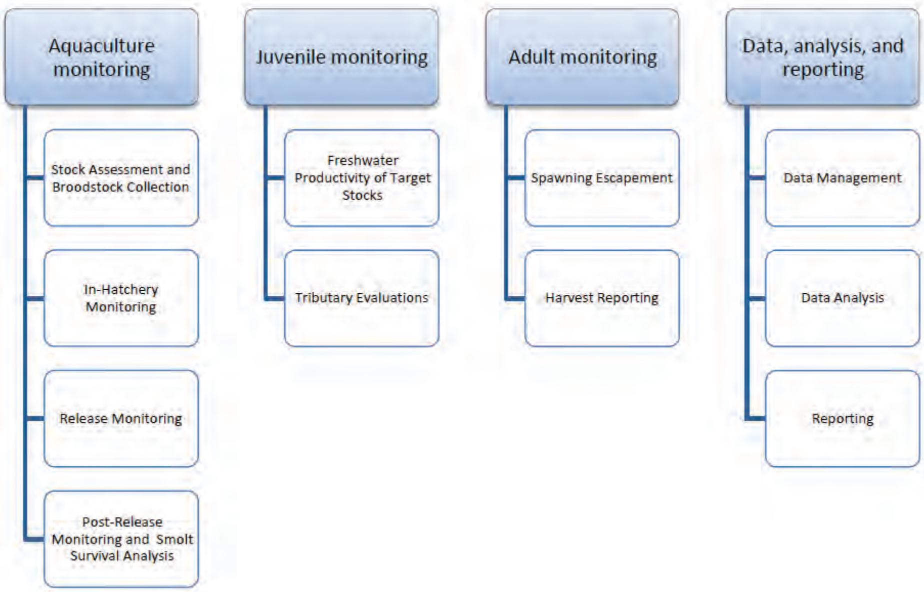

Figure 1. The four components of the hatchery monitoring and evaluation program and the study design elements within each component.

Table 1. Study design elements performed by entity, and the associated objectives for each study design element as referred to in Hillman et al. 2013.

[1] Monitoring questions relative to Objective 7 will be addressed at the next 10 year HCP check-in.
[2]CPUD crews will PIT tag in-hatchery fish.
[3]Biomark will PIT tag in-hatchery fish.
[4]In 2018, monitoring and evaluation for the Methow spring Chinook program is described in "Implementation of Comprehensive Monitoring and Evaluation of Wells Hatchery Complex Programs".
[5]Because the Chelan summer Chinook program is primarily an augmentation program, monitoring and evaluation efforts focus on straying, release characteristics, and harvest.

Deleted: 2017

2. Aquaculture Monitoring

The aquaculture monitoring component is comprised of two basic elements: (1) stock assessment and broodstock collection at adult trapping locations and (2) in-hatchery monitoring including spawning, rearing, and release of juveniles. Data collected during these elements primarily support monitoring questions 5.1.1, 5.2.1, 8.1.1, 8.2.1, 8.3.1, 8.3.2, 8.4.1, 9.1.1, 9.2.1, 9.3.1 and 9.4.1, but also contribute data to monitoring questions 3.2.1, and 3.2.2 (Hillman et al. 2013). Table 2 below provides a summary of the variables to be measured in 2018 under the aquaculture monitoring component and what objective the measure(s) supports. The text that follows in this section further describes the activities.

Deleted: 2017

Table 2. Monitoring and Evaluation Plan (Hillman et al. 2013) objectives and the associated measured variables for the aquaculture monitoring component.

Objectives	Measured Variables *(Applicable Study Component(s))*
Objective 3: Determine if the hatchery adult-to adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.	• Number of hatchery and naturally produced fish collected for broodstock (*Broodstock Collection and Stock Assessment*) • Number of broodstock used by brood year (hatchery and naturally produced fish) (*Broodstock Collection and Stock Assessment*)
Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.	• Ages of hatchery and naturally produced fish sampled via PIT tags or stock assessment monitoring (*Broodstock Collection and Stock Assessment*) • Time (Julian date) of ripeness of hatchery and natural origin steelhead captured for broodstock (*Broodstock Collection and Stock Assessment*)
Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of the natural populations.	• Size (length), gender, and total/salt age of broodstock (*Broodstock Collection and Stock Assessment*) • Assess age of fish (*Broodstock Collection and Stock Assessment*) • Length, weight, and age (covariate) of hatchery and natural-origin broodstock after eggs have been removed (*Broodstock Collection and Stock Assessment*) • Number and weight of eggs (*Broodstock Collection and Stock Assessment*)
Objective 9: Determine if hatchery fish were released at the programmed size and number.	• Fork length and weights of random samples of hatchery juveniles at release (*Release Monitoring*) • Monthly individual lengths and weights of random samples of hatchery juveniles (*In-Hatchery Monitoring*) • Numbers of smolts released from the hatchery (*Release Monitoring*)

Deleted: 2017

2.1 Broodstock Collection and Stock Assessment

Broodstock collection and stock assessment for Wenatchee summer steelhead, Wenatchee summer Chinook, Methow spring Chinook, Chelan Falls summer Chinook, and Chiwawa River spring Chinook, hatchery programs will, in most instances, occur concurrent to and consistent with the Broodstock Collection Protocol approved annually by the HCP-HC and relevant permits. Data collection during broodstock collection will be consistent with Murdoch and Peven (2005). A representative sample of fish trapped throughout the entire run, either collected for broodstock or released back to the river, will be sampled for origin, age, sex, size, and migration timing. Biological sampling of all fish trapped will include presence of internal (CWT or PIT) and external (VIE) tags or marks, scales, length, and sex (determined by ultrasound). PIT tags will be injected into all target species (Chinook and steelhead), whether collected for broodstock or released back to the river to monitor for potential fallbacks. All non-target species will be enumerated daily. Measures of central tendency and spread will be calculated and reported for each metric.

2.2 In-Hatchery Monitoring

The in-hatchery monitoring component will begin when adult fish are collected and retained for broodstock and ends when juvenile fish are released. Life stage specific in-hatchery survival and growth rates, disease monitoring, and an estimate of the number of fish released will be collected and analyzed according to Murdoch and Peven (2005). Additional data to be collected includes individual lengths and weights of juveniles during monthly sampling, and the weight of gonadal mass and body of spawned broodstock. Measures of the central tendency and spread will be calculated and reported for each metric.

Fish Marking

All of Chelan PUD's hatchery fish will be coded-wire tagged (CWT) and externally marked or marked as otherwise agreed to by the HCP HC. A comprehensive marking strategy will be developed by the HCP-HC and included as an Addendum to this Plan. The identification of these hatchery-produced fish is needed for a suite of adult metrics and may be used for adult management and/or fisheries as contemplated by the co-managers.

Using methods described in Keller and Murauskas (2012), hatchery fish will be PIT-tagged (Table 3) at Eastbank Hatchery approximately two to four weeks before the fish are transferred to acclimation ponds or in the spring prior to release. Additional PIT-tagging may occur for program specific studies/comparisons as approved by the HCP-HC. The data collected from the PIT-tags will assist in release monitoring, migration timing, juvenile survival, and smolt-to-adult survival. For all fish marking, quality control check will be performed during and immediately following tagging and prior to release.

Deleted: 2017

Table 3. Chelan PUD's hatchery program release goals and recommended number of fish PIT tagged.

Program	Release goals	Number of fish PIT tagged[1]	PIT tag rate (%)
Chiwawa spring Chinook	144,026	10,000	6.9
Wenatchee steelhead	247,300	20,000	8.0
Wenatchee summer Chinook	318,816 (CPUD Program) 181,184 (GPUD Program)	20,600	4.1
Methow spring Chinook	60,156	5,000	8.3
Chelan Falls summer Chinook	576,000	10,000	1.7

[1] Additional PIT tagging may take place for Chelan PUD approved studies and/or comparisons.

2.3 Release Monitoring

Hatchery fish will be released during smoltification in the spring, typically between 15 April and 1 June. Whenever possible, the exact release dates will coincide with environmental conditions that promote a rapid emigration that minimizes both the potential negative ecological interactions of hatchery fish with naturally produced fish and predation on hatchery fish by avian or other predators. The default release method will incorporate a volitional approach, as approved by the HCP HC, unless it can be demonstrated other approaches are better. The monitoring data collected for each stock are described below.

Chiwawa and Methow Spring Chinook

Pre-release sampling data will be conducted consistent with Murdoch and Peven (2005), including individual weights to the nearest 0.1 gram. Data collected will support monitoring questions 9.1, 9.2, 9.3 and 9.4 in the updated monitoring and evaluation plan (Hillman et al. 2013). PIT tag monitoring of spring Chinook released in the Chiwawa River will occur during the release period (April). Juvenile Chinook will pass through two 92-cm diameter PIT-tag antennas connected to Allflex 310 readers and Quantitative Sampling Technologies (QST) QuBE data logger. The release location and type (i.e., volitional, forced, or trucked) are recorded for each observation file created and uploaded to the PTAGIS database maintained by the Pacific States Marine Fisheries Commission after each year of release. PIT-tagged fish in each observation (release) file are assumed to represent untagged fish. Observation files contain the PIT tags associated with the original tag files and will be used for analysis (see Post-release Monitoring Section). The total number of fish released will be based on the population size at CWT tagging (100%), subtracting mortality enumerated by hatchery staff that occurred from tagging to release.

Deleted: 2017

Wenatchee Summer Steelhead–
Pre-release sampling will be conducted consistent with Murdoch and Peven (2005), including individual weights to the nearest 0.1 gram. Data collected will support monitoring questions 9.1, 9.2, 9.3 and 9.4 in the updated monitoring and evaluation plan. Monitoring of steelhead released in the Wenatchee River sub-basin will occur during loading of fish into transport trucks, unless fish are released directly into the Chiwawa River. Steelhead will pass through a series of PIT-tag antennas, each connected to a data logger, thereby allowing the creation of a PIT-tag observation file for each truckload of steelhead consisting of unique tag records. The release location (stream and rkm), release type (volitional or forced), and hatchery group (HxH or WxW) will be recorded for each tag file created. PIT-tagged fish in each observation (release) file are assumed to represent untagged fish. However, because PIT-detection efficiency during loading will not be 100%, the number of fish in each truckload will be estimated using volumetric displacement. Observation files contain the PIT tags associated with the original tag files and will be used for analysis (see Post-release Monitoring Section). The total number of fish released will be based on the population size at CWT tagging (100%), subtracting mortality enumerated by hatchery staff that occurred from tagging to release.

Wenatchee and Chelan Falls Summer Chinook
Pre-release sampling will be conducted consistent with Murdoch and Peven (2005), including individual weights to the nearest 0.1 gram. Data collected will support monitoring questions 9.1, 9.2, 9.3 and 9.4 in the updated monitoring and evaluation plan. Should PIT tagging occur, a monitored release strategy consistent with other Chinook stocks (i.e., Chiwawa Spring Chinook) will be implemented. The total number of fish released will be based on the population size at CWT tagging (100%), subtracting mortality enumerated by hatchery staff that occurred from tagging to release.

2.4 Post-Release Monitoring and Survival Analysis
Data will be collected during rearing, acclimation, release, and the emigration period that may prove valuable in explaining variability in adult survival (Murdoch and Peven 2005). Rearing densities have been reported to influence the survival of hatchery fish (Martin and Wertheimer 1989; Banks 1994) and may also be linked to disease prevalence during rearing (Banks 1994; Ogut and Reno 2004). Acclimation of hatchery fish before release has been found to increase survival and reduce stray rates when the duration of the acclimation period is sufficient (Clarke et al. 2010, 2012; Rosenberger et al. 2013). These metrics (i.e., rearing density and acclimation period) will be collected annually to determine their influence on fish survival.

PIT-tagged groups of hatchery fish will be used to estimate survival during their emigration. Variation in survival during the emigration period may also inform observed adult survival rates. Survival during emigration and travel will be estimated using interrogation or release files and the standard Cormack-Jolly-Seber (CJS) estimator. CJS estimates are termed apparent survival estimates because it is unknown whether fish suffered mortality (e.g., size or time of release) or simply failed to emigrate (i.e., residualized or were precocial males). In the latter case, the proportion of PIT-tagged fish detected in the Methow sub-basin, Wenatchee or Columbia rivers after the emigration period is complete may explain variation in smolt survival rates. The post-release performance of PIT-tag groups will be estimated and monitored annually, consistent

Deleted: 2017

with methods in Murdoch and Peven (2005). Additionally, precocity of hatchery releases will be evaluated by examining the proportion of PIT tag releases detected in adult fish ladders and tributaries within the same year as release.

3. Juvenile Monitoring

Data collected during these elements primarily support monitoring questions 2.1.1 and 2.2.1. and the monitoring objectives described in Table 4 (Hillman et al. 2013). Table 4 below provides a summary of the variables to be measured in 2018 under the juvenile monitoring component and what objective the measure supports. The text that follows in this section further describes the activities.

Deleted: 2017

Table 4. Monitoring and Evaluation Plan (Hillman et al. 2013) objectives and the associated measured variables for the juvenile monitoring component.

Objective	Measured Variables *(Applicable Study Component(s))*
Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.	• Number of juveniles (smolts, parr [where appropriate], and emigrants) (*Freshwater Productivity of Supplemented Stocks*)

3.1 Freshwater productivity of Supplemented Stocks

Steelhead, Spring Chinook, and Summer Chinook

The freshwater productivity of supplemented stocks in the Wenatchee sub-basin will be monitored using smolt traps in the Chiwawa River and the lower Wenatchee River consistent with historical trapping efforts. Additionally, a newly derived analytical method which uses PIT-tag mark-recapture data will be utilized that reduces bias and increases precision by including estimates of emigration during the winter non-trapping periods. Up to 3,000 parr will be PIT tagged in the Chiwawa River in the fall, based on the spatial distribution and abundance estimated during parr snorkel surveys, to generate estimates of migration during the non-trapping periods. A random sample of a minimum of 10 percent of fish per remote site will be held in a live box for 24 hours to evaluate tag loss and delayed mortality. Using PIT tagged parr detections at the lower Chiwawa PIT array during the non-trapping period, the total number of PIT-tagged parr that emigrated will be estimated, and then expanded by the tag rate. Overwinter mortality of PIT-tagged parr is assumed to be the same as non-PIT-tagged parr. Overwinter survival estimates of Chiwawa River parr will be derived by estimating survival to the lower Wenatchee PIT tag array and analyses with the TribPit Survival software program and/or estimating survival of fall parr and spring smolts to McNary. PIT-tag mark-recapture trials conducted during the trapping period in the fall will also be used to estimate detection probabilities of the PIT-tag array at a given discharge level. Abundance and variance will be estimated using the same methods as those used in the smolt trap estimate. The estimated abundance and variance from each method and time period (trapping and non-trapping

Deleted: 2017

periods) will be summed to estimate a total production estimate. Under the proposed methodology, unbiased estimates of abundance during the entire migration period will be generated with relatively high precision (PSE < 15%), which is consistent with NOAA Fisheries' recommendations (Crawford and Rumsey 2011). Historical estimates will be revised using the new estimation techniques.

Specific actions to monitor the freshwater productivity of supplemented spring Chinook salmon in the Methow sub-basin have yet to be determined. As these become available, the plan will be amended and presented to the HC by December.

3.2 Tributary Evaluations

Chiwawa River

Snorkel surveys will be utilized to estimate parr abundance within the Chiwawa subwatershed during the summer. This approach has been used in the Chiwawa subwatershed since 1992. In parallel to addressing Objective 2, additional juvenile data can help to assess the habitat carrying capacity in each tributary. This information can add value to the overall M&E plans and help inform management decisions.

Sampling will follow a stratified random sampling design. Landscape classification will be used to stratify streams in the Chiwawa subwatershed that support juvenile Chinook salmon. In the Chiwawa subwatershed, WDFW found that classification "explained" most of the variability in fish numbers caused by geology, land type, valley bottom type, stream state condition, and habitat type (Hillman 2013). The same classification method was used to identify sections of the Little Wenatchee River (reference area) that corresponded to discrete reaches in the supplemented subwatersheds, but that had no release of hatchery Chinook. Consistent with previous efforts, habitat types within each land-class or reach will be identified and quantified annually. At least three units of each habitat type within each reach will be randomly selected for estimating densities of salmon and trout. Thus, overall sampling consists of a stratified- random sampling design, which increases the accuracy and precision of population estimates.

Densities of salmon and trout will be estimated in August and September by direct underwater observation within the randomly-selected habitat units. Underwater methods will follow those described by Thurow (1994), Dolloff et al. (1996), and O'Neal (2007). Habitat surface areas and volumes will be estimated during fish sampling. Numbers of fish counted will be adjusted for detection probabilities using the models published in Hillman et al. (1992). For each habitat type within a state type and reach stratum, the mean density of salmon and trout will be calculated as the ratio of mean numbers to mean area or volume sampled (Cochran 1977). Total numbers of fish will be estimated per habitat type within a state type and reach stratum as the product of mean density of fish in a given habitat type, times total area or volume of that habitat type within the stratum (Cochran 1977). Total numbers of fish within the supplemented subwatershed will be estimated as the sum of all population numbers per habitat type in state type/reach strata. Bootstrapping methods will be utilized to estimate variance and percent errors (based on 95% confidence interval) for total numbers of fish.

Deleted: 2017

4. ADULT MONITORING

The adult monitoring component is comprised of two basic elements: (1) estimating spawning escapement and (2) harvest monitoring. Data collected during these elements primarily support monitoring questions 1.1.1, 1.2.1, 2.1.1, 2.2.1, 3.2.1, 3.2.2, 4.1.1, 5.1.1, 5.2.1, 5.3.1, 5.3.2, 6.3.1, but also contribute data to monitoring questions 6.1.1, 6.2.1, 8.1.1, 8.2.1, 8.4.1, 10.1.1, 10.1.2, 10.1.3 and 10.1.4. Table 5 below provides a summary of the variables to be measured in 2018 under the adult monitoring component and what objective the measure(s) supports. The text that follows in this section further describes the activities.

Deleted: 2017under

Table 5. Monitoring and Evaluation Plan (Hillman et al. 2013) objectives and the associated measured variables for the adult monitoring component.

Objective	Measured Variables *(Applicable Study Component(s))*
Objective 1: Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.	• Number of hatchery and naturally produced fish on spawning grounds *(Spawning Escapement Estimates)* • Number of hatchery and naturally produced fish taken for broodstock (*Broodstock Collection and Stock Assessment*) • Number of hatchery and naturally produced fish taken in harvest (if recruitment is to the Columbia) *(Harvest Reporting)*
Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.	• Number of hatchery and naturally produced fish on the spawning grounds (*Spawning Escapement Estimates*) • Number of redds *(Spawning Escapement Estimates)*
Objective 3: Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.	• Number of hatchery and naturally produced fish on spawning grounds *(Spawning Escapement Estimates)* • Number of hatchery and naturally produced fish harvested *(Harvest Reporting)*
Objective 4: Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.	• Number of hatchery and naturally produced fish on spawning grounds *(Spawning Escapement Estimates)*
Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.	• Time (Julian date) of hatchery and naturally produced salmon carcasses or marked steelhead detected on spawning grounds within defined reaches *(Spawning Escapement Estimates)* • Time (Julian date) of arrival at mainstem projects and within tributaries (e.g., traps, PIT arrays) with

Deleted: 2017

Objective	Measured Variables *(Applicable Study Component(s))*
	the intent to identify biologically significant differences *(Spawning Escapement Estimates)* • Location (GPS coordinates) of female salmon carcasses observed on spawning grounds *(Spawning Escapement Estimates)*
Objective 6: Determine if stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.	• Number of hatchery fish collected for broodstock (*Broodstock Collection and Stock Assessment*) • Number of hatchery fish taken in fishery (*Harvest Reporting*) • Locations of live and dead strays (used to tease out overshoot) *(Spawning Escapement Estimates)* • Number of hatchery carcasses (PIT-tagged and/or CWT) found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas (stray data into the Entiat sub-basin will be obtained from USFWS Fisheries Resource Office-Leavenworth) *(Spawning Escapement Estimates)*
Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.	• Total and salt (ocean) age and gender of hatchery and naturally produced salmon carcasses collected on spawning grounds *(Spawning Escapement Estimates)* • Whenever possible, age at maturity and sex ratio will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling or ultrasound on live fish) *(Spawning Escapement Estimates)* • Assess age of fish, including harvested fish *(Spawning Escapement Estimates and Harvest Reporting)*
Objective 10: Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.	• Numbers of hatchery fish taken in harvest *(Harvest Reporting)* • Numbers of natural-origin fish taken in harvest *(Harvest Reporting)*

Deleted: 2017

4.1 Spawning Escapement Estimates

Chelan Summer/Fall Chinook

Chinook spawning ground surveys will be conducted in the Chelan River and (see Appendix A for survey reaches). Spawning ground surveys will be conducted via foot or raft beginning late September and continuing until spawning has ended (usually mid-November). Frequency of surveys will vary depending on method.

Summer Chinook carcass surveys will be conducted in the Chelan River beginning in September and ending in November consistent with methods described in Murdoch and Peven (2005). A representative sample (i.e., 20%) of spawners as determined by spawner abundance and distribution (typically 100% of the carcasses encountered in the Chelan River) will be sampled. Biological data will include collection of scale samples for age analysis, length measurements (POH and FKL), gender, egg voidance, and a check for tags or marks. DNA samples (five-hole punches from operculum) will be collected as needed to address different objectives. These data will be used to assess length-at-age, size-at-age, egg voidance, origin (hatchery or naturally produced), stray rates, and genetics. All carcass surveys will be conducted within the historical reaches.

Wenatchee Steelhead

The number of hatchery and naturally produced steelhead returning to the Wenatchee sub- basin will be estimated using a PIT tag mark recapture model. The estimated spawner abundance for the Wenatchee steelhead population will be a combination of PIT tag-based tributary and redd-based mainstem Wenatchee River estimates. Steelhead redd counts will be conducted weekly in all major spawning areas in the mainstem Wenatchee River (see Appendix A for survey reaches); minor spawning areas in the mainstem Wenatchee River will be surveyed once, based on the spawn timing in adjacent major spawning areas, to estimate redd abundance at peak spawning. The estimated total number of redds in the Wenatchee River mainstem will be expanded by the sex ratio of the population to estimate spawner abundance. Spawner abundance in tributaries of the Wenatchee River will be estimated using a PIT tag mark recapture model.

Chiwawa Spring Chinook

Chiwawa spring Chinook spawning escapement will be estimated based on the total number of redds found in each tributary (Murdoch et al. 2010) using methods described in Murdoch and Peven (2005). Weekly redd and carcass surveys will be conducted simultaneously from the first week of August through September (see Appendix A for survey reaches). Redd-based estimates assume that each female constructs one redd, which WDFW has found to be appropriate for this population (Murdoch et al. 2009). The total number of redds in each reach will be estimated using methods described in Millar et al. (2012) and using the observer efficiency model currently under development by WDFW. Redd counts will be expanded and the number of hatchery and naturally produced fish will be estimated using methods in Murdoch et al. (2010). Carcasses encountered during surveys will be sampled according to methods outlined in Murdoch and Peven (2005). All CWTs (i.e., snout or adipose) from carcasses will be read and the data entered into the Regional Mark Processing Center database within one year of collection.

Deleted: 2017

Additionally, all redds and female carcasses will be geo-referenced using hand-held GPS devices. Carcass recovery bias has been detected in the Chiwawa spring Chinook population (Murdoch et al. 2010) and if not corrected will bias estimates of hatchery and naturally produced fish on the spawning grounds. While it may be appropriate to correct for carcass recovery bias for some monitoring questions (e.g., 2.2), when comparisons to reference populations are made in monitoring questions 1.1.and 1.2, carcass bias will not be corrected because other monitoring programs have not corrected for a similar bias.

Wenatchee Summer Chinook

Wenatchee summer Chinook spawning ground counts will begin the first week in September and continue through the end of spawning in November (see Appendix A for survey reaches). Total census redd counts will be conducted by foot or raft depending on stream size, flow, and density of spawners within the stream reach (see Appendix A for survey reaches). All stream reaches will be surveyed once per week. Redd data will be collected using methods described in Murdoch and Peven (2005). The total number of redds in each reach will be estimated using methods described in Millar et al. (2012) and using the observer efficiency model currently under development by WDFW. Weekly ground-based census counts and the true number of redds (determined via intensive surveys) will be compared in order to generate observer efficiency. River characteristics (e.g., channel width, water depth, discharge, visibility, and habitat complexity), observer experience, and survey effort will be incorporated into a model to predict observer efficiency in all river reaches. Predicted redd generate observer efficiency for each river reach will be used to adjust ground-based redd counts to estimate the total reach redd count. Ground-based surveys will also be used to estimate redd life for each river reach. The estimated spawner abundance in the Wenatchee River and an associated level of precision will be calculated using the estimated total redd count for each reach, mean redd life, and the sex ratio of the population similar to methods described in Millar et al. (2012). Salmon carcass data collected during spawning ground surveys will be consistent with Murdoch and Peven (2005). All CWTs (i.e., snout or adipose) from carcasses will be sent to the WDFW lab in Olympia. The CWT lab will extract and read CWTs and submit all required information to RMIS within one year of collection.

4.2 Harvest Reporting

In years when the expected hatchery adult returns are in excess of the levels needed to meet the hatchery program goals (i.e., broodstock and/or escapement), surplus fish may be available for harvest. Harvesting or removal of surplus hatchery fish may have benefits to the natural populations by reducing potential negative ecological and genetic impacts (e.g., density dependent effects, loss of fitness, and loss of genetic variation). The contribution of hatchery fish to fisheries will be monitored using CWT recoveries on a brood-year basis supporting Objective 10.

To obtain the necessary data to determine if the harvest rates are meeting objectives, a statistically valid creel program will be designed and implemented for all sport and/or conservation fisheries in the Upper Columbia River to estimate harvest of hatchery fish from

Deleted: 2017

both Chelan and Grant County PUD funded hatchery programs (Murdoch and Peven 2005). Information collected during creel surveys are an integral component to calculating the HRR (Objective 3), particularly given most CWT recoveries for PUD mitigation programs occur in the Upper Columbia River and its tributaries, with the exception of summer Chinook where most CWT recoveries occur in ocean fisheries. Because of considerable time lags in reporting of CWT's to the Regional Marking Information System (RMIS) database, it requires an ongoing query of recovery data until the number of estimated fish does not change.

5. Data Management, Analysis, and Reporting

5.1 Data Management

A Microsoft Access database maintained by WDFW will contain all the monitoring data collected for hatchery evaluations. The database will contain and manage all data associated with aquaculture monitoring, juvenile monitoring, and adult monitoring.

All data entered into the database are evaluated for quality control and quality assurance by WDFW. Quality control checks using analyses such as modified Z-scores, boxplots, and the Generalized Extreme Studentized Deviate Procedure (Iglewicz and Hoaglin 1993) will be conducted for all data entry. In the event outliers are identified, discussion will occur on whether identified outliers are true data points or transcription errors. This process ensures that the data used to test statistical hypotheses are correct and accurate.

5.2 Data Analysis

The analyses proposed are consistent with the Monitoring and Evaluation Plan for PUD Hatchery Programs: 2013 Update (Hillman et al. 2013). Each of the objectives will be addressed using the appropriate statistical tests, as well as graphic analyses that convey relevant information.

5.3 Reporting

An annual M&E report will be generated following the completion of each calendar year and will be available for HCP-HC review by June 1 of the following year. Additionally, monthly progress reports will be made available to the HCP-HC.

6. Lake Wenatchee Sockeye Salmon

The Chelan PUD will conduct monitoring and evaluation (M&E) activities to track key population attributes related to Lake Wenatchee sockeye salmon in 2018(Table 6). In the absence of a sockeye hatchery program, M&E activities are no longer rooted in the context of evaluating the effects of sockeye salmon supplementation, but instead focus directly on the performance of the natural population, which is a unique departure from historic monitoring obligations. Broadly, the proposed M&E activities cover juvenile and adult life history stages and provide the data necessary to track or estimate viable salmonid population parameters (VSP): abundance, productivity, spatial structure and diversity (McElhaney et al. 2000). The data collected may also have utility in future hatchery compensation recalculation efforts.

Deleted: 2017

Deleted: 2017

Chelan PUD is conducting these M&E activities to support commitments made under the 2011 hatchery recalculation effort, which also included a steelhead production commitment for a sockeye species swap (SOA 2011). This section of the implementation plan describes the specific commitments by juvenile and adult life history stages.

6.1 Juvenile Monitoring

Chelan PUD will conduct or fund activities to monitor and evaluate the temporal distribution and age/size of out-migrating smolts, and estimate smolt production (Table 6). Smolt production will be estimated from data collected at the lower Wenatchee smolt trap and via back calculations based on collected adult return data (i.e., age-at-return estimates, SARs, and adult escapement to the tributaries). Collectively, these activities include: (1) funding of the lower Wenatchee River smolt trap concurrent with efforts aimed at evaluating Chelan PUD funded supplemented populations in the Wenatchee River sub-basin; (2) tagging up to 5,000 PIT tags for natural-origin juveniles encountered during smolt trapping activities and collecting scale samples at this location; and (3) estimating adult escapement estimates to the tributaries, and collection of adult return data at Tumwater (see the *Adult Monitoring* section for details) to back-calculate smolt production.

The monitoring data obtained will provide a useful set of tools for evaluating the performance of natural origin sockeye salmon within the sub-basin and downstream and also support the evaluation of VSP parameters [e.g., outmigration timing and size (diversity); and PIT tagging juveniles for SAR estimates (productivity)].

6.2 Adult Monitoring

Several M&E activities associated with adult returns of Lake Wenatchee sockeye salmon will be conducted and/or funded by Chelan PUD (Table 6). These efforts include (1) continuation of accurate adult counts at Rock Island, Rocky Reach, and Tumwater dams; (2) sampling of scales for age distribution, sex ratio determination, and returns of PIT-tagged adults at Tumwater Dam; (3) reach-specific conversion estimates between Rock Island Dam and spawning grounds in the White and Little Wenatchee rivers (i.e., Rock Island to Tumwater Dam to spawning tributaries); and (4) providing between 250 to 1,000 PIT tags to estimate adult spawning escapement in the Little Wenatchee and White rivers utilizing PIT tags and mark-recapture techniques (the software program Sample Size 2.0.7, developed by the University of Washington School of Aquatic and Fisheries Science (P. Westhagen, J. Lady, and J. Skalski) was used to determine the minimum number of tags required (i.e., 250) to estimate adult sockeye escapement at a +/- 7 percent confidence interval). Chelan PUD will adjust the number of PIT-tagged individuals in order to maintain precision in estimates at the lowest rate of interference to migrating populations, if it is warranted due to annual changes in escapement and detection probabilities. In an effort to PIT tag the run at large, adults will be PIT tagged at Tumwater consistent with the Tumwater Operations Protocol, daily throughout the run.

Collectively, these data will provide reliable metrics of adult returns and spawning escapement (abundance), recruits-per-spawner (productivity), distribution of spawners among tributaries (spatial structure), and run-timing and age structure for adult immigrants (diversity).

Deleted: 2017

Table 6. Chelan PUD's proposed Lake Wenatchee sockeye salmon monitoring and evaluation activities.

Life History Stage	M&E Activity	Entity Performing the Activity	Related analysis	VSP parameter addressed
Juvenile	Concurrent operation of the lower Wenatchee smolt trap to collect juvenile outmigration data	WDFW	Generate distribution of outmigration timing, estimate smolt production and determine average smolt size.	Diversity and productivity
Juvenile	PIT tagging smolts at lower Wenatchee smolt trap (up to 5,000 fish annually) and collecting/aging scale samples	WDFW	Estimate smolt-to-adult returns.	Productivity
Juvenile	Develop adult return based smolt production estimates	WDFW	Use collected data (i.e., adult age-at-return data, SARs, adult escapement to the tributaries) to back-calculate smolt production.	Productivity
Adult	Rock Island and Rocky Reach Dam adult counts	CPUD	Initial spawner abundance (Okanogan stock separation)	Abundance and spatial structure
Adult	PIT tag subsample (250 adults) of returning adults at Tumwater Dam to support mark-recapture evaluation	WDFW	Calculate spawner abundance and relative distribution among ~~in~~ tributaries	Abundance and spatial structure
Adult	Collect and age scales[1] and determine sex via ultrasound from returning adults at Tumwater Dam	WDFW	Estimate age-at-return, sex ratio, and relative productivity of contributing spawner cohorts	Productivity and diversity
Adult	Tumwater Dam adult counts	WDFW	Estimate potential spawner abundance (pre Lake-Wenatchee harvest), potential productivity (recruits/spawner), and run timing distribution	Abundance and diversity
Adult	Operate PIT detection arrays on Little Wenatchee and White River	WDFW	Calculate spawner abundance (post-Lake Wenatchee harvest and other mortality), actual productivity (recruits/spawner), and entry-to-spawning-habitat timing distribution, and spatial spawner distribution among tributaries	Abundance, productivity, spatial structure, and diversity
All	Data management, analysis, and reporting	BioAnalysts CPUD	------	NA

[1] Scales would be collected concurrently from adults that are PIT tagged at Tumwater Dam.

Monitoring and Evaluation Plan for PUD Hatchery Programs

This document is a revision of the monitoring and evaluation (M&E) plan of the salmon and steelhead hatchery programs funded by Douglas, Chelan, and Grant County Public Utility Districts (PUDs; see Table 4). Several programmatic changes, evaluation of data collection methods, and M&E results from the past five years, along with shifting management paradigms affect M&E needs, all of which have occurred under advancing fish culture and monitoring techniques. As required by the programs, this document is a result of a five-year review intended to expand on and coalesce previous M&E documents (BAMP 1998; Cates et al. 2005; Murdoch and Peven 2005; Hays et al. 2006; Pearsons and Langshaw 2009a, 2009b) with inclusion of new information.

Fishery management agencies developed the following general goal statements for hatchery programs, which were adopted by the HCP Hatchery Committees and PRCC Hatchery Sub-Committee (hereafter, Hatchery Committees):

1. Support the recovery of ESA-listed species by increasing the abundance of the natural adult population, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity.

2. Increase the abundance of the natural adult population of unlisted plan species, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity. In addition, provide harvest opportunities in years when spawning escapement is sufficient to support harvest.

3. Provide salmon for harvest and increase harvest opportunities, while segregating returning adults from natural tributary spawning populations.

Following the development of Hatchery and Genetic Management Plans (HGMPs), artificial supplementation programs are now characterized into three categories. The first type, integrated conservation programs, are intended to support or restore natural populations. These programs focus on increasing the natural production of targeted fish populations. A fundamental assumption of this strategy is that hatchery fish returning to the spawning grounds are reproductively similar to naturally produced fish. The second type, safety-net programs, are extensions of conservation programs, but are intended to function as reserve capacity for conservation programs in years of low returns. The safety-net provides a demographic and genetic reserve for the natural population. That is, in years of abundant returns they function like segregated programs, and in low return years they can be managed as conservation programs. Lastly harvest augmentation programs are intended to increase harvest opportunities while limiting interactions with wild-origin counterparts.

Monitoring is needed to determine if the hatchery programs are meeting the intended management objectives of conservation, safety-net, or harvest augmentation programs. Objectives for hatchery programs are generally grouped into three categories of performance indicators:

1. In-Hatchery: Is the program meeting the hatchery production objectives?

2. In-Nature: How do fish from the program perform after release?

    a. Conservation Program:
        i. How does the program affect target population abundance and productivity?
        ii. How does the program affect target population long-term fitness?

    b. Safety-Net Program:
        i. How does the program affect target population long-term fitness?

    c. Harvest Augmentation Program:
        i. Does the program provide harvest opportunities?

3. Risk Assessment: Does the program pose risks to other populations?

Objectives in this plan have been organized in a hierarchy where productivity indicators are the primary metrics used to assess if conservation and safety-net program goals have been met; harvest rates and effects on non-targeted populations are used for harvest programs. In cases where productivity indicators are not available or results are equivocal, monitoring indicators may be used to help evaluate the performance of the program. Evaluations of monitoring indicators may not provide sufficiently powerful conclusions on which to base management actions, although they may provide insight as to why a productivity indicator did or did not meet the program goal. Therefore, the relationship between hatchery programs and indicators can be viewed in a chain-of-causation: management actions within the hatchery programs affect the status of monitoring indicators, which in turn influence productivity indicators (Figure 1).

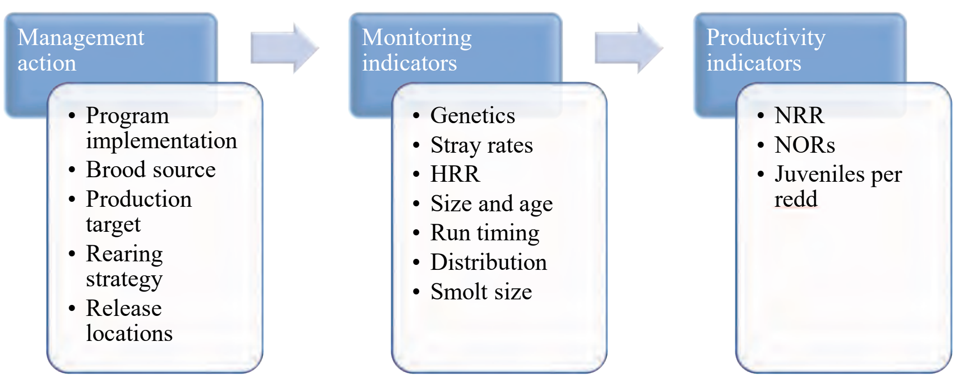

Figure 1. Relationship of indicators to the assessment of supplementation programs. Management actions affect monitoring indicators, which influence productivity indicators. Monitoring indicators may be used to hypothesize the magnitude of influence on productivity.

Deleted: 2013 Update

The primary goal of a conservation program is to contribute to the rebuilding and recovery of naturally reproducing populations within their native habitat. In this plan, natural replacement rates (NRR), recruitment of naturally-produced fish (NOR), and juvenile productivity (juveniles per redd) are important indicators for assessing the success of supplementation. These indicators are difficult to measure precisely and are quite variable in space and time. Therefore, monitoring indicators can be evaluated to help assess if productivity was related to the hatchery programs or other factors (Table 1).

A flow of information following sequential, logical steps will be employed to evaluate supplementation programs, consistent with the indicators described in Table 1. For example, a hatchery program, at a minimum, must be able to produce more adults per spawner than would occur in the natural environment. Should the program fail this test, hatchery operations should be evaluated to determine if improvements can correct the problem. If a program successfully replaces the required number of adults, it is then evaluated against a reference population or condition, if available, to determine if it has increased the overall number of naturally-spawning fish (including both hatchery- and natural-origin adults), increased the number of natural-origin spawners, and to test if productivity of the natural population has changed. When these goals are met, the program is considered successful. When these goals are not met, monitoring indicators may infer why the program is not achieving its goals

If suitable reference populations are not available, other comparisons can be used to help evaluate treatment responses. Evaluation of programs may pursue the following approaches:

- Comparison to reference population(s) that do not contain pre-treatment data
- Before treatment and after treatment comparisons
- Comparison to standard(s)
- Comparison to other suitable reference conditions

Methodologies for selecting reference streams, analyzing data from treatment and reference stream comparisons, and other comparisons are presented in Hillman et al. (2012).

The primary goals of a safety-net program are to provide demographic and genetic reserves for a population that is supplemented by a conservation program (Table 2). Harvest and adult management may be used to control escapement of spawners when appropriate. Monitoring focuses on estimating the number of fish that escape to spawn naturally and stray rates and in-hatchery performance evaluation.

The primary goal of a harvest augmentation program is to increase harvest opportunities, while segregating adults from natural spawning populations. In this plan, harvest opportunity, survival rates, and stray rates are important indicators for assessing the success of harvest augmentation. These indicators are more readily quantified compared to productivity indicators (Table 2). A flow of information will be employed to evaluate harvest augmentation programs. Since harvest augmentation programs are typically segregated, monitoring indicators will be used to determine the success of a program.

Deleted: 2013 Update

Both monitoring and productivity indicators will be used to evaluate the success of hatchery programs. In the event that the statistical power of tests that involve productivity indicators is insufficient to inform sound management decisions, some of the monitoring indicators may be used to guide management. The overarching goals of conservation, safety-net, and harvest augmentation programs, as described above, are provided below in greater detail. The flow chart (Figure 3) shows the relationship of overarching program goals, the strategies used to meet the goals, the monitoring and evaluation objectives used to evaluate the strategies and determine if goals are being met, and the adaptive management cycle associated with the programs. See Tables 1 and 2 for the indicators under each objective. The logic depicted in this flow chart shall be used to assess M&E results and apply those results to management decisions. Table 4 presents the current hatchery programs releasing fish in the Upper Columbia Basin.

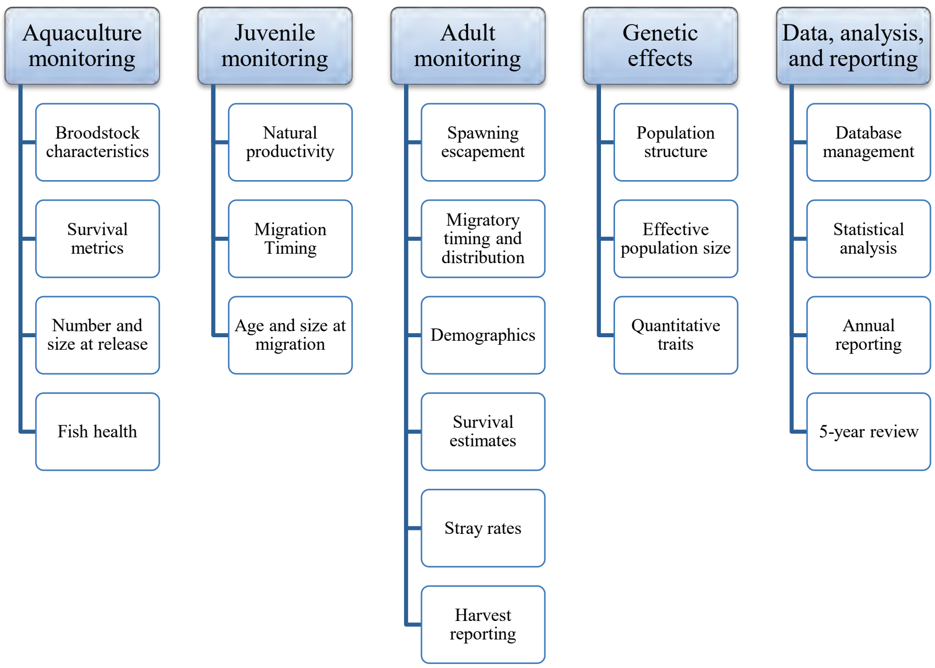

Figure 2. Overview of Monitoring and Evaluation Plan Categories and Components (not including regional objectives).

[8] Planned to increase within the next 5 years.

OBJECTIVES, QUESTIONS, AND HYPOTHESES

Productivity Indicators: Adults

Objective 1: Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.

At the core of a conservation program is the objective of increasing the number of spawning adults (i.e., the combined number of naturally produced and hatchery fish) in order to affect a subsequent increase in the number of returning naturally produced fish or natural origin recruits (NOR). In order for the natural population to remain stable or to increase, the Natural Replacement Rate (NRR), or the ratio of NORs to the parent spawning population, must be at a level where parents are being replaced by their offspring as spawners in the next generation. It is possible to affect an increase in natural origin spawners through supplementation with a stable or decreasing NRR. However, if the NRR is below replacement (NRR<1.0), termination of the supplementation program will result in a declining natural population should that state of NRR persist. The proportion of the hatchery-origin spawners (pHOS) that will increase natural production without creating adverse effects to the genetic diversity or reproductive success rate of the natural population is unknown, and may be dependent on how individual hatchery programs are operated, as well as available spawning and rearing habitat. Some programs may restrict pHOS to reduce the risk to the natural population with the intent of optimizing productivity, concomitantly reducing the overall number of spawners. All other objectives of the M&E Plan either directly support this objective or seek to minimize negative effects of the conservation programs on non-target stocks of concern.

Differences in carrying capacities of supplemented and non-supplemented streams can confound the analysis of the effects of supplementation on total number of spawners returning to the streams. For example, if the supplemented population is at carrying capacity and the non-supplemented population is not, the total number of spawners returning to the non-supplemented population may show an increasing trend over time, while the supplemented population would show no increasing trend. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on total spawners, density corrections should be included in the analyses. Hypotheses that may require density corrections are noted under each monitoring question.

1.1 Natural Replacement Rates of Supplemented[1] Populations (*Productivity Indicator*)

Monitoring Questions:

Q1.1.1 Has the supplementation program changed the adult productivity (NRRs) of the supplemented populations?[2]

Target Species/Populations:

- Q1.1.1 applies to all conservation and safety-net stocks.

Statistical Hypotheses 1.1.1[3]:

- $Ho_{1.1.1.1}$: Slope in NRRs before supplementation ≤ slope in NRRs after supplementation.
- $Ho_{1.1.1.2}$: Differences in slopes in NRRs between supplemented and reference populations before supplementation ≤ differences in slopes in NRRs between supplemented and reference populations after supplementation.
- $Ho_{1.1.1.3}$: Mean NRRs before supplementation ≤ mean NRRs after supplementation.
- $Ho_{1.1.1.4}$: Mean ratio scores in NRRs before supplementation ≤ Mean ratio scores in NRRs during supplementation.
- $Ho_{1.1.1.5}$: Mean ratio scores in NRRs (adjusted for density dependence) before supplementation ≤ Mean ratio scores in NRRs (adjusted for density dependence) during supplementation. [This hypothesis adjusts NRRs for density-dependent effects (see Hillman et al. 2012 for details; Appendix 7).]
- $Ho_{1.1.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds
- Number of naturally produced fish harvested

Derived Variables:

- Number of naturally produced recruits by brood year for both naturally produced parents and hatchery parents (≥age-3).
- NRRs (calculated as NORs/spawner).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NRRs (requires reference population[s]).
- Includes calculation of ratios NORs (requires reference population).
- Appendix 1: Spawning escapement and carrying capacity information (as applicable)

[1] Supplementation programs may include a safety net component.
[2] Because adult productivity is affected by the abundance of the population (i.e., productivity decreases with increasing abundance), the goal of supplementation is to increase or maintain productivity, but not decrease it.
[3] Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 7) for details.

Spatial/Temporal Scale:
- Calculated annually based on brood year.
- Time series.

Possible Statistical Analysis:
- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 7). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NRRs.
- On a five-year period, correlate productivity with extraneous factors such as ocean productivity indices.

Analytical Rules:
- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

1.2 Natural Origin Recruits of Supplemented Populations (*Productivity Indicator*)

Monitoring Questions:

Q1.2.1: Has the supplementation program changed the abundance of NORs within the supplemented population?

Target Species/Populations:
- Q1.2.1 applies to all supplemented or safety net stocks.

Statistical Hypotheses 1.2.1[4]:
- $Ho_{1.2.1.1}$: Slope in NORs[5] before supplementation ≥ slope in NORs after supplementation.
- $Ho_{1.2.1.2}$: Differences in slopes in NORs between supplemented and reference populations before supplementation ≥ differences in slopes in NORs between supplemented and reference populations after supplementation.
- $Ho_{1.2.1.3}$: Mean NORs before supplementation ≥ mean NORs after supplementation.
- $Ho_{1.2.1.4}$: Mean ratio scores in NORs before supplementation ≥ Mean ratio scores in NORs during supplementation.
- $Ho_{1.2.1.5}$: Mean ratio scores in NORs/Maximum Recruitment before supplementation ≥ Mean ratio scores in NORs/Maximum Recruitment during supplementation. [This hypothesis adjusts NORs for the capacity of the habitat; it tests the fraction of the habitat saturated with NORs (see Hillman et al. 2012 for details).]

[4] Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 7) for details.
[5] "Slope in NORS" refers to abundance of NORs across time (years).

- $Ho_{1.2.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and NORs; rho = 0. [If there is a significant negative association between pHOS and NORs, then hatchery fish may be reducing the reproductive success of the wild population.]

Measured Variables:
- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish taken for broodstock.
- Number of hatchery and naturally produced fish taken in harvest (if recruitment is to the Columbia).

Derived Variables:
- NORs (number of naturally produced recruits (total recruits) by brood year for both naturally produced parents and hatchery parents [≥age-3]).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NORs (requires reference population[s]).
- Estimates of carrying capacity.

Spatial/Temporal Scale:
- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:
- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NORs.
- On a five-year period, correlate NORs with extraneous factors such as ocean productivity indices.

Analytical Rules:
- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

Deleted: 2013 Update

Productivity Indicators: Freshwater Environment

Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.

Out-of-basin effects (e.g., smolt passage through the hydro system, harvest, and ocean productivity, etc.) influence the survival of smolts after they migrate from the tributaries. These effects introduce substantial variability into the adult-to-adult survival rates (NRRs and HRRs) and may mask in-basin effects (e.g., habitat quality, density-dependent mortality, and differential reproductive success of hatchery and naturally produced fish). Therefore, an estimate of freshwater productivity may help inform the performance of hatchery and natural origin spawners.

The objective of estimating freshwater productivity in the Upper Columbia ESU/DPS is to estimate the survival from egg to a critical juvenile life stage(s) of target stocks. Smolt or juvenile production models generated from the information obtained through these programs will provide a level of predictability with greater sensitivity to in-basin effects than spawner-recruitment models that take into account all effects.

Differences in the current carrying capacities of supplemented and non-supplemented streams can confound the effects of supplementation on numbers of juveniles per redd. For example, if the supplemented population is at or above carrying capacity and the non-supplemented population is not, numbers of juveniles per redd in the non-supplemented population may be significantly greater than the number of juveniles per redd in the supplemented population. In addition, pHOS may be correlated with overall spawner abundance. In these cases, it is difficult or impossible to separate density-dependent effects from the influence of pHOS on freshwater productivity. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on juveniles per redd, the capacity of the habitats must be included in the analyses. The Supplementary Hypotheses presented below are designed to address the confounding effects of different densities on the analyses.

2.1 Juvenile Productivity (*Productivity Indicator*)

Monitoring Questions:

Q2.1.1: Has the supplementation program changed the number of juveniles (smolts, parr, and/or emigrants) per redd within the supplemented population?

Q2.2.1: Does the number of juveniles per redd decrease as the proportion of hatchery spawners increases?[6]

Target Species/Populations:

- Both Q2.1.1 and Q2.2.1 apply to all conservation stocks.

[6] Information is needed to estimate the effects of density dependence on these questions. Consider spatial distribution of redds.

Statistical Hypotheses for 2.1.1[7]:

- $Ho_{2.1.1.1}$: Slope in juveniles/redd before supplementation ≤ slope in juveniles/redd after supplementation.
- $Ho_{2.1.1.2}$: Differences in slopes in juveniles/redd between supplemented and reference populations before supplementation ≤ differences in slopes in juveniles/redd between supplemented and reference populations after supplementation.
- $Ho_{2.1.1.3}$: Mean juveniles/redd before supplementation ≤ mean juveniles/redd after supplementation.
- $Ho_{2.1.1.4}$: Mean ratio scores in juveniles/redd before supplementation ≤ Mean ratio scores in juveniles/redd during supplementation.
- $Ho_{2.1.1.5}$: Mean ratio scores in juveniles/redd (adjusted for density dependence) before supplementation ≤ Mean ratio scores in juveniles/redd (adjusted for density dependence) during supplementation. [This hypothesis adjusts juveniles/redd for density-dependent effects (see Hillman et al. 2012 for details; Appendix 7).]
- $Ho_{2.1.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

Statistical Hypotheses for 2.2.1:

- $Ho_{2.2.1.1}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]
- $Ho_{2.2.1.2}$: The slope between proportion of hatchery spawners and juveniles/redd is ≥ 0.

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Numbers of redds.
- Number of juveniles (smolts, parr [where appropriate], and emigrants).

Derived Variables:

- Number of juveniles per spawner.
- Number of juveniles per redd.
- Carrying capacity.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

[7] Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 for details.

- These analyses shall be performed every five-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 7). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and juveniles/redd.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

Deleted: 2013 Update

Monitoring Indicators: Natural Environment

Objective 3: Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.

The survival advantage from the hatchery (i.e., egg-to-smolt) must be sufficient to produce a greater number of returning adults than if broodstock were left to spawn naturally. If a hatchery program cannot produce a greater number of adults than naturally spawning fish, then the program should be modified or discontinued. Production levels were initially developed using historical run sizes and smolt-to-adult survival rates (BAMP 1998). Using the stock specific NRR and agreed upon target values (see Appendix 2), comparisons to actual survival rates will be made to ensure the expected level of survival has been achieved.

Deleted: e.g. values listed in the BAMP or derived from other sources

3.1 Hatchery Replacement Rates (HRRs) (*Monitoring Indicator*)

Monitoring Questions:

Q3.2.1: Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the adult-to-adult survival rate (NRR) of naturally produced fish?

Q3.2.2: Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the Target Value identified in Appendix 2[8]?

Target Species/Populations:

- Q3.2.1 applies to all conservation stocks.
- Q3.2.2 applies to all stocks.

Statistical Hypothesis 3.2.1:

- $Ho_{3.2.1.1}$: $HRR_{\text{Year } x} \geq NRR_{\text{Year } x}$

Statistical Hypothesis 3.2.2:

- $Ho_{3.2.2.1}$: HRR ≥ Target Value identified in Appendix 2

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish harvested.
- Number of hatchery and naturally produced fish collected for broodstock.
- Number of broodstock used by brood year (hatchery and naturally produced fish).

Derived Variables:

- Number of hatchery and naturally produced adults by brood year (≥age-3).
- HRR (number of returning adults per brood year/broodstock)
- NRR (from Objective 1)
- Appendix 2: HRR targets identified in Appendix 2

[8] Target values may be adjusted by the hatchery committees.

Deleted: 2013 Update

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- For Q3.2.1 use graphic analysis and paired-sample quantile tests to compare HRR to NRR
- For Q3.2.2 use graphic analysis and one-sample quantile tests to compare HRR to the target value.
- On a five-year period, correlate HRRs with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Objective 4: Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.

Certain hatchery programs have pHOS or PNI targets, while others do not. HGMPs and permits inform the selection of targets, which are identified in Appendix 3.

4.1 Attainment of proportion of hatchery-origin spawners (pHOS or PNI) target (*Monitoring Indicator*)

Monitoring Questions:

Q4.1.1: Is the estimated proportion of hatchery-origin spawners (pHOS) less than or equal to the management target, and/or, is the estimated Percent Natural Influence (PNI) greater than or equal to the management target identified in Appendix 3?

Target Species/Populations:

- Q4.1.1 applies to all conservation and safety-net stocks that have a defined pHOS or PNI target or sliding scale (see Appendix 3).

Statistical Hypothesis 4.1.1:

- $Ho_{4.1.1.1}$: pHOS > target value or $PNI_{\text{Supplemented population}}$ < target value identified in Appendix 3

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds

Derived Variables:

- pHOS or PNI
- Appendix 3: PNI and pHOS targets and sliding scales identified in Appendix 3

Deleted: (as applicable)

Deleted: 2013 Update

Spatial/Temporal Scale:
- Calculate annually.
- Analyzed as time series.

Possible Statistical Analysis:
- Use graphic analysis and summary statistics to compare pHOS or PNI to the target value in Appendix 3.

Analytical Rules:
- This is a monitoring indicator that will be used to support management decisions.

Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.

Strategies for conservation programs typically intend that hatchery and natural-origin fish spawn together and in similar locations. However, in some cases, strategies may differ from this paradigm (e.g., summer Chinook salmon in the Wenatchee and Methow rivers; see Appendix 4). Phenotypic plasticity or selection resulting from the hatchery environment (i.e., domestication) may affect run (migration) timing, spawn timing, and spawning distribution. If conservation programs do not adequately represent the genetic diversity of the natural population, and if phenotypic traits in supplementation fish related to fitness deviate from the naturally produced spawning population, the goals of supplementation may not be achieved. Hatchery adults that migrate and/or spawn at different times or are spatially segregated from natural-origin fish may be subject to reduced fitness. Hatchery adults that spawn at different times or locations than natural-origin fish would be reproductively isolated from the natural population. The extent of such isolation, ranging from no isolation to substantial isolation, may be exploited for management purposes in some cases.

Deleted: ly produced

Deleted: R

Deleted: Run (migration) timing, spawn timing, and spawning distribution may be affected via

Deleted: p

Deleted: ly produced

Deleted: ly produced

5.1 Migration Timing (*Monitoring Indicator*)

Monitoring Questions:

Q5.1.1: Is the migration timing of hatchery and naturally produced fish from the same age class similar?

Target Species/Populations:
- Q5.1.1 applies to all conservation stocks.

Statistical Hypotheses 5.1.1:
- Ho$_{5.1.1.1}$: Migration timing $_{\text{Hatchery Age X}}$ = Migration timing $_{\text{Naturally produced Age X}}$
- Ho$_{5.1.1.2}$: The cumulative frequency of migration timing of hatchery-origin fish = the cumulative frequency of migration timing of natural-origin fish.

Deleted: 2013 Update

- $Ho_{5.1.1.3}$: The 10th percentile, 50th percentile (mode), 90th percentile, and mean migration timing of hatchery-origin fish = the 10th percentile, 50th percentile (median), 90th percentile, and mean migration timing of natural-origin fish.

Measured Variables:
- Ages of hatchery and naturally produced fish sampled via pit tags or stock assessment monitoring.
- Time (Julian date) of arrival at mainstem projects and within tributaries (e.g., traps, PIT arrays) with the intent to identify biologically significant differences.

Derived Variables:
- Mean Julian date for a given age class.

Spatial/Temporal Scale:
- Calculate annually based on return year and age class.
- Time series.

Possible Statistical Analysis:
- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.

Analytical Rules:
- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

5.2 Timing of Spawning (*Monitoring Indicator*)

Monitoring Questions:

Q5.2.1: Is the timing of spawning similar for conservation hatchery and naturally produced fish?

Target Species/Populations:
- Q5.2.1: Applies to all semelparous species and populations supplemented by conservation programs. Steelhead can only be assessed for natural spawning in situations where hatchery and natural origin fish can be appropriately marked and detected.

Statistical Hypotheses 5.2.1:
- $Ho_{5.2.1.1}$: The cumulative frequency of spawn timing of hatchery-origin fish = the cumulative frequency of spawn timing of natural-origin fish.
- $Ho_{5.2.1.2}$: The 10th percentile, 50th percentile (mode), 90th percentile, and mean spawn timing of hatchery-origin fish = the 10th percentile, 50th percentile (mode), 90th percentile, and mean spawn timing of natural-origin fish.
- $Ho_{5.2.1.3}$: The relationship between elevation and spawn timing of hatchery-origin fish = the relationship between elevation and spawn timing of natural-origin fish.

Deleted: 2013 Update

Measured Variables:

- Time (Julian date) and elevation (m) of hatchery and naturally produced salmon carcasses or marked steelhead detected on spawning grounds within defined reaches.
- Time (Julian date) of ripeness of hatchery and natural origin steelhead captured for broodstock.

Derived Variables:

- Mean Julian date.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.
- Graphic and regression analysis to assess relationships between elevation and spawn timing.

Deleted: ANCOVA with elevation as a covariate

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

5.3 Spatial Distribution of Redds (*Monitoring Indicator*)

Monitoring Questions:

Q5.3.1: Is the distribution of redds similar for conservation hatchery and naturally produced fish?

Q5.3.2: Is the distribution of redds similar to defined management targets (see Appendix 4)?

Target Species/Populations:

- Q5.3.1 applies to all conservation program stocks.
- Q5.3.2 applies only to conservation program stocks with specific spawning distribution targets (Carlton and Dryden summer Chinook programs; Appendix 4).

Deleted: Table 5.3.1

Statistical Hypothesis 5.3.1:

- $Ho_{5.3.1.1}$: The distribution of hatchery-origin redds (hatchery females) = the distribution of natural-origin redds (natural-origin females).

Statistical Hypothesis 5.3.2:

- $Ho_{5.3.2.1}$: The distribution of hatchery-origin redds (hatchery females) = the target distribution identified in Appendix 4.

Deleted: Tables 5.3.1

Deleted: 2013 Update

Measured Variables:

- Location (GPS coordinate) of female salmon carcasses observed on spawning grounds. The distribution of hatchery and naturally produced steelhead redds may be evaluated if marking or tagging efforts provide reasonable results.

Derived Variables:

- Location of female salmon carcass at the historic reach scale and at the 0.1 km scale.
- Calculate percent overlap in distribution across available spawning habitat or historical reaches.
- Appendix 4: Management targets for spatial distribution of spawners or redds (as applicable).

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates' Chi-square analysis for both Q5.3.1 and Q5.3.2.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Objective 6: Determine if the recipient stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.

Maintaining locally adapted traits among independent fish populations requires that returning hatchery fish have a high rate of site fidelity to the target population or stream. Hatchery practices (e.g., imprinting on water sources at key life history stages, release methodology, release location, age at return, and environmental conditions) are the main variables thought to affect stray rates. Regardless of the magnitude of homing of adult returns, if adult hatchery fish do not contribute to the natural population, the program will not meet the basic condition of a supplementation program.

Deleted: r

Independent populations are populations that are genetically differentiated from other populations. In some cases, genetic differentiation may be assumed based on phenotypic traits or geographic isolation when molecular genetics analyses are not available. When populations are not independent, straying among them does not pose a risk of genetic homogenization. In addition, stray rates of hatchery-origin fish cannot be expected to be lower than for natural-origin fish. When estimates of stray rates for natural-origin fish are available and if they exceed the 5% among population stray rate or 10% within population stray rate thresholds identified in this plan, analysis and interpretation of stray rates must take into account the concept that hatchery programs may be held to unattainable standards based on the natural stray rate. Current criteria established by the ICBTRT (2005) and the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) indicate that fish that do stray to other non-target populations

Deleted: 2013 Update

should not comprise greater than 5% of the non-target spawning population. Likewise, fish that stray into non-target spawning areas within an independent population should not comprise greater than 10% of the non-target spawning aggregate (see Tables 6.1 and 6.2).

This plan identifies three stray rate metrics; brood-year stray rate, among population return-year stray rate, and within population return-year stray rate. The return-year stray rates have specific targets that are from the ICBTRT (2005) and Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007), and are linked to extinction risk. That is, hatchery strays from other populations cannot make up more than 5% of the spawning escapement within a non-target, recipient population. In addition, hatchery strays from other spawning aggregations within a population (e.g., Chiwawa spring Chinook) cannot make up more than 10% of the spawning escapement within a non-target, recipient spawning aggregate (e.g., Peshastin Creek). Brood-year stray rate, on the other hand, is not discussed in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) or ICBTRT (2005) and therefore has no specific target. Nevertheless, it is important to track brood-year stray rates to determine if hatchery operations affect the homing and straying of specific brood years. These data support the return-year stray metrics and are used to explain possible changes in genetic variation among stocks.

Deleted: ¶

6.1.1 Brood-Year Stray Rates (*Monitoring Indicator*)

Deleted: among Populations by Brood Return

Monitoring Questions:

Q6.1.1: What is the brood-year stray rate of hatchery fish?

Deleted: I

Deleted: less than 5% for the total brood return

Target Species/Populations:

- Q6.1.1 applies to all hatchery stocks.

Statistical Hypothesis 6.1.1:

- $Ho_{6.1.1.1}$: None.

Deleted: Stray rate of hatchery fish ≥ 5% of total hatchery brood return

Measured Variables:

- Number of hatchery carcasses found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.
- Number of hatchery fish collected for broodstock.
- Number of hatchery fish taken in fishery.
- Locations of live and dead strays (used to tease out overshoot).

Derived Variables:

- Total number of hatchery carcasses and take in fishery estimated from expansion analysis.
- Percent of the total brood return that strays.
- Appendix 5: Reciprocal stray rates

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Deleted: 2013 Update

Possible Statistical Analysis:
- Use graphical analysis to track brood-year stray rates over time.

Deleted: and one-sample quantile tests to compare the estimated stray rate with the target (5%) stray rate.

Analytical Rules:
- This is a monitoring indicator that will be used to support management decisions.

Deleted: <#>Type I Error of 0.05.¶

6.2 Among Population Return-Year Stray Rates (*Monitoring Indicator*)

Deleted: Stray Rates a

Deleted: s by

Deleted:

Monitoring Questions:

Q6.2.1: Do hatchery strays make up less than 5% of the spawning escapement within other non-target independent populations?

Target Species/Populations:
- Q6.2.1 applies to all hatchery stocks.

Statistical Hypothesis 6.2.1:
- $Ho_{6.2.1.1}$: Stray hatchery fish make up ≥ 5% of the spawning escapement (based on run year) within other independent populations [9]

Measured Variables:
- Number of hatchery carcasses (PIT-tagged steelhead) found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

Derived Variables:
- Total number of hatchery salmon carcasses (PIT-tagged steelhead, spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target population that is made up of hatchery strays.
- Appendix 5: Reciprocal stray rates

Spatial/Temporal Scale:
- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:
- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (5%) stray rate.

[9] This stray rate is suggested based on a literature review and recommendations by the ICBTRT (2005) and is identified in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007). It can be re-evaluated as more information on naturally-produced Upper Columbia salmonids becomes available. This will be evaluated on a species and program specific basis and decisions made by the HCP HC. It is important to understand the actual spawner composition of the population to determine the potential effect of straying.

Deleted: 2013 Update

Analytical Rules:
- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

6.3 Within Population Return-Year Stray Rates (*Monitoring Indicator*)

Deleted: among Spawning Areas within the Population

Monitoring Questions:

Q6.3.1: Do hatchery strays make up less than 10% of the spawning aggregate within non-target spawning areas within the target population?[10]

Target Species/Populations:
- Q6.3.1 applies to all hatchery stocks.

Statistical Hypothesis 6.3.1:
- $Ho_{6.3.1}$: Stray hatchery fish make up ≥ 10% of spawning escapement (based on run year) within non-target spawning areas within the target population

Measured Variables:
- Number of hatchery carcasses (possibly PIT-tagged steelhead) found in non-target and target spawning aggregates or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

Derived Variables:
- Total number of hatchery salmon carcasses (possibly PIT-tagged steelhead or spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target spawning aggregate that is made up of hatchery strays.
- Appendix 5: Reciprocal stray rates

Spatial/Temporal Scale:
- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:
- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (10%) stray rate.

Analytical Rules:
- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

[10] The value of 10% should be reviewed by the Hatchery Committee. See footnote 3 for additional information.

Monitoring Indicators: Population Genetics

Objective 7: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.

The genetic component of the M&E Plan specifically addresses the potential for changes in genetic diversity in natural populations as a result of a hatchery program(s). The long-term fitness of populations is assumed to be related to maintaining the genetic diversity of natural populations. However, hatchery programs select a subset of individuals from the population to pass on genetic material to the next generation. This is often a relatively small number of individuals that produce a large number of offspring, and can result in changes in allele frequencies and reductions of effective population size. Therefore, it is important to monitor the genetic status of the natural populations to determine if there are signs of changes in genetic distance among populations, changes in allele frequencies, and to estimate effective population size. Assessing the genetic effects of the hatchery program does not require annual sampling. Meeting stray-rate targets (hypotheses tested under Objective 5) should reduce significant changes in population genetics. Stray rates may inform population genetic analyses. Testing statistical hypotheses associated with genetic components (Hypotheses 3.1, 3.2, and 3.3) should be conducted every ten years or two generations.

7.1 Allele Frequency (*Monitoring Indicator*)

Monitoring Questions:

Q7.1.1: Is the allele frequency of hatchery fish similar to the allele frequency of naturally produced and donor fish?

Target Species/Populations:

- Q7.1.1 applies to all conservation stocks.

Statiscial Hypotheses 7.1.1:

- $Ho_{7.1.1}$: Allele frequency $_{\text{Hatchery}}$ = Allele frequency $_{\text{Naturally produced}}$ = Allele frequency $_{\text{Donor pop.}}$
- $Ha_{7.1.1}$: Allele frequency $_{\text{Hatchery}}$ ≠ Allele frequency $_{\text{Naturally produced}}$ = Allele frequency $_{\text{Donor pop.}}$ or
- $Ha_{7.1.1}$: Allele frequency $_{\text{Hatchery}}$ = Allele frequency $_{\text{Naturally produced}}$ ≠ Allele frequency $_{\text{Donor pop.}}$ or
- $Ha_{7.1.1}$: Allele frequency $_{\text{Hatchery}}$ ≠ Allele frequency $_{\text{Naturally produced}}$ ≠ Allele frequency $_{\text{Donor pop.}}$

Measured Variables:

- Microsatellite genotypes or SNP genotypes, as appropriate

Derived Variables:

- Allele frequency

Spatial/Temporal Scale:
- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples within drainages.

Possible Statistical Analysis:
- Population differentiation tests, analysis of molecular variance (AMOVA), and relative genetic distances.

Analytical Rules:
- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

7.2 Genetic Distances Between Populations (*Monitoring Indicator*)

Monitoring Questions:

Q7.2.1: Does the genetic distance among subpopulations within a supplemented population remain the same over time?

Target Species/Populations:
- Q7.2.1 applies to all conservation and safety-net stocks.

Statistical Hypothesis 7.2.1:
- $Ho_{7.2.1.1}$: Genetic distance between subpopulations $_{\text{Year } x}$ = Genetic distance between subpopulations $_{\text{Year } y}$

Measured Variables:
- Microsatellite genotypes or SNP genotypes

Derived Variables:
- Allele frequencies

Spatial/Temporal Scale:
- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples among spawning aggregates.

Possible Statistical Analysis:
- Population differentiation tests, AMOVA, and relative genetic distances.

Analytical Rules:
- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Deleted: 2013 Update

7.3 Effective Spawning Population (*Monitoring Indicator*)

Monitoring Questions:

Q7.3.1: Is the ratio of effective population size (N_e) to spawning population size (N) constant over time?

Target Species/Populations:

- Q7.3.1 applies to all supplemented stocks.

Statistical Hypothesis 3.3:

- $Ho_{7.3.1.1}$: $(N_e/N)_{t0} = (N_e/N)_{t1}$ for each population

Measured Variables:

- Microsatellite genotypes or SNP genotypes

Derived Variables:

- Allele frequencies

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.

Possible Statistical Analysis:

- Population differentiation tests, relative genetic distances, statistics to calculate effective population size (e.g., harmonic means).

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Monitoring Indicators: Phenotypic Traits

Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

Fitness, or the ability of individuals to survive and pass on their genes to the next generation in a given environment, includes genetic, physiological, and behavioral components.[11] Maintaining the long-term fitness of supplemented populations requires a comprehensive evaluation of genetic and phenotypic characteristics. Evaluation of some phenotypic traits (i.e., run timing, spawn timing, spawning location, and stray rates) is addressed under Objective 5. Objective 8 assess the potential effects of domestication, including size at maturity, age at maturity, sex ratio, and fecundity. Age and size at maturity shall be assessed for both fish arriving in the Columbia system, and those recovered on the spawning grounds. Size (or age) selective mortality during migration through the Columbia system, such as through fisheries, could alter the age and size of fish on the spawning grounds.

8.1 Age at Maturity (*Monitoring Indicator*)

Monitoring Questions:

Q8.1.1: Is the age at maturity of hatchery and naturally produced fish similar at the time they enter the Columbia River and when they spawn?

Target Species/Populations:

- Q8.1.1 applies to all conservation program stocks.

Statistical Hypotheses 8.1.1:

- $Ho_{8.1.1.1}$: Age at Maturity $_{\text{Hatchery produced spawners Gender X}}$ = Age at Maturity $_{\text{Naturally produced spawners Gender X}}$
- $Ho_{8.1.1.2}$: Age at Maturity $_{\text{All hatchery produced adults Gender X}}$ = Age at Maturity $_{\text{All naturally produced adults Gender X}}$

Measured Variables:

- Total and salt (ocean) age of hatchery and naturally produced salmon carcasses collected on spawning grounds.
- Total and salt age of broodstock.
- Total and salt age of fish at stock assessment locations (e.g., Dryden, Tumwater, Wells, Priest Rapids).
- Whenever possible, age at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).
- Assess age of fish, including harvested fish.

[11] These metrics are difficult to measure, and phenotypic expression of these traits may be all we can measure and evaluate.

Deleted: 2013 Update

Derived Variables:
- Total age and saltwater age
- Age of fish entering the Columbia River.

Spatial/Temporal Scale:
- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:
- Use graphic analysis and Yates' Chi-square.

Analytical Rules:
- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

8.2 Size at Maturity (*Monitoring Indicator*)

Monitoring Questions:

Q8.2.1: Is the size (length) at maturity of a given age and sex of hatchery fish similar to the size at maturity of a given age and sex of naturally produced fish?

Target Species/Populations:
- Q8.2.1 applies to all conservation and safety-net stocks.

Statistical Hypothesis 8.2.1:
- $Ho_{8.2.1.1}$: Size (length) at Maturity $_{\text{Hatchery Age X and Gender Y}}$ = Size (length) at Maturity $_{\text{Naturally produced Age X and Gender Y}}$
- $Ho_{8.2.1.2}$: Size (length) at Maturity $_{\text{All hatchery adults Gender X}}$ = Size (length) at Maturity $_{\text{All naturally produced adults Gender X}}$

Measured Variables:
- Size (length), age, and gender of hatchery and naturally produced salmon carcasses collected on spawning grounds.
- Size (length), age, and gender of broodstock.
- Size (length), age, and gender of fish at stock assessment locations (e.g., Priest Rapids, Dryden, Tumwater, Wells, Twisp Weir).
- Whenever possible size at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).

Derived Variables:
- Total age and saltwater age

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:
- Use graphic analysis and three-way ANOVA by origin, gender, and age

Analytical Rules:
- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

8.3 Fecundity at Size (*Monitoring Indicator*)[12]

Monitoring Questions:

Q8.3.1: Is the fecundity vs. size relationship of hatchery and naturally produced fish similar?

Q8.3.2: Is the gonadal mass vs. size relationship of hatchery and naturally produced fish similar?

Target Species/Populations:
- Both Q8.3.1 and Q8.3.2 apply to all conservation stocks using both natural- and hatchery-origin broodstock.

Statistical Hypothesis 8.3.1:
- $Ho_{8.3.1.1}$: Slope of Fecundity vs. Size $_{Hatchery}$ = Slope of Fecundity vs. Size $_{Naturally\ produced}$

Statistical Hypothesis 8.3.2:
- $Ho_{8.3.2.1}$: Gonadal Mass vs. Size $_{Hatchery}$ = Gonadal Mass vs. Size $_{Naturally\ produced}$

Measured Variables:
- Length, weight, and age (covariate) of hatchery and natural-origin broodstock after eggs have been removed.
- Number and weight of eggs

Derived Variables:
- Total age and saltwater age.
- Mean weight per egg.

Spatial/Temporal Scale:
- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

[12] May not apply to all programs.

- Use graphic analysis, regression, t-test, and ANCOVA.

Analytical Rules:
- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

8.4 Sex Ratio (*Monitoring Indicator*)

Monitoring Questions:

Q8.4.1: Is the sex ratio of hatchery and naturally produced fish similar?

Target Species/Populations:
- Q8.4.1 applies to all conservation stocks.

Statistical Hypothesis 8.4.1:
- $Ho_{8.4.1.1}$: Sex Ratio $_{\text{Hatchery}}$ = Sex Ratio $_{\text{Naturally produced}}$

Measured Variables:
- Age and sex of hatchery and naturally produced salmon carcasses collected on spawning grounds or sampled at dams or weirs.
- Whenever possible sex ratio will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling or ultrasound on live fish).

Derived Variables:
- Ratio of sexes based on brood year returns

Spatial/Temporal Scale:
- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:
- Use graphic analysis and Yates'Chi-square.

Analytical Rules:
- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Deleted: 2013 Update

Monitoring Indicators: Hatchery Environment

<u>Objective 9</u>: Determine if hatchery fish were released at the programmed size and number.

The HCP outlines the number and size of fish that are to be released to meet NNI and inundation compensation levels. The size of the fish at release may be altered according to an adaptive management process in the Hatchery Committee(s), and the number of fish can be altered by survival study results and adjustment of hatchery production for population dynamics. Size of fish at release can affect survival, sex ratios, age at return, stray rate, and fecundity. In addition, the variation in size at release may affect performance of the fish.

The coefficient of variation (CV) will be evaluated to ascertain if program performance is related to variation in size at release. Note also that variation in a population is a natural condition and striving to control this variation could result in directional or stabilizing artificial selection that could have unforeseen long-term consequences. Attaining uniform or multi-modal growth in a hatchery environment may not be adaptive for fitness in the wild. Therefore, pursuit of a CV target should be seen as an informative exercise, but is not in itself indicative of success or failure of a hatchery program. Furthermore, growth regimes may prove to be important in affecting adult returns and age structure. Although many factors can influence both the size and number of fish released, past hatchery cultural experience with these stocks should assist in meeting program production levels. Appendix 5 presents the target size at release and CVs for the programs. These targets shall be assessed annually to ensure they are optimized to inform management decisions.

Deleted: Table 9.1

9.1 Size at Release of Hatchery Fish (*Monitoring Indicator*)

Monitoring Questions:

Q9.1.1: Is the size (length and weight) of hatchery fish released equal to the program goal?

Commented [TH1]: Do we need to add these to Appendix 5?

Target Species/Populations:

- Q9.1.1 applies to all hatchery stocks.

Statistical Hypothesis 9.1.1:

- $Ho_{9.1.1.1}$: Hatchery fish $_{\text{Size at release}}$ = Programmed $_{\text{Size at release}}$

Measured Variables:

- Fork length and weights of random samples of hatchery juveniles at release.

Derived Variables:

- Mean length (FL) and mean weight
- Appendix 6: Rearing targets

Spatial/Temporal Scale:

Deleted: 2013 Update

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated size of hatchery fish at time of release with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

9.2 Coefficient of Variation (CV) of Hatchery Fish Released (*Monitoring Indicator*)

Monitoring Questions:

Q9.2.1: Is the CV of hatchery fish released equal to the program target identified in Appendix 5?

Target Species/Populations:

- Q9.2.1 applies to all hatchery stocks.

Statistical Hypothesis 9.2.1:

- $Ho_{9.2.1.1}$: Hatchery fish CV $_{\text{at release}}$ = Programmed CV in Appendix 5

Measured Variables:

- Length and weights of random samples of hatchery smolts.

Derived Variables:

- Coefficient of Variation: $cv = (1 + 1/4n) \times (s/x)$ (where s = standard deviation, x = estimated mean, n = sample size)
- Appendix 5: Rearing targets

Deleted: 6

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated CV of size of hatchery fish released with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

9.3 Condition Factor (K) of Hatchery Fish Released (*Monitoring Indicator*)

Monitoring Questions:

Deleted: 2013 Update

Q9.3.1: Is the K of hatchery fish released equal to the program target identified in Appendix 5?

Commented [TH2]: At this time there is no program target for K.

Target Species/Populations:
- Q9.3.1 applies to all hatchery stocks.

Statistical Hypothesis 9.3.1:
- $Ho_{9.3.1.1}$: Hatchery fish $K_{\text{at release}}$ = Programmed K identified in Appendix 5

Measured Variables:
- Monthly individual lengths and weights of random samples of hatchery juveniles.

Derived Variables:
- Condition Factor: $K = W/L^3 \times 10^5$

Spatial/Temporal Scale:
- Calculate annually.
- Time series.

Possible Statistical Analysis:
- Use graphic analysis and descriptive statistics to compare the estimated K of released hatchery fish with the program goal.

Analytical Rules:
- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

9.4 Number of Hatchery Fish (*Monitoring Indicator*)

Monitoring Questions:

Q9.4.1: Is the number of hatchery fish released equal to the program goal identified in Appendix 2?

Commented [TH3]: Suggest putting the release targets in Appendix 5

Target Species/Populations:
- Q9.4.1 applies to all hatchery stocks.

Statistical Hypothesis 9.4.1:
- $Ho_{9.4.1.1}$: Hatchery Fish Number = Programmed Number identified in Appendix 2

Measured Variables:
- Numbers of smolts released from the hatchery.

Derived Variables:
- Appendix 2: Rearing targets

Deleted: 6

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and one-sample quantile tests to compare the estimated number of hatchery fish released with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Deleted: 2013 Update

Monitoring Indicators: Harvest

Objective 10: Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.

Harvest will be applied to different types of programs in an effort to achieve the management objectives of those programs. Programs designed to augment harvest should routinely contribute to harvest at a rate that greatly reduces the incidence of straying to natural spawning grounds, but also allows the program to be sustained. Safety-net programs may be harvested as part of an adult management strategy to minimize excessive escapement of hatchery-origin fish to spawning grounds. Similarly, conservation programs may undergo harvest to manage returning adults, but the emphasis for these programs should be to achieve escapement goals. In all cases, harvest effort should not have the unintended consequence of removing excessive numbers of conservation or natural-origin fish. In years when the expected returns of hatchery adults are above the level required to meet program goals (i.e., supplementation of spawning populations and/or brood stock requirements), surplus fish may be available for harvest. The M&E Plan specifically addresses harvest and harvest opportunities upstream of Priest Rapids Dam. Harvest or removal of surplus hatchery fish from the spawning grounds may assist in reducing potential adverse ecological and genetic impacts to natural populations (e.g., loss of genetic variation within and between populations, loss of fitness, reduced effective population size, and density-dependent effects).

10.1 Harvest Rates (*Monitoring Indicator*)

Monitoring Questions:

Q10.1.1: Conservation Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of conservation hatchery fish but low enough to sustain the hatchery program?

Q10.1.2: Safety-Net Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of safety-net hatchery fish but low enough to sustain the hatchery program?

Q10.1.3: Is the harvest on hatchery fish produced from harvest-augmentation programs high enough to manage natural spawning but low enough to sustain the hatchery program?

Q10.1.4: Is the escapement of fish from conservation and safety-net programs in excess of broodstock and natural production[13] needs to provide opportunities for terminal harvest?

Target Species/Populations:

- Q10.1.1 applies to conservation programs.
- Q10.1.2 applies to safety-net programs.
- Q10.1.3 applies harvest augmentation programs.

[13] The current best estimates of carrying capacity (maximum recruits) will be used, as available.

Deleted: 2013 Update

- Q10.1.4 applies to conservation and safety-net programs.

Statistical Hypothesis 10.1.1:
- $Ho_{10.1.1.1}$: Harvest rate ≤ Maximum level to meet program goals

Statistical Hypothesis 10.1.2:
- $Ho_{10.1.2.1}$: Harvest rate ≤ Maximum level to meet program goals

Statistical Hypothesis 10.1.3:
- $Ho_{10.1.3.1}$: Escapement ≤ Maximum level to meet supplementation goals

Statistical Hypothesis 10.1.4:
- $Ho_{10.1.4.1}$: Harvest rate ≤ Maximum level to meet program goals

Measured Variables:
- Numbers of hatchery fish taken in harvest.
- Numbers of natural-origin fish taken in harvest.

Derived Variables:
- Total harvest by fishery estimated from expansion analysis.

Spatial/Temporal Scale:
- Calculated annually.
- Time series.

Possible Statistical Analysis:
- Use graphic analysis and one-sample quantile tests to compare the estimated harvest of hatchery fish with the program goal.

Analytical Rules:
- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Regional Objectives

Hatchery programs have the potential to increase diseases that typically occur at low levels in the natural environment (Objective 9). In addition, hatchery fish can reduce the abundance, size, or distribution of non-target taxa through ecological interactions (Objective 10). These are important objectives that will be monitored at a later time. Analytical rules will be established for these objectives before monitoring activities begin.

Objective 11: Determine if the incidence of disease has increased in the natural and hatchery populations.

The hatchery environment has the potential to amplify diseases that are typically found at low levels in the natural environment. Amplification could occur within the hatchery population (i.e., vertical and horizontal transmission) or indirectly from the hatchery effluent or commingling between infected and non-infected fish (i.e., horizontal transmission). Potential impacts to natural populations have not been extensively studied, but should be considered for programs in which the hatchery fish are expected to commingle with natural fish. This is particularly important for supplementation type programs. Specifically, the causative agent of bacterial kidney disease (BKD), *Renibacterium salmoninarum* (Rs), could be monitored at selected acclimation ponds, both in the water and fish, in which the risk and potential for transmission from the hatchery is highest. Although it is technologically possible to measure the amount of Rs in water or Rs DNA in smolts and adults non-lethally sampled, the biological meaning of these data are uncertain. Currently, the only metric available for M & E purposes is measuring the antigen level from kidney/spleen samples (i.e., ELISA, PCR). When available, non-lethal sampling may replace or be used in concert with lethal sampling.

Implementation of this objective will be conducted in a coordinated approach within the hatchery and natural environment. BKD management within the hatchery population (e.g., broodstock or juveniles) has the potential to reduce the prevalence of disease through various actions (e.g., culling or reduced rearing densities). BKD management must also take into account and support other relevant objectives of the M & E program (e.g., Hatchery Return Rate [HRR], number of smolts released). Hence, the goal of BKD management is to decrease the prevalence of disease and maintain hatchery production objectives (i.e., number and HRR).

As previously discussed, disease transmission from hatchery to naturally produced fish may occur at various life stages and locations. Of these, horizontal transmission from hatchery effluent, vertical transmission on the spawning grounds, and horizontal transmission in the migration corridor have been identified as disease interactions that could be examined under this objective, although others may also be relevant. Experimental designs addressing this objective may require technology not yet available, although in some instances samples may be collected, but not analyzed until a link can be established between bacteria levels in samples and disease prevalence.

Deleted: 2013 Update

Developing a complete set of questions and hypotheses statements for this objective may not be practical at this time, because there is currently no BKD Management Plan. However, while developing experimental designs for this objective, it may be feasible to incorporate both hatchery and natural environment monitoring under a single study design. Integration of the different aspects of the objective would likely result in a more robust approach into understanding the effectiveness of disease management strategies.

Proposed Tasks:

T1: Assemble fish health data for fish used as brood (e.g., ELISA results).

T2: Conduct data exploration exercise to identify potential relationships between pathogen profiles and likely causative variables (e.g., rearing conditions and management actions).

T3: Develop hypotheses for potential testing to meet objective.

Objective 12: Determine if the release of hatchery fish affects non-target taxa of concern (NTTOC) within acceptable limits.

Ecological risks of Pacific salmon (spring, summer, and fall run Chinook, coho, and sockeye salmon) and steelhead trout hatchery programs operated between 2013 and 2023 in the Upper Columbia Watershed will be assessed using Delphi and modeling approaches. Committees composed of resource managers and public utility districts identified non-target taxa of concern (i.e., taxa that are not the target of supplementation), and acceptable hatchery impacts (i.e., change in population status) to those taxa. Biologists assembled information about hatchery programs, non-target taxa, and ecological interactions and this information will be provided to expert panelists in the Delphi process to facilitate assessment of risks and also used to populate the Predation, Competition, and Disease (PCD) Risk 1 model. Delphi panelists will independently estimate the proportion of a non-target taxa population that will be affected by each individual hatchery program. Estimates from each of the two approaches will be independently averaged, a measure of dispersion calculated (e.g., standard deviation), and subsequently compared to the acceptable hatchery impact levels that were determined previously by committees of resource managers and public utility districts. Measures of dispersion will be used to estimate the scientific uncertainty associated with risk estimates. Delphi and model results will be compared to evaluate the qualities of the two approaches. Furthermore, estimates of impacts from each hatchery program will be combined together to generate an estimate of cumulative impact to each non-target taxa.

The Hatchery Evaluation Technical Team (HETT) is currently addressing this objective. Work has been underway for several years. The study is expected to provide risk assessment using both an ecological modeling approach and a panel of expert opinion. These two methods will be compared to establish the potential to use modeling in place of expert panels to conduct such risk assessments in the future.

Deleted: 2013 Update

Adaptively Managing Using Monitoring and Evaluation Results

Because of naturally large variation in productivity indicators, several years of data may be required before statistical inferences can be made regarding the effects of hatchery fish on productivity of naturally produced fish. Furthermore, given the large natural variation of productivity indicators, productivity could increase or decrease as a result of the hatchery programs before a difference is detected statistically. In the interim, risk associated with supplementation programs and the productivity of naturally produced fish can be quantified based on observed natural variation in the indicator of interest (Table 1). If large differences in rates of change between supplemented and reference populations are observed, management actions may be required.

Assuming hatchery programs do not negatively affect the productivity of naturally produced fish, the observed difference in rates of change between the supplemented and reference populations should decrease over time as more of the natural variation within and between populations is incorporated into these data. More simply, as the number of years increases, the acceptable observed difference in the indicator(s) decreases. The value of the difference at any point in time would determine if management actions are warranted.

Glossary

Term	Definition
Adult-to-Adult survival (Ratio)	The number of parent broodstock relative to the number of returning adults.
Age at maturity	The age of fish at the time of spawning (hatchery or naturally)
Augmentation	A hatchery strategy where fish are released for the sole purpose of providing harvest opportunities.
Broodstock	Adult salmon and steelhead collected for hatchery fish egg harvest and fertilization.
Donor population	The source population for supplementation programs before hatchery fish spawned naturally.
Effective population size (Ne)	The number of reproducing individuals in an ideal population (i.e., Ne = N) that would lose genetic variation due to genetic drift or inbreeding at the same rate as the number of reproducing adults in the real population under consideration (Hallerman 2003).
ESA	Endangered Species Act passed in 1973. The ESA-listed species refers to fish species added to the ESA list of endangered or threatened species and are covered by the ESA.
Expected value	A number of smolts or adults derived from survival rates agreed to in the Biological Assessment and Management Plan (BAMP 1998).
Extraction rate	The proportion of the spawning population collected for broodstock.
Genetic diversity	All the genetic variation within a species of interest, including both within and between population components.
Genetic stock structure	A type of assortative mating, in which the gene pool of a species is composed of a group of subpopulations, or stocks, that mate panmictically within themselves.
Genetic variation	All the variation due to different alleles and genes in an individual, population, or species.
HCP	Habitat Conservation Plan is a plan that enables an individual or organization to obtain a Section 10 Permit which outlines what will be done to “minimize and mitigate” the impact of the permitted take on a listed species.
HCP-HC	Habitat Conservation Plan Hatchery Committee is the committee that directs actions under the hatchery program section of the HCP’s for Chelan and Douglas PUDs.
HRR	Hatchery Replacement Rate is the ratio of the number of returning hatchery adults relative to the number of adults taken as broodstock, both hatchery and naturally produced fish (i.e., adult-to-adult replacement rate).
Long-term fitness	Long-term fitness is the ability of a population to self-perpetuate over successive generation.
Naturally produced	Progeny of fish that spawned in the natural environment, regardless of the origin of the parents.
Mean Ratio	The ratio between a treatment and control population, with the mean taken across a time period, such as years. Used in analysis in Before-After-Control-Impact studies.
Ne	Effective population size

Deleted: 2013 Update

Non-target taxa of concern (NTTOC)	Species, stocks, or components of a stock with high value (e.g., stewardship or utilization) that may suffer negative impacts as a result of a hatchery program.
NRR	Natural replacement rate is the ratio of the number of returning naturally produced adults relative to the number of adults that naturally spawned, both hatchery and naturally produced.
NTTOC	Non-target taxa of concern.
pHOS	Proportion of Hatchery Origin Spawners
PNI	Proportionate Natural Influence
pNOB	Proportion of Natural Origin Broodstock
Productivity	The capacity in which juvenile fish or adults can be produced.
Reference population	A population in which no directed artificial propagation is currently directed, although may have occurred in the past. Reference populations are used to monitor the natural variability in survival rates and out of basin impacts on survival.
SAR	Smolt-to-adult survival rate
SAR Smolt-to-adult survival rate (SAR)	Smolt-to-adult survival rate is a measure of the number of adults that return from a given smolt population.
Segregated	A type of hatchery program in which returning adults are spatially or temporally isolated from other populations.
Size-at-maturity	The length or weight of a fish at a point in time during the year in which spawning will occur.
Smolts per redd	The total number of smolts produced from a stream divided by the total number of redds from which they were produced.
Spawning Escapement	The number of adult fish that survive to spawn.
Stray rate	The rate at which fish spawn outside of natal rivers or the stream in which they were released.
Supplementation	A hatchery strategy where the main purpose is to increase the relative abundance of natural spawning fish without reducing the long-term fitness of the population.
Target population	A specific population in which management actions are directed (e.g., artificial propagation, harvest, or conservation).

Methods for Identifying Reference Populations and Testing Differences in Abundance and Productivity between Reference Populations and Supplemented Populations: Chiwawa Spring Chinook Case Study

T. Hillman
A. Murdoch
T. Pearsons
M. Miller
G. Mackey

September 2011

An important goal of supplementation is to increase spawning abundance and natural-origin recruitment of the supplemented population, and not reduce the productivity of the supplemented population. Indeed, a successful supplementation program must increase spawning abundance and natural-origin recruitment to levels above those that would have occurred without supplementation. There are several methods that can be used to test the effects of supplementation programs on these population metrics. One important method is to compare the performance of population metrics (e.g., spawning abundance, natural-origin recruitment, and productivity) in the supplemented population to those in un-supplemented (reference) populations. By comparing supplemented populations to reference populations, one can determine if the supplementation programs benefit, harm, or have no effect on the supplemented populations. These comparisons, however, are only valid if the performance of the reference populations is similar to the performance of the supplemented population prior to the period of supplementation. If the performance of the two populations differs significantly before any supplementation occurs, then any results from comparing the two populations after supplementation will be suspect. It is therefore important to select reference populations that are as similar as possible to the supplemented populations.

One of the goals of the Conceptual Approach to Monitoring and Evaluating the Chelan County PUD Hatchery Programs (Murdoch and Peven 2005) is to use reference populations to analyze the potential effects of hatchery supplementation programs on natural-origin salmon and steelhead spawner abundance and productivity[14]. Murdoch and Peven (2005) identified specific objectives to evaluate the performance of the program. For example, Objective 1 determines if the supplementation programs have increased the number of naturally spawning and naturally produced adults of the target population (supplemented population) relative to a reference population. Objective 7 determines if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity (e.g., number of juveniles per redd) of supplemented streams when compared to reference streams. The relevant questions tested under each objective are as follows:

[14] Productivity is defined as adult recruits per spawner, where recruits are the number of adults produced from a given brood year (i.e., spawners plus adults harvested).

Objective 1:

- Is the annual change in the number of natural-origin recruits produced from the supplemented populations greater than or equal to the annual change in natural-origin recruits in an un-supplemented population?
- Is the change in natural replacement rates within the supplemented population greater than or equal to the change in natural replacement rates in an un-supplemented population?

Objective 7:

- Is the change in numbers of juveniles (smolts, parr, or emigrants) per redd in the supplemented population greater than or equal to that in an un-supplemented population?[15]

In this paper, we describe methods used to identify suitable reference streams and statistical techniques that can be used to compare reference populations with supplemented populations. Although we apply the methods described in this paper to Chiwawa spring Chinook salmon (hereafter referred to as Chinook), the methods should also apply to steelhead and other supplemented salmon stocks in the Upper Columbia Basin.

Identification of Reference Populations

Reference populations are an important component of an effectiveness monitoring design because they provide the standard by which treatment conditions are compared (ISRP and ISAB 2005; Murdoch and Peven 2005; Galbreath et al. 2008). Selecting appropriate reference areas and maintaining them over long periods of time is needed to establish the effectiveness of supplementation programs.

We developed a three-step process for identifying suitable reference populations (Figure 1). Each step serves as a filter. That is, potential reference populations are evaluated based on specific criteria under each step. Populations that pass through each step are considered suitable reference populations for a specific supplemented population.

[15] In this paper we only address adult recruits, not juvenile recruits. This is because we were unable to find suitable reference populations for analysis of juveniles. However, the methods described in this paper would also apply to juveniles.

Deleted: 2013 Update

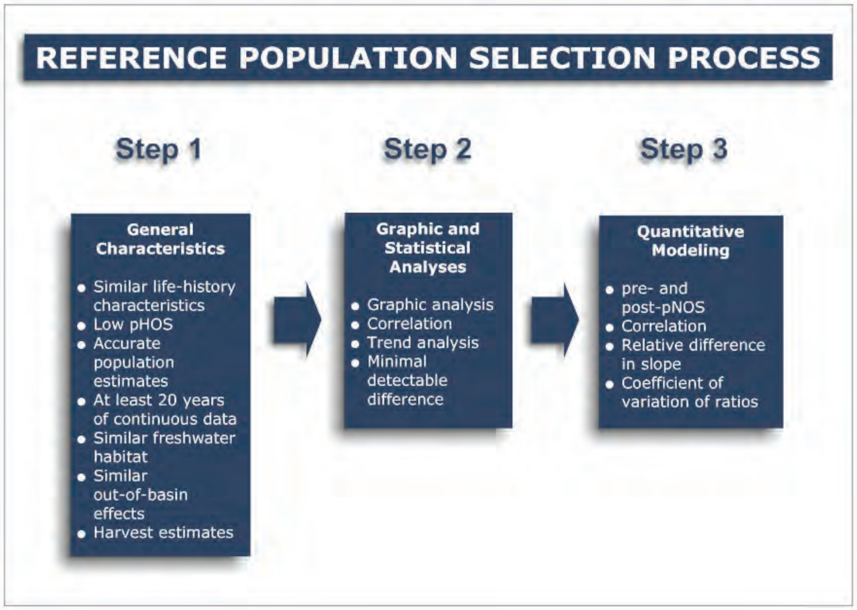

Figure 1. Criteria evaluated during each step in the process of identifying suitable reference populations.

Step 1: General Characteristics

Under step 1, potential reference populations are evaluated based on several general criteria. When compared to the supplemented population, potential reference populations should have:

- Similar life-history characteristics (e.g., run timing, migration characteristics, etc.).
- No or few hatchery fish in the reference area (pHOS < 10%).
- Accurate abundance estimates.
- Long time series of natural-origin abundance and productivity estimates (at least 20 years of continuous data).
- Similar trends in freshwater habitat.
- Similar out-of-basin effects (i.e., similar migration and ocean survivals).
- Harvest estimates for adjusting escapement estimates.

We used these criteria to begin the process of selecting suitable reference populations for the Chiwawa spring Chinook program. We began by identifying stream-type Chinook populations within the Columbia Basin. Galbreath et al. (2008; their Table 1) identified stream-type Chinook populations within the Columbia River Basin that may serve as suitable reference populations for hatchery programs. Supplementing their work with data from the NOAA Fisheries Salmon Population Summary Database, we identified 18 candidate stream-type Chinook populations that may serve as reference populations for the Chiwawa supplementation program (Table 1).

Deleted: 2013 Update

Table 1. Populations of stream-type Chinook salmon and their comparison to Chiwawa spring Chinook.

Population	Similar life-history	No or few hatchery fish	Accurate abundance estimates	Long time series (at least 20 years)	Similar freshwater habitat impairments	Similar out-of-basin effects	Comments
Deschutes River	Yes	Yes	Yes	Yes	No	No

Entiat River	Yes	No	Yes	Yes	No	No	Hatchery release ending

We then assessed the accuracy and length of the series of abundance estimates. We assumed that abundance estimates generated from expanded redd counts or adjusted weir counts would compare well with estimates in the Chiwawa Basin, which were based on expanded redd counts. In addition, we looked for populations that had an abundance data series that extended from at least 1981 to present. Based on this analysis, we identified 18 populations with abundance estimates that could be compared to those from the Chiwawa Basin (Table 1).

Next, we determined if the potential reference populations came from watersheds with habitat conditions similar to those in the Chiwawa Basin. For this exercise, we searched recovery plans and draft recovery plans to identify tributary factors that limit Chinook abundance, productivity, and survival within the reference populations. We compared these factors with those limiting

Chinook salmon in the Chiwawa Basin. Based on this analysis, we identified eight populations with habitat impairments similar to those in the Chiwawa Basin (Table 1).

Finally, we examined the potential reference populations to see if they experienced out-of-basin effects similar to spring Chinook from the Chiwawa Basin. In this case, we compared the number of mainstem dams that each potential reference population passes during migration. Six of the potential reference populations pass less than six mainstem dams; the other populations pass eight mainstem dams (Table 1). Only the Little Wenatchee population passes seven dams, similar to the Chiwawa population.

In sum, there were no reference populations that matched the Chiwawa spring Chinook population on all the criteria identified above. Differential out-of-basin effects and freshwater habitat conditions prevented most reference populations from matching with Chiwawa spring Chinook. However, some of the potential reference populations were similar to the Chiwawa population on several criteria and warranted further investigation. We selected the following populations for further investigation: Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River.

We included the Little Wenatchee because it is within the Wenatchee River basin and experiences similar out-of-basin effects and has the same climatic and environmental conditions as the Chiwawa. A confounding effect with the Little Wenatchee is that Chiwawa hatchery fish have strayed into the Little Wenatchee. However, straying of Chiwawa hatchery fish should decrease with the change in source water to the Chiwawa acclimation ponds in 2006. We also included the Entiat River because it is an adjacent basin to the Chiwawa and experiences similar climatic and environmental conditions. The spring Chinook hatchery program that has operated in the Entiat since 1975 has been discontinued. Therefore, this population offers a unique opportunity to compare the Chiwawa population to a population in which the hatchery program has been discontinued.

Step 2: Graphic and Statistical Analysis

Graphic Analysis

Although we were unable to find potential reference populations that matched with the Chiwawa population on all criteria considered under Step 1, spawner abundance, natural-origin recruits (NORs), and productivity of some of the potential reference populations may nevertheless track closely with the Chiwawa population. If the time series of abundance, NORs, and productivity of a potential reference population tracks closely with the abundance, NORs, and productivity of the Chiwawa population, the reference population may provide a reasonable reference condition for testing the effects of supplementation on the Chiwawa population.

Under Step 2, we used graphing techniques to examine the relationship of abundance, NORs, and productivity between the Chiwawa population and the five reference populations (Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River). We compiled spawner abundance, NORs, and productivity data from local biologists and the NOAA Fisheries Salmon Population Summary Database. We then compared time series plots of spawner abundance, NORs, and productivity data of potential reference populations with the Chiwawa population (Figures 2, 3, and 4; plots on the left side of figures). The time series only included the period 1981 to 1992, which represented the period before supplementation of the Chiwawa population (pre-treatment period). We also plotted the relationship between the abundance, NORs, and productivity of each

Deleted: 2013 Update

potential reference population to the Chiwawa population (Figures 2, 3, and 4; plots on right side of figures). These plots show whether the reference populations closely tracked the Chiwawa population. As a point of reference, data points that fall along the dashed line would represent a perfect relationship between the two populations (i.e., both populations have identical abundance, NORs, and productivity estimates). While a perfect relationship between two independent populations is unrealistic, a strong linear relationship between the two populations indicates populations with similar trends.

Based on analysis of spawner abundance, the Naches River time series tracked more closely with the abundance of Chiwawa spring Chinook than did the other potential reference populations. The poor relationship with the other potential reference streams was largely because of the relatively high abundance of Chiwawa spring Chinook during the mid-1980s. As with spawner abundance, analyses of NORs indicated a close relationship between the Naches and Chiwawa populations. The other potential reference populations tracked poorly with the Chiwawa. The analyses of productivity indicated close relationships between potential reference populations and the Chiwawa population. The Naches, Sesech, and Little Wenatchee populations tracked the closest with the Chiwawa population.

When analyzing the potential effects of a supplementation program on fish performance, it is common to transform the data to meet various assumptions of statistical analysis. The most common transformation used to adjust abundance, NORs, and productivity data is the natural logarithm (LN or $\log_e$). We therefore transformed the spawner abundance, NORs, and productivity data using LN and re-plotted the relationships between the potential reference populations and the Chiwawa population (Figures 5, 6, and 7). We added 1 to each observation before taking its logarithm to avoid taking the logarithm of 0, which is undefined (note that the LN of 1 is 0).

By transforming spawner abundance, NORs, and productivity data, most of the potential reference populations tracked more closely with the Chiwawa population. The Naches, Entiat, and Little Wenatchee abundance data tracked the closest with the Chiwawa abundance data (Figure 5). For NORs, Marsh Creek and the Little Wenatchee populations tracked the closest with the Chiwawa (Figure 6). For productivity, the Naches, Sesech, and Little Wenatchee tracked the closest with the Chiwawa (Figure 7).

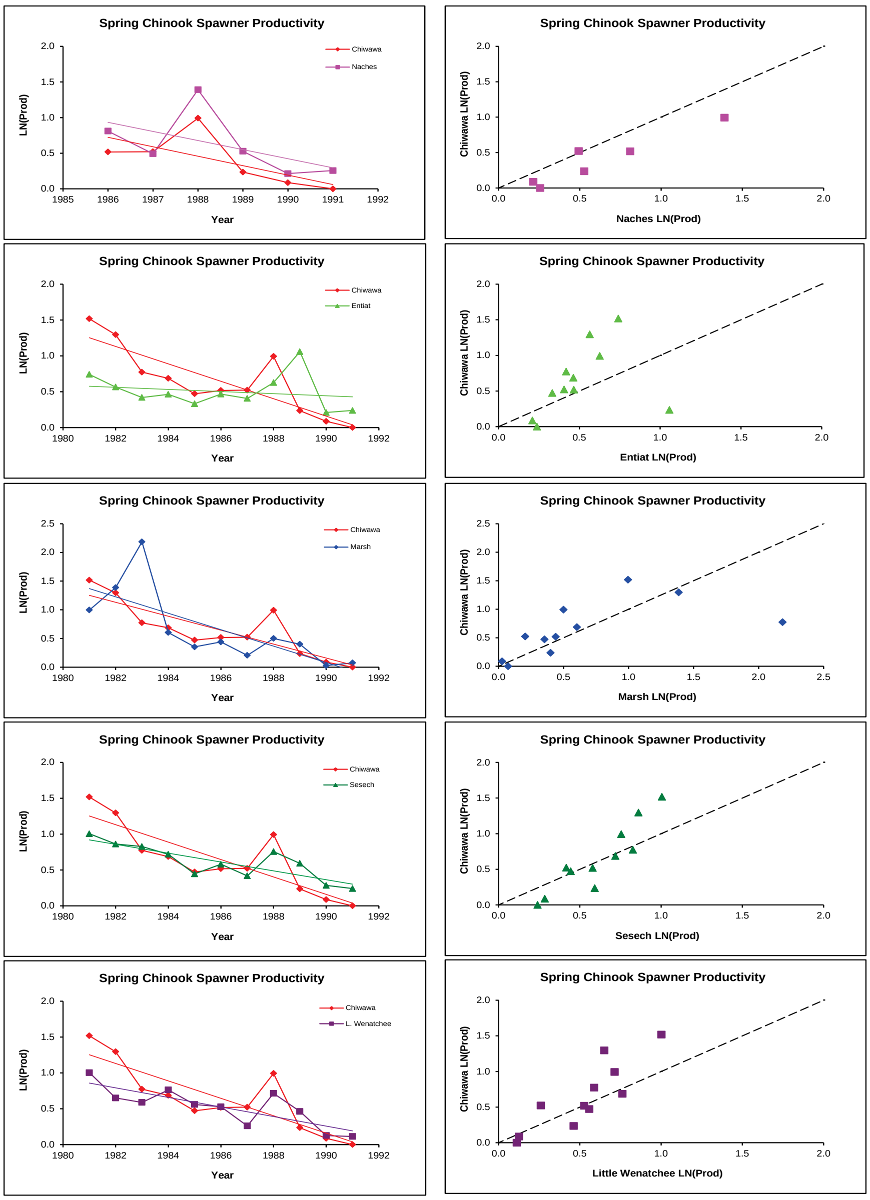

Figure 7. Time series of natural log adult productivity of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

Correlations and Trends

Other methods for evaluating the suitability of potential reference populations under Step 2 include correlation and trend analyses. For correlation analysis, we simply calculated the Pearson correlation coefficient, which is an index of the strength of the association between the potential reference populations and the Chiwawa population. The coefficient ranges from -1 to 1, where a value near 1 or -1 represents that strongest association between the populations. A value of 0 means no association. We used only spawner abundance, NORs, and productivity data during the pre-treatment period (1981-1992). We assumed that populations with coefficients greater than 0.6 represented reasonable reference conditions.

For trend analyses, we used least squares techniques to compute a straight-line trend through the spawner abundance and productivity data for the potential reference populations and the Chiwawa population. Trends were fit to the pre-treatment time series data (1981-1992). We then used t-tests to determine if the slopes of the trends between potential reference populations and the Chiwawa population differed significantly.

It is important to note that time-series trend analyses are susceptible to temporal correlations in the data. Autoregressive integrated moving average (ARIMA) models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). However, these models require a long time series (N > 40) and therefore we could not use them to model the spring Chinook data. As such, we were unable to correct for any temporal correlation that may exist within the time series.

Tests of correlation with spawner abundance data indicated that the Naches River closely correlated with the Chiwawa population (Table 2). There was no difference in abundance trends between the potential reference populations and the Chiwawa population (Table 2; Figure 2). For NORs, all potential reference populations correlated with the Chiwawa population (Table 2). However, trends in NORs of all reference populations, except Naches, differed significantly from the Chiwawa population (Table 2; Figure 3). For productivity, the Naches, Sesech, and Little Wenatchee correlated with the Chiwawa population (Table 2). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 2; Figure 4).

Table 2. Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (*) indicates significance at P < 0.05.

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Spawner Abundance Data				
Naches	0.684*	-0.659	8	0.528
Entiat	0.598*	-0.596	18	0.559
Marsh	0.147	-1.341	18	0.197
Sesech	0.274	-1.265	18	0.222
Little Wenatchee	0.399	-0.591	18	0.562
Natural-Origin Recruits

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Sesech	0.648*	-6.874	18	0.000
Little Wenatchee	0.880*	-7.206	18	0.000
Productivity Data				
Naches	0.960*	0.169	8	0.870
Entiat	0.272	-3.057	18	0.007
Marsh	0.320	0.605	18	0.553
Sesech	0.903*	-2.059	18	0.054
Little Wenatchee	0.848*	-2.065	18	0.054

We also ran correlation and trend analyses on natural-log transformed spawner abundance, NORs, and productivity data. These analyses indicated that the Naches, Entiat, and Little Wenatchee abundance data correlated with the Chiwawa population data (Table 3). None of the abundance trends of the potential reference populations differed significantly from the Chiwawa population trend (Table 3; Figure 5). For NORs, all potential reference populations correlated with the Chiwawa population (Table 3). Only trends in NORs of the Entiat and Sesech differed significantly from the Chiwawa population (Table 2; Figure 6). For productivity, the Naches, Marsh, Sesech, and Little Wenatchee correlated with the Chiwawa population data (Table 3). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 3; Figure 7).

Table 3. Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (*) indicates significance at $P < 0.05$. Analyses were conducted on natural-log transformed abundance and productivity data.

In summary, based on correlation, trend, and graphic analyses, the Naches, Entiat, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. For NORs, the Naches, Marsh, and Little Wenatchee appear to be reasonable reference populations. For productivity, the Naches, Marsh, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for the Chiwawa population.

Minimal Detectable Differences (MDD)

Given a suite of potential reference populations, it is important to conduct power analyses to determine the minimum differences that can be detected when comparing the reference populations to the supplemented population. As a final exercise under Step 2, we examined potential reference populations for the smallest minimal detectable differences. Before conducting power analyses, several decisions needed to be made, including what statistical procedures will be used to analyze the data, the desired level of statistical power (probability of rejecting a false null hypothesis), the size of the type-I error (the probability of rejecting a true null hypothesis of no difference), and the number of samples (i.e., years) included in the analysis. In this case, the number of samples represents the number of treatment (supplementation) years. The number of pre-treatment years (1981-1992) was based on the number of years of quality data available for Chiwawa spring Chinook and potential reference populations.

We designed the study as a modified BACI (Before-After, Control-Impact) design, which includes replication before and after supplementation in both the treated (T) population and the reference (R) populations. A common approach used to analyze data from BACI designs includes analysis of difference scores (Stewart-Oaten et al. 1992; Smith et al. 1993). Differences are calculated between paired treatment and reference population scores (i.e., T-R). Another approach is to calculate ratios (treatment/reference; T/R) for paired treatment and reference population scores (Skalski and Robson 1992). Finally, differences in annual changes in paired treatment and reference population scores can be calculated (i.e., ΔT-ΔR) (Murdoch and Peven 2005; Hays et al. 2006).[16] These derived difference and ratio scores are then analyzed for a before-after treatment effect with a two-sample t-test, Aspin-Welch modification of the t-test, or a randomization test. For power analyses, we calculated minimal detectable differences assuming the use of an independent two-sample t-test with a type-I error rate of 0.05, power of 0.80 (beta or type-II error rate of 0.20), and sample sizes (treatment years) of 5, 10, 15, 20, 25, and 50 years.

[16] The difference of annual difference scores was estimated by first subtracting the population parameter (e.g., spawner abundance) in year 2 from year 1. This continues for all years in the data series for both treatment ($T_{t+1} – T_t$) and reference populations ($R_{t+1} – R_t$). We then calculated differences between paired treatment and reference annual difference scores $[(T_{t+1} – T_t) - (R_{t+1} – R_t) = \Delta T\text{-}\Delta R]$.

Deleted: 2013 Update

The power analysis calculated the minimal detectable difference between mean difference or ratio scores before and during supplementation. We used existing data to calculate variances for the pre-supplementation and supplementation periods. Thus, variances were known and unequal. For both spawner abundance and NORs, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was less than the mean difference during supplementation (one-tail test; Difference < 0). For productivity, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was greater than the mean difference during supplementation (one-tail test; Difference > 0).

Based on spawner abundance data, power analysis indicated that the Sesech-Chiwawa pairing consistently produced the smallest detectable differences (Table 4). However, when the abundance data were transformed using natural logs, the Entiat-Chiwawa pairing produced the smallest detectable difference (Table 5). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 334 to 394 adult spawners; transformed data ranged from 0.479 to 1.010. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

Based on NORs, power analysis indicated that the Entiat-Chiwawa, Marsh-Chiwawa, and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 6). When NORs were transformed using natural logs, the Little Wenatchee-Chiwawa pairing produced the smallest detectable difference (Table 7). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 483 to 640 NORs; transformed data ranged from 0.958 to 2.262. These analyses indicate that the Entiat, Marsh, and Little Wenatchee populations appear to be reasonable reference populations for comparing NORs with Chiwawa data.

Using untransformed productivity data, power analysis indicated that the Little Wenatchee-Chiwawa pairing consistently produced the smallest detectable differences (Table 8). The Marsh-Chiwawa pairings produced the largest detectable differences. When we analyzed natural-log transformed productivity data, the Naches-Chiwawa and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 9). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 0.754 to 1.839; transformed data ranged from 0.277 to 0.477. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing productivity data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

Step 3: Quantitative Method for Ranking Selection Criteria

Not surprisingly, different selection criteria produced different results (Table 10). Determining whether a given population is or is not a suitable reference population based on selection criteria such as graphic analysis can be subjective. In addition, treating each selection criterion as equally important may not be appropriate. For example, using the information in Table 10, is it appropriate to select a reference population that has two or three "Yes" entries, or should only populations with four "Yes" entries be selected as suitable reference populations? This approach does not allow certain selection criteria to carry more weight in the overall selection process. That is, correlation may be more important than graphic analysis in the overall selection process. In order to reduce subjectivity, we developed a method of scoring and weighting each selection criterion. This method allows a more quantitative process for selecting suitable reference populations.

Deleted: 2013 Update

Table 10. Summary of results from graphic analysis, correlations, trend analysis, and power analysis (minimal detectable differences). "Yes" indicates that the population is a suitable reference population for the Chiwawa population; "No" indicates that it may not be a suitable reference population.

Potential reference populations	Graphic analysis	Correlation	Trends	Minimal detectable differences
Spawner Abundance				
Naches	Yes	Yes	Yes	Yes
Entiat	Yes	Yes	Yes	Yes
Marsh	No	No	Yes	No
Sesech	No	No	Yes	Yes
Little Wenatchee	Yes	Yes	Yes	Yes
Natural-Origin Recruits				
Naches	Yes	Yes	Yes	No
Entiat	No	Yes	No	Yes
Marsh	Yes	Yes	Yes	Yes
Sesech	No	Yes	No	No
Little Wenatchee	Yes	Yes	Yes	Yes
Productivity				
Naches	Yes	Yes	Yes	Yes
Entiat	No	No	No	Yes
Marsh	No	Yes	Yes	No
Sesech	Yes	Yes	Yes	Yes
Little Wenatchee	Yes	Yes	Yes	Yes

We developed scoring methods for each of the following five selection criteria:

(1) The proportion of natural-origin spawners (pNOS) in the reference population for the period before supplementation (pre-pNOS);

(2) pNOS in the reference population for the period following supplementation (post-pNOS);

(3) The correlation between the reference and supplemented populations before supplementation;

(4) The relative difference in slopes between the reference and supplemented populations before supplementation; and

(5) The coefficient of variation (CV) of the ratio of supplemented to reference populations before the period of supplementation.

Each selection criteria was scored from 0 to 1, with 0 being the worst possible score and 1 being the best.

The pre- and post-pNOS values were calculated as the average pNOS values before and after supplementation, respectively. Because pNOS values range from 0-1, we did not need to rescale these values. When using reference populations to evaluate the effects of supplementation programs, it is important that the reference populations maintain high values of pNOS throughout

Deleted: 2013 Update

the life of the monitoring program. Therefore, we heavily weighted the mean pNOS scores. We assigned weights of 30 and 40 to the mean pre- and post-pNOS scores, respectively. The relatively larger weight for the post-supplementation period is to reduce the likelihood of retaining a reference population that becomes influenced by hatchery fish during the supplementation period.

We assessed the association between the reference and supplemented populations during the pre-supplementation period by calculating the Pearson correlation coefficient, which ranges from -1 to 1. To scale the coefficient between 0 and 1, we took the absolute value of the coefficient. Thus, a coefficient of -0.92 would be reported as 0.92. For our analyses, we were not concerned with the direction of the relationship, only the strength of the relationship. The correlation coefficient was given a weight of 12.5.

As noted earlier, we used least squares to fit a linear trend to each of the reference populations and the supplemented population during the pre-supplementation period. Using the slope estimates for each trend line, we calculated the relative difference in slopes as the slope of the supplemented population minus the slope of the reference population, divided by the slope of the reference population. To scale this value between 0 and 1, we used absolute values, and depending on the direction of the slopes, we subtracted the relative difference from 1. The latter was needed to make sure a larger relative difference value indicated a small difference in slopes between the supplemented and reference populations. The relative difference score was given a weight of 7.5.

Finally, as a means to score effect size, we calculated the CV of the ratio of supplemented to reference population parameters (i.e., T/R). The CV was calculated as the standard deviation of the ratios divided by the absolute value of the mean ratios. The CV was subtracted from 1. This scaled the value from 0 to 1 with larger values representing the best condition. The CV was given a weight of 10, which is greater than the weight for trend, but less than the weight for correlation.

The total score for a reference population was calculated by multiplying the estimated value, which ranged from 0 to 1, by its weight. The sum of the five weighted values provided a total score, which ranged from 0 to 100. Based on several simulations, we set the cut-off score at 81. That is, if the total score for a given reference population equaled or exceeded 81, the population was included as a suitable reference population. If the total score fell below 81, the population was not considered a suitable reference. Based on the distribution of all scores possible, a score of 81 or greater represented only 3% of the total distribution. Thus, a cut-off of 81 is quite conservative.

Under Step 3, we used this method to select the final suite of suitable reference populations. Table 11 shows results from scoring each of the reference populations using the quantitative method. Using the cut-off criterion of 81, only the Naches, Marsh, and Sesech populations would be considered suitable reference populations for the Chiwawa supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values).

Table 11. Results from scoring potential reference populations using the selection criteria (pNOS, correlation, trend, and effect size). Populations with scores less than 81 were considered unsuitable as reference populations. Populations with scores equal to or greater than 81 were considered suitable references. These results were based on natural-log transformed data.

Potential reference populations	Population metric		
	Abundance	NORs	Productivity
Naches	85	88	91

Deleted: 2013 Update

Potential reference populations	Population metric		
	Abundance	NORs	Productivity
Entiat	23	21	16
Marsh	79	91	87
Sesech	84	85	88
Little Wenatchee	51	53	49

An important benefit from scoring the different selection criteria is that the total scores can be used to weight the outcome of differing statistical results. For example, analyses may show that when three suitable reference populations are compared to the supplemented population, two of the reference populations may indicate a significant treatment effect, while the third indicates no effect. Under this scenario it is not clear if the supplementation program has or has not affected the abundance or productivity of the supplemented population. If, however, the two reference populations that produced a significant result had higher total scores than the reference population that did not indicate a significant result, one can place more weight on the results from populations with higher total scores.

Conclusions

The purpose of this exercise was to develop a method for selecting suitable reference populations that could be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity. The selection process included a three-step process (Figure 8). Step 1 identified populations with similar life-history characteristics, few or no hatchery spawners, a long time series of accurate abundance and productivity estimates, and similar freshwater habitat impairments and out-of-basin effects. Populations that met these criteria were then examined for their graphical and statistical relationship with the supplemented population (Step 2). The statistical analysis under Step 2 were converted to a quantitative model (Step 3) that was used to generate a weighted score for pNOS, correlation, trends, and effect sizes for each potential reference population. Reference populations with total scores of 81 or greater were selected as suitable reference populations.

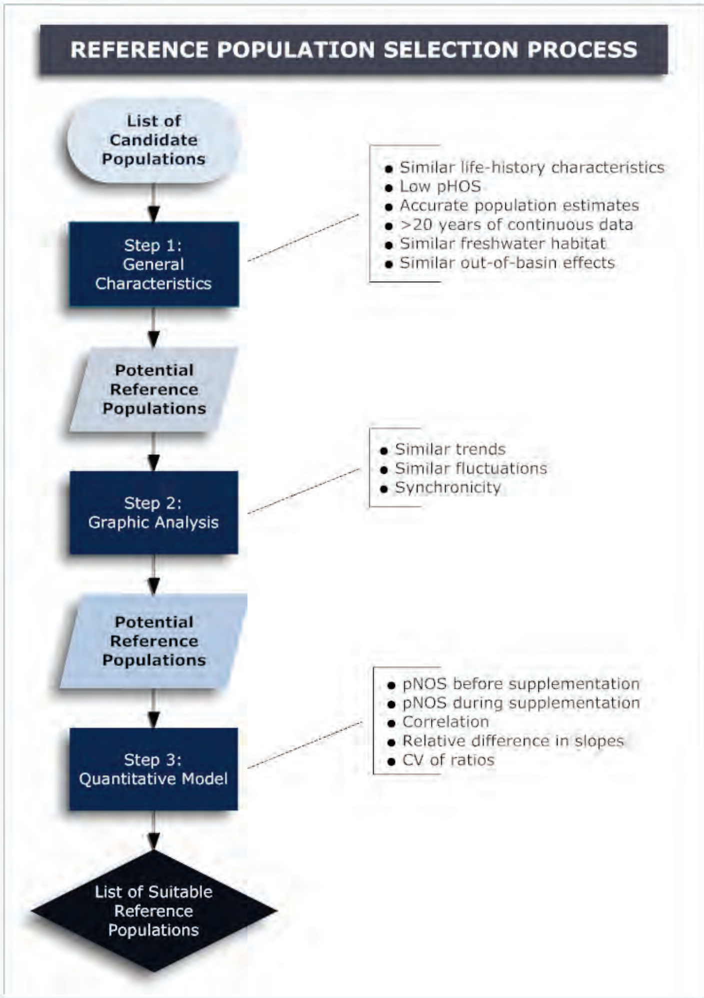

Figure 8. Three-step process for selecting suitable reference populations for supplemented populations.

We used this approach to select suitable reference populations for analyzing the effects of the Chiwawa spring Chinook supplementation program on fish abundance and productivity. The method indicated that the Naches, Marsh, and Sesech populations would serve as suitable reference populations for the Chiwawa spring Chinook supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values). However, because the presence of hatchery spring Chinook within those populations should decrease, they may serve as unique reference populations in which the comparisons change from all populations receiving

hatchery fish to only the Chiwawa population receiving hatchery fish. Therefore, we will continue to include both the Little Wenatchee and Entiat populations in future analyses.

An important assumption in the use of reference populations is that the supplemented and reference populations that tracked each other before supplementation would continue to track each other in the absence of supplementation. Given that the reference populations did not match the Chiwawa population on all criteria examined (Table 1) and some reference populations tracked the Chiwawa population more poorly than others (Figures 2-7; Tables 2-4), there may be some uncertainty as to whether differences observed between the Chiwawa and reference populations during the supplementation period are associated with the hatchery program, "nuisance" factors[17], or a combination of both. In addition, we have no ability to regulate or control activities in reference areas. Any large-scale change (man-made or natural) in reference areas could affect our ability to assess the effectiveness of the supplementation program.

Because we have no ability to maintain reference areas for long periods of time and may not be able to control all activities even within the supplemented populations, we propose the use of a "causal-comparative" approach to strengthen the certainty of our inferences (Pearsons and Temple 2010). The causal-comparative approach relies on correlative data to try and make a case for causal inference.[18] Correlation is used to rule out alternative hypotheses (note that we make our case as much if not more by disproving plausible alternatives as we do by showing that the data are consistent with a hypothesis). For example, large scale land-use activities or natural events can affect stream flows, fine sediment recruitment, and water temperatures. Changes in these factors can affect the freshwater survival and productivity of fish independently of supplementation programs. If changes in habitat, migratory, and ocean conditions do not affect reference and treatment populations similarly, inferences associated with supplementation programs may be confounded. By measuring and tracking these extraneous factors within reference and treatment areas, we can assess the effects of these state variables on population conditions independent of the supplementation programs. This allows us to more effectively assess the influence of supplementation programs on populations.

To that end, we recommend that the following state variables be measured and tracked within the Chiwawa Basin and each of the reference areas: mean annual precipitation, total and riparian forest cover, road density, impervious surface, and alluvium. These variables can be used to describe differences in water temperatures at different life stages (pre-spawning, egg incubation, and summer rearing) and substrate characteristics, including fine sediments and embeddedness (Jorgensen et al. 2009). They can be used to assess possible changes in spawner abundance, NORs, and productivity that are independent of supplementation.

[17] A "nuisance" factor is any factor that is outside the control of the experimenter and can affect the response variable (spawner abundance or productivity). In this case, nuisance factors may include differences in freshwater habitat trends and conditions, out-of-basin effects (e.g., migration and ocean survival), and hatchery strays that affect the Chiwawa and reference populations differently.

[18] It is important to point out that correlation does not demonstrate cause-and-effect. It only suggests a relationship between variables. Thus, inferences based on correlation lack the certainty that is associated with a design-based approach.

Analyses with Reference Populations

Once suitable reference populations are selected, methods for analyzing the supplemented and reference populations need to be identified. What follows is a description of different analyses that can be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity using reference populations. Later in this report we describe methods for assessing supplementation effects when reference populations are not available.

We used some of the reference populations selected for the Chiwawa program to illustrate the different methods for evaluating the effects of the supplementation program on spawner abundance, NORs, and productivity. For abundance, we selected the Naches, Entiat, Little Wenatchee, and Sesech populations as suitable references for the Chiwawa population. For NORs, we selected the Naches, Entiat, Marsh, and Little Wenatchee populations as suitable references. For productivity, we selected the Naches, Sesech, Little Wenatchee, and Marsh Creek as suitable references for the Chiwawa. As noted earlier, we included the Little Wenatchee and Entiat populations, even though they did not meet all the criteria for suitable reference populations.

Analysis of Trends

As a first step, we used trend analyses to assess the effects of the Chiwawa supplementation program on spring Chinook spawner abundance, NORs, and productivity. Here, we compared the slopes of the trends between each treatment/reference pair before and during supplementation using t-tests. If the hatchery program is successfully supplementing the natural spring Chinook population, trends in spawner abundance and NORs should deviate significantly (i.e., the slope of the supplemented population should be greater than the slopes of the reference populations during the supplementation period). For productivity, the slope of the supplemented population, relative to the reference population, should increase or remain the same.

Trend analysis indicated that the relationship of slopes of spawner abundance between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 9; Table 12). This was true for both transformed and untransformed abundance data. Before supplementation, spawner abundances trended down in both the Chiwawa and reference populations (Figure 9). During the period of supplementation, abundances in both the Chiwawa and reference populations trended upward. Interestingly, in nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the supplementation period than in the pre-supplementation period (Table 12). This was most evident in the transformed abundance data (Figure 9).

Trend analysis indicated that the relationship of slopes of NORs between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 10; Table 13). Before supplementation, Chiwawa NORs trended downward more strongly than the reference populations (Figure 10). However, during the supplementation period, both the Chiwawa and reference population NORs trended upward in parallel. In nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the pre-supplementation period than in the supplementation period (Table 13).

As with NORs and spawner abundance data, trend analysis indicated that the relationship of slopes of productivity (recruits/spawner) between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 11; Table 14). This was true for both transformed and untransformed productivity data. Before supplementation, productivities trended down in both the Chiwawa and reference populations (Figure 11). During the period of supplementation, productivities fluctuated widely in both the Chiwawa and reference populations. Nevertheless, during the supplementation period, productivities generally increased in both the reference and Chiwawa populations. Unlike with spawner abundance, the Pearson correlation coefficients resulting from analysis of productivity data were generally higher in the pre-supplementation period than during the supplementation period (Table 14).

Using trend analysis, we found no evidence that the supplementation program has significantly increased the spawner abundance and NORs of spring Chinook in the Chiwawa Basin. Even though we documented an increasing trend in spawner abundance and NORs during the supplementation period, a similar increase in spawner abundance and NORs was observed in the reference populations. In addition, we found no evidence that the supplementation program has increased the productivity of spring Chinook in the Chiwawa Basin. Importantly, the productivity of spring Chinook in the Chiwawa Basin did not trend downward during the supplementation period. Thus, based on trend analysis, it appears that the supplementation program has not increased or decreased the abundance and productivity of spring Chinook in the Chiwawa Basin.

We note that this exercise only tests the slopes of the trend lines. It does not test for differences in elevations of the trend lines. A supplementation program could increase spawner abundance, NORs, and productivity of the target population without changing the slopes of the trend lines. That is, supplementation could cause the elevation of the trend line to be greater during the supplementation period than during the pre-supplementation period. In the next section we evaluate elevation differences by testing mean differences before and after supplementation.

Analysis of Mean Differences, Ratios, and Rates

For assessing mean differences between supplemented and reference populations, we derived three different response variables using transformed and untransformed spawner abundance, NORs, and productivity data. The first included difference scores, which were calculated as the difference between paired treatment and reference data (T-R). The second included ratios, which were calculated as the ratio of paired treatment and reference data (T/R). Finally, we calculated the differences in annual changes in paired treatment and reference population data (ΔT-ΔR; see footnote #2).

Deleted: 2013 Update

If the hatchery program is successfully supplementing the natural spring Chinook population, the mean difference or ratio score of paired spawner abundance data and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean difference or ratio score during the supplementation period should be equal to or higher than the pre-supplementation period. We tested the following statistical hypotheses.

Spawner Abundance and NORs:

Ho: Mean Difference (or Ratio) before supplementation ≥ Mean Difference (or Ratio) during supplementation.

Ha: Mean Difference (or Ratio) before supplementation < Mean Difference (or Ratio) during supplementation (i.e., $\mu_{pre} - \mu_{post} < 0$).

Productivity (Recruits/Spawner):

Ho: Mean Difference (or Ratio) before supplementation ≤ Mean Difference (or Ratio) during supplementation.

Ha: Mean Difference (or Ratio) before supplementation > Mean Difference (or Ratio) during supplementation (i.e., $\mu_{pre} - \mu_{post} > 0$).[19]

For each set of response variables, we tested before/after supplementation effects using a one-tailed Aspin-Welch unequal-variance test. We used the Aspin-Welch unequal-variance test instead of Student's t-test, because in nearly every case, the variances of response variables in the pre-treatment and supplementation periods were unequal.[20] This was true even for natural-log transformed variables. We used the modified Levene equal-variance test to assess the equality of variance. In some cases, the distributions of response variables were not normal (based on the Omnibus Normality test and examination of histograms, normal probability plots, and box plots). Therefore, we also used a randomization test, based on 10,000 Monte Carlo simulations, to assess differences in response variables before and during supplementation. The randomization procedure only allowed the testing of two-tailed hypotheses. Therefore, we generated 95% confidence intervals on the mean difference ($\mu_{pre} - \mu_{post}$) using bootstrapping methods to determine the direction of the difference. We generated 5,000 bootstrap samples to calculate confidence intervals.

All these statistical methods assume that the samples of derived difference or ratio scores from the pre-supplementation and supplementation periods were independent. However, BACI designs, like time-series trend analysis, are repeated-measures designs and therefore are susceptible to temporal correlations in the data. This means that the two samples of difference or ratio scores may not be independent. Under this scenario, ARIMA models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). ARIMA models can be fit individually to the reference and supplemented time series data, or to a derived data series created by taking the ratio or difference of the supplemented/reference data at each time step. ARIMA models, however, require a long time series (N > 40) and therefore we could not use them to model

[19] Because of the logic of null hypothesis testing, the rejection of the null hypothesis of no difference in productivity would mean that the supplementation program has reduced the productivity of the target population (here rejection of the null indicates "harm"). Notice that the rejection of the null hypothesis of no difference in spawner abundance means that the supplementation program has improved the spawner abundance in the target population (here rejection of the null indicates "benefit").

[20] In cases in which the variances were equal, both the Aspin-Welch test and Student's t-test gave the same result.

the spring Chinook data. Thus, we acknowledge that our analyses may be confounded if the samples are not independent.

Difference Scores (T-R)

Analysis of supplementation effects on spawner abundance using difference scores indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 15; Figure 12). Only the Little Wenatchee-Chiwawa pairing using transformed abundance data indicated a significant increase in spawning abundance following supplementation. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction (i.e., CIs > 0). That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 12).

Table 15. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed spawner abundance data. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

Analysis of supplementation effects on productivity (adult recruits/spawner) using difference scores indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 17; Figure 12). All tests, regardless of treatment-reference pairs, indicated that productivity did not change significantly during the supplementation period. These tests indicate that supplementation has not negatively affected the productivity of spring Chinook salmon in the Chiwawa Basin.

Table 17. Ratio Scores (T/R)

As with difference scores, analysis of supplementation effects on spawner abundance using ratios indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 18; Figure 13). Only the Little Wenatchee-Chiwawa pairing indicated a significant increase in spawning abundance following supplementation. Analysis with both transformed and untransformed Little Wenatchee-Chiwawa data indicated a significant effect. In contrast, only difference scores derived from transformed data indicated a significant effect. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction. That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 13).

Table 18. Figure 13. Mean ratios (Treatment/Reference) scores of untransformed (figures on the left) and transformed (figures on the right) spawner abundance, natural-origin recruits (NORs), and productivity data before (pre) and after (post) spring Chinook supplementation in the Chiwawa Basin. Positive effects of supplementation on spawner abundance and NORs are indicated when the post-supplementation (red) bars are greater than their corresponding pre-supplementation (blue) bars. Negative effects of supplementation on productivity are indicated when the pre-supplementation (blue) bars are greater than their corresponding post-supplementation (red) bars.

Analysis of supplementation effects on NORs using ratios indicated that supplementation did not significantly increase NORs in the Chiwawa Basin (Table 19; Figure 13). Only the Little Wenatchee-Chiwawa pairing indicated a significant increase in transformed NORs following supplementation. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction. That is, compared to the reference populations, NORs decreased in the Chiwawa Basin during the supplementation period (Figure 13).

Table 19. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed natural-origin recruits. Tests determined if the mean ratios during the supplementation period were greater than mean ratios during the pre-supplementation period.

Analysis of supplementation effects on productivity (adult recruits/spawner) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 20; Figure 13). Although the Aspin-Welch test indicated a significant effect when comparing the Chiwawa to the Marsh Creek population, both the randomization test and the bootstrap CI did not indicate a significant effect. These tests indicate that supplementation has probably not negatively affected the productivity of spring Chinook salmon in the Chiwawa Basin.

Table 20. Difference of Annual Difference Scores (ΔT-ΔR)

Analysis of supplementation effects on spawner abundance using difference scores of annual changes indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 21; Figure 14). None of the statistical analyses detected a significant increase in annual change in the Chiwawa Basin relative to the reference populations.

Table 21. We believe results from analysis of mean differences of annual change (ΔT-ΔR) in spawning abundance, NORs, and productivity are difficult to interpret and may be insensitive to treatment effects. A simpler analysis, which is also easier to interpret, is the use of trend analysis. Therefore, we recommend that analyses using differences of annual change be replaced with trend analysis.

Corrections for Density Dependence and Carrying Capacity

The analyses described above assume that the density of spawners or recruits does not affect the survival and productivity of fish. However, it is well known that the density of fish can affect the number of recruits as well as the productivity of the population. This occurs through the relationship between density and mortality. Mortality of fish can be generally classified as density independent and density dependent. In general, when densities are low, the mortality is density independent, but as densities increase, the amount of density-dependent mortality increases. Monitoring programs can make use of this information to derive density-corrected estimates of productivity. In this section, we describe two different methods for deriving density-corrected estimates of productivity.

The first method controlled the effects of density on productivity (adult recruits/spawner; R/S) by partitioning observed productivities into density-independent and density-dependent productivity. When abundance is below the minimum number of spawners (S) needed to produce the maximum number of recruits (K_{sp}), the observed productivity is used in statistical tests. However, when the abundance is equal to or above K_{sp}, the modeled value of productivity (R/K_{sp}) is used in statistical tests.

$$\boldsymbol{Adj\ R/S} = \begin{cases} \boldsymbol{R/S}, & \boldsymbol{if\ S < K_{sp}} \\ \boldsymbol{R/K_{sp}}, & \boldsymbol{if\ S \geq K_{sp}} \end{cases}$$

The density-independent and density-dependent productivities were then combined in a single test.

The second method was based on one of the goals of supplementation, which is to fill the capacity of the environment with fish. This method corrects for differences in carrying capacities between the supplemented and reference populations. We did this by calculating the percent saturation of NORs. That is, we calculated the fraction of the habitat (τ) that was filled with NORs by dividing the observed NOR by the modeled maximum number of NORs (K_R) that the habitat could support.

$$\boldsymbol{\tau} = \frac{\boldsymbol{NOR_{obs}}}{\boldsymbol{K_R}}$$

Note that 1-τ represents the unused portion of the carrying capacity and is the term that is multiplied by the exponential growth equation to derive the logistic growth equation. We included τ in the statistical analyses.

These two methods require the estimation of carrying capacity (K_R) and the spawning abundance that produces the maximum number of recruits (K_{sp}). We estimated these parameters for both reference populations and the supplemented population using Ricker, Beverton-Holt, and smooth hockey stick stock-recruitment models. We used only spawner abundance as a predictor of subsequent brood recruitment. We made the following assumptions in proceeding with the analysis:

- *Density-dependent mortality*—For some time period before recruitment, the brood instantaneous mortality rate is proportional to the number of parent spawners (Ricker 1954).
- *Lognormal variation*—At any particular spawning stock size, the variation in recruitment is log-normally distributed about its average, and acts multiplicatively (Quinn and Deriso 1999).
- *Measurement error*—Error in spawning stock size estimates (measurement error) is small relative to the range of spawning stock sizes observed (Hilborn and Walters 1992). Variation in realized recruitment at any particular spawning stock size (process error) dominates recruitment measurement error.
- *Stationarity*—The average stock-recruitment relationship is constant over time (Hilborn and Walters 1992). That is, environmental conditions randomly affect survival independent of stock size or time.

In general, the methods we used to fit the models to the data followed those outlined in Hilborn and Walters (1992) and Froese (2008). The Ricker model, which assumes that the number of recruits increases to a maximum and then declines as the number of spawners increases, takes the form:

$$\boldsymbol{E(R) = \alpha S e^{-\beta S}}$$

where E(R) is the expected recruitment, S is spawner abundance, α is the number of recruits per spawner at low spawning levels, and β describes how quickly the recruits per spawner drop as the number of spawners increases. We estimated K_R as:

$$\boldsymbol{K_R = \left(\frac{\alpha}{\beta}\right) e^{-1}}$$

and K_{sp} as:

$$\boldsymbol{K_{sp} = \frac{1}{\beta}}$$

The Beverton-Holt model assumes that the number of recruits increases constantly toward an asymptote as the number of spawners increases. After the asymptote is reached, the number of recruits neither increases nor decreases. The asymptote represents the maximum number of recruits the system can support (i.e., carrying capacity for the system; K_R). The Beverton-Holt curve takes the form:

$$\boldsymbol{E(R) = \frac{(\alpha S)}{(\beta + S)}}$$

where E(R) and S are as above, α is the maximum number of recruits produced (K_R), and β is the number of spawners needed to produce (on average) recruits equal to one-half the maximum number of recruits. Because $K_{sp} = \infty$ in the Beverton-Holt model, we estimated K_{sp} as the number of spawners needed to produce 0.99(K_R).

Like the Beverton-Holt model, the smooth hockey stick model assumes that the number of recruits increases toward an asymptote (carrying capacity; K_R) as the number of spawners increases. After the carrying capacity is reached, the number of recruits neither increases nor decreases. The carrying capacity represents the maximum number of recruits the system can support. This curve

takes the form (Froese 2008):

$$E(R) = R_{\infty}\left(1 - e^{-\left(\frac{\alpha}{R\infty}\right)S}\right)$$

where E(R) and S are as above, α is the slope at the origin of the spawner-recruitment curve, and R_{∞} is the carrying capacity of recruits (note that $R_{\infty} = K_R$). As with the Beverton-Holt model, we estimated K_{sp} as the number of spawners needed to produce $0.99(K_R)$.

We used non-linear regression to fit the three models to spawner-recruitment data. Before fitting the models, we transformed recruitment data using natural logs. We estimated bias and uncertainty measures (95% CI) for the model parameters using bootstrap procedures, which assumed that the {R, S} sample represented or approximated the population. The number of bootstrap samples was 3,000. We computed and stored the non-linear regression results for each bootstrap sample. We then calculated the bootstrap 95% CI by arranging the 3,000 bootstrap parameter values in sorted order and selected the 2.5 and 97.5 percentiles from the list.

We used Akaike's Information Criterion for small sample size (AIC_c) to determine which model(s) best explained the relationship between spawners and recruitment in the supplemented and reference populations. AIC_c was estimated as:

$$AIC_c = -2log(£(\theta|data)) + 2K + \left(\frac{2K(K+1)}{n-K-1}\right)$$

where $log(£(\theta|data))$ is the maximum likelihood estimate, K is the number of estimable parameters (structural parameters plus the residual variance parameter), and n is the sample size (Burnham and Anderson 2002). We used least-squares methods to estimate $log(£(\theta|data))$, which was calculated as $log(\sigma^2)$, where σ^2 = residual sum of squares divided by the sample size ($\sigma^2 = RSS/n$). AIC_c assessed model fit in relation to model complexity (number of parameters). The model with the smallest AIC_c value represented the "best approximating" model within the model set. Remaining models were ranked relative to the best model using AIC_c difference scores (ΔAIC_c), Akaike weights (w_i), and evidence ratios. Models with ΔAIC_c values less than 2 indicated that there is substantial support for these models as being the best-fitting models within the set (Burnham and Anderson 2002). Models with values greater than 2 had less support. Akaike weights are probabilities estimating the strength of the evidence supporting a particular model as being the best model within the model set. Models with small w_i values are less plausible as competing models (Burnham and Anderson 2002). If no single model could be specified as the best model, a "best subset" of competing models was identified using (1) AIC_c differences to indicate the level of empirical support each model had as being the best model, (2) evidence ratios based on Akaike weights to indicate the relative probability that any model is the best model, and (3) coefficients of determination (R^2) assessing the explanatory power of each model.

Stock-Recruitment Analysis

We successfully fit stock-recruitment models to the Chiwawa and reference population data. The span of spawner data for the Chiwawa and reference populations was greater than 14 times the minimum observed spawners, which should provide sufficient contrast for estimation of model parameters. In addition, the span of recruitment data was greater than 12 times the minimum observed recruitment, again providing sufficient contrast for estimation of parameters. The relationship between natural log R/S and spawners indicated that some of the highest productivities occurred at the lower spawner levels and the lowest productivities generally occurred at the highest spawner levels (Figure 15). This is consistent with the assumption of density-dependent mortality.

Although model fits were generally poor, explaining less than 40% of the residual variation in natural-log recruitment data, we were able to estimate average maximum recruitment levels (K_R) and the spawning levels needed to produce maximum recruitment (K_{sp}) (Table 24; Figure 15). For all populations examined, Akaike information criterion was unable to identify a best approximating model (i.e., ΔAIC_c values were less than 2, indicating support for all three models). However, evaluation of 95% CIs and the asymptotic correlation coefficients indicated that the smooth hockey stick model may be the best approximating model for each population. Therefore, we used estimates of K_R and K_{sp} derived from the smooth hockey stick model to correct for density dependence and different carrying capacities in treatment-reference comparisons.

As part of the regression diagnostics, we examined the dependence of the model residuals on time and found a significant ($P < 0.05$), positive, one-year-lag autocorrelation for the Entiat (0.562), Marsh (0.551), Sesech (0.564), and Little Wenatchee (0.629) populations. For the purposes of our work here, we did not attempt to correct for this one-year-lag correlation in the residuals. Future analyses will explore the use of autoregressive models (e.g., AR1; Noakes et al. 1987) to correct for autocorrelation.

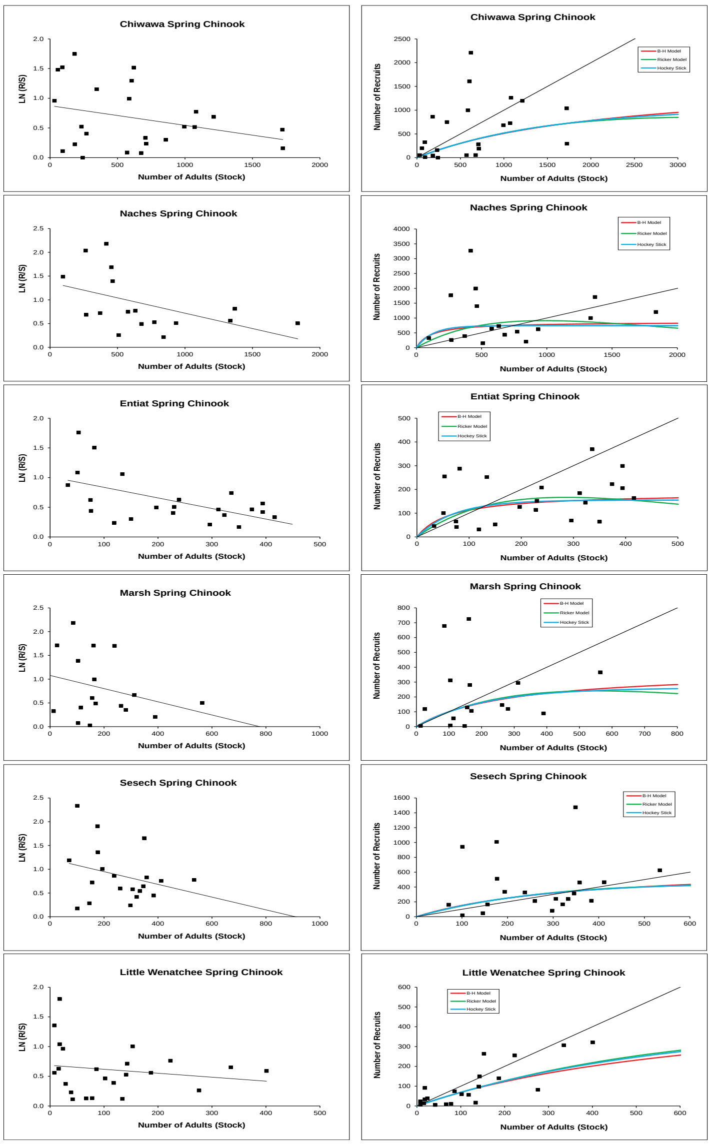

Figure 15. Relationships between natural log recruits/spawner (LN R/S) and spawners (Stock) in the Chiwawa and reference populations (figures on the left) and relationships between numbers of untransformed recruits and spawners in the Chiwawa and reference populations (figures on the right). Figures on the right also show the fit of the Ricker, Beverton-Holt, and the smooth hockey stick models to the data (black straight line represents R=S).

Table 24. Results from fitting Ricker, Beverton-Holt, and smooth hockey stick models to stock-recruitment data from the Chiwawa and reference populations. 95% CI on parameter estimates are based on 3,000 bootstrap trials; Corr coef = asymptotic correlation of the parameter estimates; K_R = maximum natural origin recruits (recruits at carrying capacity); K_{sp} = number of spawners needed to produce K_R; AICc = Akaike's Information Criterion for small sample size; Adj R^2 = coefficient of determination that is adjusted for the number of parameters in the model.

Method 1: Productivity Data Adjusted for Density Dependence

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects based on the smooth hockey stick model) using difference scores indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 25; Figure 16). All tests, regardless of treatment-reference pairs, indicated that productivity did not change significantly during the supplementation period, even though productivity did decrease during the supplementation period (Figure 16). These results are consistent with those based on unadjusted productivity data (Table 17). This is because most abundance estimates were below the level of assumed density dependence.

Table 25. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

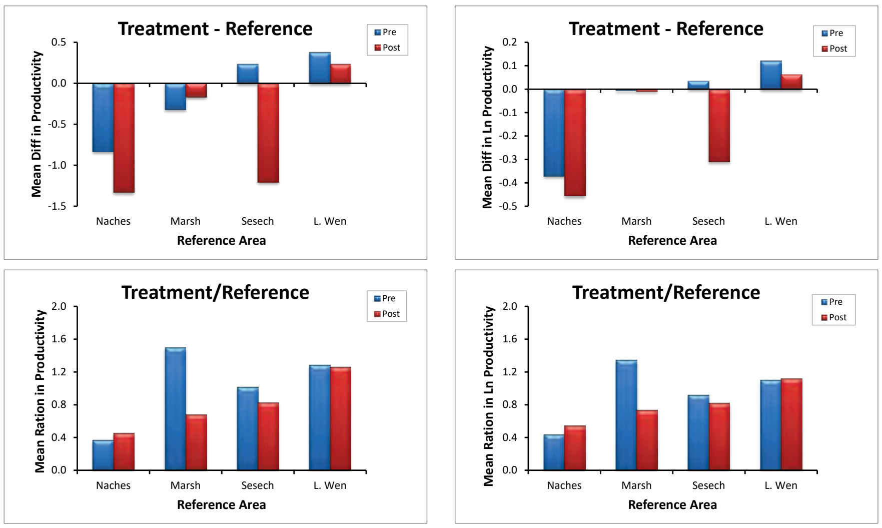

Figure 16. Mean differences (Treatment – Reference; figures on the top) and mean ratios (Treatment/Reference; figures on the bottom) of transformed and untransformed productivity data (adjusted for density dependence) before (pre) and after (post) spring Chinook supplementation in the Chiwawa Basin. Negative effects of supplementation on productivity are indicated when the pre-supplementation (blue) bars are greater than their corresponding post-supplementation (red) bars.

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 26; Figure 16). The Aspin-Welch test and the 95% CIs did indicate a significant effect when comparing the Chiwawa to the Marsh Creek population. These results are consistent with those using unadjusted productivity data (Table 20). Again, this is because most abundance estimates were below the level of assumed density dependence.

Table 26. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean ratios during the supplementation period were less than mean ratios during the pre-supplementation period.

Our analyses assume that there is a spawner abundance (K_{sp}) at which density-independent effects end and density-dependent effects begin. In reality, density-dependent effects occur at low spawning abundance and intensify as spawning abundance increases (evident in the changing slope of the three stock-recruitment curves used in our analyses). We did not account for these increasing density-dependent effects at spawner abundances less than K_{sp}. If we accounted for the increasing effects of density dependence at spawning abundances less than K_{sp}, the analysis with and without productivity adjustments may give different results.

Method 2: Fraction of Carrying Capacity Filled with NORs

We analyzed the effects of supplementation on filling the capacity of the habitat with natural-origin recruits. The smooth hockey stick model derived the carrying capacity (K_R) estimates for the Chiwawa and reference populations. The fraction of the carrying capacity filled with Chinook recruits before and during supplementation for the Chiwawa and reference populations is provided in Table 27. These data indicate that for the Chiwawa population, the mean fraction of the K_R filled with fish decreased significantly from the pre-supplementation period through the supplementation period (Table 27). Likewise, the Entiat and Little Wenatchee populations showed a significant decline in the mean fraction of K_R filled with adult recruits. In contrast, the mean fraction of K_R in the Naches and Marsh Creek populations increased during the same period (Table 27).[21] Interestingly, the fraction of K_R filled with adult recruits for all populations trended downward during the pre-supplementation period (Figure 17). During the supplementation period, however, the fraction of K_R filled with adult recruits trended upward for all populations. These results suggest that agents of mortality outside the Chiwawa and reference populations were reducing recruitment to the populations.

[21] Although we do not show the results here, statistical analysis of the mean fraction of carrying capacity filled by adult recruits using natural-log transformed data produced the same result as using untransformed data. This was true for all populations.

Deleted: 2013 Update

Table 27. Fraction of the carrying capacity that was filled with Chinook salmon adult recruits in the Chiwawa and reference populations before (pre) and during (post) supplementation in Chiwawa Basin. The smooth hockey stick model estimated carrying capacity for each population. Statistical results from comparing the pre and post mean scores using the Aspin-Welch unequal-variance test are provided at the bottom of the table.

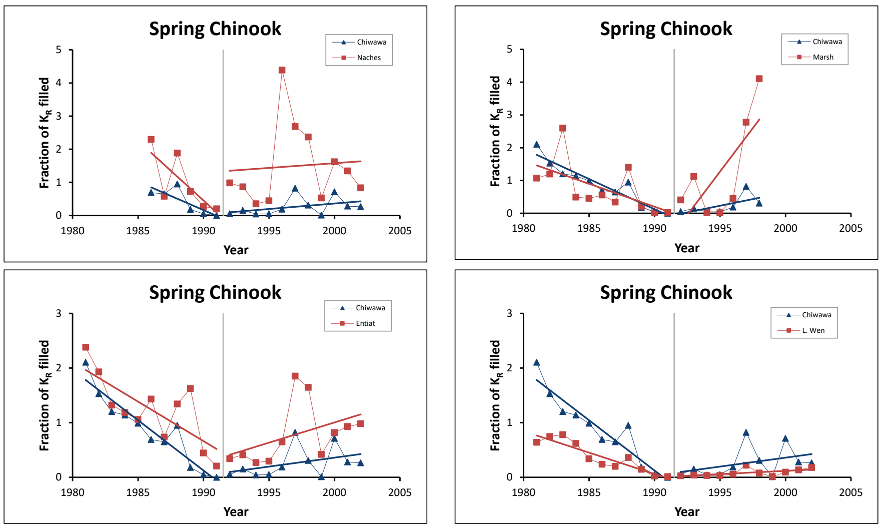

Figure 17. Trends in the fraction of the carrying capacity that was filled with Chinook salmon adult recruits in the Chiwawa and reference populations before (pre) and during (post) supplementation in Chiwawa Basin. The vertical lines in the figures separate the pre- and post-supplementation periods. The smooth hockey stick model estimated carrying capacity for each population.

We then compared the mean difference scores and ratios between the Chiwawa and reference populations before and during supplementation using data representing the fraction of K_R filled with adult recruits. In most of the Chiwawa-reference population comparisons, the absolute value of the mean difference between the fraction of K_R filled with recruits was greater in the supplementation period than during the pre-supplementation period; two of the four pairings were significant (Table 28; Figure 18). Analysis of difference scores using natural-log transformed data indicated that three of the four pairings were significant (Table 28).

Results from analyses using ratios were similar to results using difference scores. Mean ratio scores were generally smaller during the supplementation period than during the pre-supplementation period (Figure 18). This indicated that the mean fraction of K_R filled by adult recruits in most reference populations was greater during the supplementation period than during the pre-supplementation period (i.e., the denominator in the ratio increased between the pre- and post-supplementation periods). In contrast, the fraction of K_R filled by adult recruits in the Chiwawa decreased from the pre- to post-supplementation period (i.e., the numerator in the ratio decreased between the pre- and post-supplementation periods). Thus, unlike the Chiwawa population, the capacity of most reference populations was becoming more saturated during the period when the Chiwawa was being supplemented. Statistical analysis with mean ratios indicated that two of the four pairings were significant (Table 29).

Analyses comparing the Little Wenatchee with the Chiwawa indicate that adult recruits to the Little Wenatchee have been well below its carrying capacity. During the pre-supplementation period, the capacity of the Little Wenatchee was on average 37% saturated with adult recruits. During the supplementation period, the capacity of the Little Wenatchee declined to 8% saturation

Deleted: 2013 Update

with adult recruits (a 22% decline). The Chiwawa, during the pre-supplementation period, was on average 86% saturated. During the supplementation period, percent saturation in the Chiwawa decreased to 26% (a 30% decrease). During the same time periods, the capacity of the Entiat population, which until recently has been supplemented, declined from 124% to 78% saturation (a 63% decline).

Table 28. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on the fraction of the habitat capacity (K_R) that is filled with natural origin recruits. Analyses include both transformed and untransformed data. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

Comparing Stock-Recruitment Curves

As a final set of treatment and reference population comparisons, we compared the stock-recruitment curves of the Chiwawa population (using {R, S} data only from the supplementation period) to the reference populations (using all available {R, S} data). Specifically, we tested whether the regression parameters were equal between the Chiwawa population and the reference populations, and whether the fitted curves coincided between populations. Earlier in this report we described the data, methods, and results of fitting the Ricker, Beverton-Holt, and smooth hockey stick curves to the data. Because AIC_c was unable to identify a best approximating model, here we included all three models in our analyses. We tested the following hypotheses.

Parameter equivalence:

Ho: Stock-recruitment parameters (α and β) of the Chiwawa population = Stock-recruitment parameters of the reference populations.

Ha: Stock-recruitment parameters (α and β) of the Chiwawa population ≠ Stock-recruitment parameters of the reference populations.

Curve equivalence:

Ho: Modeled stock-recruitment curves of the Chiwawa population = Modeled stock-recruitment curves of the reference populations.

Ha: Modeled stock-recruitment curves of the Chiwawa population ≠ Modeled stock-recruitment curves of the reference populations.

We used two-sided randomization tests to test the null hypotheses of equal model parameters and that fitted curves coincided. Because the total number of permutations was in the millions, we used a Monte Carlo approach to randomly select 10,000 permutations. The test statistic for comparing the model parameters was formed by summing the difference between the population parameter estimates for each pair of populations. The test statistic for comparing the whole curve was formed by summing the difference between the estimated predicted values for each pair of populations at 500 equally spaced points along the curve.

Ricker Relationships

Ricker curves differed significantly between the Chiwawa and reference populations (Figure 19; Table 30). Interestingly, however, the parameters in the Ricker model did not differ significantly among most populations (Table 30). Only the β parameter differed significantly between the Chiwawa and Entiat populations.

In the Ricker model, the α parameter represents intrinsic productivity (i.e., recruits per spawner at low spawner densities). In this analysis, there was not enough evidence in the stock-recruitment data to reject the hypothesis of inequality in intrinsic productivity. Thus, this test was unable to demonstrate that supplementation, based on the Ricker curve, affected productivity in the Chiwawa population.

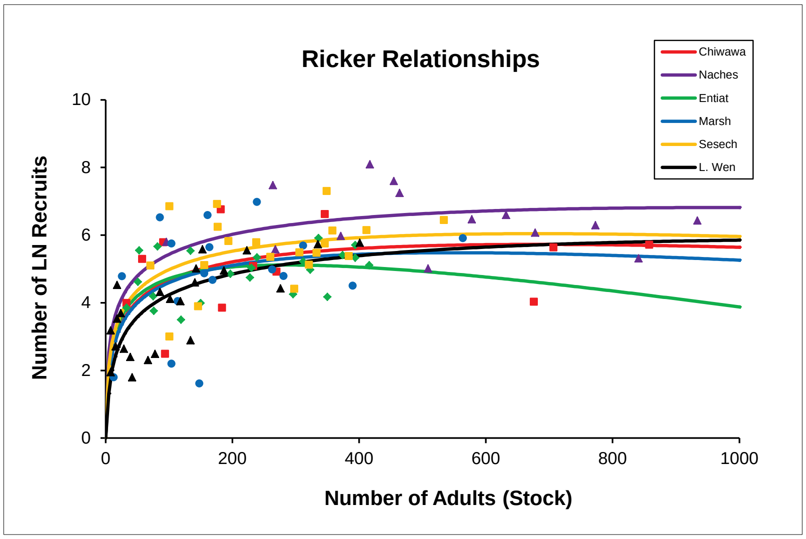

Figure 19. Scatter plot of the number of spawners and natural log adult recruits and fitted Ricker curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

Table 30. Randomization test results comparing the equality of Ricker curves and equality of parameter values (α and β). Randomization tests were based on 10,000 Monte Carlo samples. Equality or curves was based on 500 points along the x-axis (spawner abundance axis).

Curves tested	Curve inequality randomization P-value	Parameter inequality

		$\beta = 0.0015$	$\beta = 0.0008$	0.203

Beverton-Holt Relationships

Beverton-Holt curves differed significantly only between the Chiwawa and Naches populations (Figure 20; Table 31). There was no significant difference in curves between the Chiwawa and the other reference populations. The parameters in the Beverton-Holt model did not differ significantly among any of the populations (Table 31). This was true even for the Chiwawa and Naches populations.

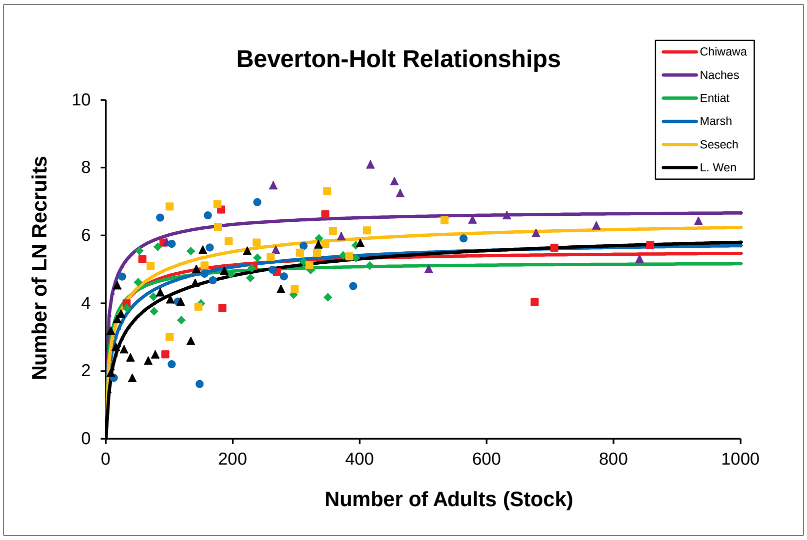

Figure 20. Scatter plot of the number of spawners and natural log adult recruits and fitted Beverton-Holt curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

Table 31. Randomization test results comparing the equality of Beverton-Holt curves and equality of parameter values (α and β). Randomization tests were based on 10,000 Monte Carlo samples. Equality or curves was based on 500 points along the x-axis (spawner abundance axis).

		β = 113.79	β = 725.87	0.751

Smooth Hockey Stick Relationships

Smooth hockey stick curves differed significantly between the Chiwawa and Naches populations and the Chiwawa and Sesech populations (Figure 21; Table 32). There was no significant difference in curves between the Chiwawa and the other reference populations. Most of the parameters in the smooth hockey stick model did not differ significantly among the populations (Table 32). However, the productivity parameter β did differ significantly between the Chiwawa and the Naches and the Chiwawa and Little Wenatchee populations. The β parameter for the Naches was significantly greater than the Chiwawa, while the β parameter for the Little Wenatchee was significantly less than the Chiwawa.

		β = 1.84	β = 1.27	0.999
Chiwawa v. Sesech	0.000	α = 5.41	α = 6.15	0.000
		β = 1.84	β = 1.80	0.999
Chiwawa v. L. Wenatchee	0.990	α = 5.41	α = 6.02	0.999
		β = 1.84	β = 0.75	0.000

Comparing different stock-recruitment curves and their parameters did not provide strong evidence that the supplementation program has negatively affected the productivity of the Chiwawa population.

Analysis without Reference Populations

In some cases, suitable reference populations may not exist to compare with supplemented populations. It is therefore important to have alternative analyses to assess supplementation effects. In this section, we describe methods that can be used to assess supplementation effects when suitable reference populations are not available. We discuss before-after comparisons, correlation analysis, and comparisons to standards as alternatives when reference populations are unavailable.

Before-After Comparisons

Before-after analyses compare population metrics (spawner abundance, NORs, and productivity) before supplementation to those during supplementation. In this case, data collected before supplementation represent the reference condition. The assumption is that population trajectories measured during the pre-supplementation period would continue in the absence of supplementation. We compared trends in abundance and productivity, mean abundance and productivity, and stock-recruitment relationships before and after supplementation.

Trend Analysis

Comparing trends before and after supplementation can be used to assess the effects of supplementation. Here, we compared the slopes of trends of spawner abundance, NORs, and productivity before and during supplementation using t-tests. If the hatchery program is successfully supplementing the natural spring Chinook population, the trend for spawner abundance and NORs during supplementation should be greater than the slope during the pre-supplementation period. For productivity, the slope during the supplementation period should increase or remain the same as that during the pre-supplementation period.

Visual examination of trends of Chiwawa data indicates that spawner abundance, NORs, and productivity decreased during the pre-supplementation period, but increased during the supplementation period (Figure 22). Only the changes in NOR trends were significant (Figure 22). This was true for both transformed and untransformed data.

Deleted: 2013 Update

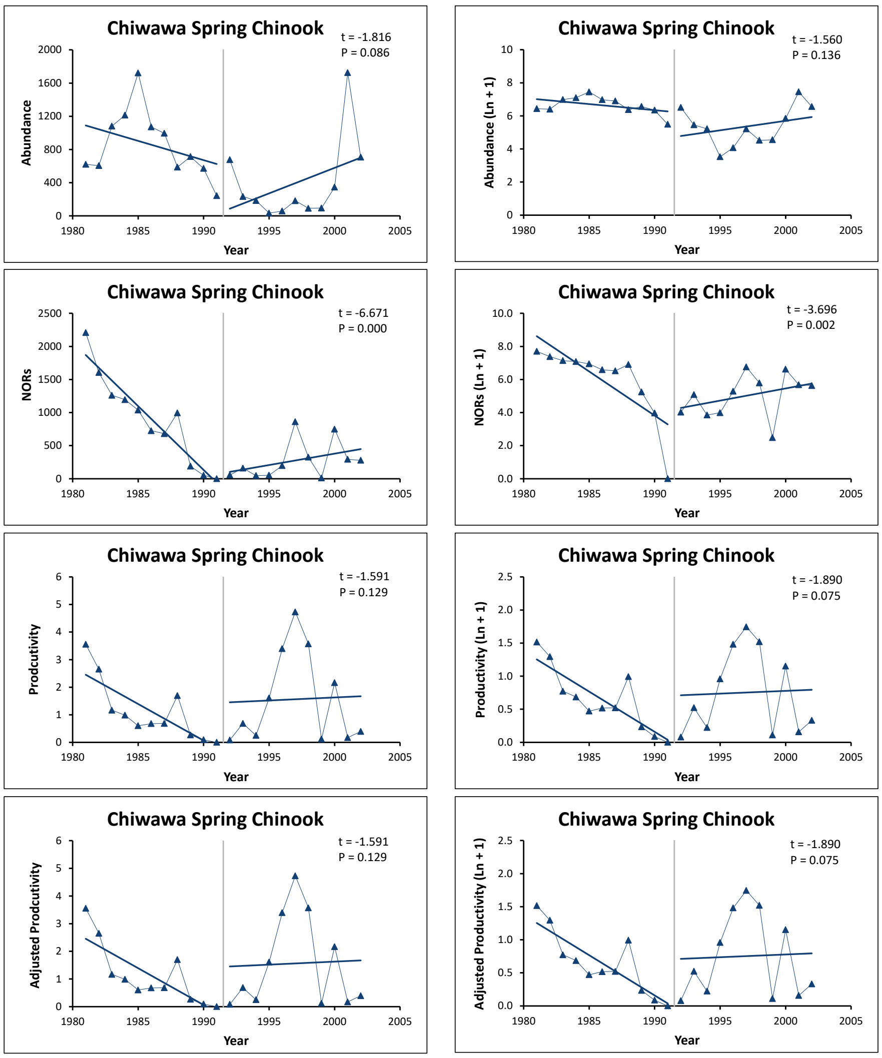

Figure 22. Trends in Chiwawa spring Chinook spawner abundance, natural-origin recruits (NORs), productivity (adults recruits per spawner), and adjusted productivity (adjusted for density dependence) before and during supplementation. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left show untransformed data; figures on the right include natural-log transformed data. Figures include results of t-tests comparing slope of trends before and during supplementation.

Analysis of Mean Scores

We also compared mean spawner abundance, NORs, and productivity data before and after supplementation. If the hatchery program is successfully supplementing the natural spring Chinook population, mean spawner abundance and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean productivity during the supplementation period should be equal to or higher than the pre-supplementation period. We tested the following statistical hypotheses.

Spawner Abundance and NORs:

Ho: Mean spawner abundance and NORs before supplementation ≥ Mean spawner abundance and NORs during supplementation.

Ha: Mean spawner abundance and NORs before supplementation < Mean spawner abundance and NORs during supplementation.

Productivity (Recruits/Spawner):

Ho: Mean productivity before supplementation ≤ Mean productivity during supplementation.

Ha: Mean productivity before supplementation > Mean productivity during supplementation.

We tested before-after supplementation effects using a one-tailed Aspin-Welch unequal-variance test. We also used a randomization test, based on 10,000 Monte Carlo simulations, to assess differences in spawner abundance and productivity before and during supplementation. The randomization procedure only allowed the testing of two-tailed hypotheses. Therefore, we generated 95% confidence intervals on the mean difference (μ_{pre} - μ_{post}) using bootstrapping methods to determine if the significant result from the randomization test was in the right direction. We generated 5,000 bootstrap samples to calculate confidence intervals.

Mean spawner abundance during the supplementation period was significantly less than the pre-supplementation spawner abundance (Table 33). Mean spawner abundance decreased 46% between the pre- and post-supplementation periods. Likewise, mean NORs decreased significantly between the two periods (Table 33). On the other hand, productivity increased slightly, but not significantly, between the pre- and post-supplementation periods (Table 33). This was true for both adjusted and transformed productivity data.

Table 33. Statistical results comparing mean scores of spawner abundance, natural-origin recruits (NORs), and productivity (using both untransformed and natural-log transformed) before and during supplementation of Chiwawa spring Chinook. Randomization tests were based on 10,000 Monte Carlo samples and 95% CI were based on 5,000 bootstrap samples.

Analysis of Stock-Recruitment Curves

The third method compared stock-recruitment curves of the Chiwawa population during supplementation with those generated before supplementation. Specifically, we tested whether the regression parameters were equal between the pre- and post-supplementation periods, and whether the fitted curves coincided between the two time periods. We used the methods described earlier to fit the Ricker, Beverton-Holt, and smooth hockey stick curves to the two data sets. We tested the following hypotheses.

Parameter equivalence:

Ho: Stock-recruitment parameters (α and β) of the pre-supplementation period = Stock-recruitment parameters of the supplementation period.

Ha: Stock-recruitment parameters (α and β) of the pre-supplementation period ≠ Stock-recruitment parameters of the supplementation period.

Curve equivalence:

Ho: Modeled stock-recruitment curves from the pre-supplementation period = Modeled stock-recruitment curves from the pre-supplementation period.

Ha: Modeled stock-recruitment curves from the pre-supplementation period ≠ Modeled stock-recruitment curves from the pre-supplementation period.

We were only able to fit stock-recruitment curves to the post-supplementation data. Non-linear regression was unable to converge on a solution using only pre-supplementation data. Therefore, we were unable to use this method to test supplementation effects on the Chiwawa spring Chinook population. If we could have fit curves to both the pre- and post-supplementation periods, we would have used two-sided randomization tests to evaluate the null hypotheses of equal model parameters and that fitted curves coincided.

Before describing correlation approaches, it is important to note that comparing before-after data can sometimes be misleading. For example, the spawner abundance, NORs, and productivity data presented in Figure 22 suggest that supplementation is increasing the abundance and productivity of spring Chinook in the Chiwawa Basin. However, when we compared these trends to those from reference populations during the same time periods (Figures 9-11), it becomes clear that supplementation was not responsible for increasing the trends in spawner abundance, NORs, and productivity of the Chiwawa population. Thus, whenever possible, it is wise to compare before-after data with a reference population.

Correlation Analyses

A simple way to see if the supplementation program is increasing or decreasing productivity is to assess the association between the proportion of adult spawners that are made up of hatchery adults (pHOS) and productivity (recruits/spawner). If the supplementation program is working as planned, the increase in hatchery fish spawning naturally should increase the productivity of the population. It should not decrease the productivity of the population.

We tested the association between pHOS and adult productivity[22] using Pearson correlation. During the pre-supplementation period, productivity averaged 1.13 recruits/spawner; during the supplementation period, productivity averaged 1.39 recruits/spawner. This increase in productivity did not appear to be strongly correlated to pHOS (Figure 23). Correlation analysis showed that there was no significant association between pHOS and productivity, even though productivity increased with increasing pHOS.

[22] Note that the analysis could also include juvenile productivity (e.g., smolts/spawner).

Deleted: 2013 Update

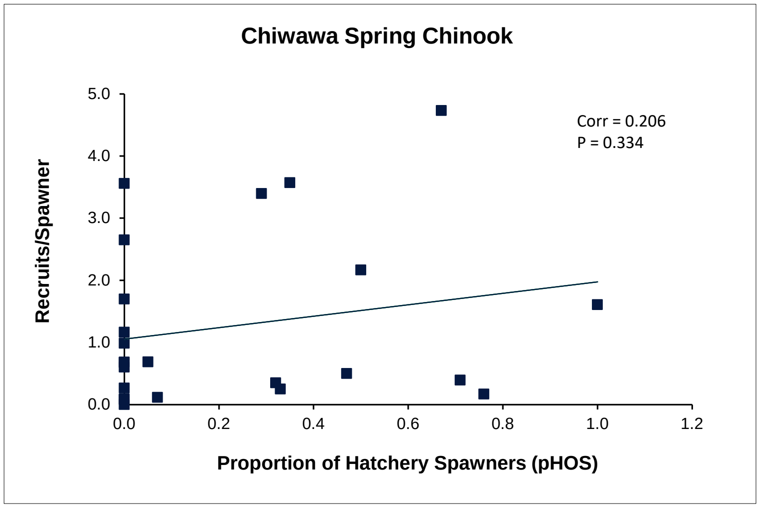

Figure 23. Association between the proportion of spawners that are made up of hatchery adults (pHOS) and the number of natural-origin recruits. The Pearson correlation coefficient (Corr) and its P-value (P) are shown in the figure.

The association between pHOS and productivity can also be assessed by testing the correlation between pHOS and the residuals from stock-recruitment curves fitted to the Chiwawa spawner and natural-origin recruitment data. This approach removes the effects of density dependence on the relationship between pHOS and productivity. A significant negative association provides evidence that hatchery-origin spawners may not be as productive as natural-origin spawners.

The Ricker, Beverton-Holt, and smooth hockey stick models were fit to the Chiwawa stock and recruitment data (including {S, R} data from both the pre- and post-supplementation period, 1981-2004) using methods described earlier. Residuals were calculated by subtracting the predicted recruitment values from the observed (modeled) values. Pearson correlation then tested the association between pHOS and the residuals from each model.

Although there was a negative trend in residuals with increasing pHOS, suggesting that hatchery-origin spawners may not be as productive as natural-origin spawners, the association was not significant (Figure 24). Thus, based on these analyses, there is no strong evidence that the supplementation program has significantly benefited or harmed the natural spring Chinook population.

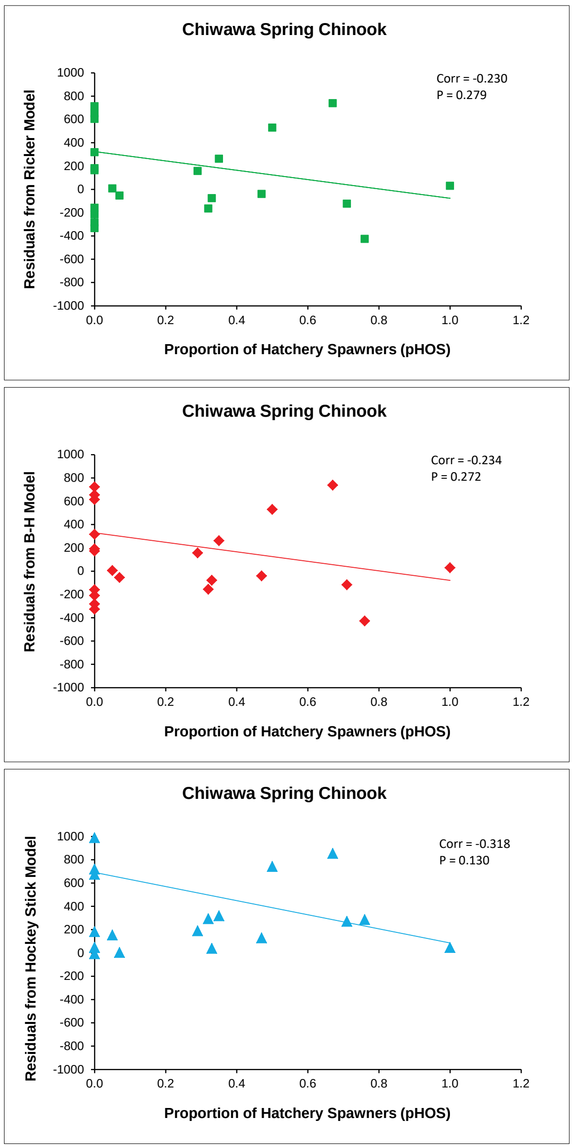

Figure 24. Association between the proportion of spawners that are made up of hatchery adults (pHOS) and the residuals from Ricker, Beverton-Holt (B-H), and smooth hockey stick stock-recruitment models. The Pearson correlation coefficient (Corr) and its P-value (P) are shown in the figures.

Comparison to Standards

In those cases in which suitable reference populations are not available and there are no pre-supplementation data, the investigator is left with comparing population parameters to relevant standards. Standards can include performance of natural-origin fish in similar environments (a type of reference condition), mitigation requirements, quantitative objectives of the program, Biological Assessment and Management Plan (BAMP) values, or other appropriate standards. An example of a statistical hypothesis would be:

Ho: Productivity (Recruits/Spawner) of the supplemented population $\geq$ standard productivity.

Ha: Productivity (Recruits/Spawner) of the supplemented population < standard productivity.

For these analyses to be useful, the standards must be based on biological reality.

Conclusions and Recommendations

Hatcheries are an important component of fish production within the Upper Columbia Basin. The goal of some of these programs is to supplement natural production in declining populations. The supplementation programs generally use both hatchery and natural (spawned and reared in nature from either wild or hatchery parents) adults for hatchery broodstock. These programs are designed to supplement natural populations by increasing natural reproduction while preventing the establishment of a domesticated hatchery stock. Thus, the programs should increase total spawning escapement and NORs, and not reduce the productivity of the natural population. Measuring the success of these programs is challenging and expensive.

In this paper, we described methods that can be used to determine if supplementation programs are achieving some of their goals. This paper focused on the use of reference populations to determine if the supplementation programs increase total spawning escapement, NORs, and maintain or increase productivities. In some cases, suitable reference populations may not be available (e.g., we found no suitable reference populations for Upper Columbia steelhead and sockeye). In these cases, alternative methods are needed to assess supplementation effects. We also described these alternative methods in this paper.

Identification of Reference Populations

Finding suitable reference populations that match well with supplemented populations is a difficult and time-consuming process. Our three-step selection process included identification of populations with similar life-history characteristics, few or no hatchery spawners, a long time series of accurate abundance and productivity estimates, and similar freshwater habitat impairments and out-of-basin effects. Those populations that met these criteria were then examined for their relationship with the supplemented population (in this case, the Chiwawa spring Chinook population). Several criteria were scored, including pNOS, correlation, trend, and effect size. Reference populations with total weighed scores of 81 or greater were selected as suitable reference populations.

This selection process provided a valuable framework for selecting suitable reference populations for supplemented populations. Interestingly, we found that a given reference population may match well with one parameter of the supplemented population (e.g., spawning escapement), but not for all parameters (e.g., not NORs or productivity). The reason for this may be related to errors in the estimation of population parameters and/or differential factors limiting population parameters of supplemented and reference populations. Therefore, depending on the parameter analyzed, a different suite of reference populations may be needed.

An important assumption in the use of reference populations is that the supplemented and reference populations that tracked each other before supplementation would continue to track each other in the absence of supplementation. Given that the reference populations did not match the Chiwawa population on all criteria examined, and some reference populations tracked the Chiwawa population more poorly than others, there may be some uncertainty as to whether differences observed between the supplemented and reference populations during the supplementation period are associated with the hatchery program, or other unaccounted factors. For example, any large-scale change (man-made or natural) within the reference or supplemented population could affect our ability to assess the effectiveness of the supplementation program.

To account for some of these uncontrollable factors, we recommend the use of a “causal-comparative” approach to strengthen the certainty of our inferences. This approach relies on correlative data to try and make a case for causal inference. We recommend that the following state variables be measured and tracked within the supplemented and reference populations: mean annual precipitation, total and riparian forest cover, road density, impervious surface, and alluvium. These variables can be used to describe differences in water temperatures at different life stages (pre-spawning, egg incubation, and summer rearing) and substrate characteristics, including fine sediments and embeddedness. These state variables can be used to help explain possible changes in spawner abundance, NORs, and productivity that are independent of supplementation. In addition, the use of multiple reference streams reduces the possibility that man-made changes to a single reference stream will influence the interpretation of the results.

Analyses with Reference Populations

Using reference populations, we evaluated the effects of supplementation on natural-log transformed and untransformed total spawning escapement, NORs, and productivity by comparing trends, analyzing mean differences, ratios, and rates, and comparing stock-recruitment curves and their parameters. For trend analysis, we compared the slopes of the trends between each supplemented/reference pair before and during supplementation. If the hatchery program is successfully supplementing the natural population, trends in spawner abundance and NORs should deviate significantly during the supplementation period (i.e., the slope of the supplemented population should be greater than the slopes of the reference populations during the supplementation period), but not during the pre-supplementation period. For productivity, the slope of the supplemented population, relative to the reference population, should increase or remain the same.

Because trend analysis only tests the slopes of the trend lines, it does not test for differences in elevations of the trend lines, additional analyses were needed to determine if supplementation increased spawner abundance, NORs, and productivity of the target population without changing the slopes of the trend lines. To do this, we derived three different response variables using natural-log transformed and untransformed spawner abundance, NORs, and productivity data. The first derived variable included difference scores, which were calculated as the difference between paired treatment and reference data (T-R). The second included ratios, which were calculated as the ratio of paired treatment and reference data (T/R). Finally, we calculated the differences in annual changes in paired treatment and reference population data (ΔT-ΔR). If the hatchery program is successfully supplementing the natural population, the mean difference or ratio score of paired spawner abundance data and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean difference or ratio score during the supplementation period should be equal to or higher than the pre-supplementation period.

As a final set of analyses, we compared the stock-recruitment curves of the supplemented population (using stock and recruitment data only from the supplementation period) to the reference populations (using all available stock and recruitment data). Specifically, we tested whether the regression parameters were equal between the supplemented population and the reference populations, and whether the fitted curves coincided between populations. Here, we were most interested in comparing the productivity parameters in the models.

Surprisingly, these different analyses yielded similar results when they were applied to the Chiwawa spring Chinook and reference population data. Trend analysis was unable to detect a significant difference in trends between the supplemented and reference populations during the supplementation period. Even though we measured an increasing trend in spawner abundance, NORs, and productivity in the supplemented population during the supplementation period, these same parameters trended upward in the reference populations. Likewise, we were unable to detect a significant supplementation effect using difference scores, ratios, and differences in annual changes. However, we found the results from analysis of mean differences of annual change difficult to interpret and they may be insensitive to treatment effects. A simpler analysis, which is also easier to interpret, is to use trend analysis. Finally, comparing stock-recruitment curves and their parameters did not provide strong evidence that supplementation has affected the productivity of the natural population.

Based on these results, we do not recommend using difference scores of annual change (ΔT-ΔR), nor do we recommend comparing stock-recruitment curves and their parameters. As noted above, difference scores of annual change are difficult to interpret and may be redundant with trend analysis. Testing stock-recruitment curves and their parameters appears redundant with testing differences in productivity using difference scores or ratios. In addition, the analyses are computer intensive and do not appear to be very sensitive to changes.

There was little difference in results using difference scores and ratios. It appears that ratios may be more sensitive to change than difference scores (e.g., we found significant differences in some comparisons using ratios but not with difference scores), but ratios can be more difficult to interpret than difference scores. Nevertheless, we recommend the use of ratios in future analyses.

Correcting for Density Dependence and Carrying Capacity

The analyses described so far assumed that the density of spawners or recruits did not affect the survival and productivity of fish. However, without controlling for density effects, productivity of the population would continue to decline with increasing abundance. This scenario could occur in supplementation programs that increase the number of spawners, and could result in lower productivities relative to reference populations. In addition, lower productivities may be caused by differential environmental carrying capacities rather than the capacity of the supplemented fish to produce offspring. Therefore, we described two different methods for deriving density-corrected estimates of productivity. The first controlled the effects of density on productivity by partitioning observed productivities into density-independent and density-dependent productivity. These productivities were then combined in a single test. The second method corrected for differences in carrying capacities between the supplemented and reference populations. This was accomplished by calculating the percent saturation of NORs, which was estimated as the ratio of observed NORs to the maximum number of NORs that the habitat could support.

We fit Ricker, Beverton-Holt, and smooth hockey stick models to stock and recruitment data to estimate the maximum number of NORs (NORs at carrying capacity) and the maximum number of spawners needed to produce maximum NORs. We fit models to the supplemented and reference populations. Using information-theoretic criterion and evaluating the precision of estimated parameters, we found that the smooth hockey stick model provided the best estimates of maximum NORs and spawners. We used these modeled values to estimate density-independent and density-dependent productivities, and saturation of NORs.

Statistical analyses, using difference scores and ratios of adjusted Chiwawa spring Chinook productivity data, found no significant effects of supplementation on the productivity of the supplemented population. Indeed, the results from correcting for density dependence were similar to those without correcting for density dependence. This is in part because the abundance of the supplemented and reference populations has been below their respective carrying capacities in most years. This was clearly demonstrated in the analyses of NORs corrected for carrying capacity. In the supplemented population, the mean fraction of the carrying capacity filled with NORs decreased significantly during the supplementation period. In other words, the carrying capacity was filled with more NORs during the pre-supplementation period than during the supplementation period, which is contrary to the goal of supplementation. By comparison, two of the reference populations showed a similar decrease in saturation, while the other two reference populations actually increased in saturation. Analyzing the saturation scores using BACI-design analyses indicated that two of the four pairings differed significantly. That is, the percent saturation of the supplemented population decreased significantly relative to two reference populations.

Because productivity can be affected by the abundance of spawners and recruits, we recommend that future analyses comparing supplemented and reference populations adjust for density-dependent effects and differential carrying capacities. Although we detected only slight differences between adjusted and unadjusted results, as supplemented stocks recover, it will become more important to adjust productivities to account for density dependence. Importantly, the analyses using percent saturation placed NORs in the context of the carrying capacity of the environment. This will help managers determine if supplementation programs are filling or over-filling the capacity of the habitat with NORs.

Deleted: 2013 Update

As we noted earlier, analyses using productivities adjusted for density dependence assume that there is a spawner abundance at which density-independent effects end and density-dependent effects begin. In reality, density-dependent effects occur at low spawning abundance and intensify as spawning abundance increases. We did not account for these increasing density-dependent effects at lower spawner abundances. This is an area that needs additional attention.

Analyses without Reference Populations

Because of the rigorous criteria we used to select reference populations, it is likely that reference populations may not exist for making comparisons with supplemented populations. For example, we used the criteria described in this paper to identify reference populations for supplemented steelhead and sockeye populations in the Upper Columbia Basin. We were unsuccessful in identifying any suitable reference populations. Therefore, in the absence of suitable reference populations, it is important to have alternative methods for assessing supplementation effects. We described three different types of analyses one can use to assess supplementation effects in the absence of reference populations. They include before-after comparisons, correlation analysis, and comparisons to standards.

Before-after analyses compare population metrics before supplementation with those during supplementation. In this case, data collected before supplementation represent the reference condition. The assumption is that population trajectories measured during the pre-supplementation period would continue in the absence of supplementation. We compared trends in spawner abundance, NORs, and productivity before and after supplementation. In addition, we compared mean scores in these three parameters before and after supplementation. Finally, we attempted to compare stock-recruitment parameters before and after supplementation. The hypotheses examined were that the spawner abundance and NORs would be greater during the supplementation period, and that productivities would not decline during the supplementation period.

Trend analysis indicated that the all three Chiwawa spring Chinook population parameters trended downward during the pre-supplementation period, but trended upward during supplementation. On the other hand, mean spawner abundance and NORs were lower during the supplementation period than during the pre-supplementation period. Mean productivities increased, but not significantly, during the supplementation period. We were unable to compare pre- and post-supplementation stock-recruitment curves because we were unable to fit stock-recruitment models to the pre-supplementation data.

We used correlation analyses to determine if the proportion of hatchery-origin fish that spawn naturally on the spawning grounds (pHOS) increased productivity. In addition, we used correlation to assess the association between pHOS and the residuals from stock-recruitment relationships. A significant negative association provides evidence that hatchery-origin spawners may not be as productive as natural-origin spawners. The analysis indicated that the productivity of Chiwawa spring Chinook increased with increasing pHOS, but the association was not significant. In contrast, there was a negative association between pHOS and the stock-recruitment residuals, but again the association was not significant. The latter analysis accounts for density-dependent effects.

In concert, the before-after comparisons and correlation analyses do not provide conclusive evidence that the supplementation program has increased spawner abundance and NORs, or that it has significantly reduced the productivity of the supplemented population. Although increasing

Deleted: 2013 Update

the number of hatchery fish on the spawning grounds appears to reduce NORs and productivity, mean productivity actually increased during the supplementation period compared to the pre-supplementation period.

It is important to note that relying on only one set of analysis could result in drawing a wrong conclusion. For example, if we had only conducted trend analysis, we may have concluded wrongly that the Chiwawa spring Chinook supplementation program significantly increased spawner abundance, NORs, and productivity in the supplemented population. The analysis of mean scores and correlations indicates that the supplementation program has not increased spawner abundance or NORs in the supplemented population. Therefore, in the absence of suitable reference populations, we recommend that analyses include the evaluation of trends, means scores, and correlations. By conducting more than one set of analyses, one can use weight-of-evidence to assess the effects of supplementation programs.

Under the scenario that there are no reference populations or pre-supplementation data, one is left with comparing population parameters to relevant standards. These standards could come from mitigation requirements, quantitative objectives, or published or unpublished standards. One could also use correlation to evaluate the association between productivity and pHOS, but this requires a wide range in pHOS values to be most effective. A more extreme approach, which probably would not gain much traction with managers, is to shutoff the supplementation program for some time and then evaluate the effects of the program in a before-after design. The Entiat spring Chinook hatchery program provides a unique opportunity to evaluate this type of management decision.

Some Concerns and Limitations

No matter how hard we try to explain different sources of variation in population data, we are limited by the quality of the data. Teasing out the effects of supplementation requires long time series of population data. Because funding levels and methods change over time, the quality (i.e., accuracy and precision) of the data also changes over time. Importantly, the population parameters examined in this paper (spawner abundance, NORs, and productivity) are rarely measured directly in the field. That is, other population metrics, such as numbers of redds, number of fish counted at weirs or dams, scales, tags, etc., are sampled in the field. These metrics are then used to calculate spawner abundance[23], NORs, and productivity, often based on assumptions about fish/redd, pre-spawning loss, marking rates, and sampling rates. This has a tendency to increase the variability in the data independent of supplementation programs. In our studies, we can only control sampling within the supplemented populations, and even that is limited by available funding. We have no control over the sampling within reference populations. Thus, we have to assume that sampling within the reference populations will continue and that sampling effort will remain comparable to that in the supplemented populations.

In our analyses, we included both the Entiat and Little Wenatchee populations as references for the Chiwawa population. In the analyses, we treated them as equivalent to the other reference populations. That is, the statistical procedures used to compare the supplemented population to each reference population were identical. This is appropriate. However, the interpretation of the results must be different when comparing the Entiat and Little Wenatchee to the supplemented

[23] The smooth hockey stick model, which we used to estimate density-dependent correction factors for productivity and NORs, is sensitive to errors in spawner escapement estimates. Therefore, it is important to use accurate and precise estimates of spawner escapement.

Deleted: 2013 Update

population, because they are populations that were influenced by hatchery fish. As noted earlier, the Entiat spring Chinook hatchery program has been discontinued. Therefore, it provides a unique type of reference where the comparison changes from both populations being supplemented to only one population being supplemented. For the Little Wenatchee, nearly all the strays came from the Chiwawa program. Straying should stop or be greatly reduced with the change in water supply to the Chiwawa Rearing Ponds. In sum, one must be careful in how they interpret these test-reference results.

Finally, it is important to point out that for this paper, we conducted 463 statistical tests. Because we set our Type I error rate at 0.05, by random chance alone, we may have incorrectly rejected about 23 null hypotheses. Inasmuch as this work was designed to evaluate different ways to analyze test-reference data, the number of future analyses will be greatly reduced based on the results from this work. However, if the Type I error rate is a concern to managers, researchers can use a lower error rate, such as $\alpha = 0.01$. Another option is to analyze test-reference data graphically. Although this is subjective, there are no statistical analyses and therefore no concerns with violating assumptions of statistical tests, including temporal correlation. We believe researchers should use the statistical procedures recommended in this report to support graphic analysis.

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Hatchery Committees

Date: September 22, 2017

From: Tracy Hillman, HCP Hatchery Committees Chairman

cc: Sarah Montgomery, Anchor QEA, LLC

Re: Final Minutes of the August 16, 2017, HCP Hatchery Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Hatchery Committees meeting was held at the Grant PUD office in Wenatchee, Washington, on Wednesday, August 16, 2017, from 9:00 a.m. to 12:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A). *(Note: this item is ongoing.)*
- Sarah Montgomery will clarify the review period for the Chelan PUD Draft Statement of Agreement (SOA) Regarding the District's Coho Obligation and provide an update to the Hatchery Committees (Item II-A). *(Note: Montgomery clarified this in the action items from the August 16, 2017, meeting.)*
- Mike Tonseth will coordinate with Todd Seamons (WDFW) to produce an outline or recommended approach for genetic monitoring (Item III-E).
- Mike Tonseth will send the revised Table 3 of the Hatchery Monitoring and Evaluation (M&E) Plan to Tracy Hillman for inclusion in the 2017 Update (Item III-G). *(Note: Tonseth provided the table to Hillman on August 17, 2017.)*
- Sarah Montgomery will send SOAs regarding Non-target Taxa of Concern (NTTOC) study results to Tracy Hillman (Item III-G). *(Note: Montgomery did this on September 20, 2017.)*
- Tracy Hillman and Todd Pearsons will revise NTTOC and adaptive management language in the Draft 2017 Update to the M&E Plan for PUD Hatchery Programs and provide a revised version for Hatchery Committees review (Item III-G). *(Note: Hillman revised the plan and Montgomery distributed a revised version for review on September 2, 2017.)*

Decision Summary

- The Rocky Reach and Rock Island Hatchery Committees representatives approved Chelan PUD's Draft 2018 Hatchery M&E Implementation Plan as follows: Chelan PUD, WDFW, U.S. Fish and Wildlife Service (USFWS), Yakama Nation (YN), and National Marine Fisheries Service (NMFS) approved during the meeting on August 16, 2017, and Colville Confederated Tribes (CCT) approved on August 18, 2017 (Item II-B).

Agreements

- There were no agreements discussed during today's meeting besides the decision above.

Review Items

- Sarah Montgomery sent an email to the Rocky Reach and Rock Island Hatchery Committees on August 15, 2017, notifying them that the Chelan PUD Draft SOA Regarding District's Coho Obligation is available for a 30-day review, with comments due to Catherine Willard by September 14, 2017. Chelan PUD indicated they will request approval of the SOA at the Hatchery Committees September 20, 2017, meeting.
- Sarah Montgomery sent an email to the Hatchery Committees on September 1, 2017, notifying them that the Draft 2016 Douglas PUD and Grant PUD M&E Annual Report is available for a 60-day review, with edits and comments due to Greg Mackey by October 31, 2017. (Note: Douglas PUD requested comments in 30 days if possible, which would be October 2, 2017.)

Finalized Documents

- Sarah Montgomery sent an email to the Hatchery Committees on September 15, 2017, notifying them the Chelan PUD and Grant PUD 2016 Final M&E Annual Report and Appendices is now available for download from the Hatchery Committees Extranet site.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the July 19, 2017, Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the Hatchery Committees and asked for any additions or changes to the agenda. Catherine Willard added the Chelan Falls Trap to the agenda. *(Note: Sarah Montgomery combined the two items regarding spring Chinook salmon in the Methow basin because discussions were interrelated.)*

The Hatchery Committees reviewed the revised draft July 19, 2017, meeting minutes.
Sarah Montgomery said there are no outstanding comments to be discussed. Hatchery Committees

representatives present approved the draft July 19, 2017, meeting minutes, as revised. Kirk Truscott provided his approval of the meeting minutes prior to the meeting.

Action items from the Hatchery Committees meeting on July 19, 2017, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meeting on July 19, 2017)*:

- *Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A).*
  This item is ongoing. Keely Murdoch requested that Cory Kamphaus (YN) be involved in this discussion.
- *Hatchery Committees representatives will review McLain Johnson's Genetic Monitoring Update (Item I-A).*
  This item will be discussed today.
- *Sarah Montgomery will clarify the review period for the Chelan PUD Draft 2018 Hatchery Monitoring and Evaluation (M&E) Implementation Plan and provide an update to the Hatchery Committees (Item II-A).*
  This item is complete.
- *Tracy Hillman will revise Appendix 4 of the Draft 2017 Update to the Monitoring and Evaluation Plan for PUD Hatchery Programs to include release number targets, and provide it for Hatchery Committees review (Item III-C).*
  This item is complete and available for review.
- *Tracy Hillman will revise the Draft 2017 Update to the M&E Plan for PUD Hatchery Programs and provide it for Hatchery Committees review (Item III-C).*
  This item is complete and will be discussed today.

II. Chelan PUD

A. Draft Coho Salmon Mitigation SOA (Catherine Willard)

Catherine Willard shared the document titled *Draft Statement of Agreement Regarding District's Coho Obligation*, which Sarah Montgomery distributed to the Hatchery Committees on August 15, 2017 (Attachment B). Willard said the 7 percent coho salmon hatchery compensation rate was agreed to by the Rocky Reach and Rock Island Coordinating Committees. She said the SOA is an agreement about the methodology used to calculate hatchery compensation levels (the same methodology as used in recalculation) and is also an agreement that Chelan PUD will meet its obligation through funding and/or facility use to support a coho salmon reintroduction project. She said she also distributed a revised presentation (originally presented at the May 17, 2017, Hatchery Committees meeting), *Approach Used to Determine Chelan PUD's Coho Hatchery Mitigation*, which Montgomery distributed to the Hatchery Committees on August 15, 2017. She said the presentation includes more detail about how the smolt numbers were calculated.

Montgomery said the SOA is available for a 30-day review, with comments due to Willard on September 14, 2017, and said she would remind the Hatchery Committees of this review timeline. Willard said Chelan PUD will request approval of this SOA at the September 20, 2017, Hatchery Committees meeting and asked for any immediate questions.

Mike Tonseth asked why calculations for Rocky Reach coho salmon mitigation are based on mortality at both Rocky Reach and Rock Island dams. Keely Murdoch said coho salmon from the Methow basin migrate past both dams. Willard said Rocky Reach Dam has mitigation related to the Methow basin, whereas Rock Island Dam has mitigation associated with the Wenatchee and Methow basins. Willard said she would clarify this language in the final version of the SOA.

B. Draft 2018 Hatchery M&E Implementation Plan (Catherine Willard)

Catherine Willard said the Chelan PUD Draft 2018 Hatchery M&E Implementation Plan (Attachment C) is currently available for a 30-day review. Tracy Hillman said the changes between the 2017 and 2018 plans are minor and include only date and authorship changes. Willard said Chelan PUD requests that the Rocky Reach and Rock Island Hatchery Committees approve this plan, which they did as follows: Chelan PUD, USFWS, WDFW, YN, and NMFS approved during the meeting on August 16, 2017. CCT did not have representation at the meeting, and Hillman received approval from Kirk Truscott via phone on August 18, 2017.

III. Joint HCP-HC/PRCC HSC

A. USFWS Bull Trout Consultation Update (Bill Gale)

Bill Gale said he received a consultation update from Karl Halpuka (USFWS), which he shared with the Hatchery Committees as follows:

- The USFWS is working on the Methow steelhead consultation, and Halpuka plans to write a coverage memorandum similar to the one completed for spring Chinook salmon.
- The USFWS is working on finalizing the Biological Opinion for the batch of Wenatchee subbasin programs.

Emi Kondo (NMFS) added that NMFS and USFWS have not yet received feedback from the U.S. Army Corps of Engineers regarding consulting for the Ringold program, so consultation for the batch of unlisted upper Columbia River (UCR) summer Chinook salmon programs is on hold. Mike Tonseth said he has been discussing the UCR unlisted programs' consultations with the USFWS and National Oceanic and Atmospheric Administration. He understands that in order for the consultation to move forward, the Ringold program's Hatchery and Genetic Management Plan needs a proposed action, the proposed action for the consultation needs to be finalized, and cover letters that identify consultation pathways need to be submitted.

B. NMFS Consultation Update (Brett Farman/Emi Kondo)

Emi Kondo said she is providing an update on consultation for the unlisted programs in the UCR. She said the Ringold program involves consultation with the U.S. Army Corps of Engineers, and that consultation has not yet been initiated. She said she is working on finalizing the proposed action, which is necessary to initiate consultation with USFWS. Kondo said she will soon send an updated version of the proposed action for applicants and others to review, then everyone can meet to discuss changes. She asked for interested parties outside of the applicant pool to please let her know so she can include them in the meeting.

She said applicants have made progress deciding which Endangered Species Act (ESA) pathway to pursue for these consultations. She said Douglas PUD representatives indicated they intend to use Section 10 coverage and Chelan PUD representatives indicated they intend to use Section 4(d) coverage. She said discussions with Grant PUD representatives regarding coverage for their programs are ongoing. She said one topic of discussion is Chelan PUD's trap on the Chelan River. She said it is operated when water temperatures are over 21 degrees, which could be an issue if ESA-listed species are being trapped. She said this discussion is ongoing with Chelan PUD and WDFW.

Kondo said the next steps for this consultation are finalizing the proposed action, determining the ESA pathways, initiating consultation with a request letter, and NMFS replying with a letter of sufficiency. She said effects to bull trout can be analyzed by USFWS after those steps are complete.

Tracy Hillman asked which listed species have the potential to be collected in the Chelan Falls Trap. Mike Tonseth said steelhead and spring Chinook salmon could be collected at the Chelan Falls Trap and the trap would operate starting on July 1. Bill Gale said, while unlikely, bull trout are also a listed species that could be collected in the trap. Catherine Willard said monthly snorkel surveys have shown no bull trout present in past years during July and August, the period the trap would be in operation. Tonseth said spring Chinook salmon are difficult to differentiate from unlisted summer/fall Chinook salmon, particularly in the early part of the trapping season. Willard said the start date will be later than July 1, and said the trap cannot be operated until July 15, which could reduce the potential to trap ESA-listed species.

C. Wenatchee Spring Chinook Salmon Update (Mike Tonseth)

Mike Tonseth said he has provisional data regarding the status of Wenatchee spring Chinook salmon in 2017. He said WDFW switched to video analysis in the middle of July, but continued sampling. At that point, he said approximately 1,300 spring Chinook salmon had passed Tumwater Dam. Tonseth said WDFW surplused 302 male Chinook, which were mostly jacks. Two fish were not jacks, and an additional 30 fish appear to originate from Leavenworth National Fish Hatchery (NFH) because they are adipose-clipped and coded wire tag-absent; however, these fish are difficult to characterize. Keely Murdoch emphasized that these fish should not be labeled as fish of a certain program unless their origin is definitively known. Tonseth agreed and said WDFW are calling these fish "maybe Leavenworth NFH-origin" fish. Tracy Hillman asked if 300 of the total spring Chinook salmon observed at Tumwater Dam is a particularly high proportion of jacks. Tonseth said yes, and this could be due to a poor migration year in 2015 and ocean conditions.

Tonseth said the Wenatchee spring Chinook salmon program has collected sufficient spring Chinook salmon to meet its production obligations. However, he said the natural-origin target for the Chiwawa program has not been met due to three factors: 1) adult natural-origin fish are limited and hard to acquire, 2) the collection weir was not operational as early in the season as intended because of high flows, and 3) towards the end of the collection season, mechanical issues took the weir out of operation for 1 week at a critical point. He said towards the end of the collection season, the weir was lowered to avoid impinging fish.

Bill Gale asked what the forecasted proportion of natural origin broodstock (pNOB) is using these provisional data. Willard replied the forecasted pNOB for the Wenatchee spring Chinook salmon program is 0.73. Tonseth said WDFW is still sampling at Tumwater Dam as part of broodstock collection, and video data were being used to differentiate spring and summer Chinook salmon. The WDFW genetics lab will help finalize assignments using scale analysis.

Alene Underwood asked how many females the program is short. Tonseth replied the program is approximately four females short of its natural-origin target.

Todd Pearsons asked about spring Chinook salmon collection for the Nason Creek Program. Tonseth said WDFW has collected the full conservation and safety-net program broodstock targets. Hillman asked if any White River-origin fish were collected. Tonseth said WDFW over collects for the Nason Creek Program by approximately 10 percent to account for White River origin fish. He said some fish are also of Chiwawa River origin, so those fish are collected and retained for the Chiwawa River program. Pearsons asked how many fish are genetically typed. Tonseth said any fish genetically sampled as part of broodstock collection are checked against the genetic baselines for those rivers. The baseline includes genetic signatures for Nason Creek, Chiwawa River, and the White River.

Pearsons asked if 10 percent of the broodstock collected are genetically typed. Tonseth said yes, and since the broodstock target is 70 fish, they collected 77 fish. He said 6 of the collected fish were not retained for the program.

D. Chelan Falls Trap (Catherine Willard)

Catherine Willard said the Chelan Falls Trap has been operating and the Chelan Falls summer Chinook salmon program is currently about 30 females short of its broodstock collection target. She said trapping will continue through this week, but will not occur next week because of habitat improvement projects in the Habitat Channel of the Chelan River. She said the first week of September will be the last week the trap is operational and there is a chance the program will fall short of its broodstock collection target by the end of the trapping period. She said the Brood Year 2017 Salmon Broodstock Collection Protocols state the Hatchery Committees will discuss the potential shortage and whether broodstock collection may default to surplus summer Chinook from the Entiat National Fish Hatchery (NFH), which would be a transfer of 30 or less female summer Chinook salmon. Mike Tonseth said he understands that many summer Chinook salmon have returned to the area around Eastbank Fish Hatchery (FH) and that could be an additional or alternate source of collection. Willard said Chelan PUD prefers using fish that are surplused from Entiat NFH due to safety concerns with collecting broodstock at the Eastbank FH outfall. Tracy Hillman noted that the Hatchery Committees previously discussed alternate broodstock sources for this program in case it fell short of its target. Tonseth said the Hatchery Committees discussed Entiat NFH as the back-up source of broodstock, but would still need to discuss it with USFWS to see if Entiat NFH can support the request. Bill Gale asked when Chelan PUD would know if the program is short. Willard said September 1 is the last day for trapping. Gale said that timing would likely not be a problem, so he and Chelan PUD will begin coordinating the logistics of this potential transfer. Genetic Monitoring Update (Mike Tonseth)

Tracy Hillman said the genetic monitoring update is related to the update to the Hatchery M&E Plan (Item III-G). Mike Tonseth said McLain Johnson (WDFW) sent an update regarding genetic monitoring including a memo, *Update - Hatchery M&E Genetic Monitoring Objectives* (Attachment D), and a spreadsheet, *Genetic Tables* (Attachment E), which Sarah Montgomery distributed to the Hatchery Committees on April 6, 2017. Tonseth said there are two key decisions the Hatchery Committees need to make. He said the Hatchery Committees had previously requested that Todd Seamons conduct a power analysis to determine how frequently genetic analyses should be performed in order to determine whether hatchery programs are having an effect on natural populations. He said he discussed this with Seamons and the power analysis is a complex task that WDFW is not comfortable undertaking without a contract. He said the power analysis will be important to making decisions about analysis frequency, and he thinks Chelan, Douglas, and Grant PUDs should make the decision whether or not to fund the analysis.

He said the second key decision the Hatchery Committees need to make is about genetic panels. He said any new analysis will use a single nucleotide polymorphism (SNP) panel; however, baseline data were analyzed using a microsatellite panel. A decision about rerunning past samples with the SNP panel could be made soon in order to complete those re-analyses by the time the new analysis frequency is determined. He said a related decision is where the genetic baseline starts for each program. Tonseth said the baseline is currently in the 1980s or 1990s for most programs and tissue is still available to rerun the analyses using the newer SNP methodology. Catherine Willard asked if the new genetic samples could be run using the older microsatellite methods so that they are comparable to past results, yet still answer the genetic objectives in the M&E Plan. Tonseth said the analyses could probably be performed, but using SNPs is the preferred method because it is more accurate and provides better resolution. Tonseth said one additional decision would be whether to increase the number of markers analyzed for certain programs. Bill Gale said one benefit of using SNP panels is that it provides higher resolution and has more available markers.

Gale suggested asking Seamons to outline these questions and the costs and benefits associated with each. Keely Murdoch agreed and said it would be helpful to have something documented that she can discuss internally. Todd Pearsons said there are many genetic tests being performed to meet the M&E objectives and perhaps fewer tests could be run in a way that would still meet the objectives.

Tonseth said it's possible that the two objectives in the M&E Plan are not the "right" questions to be asking to determine if hatchery programs are having genetic effects on natural populations. He said from a recovery perspective, maintaining or building diversity is important and it is also important to make sure hatchery programs do not pose a genetic risk to recovery. He said asking Seamons to consider the objectives could change the outlook of genetic monitoring in this basin and create more delays, but it is important to consider the purpose of the genetics monitoring and objectives.

Hillman summarized that members present would like Seamons to produce a small paper including appropriate questions, tasks, and necessary analyses, and asked if the WDFW Genetics Lab would need funding to complete the paper. Tonseth said he would check. Pearsons said determining if the M&E Plan objectives are asking the "right" questions is a good first step and asked if gathering geneticists from multiple agencies would be helpful to identify key questions and long-term monitoring objectives. Tonseth said he thinks he should talk to Seamons first and see if he (Seamons) has a recommended approach or outline, then it could be circulated amongst other geneticists. Hillman suggested that Seamons start by looking at the current Hatchery M&E Plan. Pearsons said the Hatchery M&E Plan objectives were established in 2005, so it might be time to update the objectives. Tonseth said the M&E Plan is a good starting point and getting geneticists to agree on the right monitoring questions would give future discussions and analyses more direction.

E. Spring Chinook Salmon in the Methow Basin: Status of Adult Management and Translocation to the Chewuch River (Mike Tonseth)

Mike Tonseth said Greg Mackey asked him for an update on adult management of spring Chinook salmon in the Methow basin and the status of the Chewuch River translocation study planned for 2017.

Tonseth said Charles Frady (WDFW) provided provisional estimates of spring Chinook salmon to Wells FH, which were 529 wild fish and 4,471 hatchery-origin fish. He estimated that 2,356 hatchery fish are likely bound for the Methow basin and the rest would go to the Okanogan basin. Tonseth said Winthrop NFH's broodstock collection target for spring Chinook salmon is 551 fish and he believes this target has been met in 2017, but not all the fish originate from the conservation program. Bill Gale said of the roughly 2,400 hatchery spring Chinook salmon estimated to enter the Methow basin, approximately 1,500 fish originate from Winthrop NFH and 900 originate from Methow FH.

Tonseth said the Methow spring Chinook program was not able to meet the full natural-origin return component in 2017 through trapping at Wells Dam despite trapping 5 days per week. A total of 74 of the 122 required wild fish were collected. As a result, the balance of the program will be backfilled with returning conservation hatchery fish to fulfill the production obligation. In addition, conservation hatchery fish returns to Methow and Winthrop hatcheries are insufficient to meet the Winthrop NFH safety-net production target and will therefore backfill the production shortage with adults from the safety-net program. Michael Humling (USFWS) said Winthrop NFH to date has surplussed 1,108 hatchery fish.

Additionally, Tonseth said the collection shortage means that the translocation study in the Chewuch River planned for 2017 will not occur this year. Gale said that it seems outplanting is not needed in this case because trapping efficiency in the Methow basin is lower than desired, so there are enough hatchery fish out in the system that outplanting hatchery fish would not be desirable. Keely Murdoch said the purpose of the outplanting study is not to make sure there are enough conservation fish on spawning grounds, but to get these conservation fish spawning in harder-to-reach places. She said if there were enough conservation fish for the program, but they were all spawning in one area, translocation would still be appropriate. Tonseth agreed and said the study is intended to evaluate the efficacy of adult translocation as a surrogate to early-term imprinting, in order to address homing fidelity issues in Methow spring Chinook salmon. Tonseth said he thinks there are years that the study would not be necessary or appropriate because there are sufficient hatchery fish on spawning grounds. Gale asked how many of the adipose-present, conservation fish were trapped out of the approximately 900 entering the Methow basin. Tonseth said Methow FH retained 71 of these fish and any more of these fish would have been transported to Winthrop NFH. Gale said Winthrop NFH has been successful in removing Winthrop hatchery-origin fishreturning to the basin and, of the 1,100 fish surplused and with broodstock collected, approximately 80 to 90 percent of the Winthrop hatchery-origin run has been removed between Methow FH and Winthrop NFH; however, the Methow FH trap does not appear to be removing enough fish to meet targets.

Tonseth said current operations need to be evaluated to determine whether percent natural influence (PNI) and proportion of hatchery origin spawners objectives can be reasonably met in the basin. Gale said he hopes under current operations that 80 percent of the run can be removed. Tom Kahler suggested discussing this with Charlie Snow (WDFW). Snow said the Methow FH trap is open and is checked at least every weekday and he is not certain about weekend trapping operations, but he thinks fish are trapped and held. Humling said he believes that in previous years the trap was not operated on weekends, but this year it is.

Gale asked if there is a way to know whether fish enter the Methow Fish Hatchery outfall then turn around (trap avoidance). Murdoch said a PIT tag array was used last year during the beginning of the trapping season. Kahler said Douglas PUD does not own the property where the PIT tag array would go, so it is challenging to install and maintain, and in the past, the YN have done so. Tonseth said using the 3-population PNI model, and if the preliminary numbers discussed today are accurate, PNI would be roughly 0.6 or 0.7. Gale said once final numbers of fish are available and the 3-population PNI is being calculated, the Hatchery Committees should discuss how to improve trapping for future years.

F. M&E Plan for PUD Hatchery Programs 2017 Update (All)

Tracy Hillman said he revised the M&E Plan for PUD Hatchery Programs to reflect changes discussed during the July 19, 2017, Hatchery Committees meeting and also incorporated comments from reviewers. Sarah Montgomery distributed a revised version of the plan for review on July 26, 2017 (Attachment F).

Hillman reviewed the edits in the document, and questions and comments were discussed as summarized in the following paragraphs.

Hillman asked if Table 3 should be updated for the 2017 version. Mike Tonseth said he has an updated version of Table 3 and will send it to Hillman for incorporation.

In Section 4, Natural Environment Monitoring Indicators, Hillman said fecundity at size is not currently included in the M&E annual report, so the Hatchery Committees might consider adding this section to the report. Tonseth said fecundity at size is used during the season to assess broodstock needs due to differences in age-at-return. He said it is used to adaptively manage broodstock targets. Hillman said in the annual report, mean fecundity for brood year is reported, but not fecundity at size. He said because it will be analyzed in the comprehensive (10-year) and statistical (5-year) reports, maybe it should be included in the annual report as well. Todd Pearsons said the annual report for the Priest Rapids programs includes fecundity by age.

In Section 6, Harvest Monitoring Indicators, Hillman said McLain Johnson pointed out that adult management is mentioned, but it is not mentioned elsewhere in the document. Hillman asked if language about adult management should be added to other sections. Tonseth said adult management is alluded to in other sections because it is necessary to meet objectives.

In Section 7, Regional Objectives, Hillman asked if NTTOC objectives have been completed. Bill Gale said it is complete for all species except Pacific lamprey. Tom Kahler said the Hatchery Committees originally determined not to include Pacific lamprey, so they would have to make a new determination to include lamprey in this section. Mike Tonseth said one reason lamprey were not included was because there were coding issues with the NTTOC model. Keely Murdoch added that sufficient data for lamprey were not available. Gale said as additional information becomes available, NTTOC species could be an issue, so programs still have the responsibility to manage to minimal impacts towards NTTOC species. Kahler said the Hatchery Committees approved an SOA in 2014 regarding this topic and suggested summary language from that SOA be added here. Montgomery said she would find the SOA and send it to Hillman.

In Section 8, Adaptive Management, Hillman said Pearsons included a comment with multiple items to discuss. Pearsons said one question he has is which data to include during the next 5-year or 10-year review and how to evaluate hypotheses. He said programs change through time and they could be analyzed as one program that is adaptively managed through time (treatment is one program with changes), or the programs could be blocked into major periods and analyzed as different treatments. He said one concern for blocking the programs into different treatments is not having sufficient sample size to assess important variables. Hillman said, for example, in a time series of natural-origin returns, the entire series could be evaluated as one treatment, or it could be broken into a few important treatment periods. Breaking the series into several treatment units results in lost statistical power. Thus, it is important to identify important treatment breaks in the time series. He said a program that has changed significantly over time should not be analyzed as one treatment. Pearsons suggested performing an analysis on each hatchery program and parsing out periods of the program to see if improvements that can be explained by program changes have been made over time. Gale said each hatchery program might have individual breakpoints for program changes, but hatchery programs influence each other and it would be difficult to blend peripheral program changes or basin changes in this type of analysis. He gave the example of the Nason Creek program, when the Chiwawa program underwent recalculation, potentially affecting natural-origin recruits in Nason Creek. Peter Graf said he began looking at the hatchery programs and levels of scale and suggested starting each analysis by looking at each species in each basin at a time and determining issues and changes for that species and basin first. Tonseth said this topic clearly requires more discussion and suggested adding language to the M&E Plan stating that discussion about adaptive management is ongoing.

Hillman emphasized that as discussions move forward, it will be important to consult with staff who know the program history. Tonseth said determining a chronology of major events for each program would be helpful and the Hatchery Committees could start by looking at the latest version of the Hatchery Report written by the Upper Columbia Salmon Recovery Board, which included a timeline of programs and changes.

Pearsons said his second question pertaining to Section 8 is about the number of NORs between treatment and control streams decreasing after supplementation. He said in comparing the NOR numbers between treatment and control streams before and after supplementation, reference populations decreased, and supplemented programs also decreased. He asked if this is a result of supplementation or an in-basin or out-of-basin effect. He said since there are no "clean" in-basin reference streams, it is difficult to determine the cause of this decline. He said in-basin reference streams are important to understanding hatchery effects, but the patterns in this basin are unclear. Gale asked what the "before" period represents, and Pearsons said before 1989, and the "after" period is the entire supplementation period. Gale suggested blocking the analysis into 5-year periods to determine variability over time. Gale said blocking the analysis in this way would result in a more detailed graph and dataset and more programs could be added for comparison. Hillman said that would include looking at more breakpoints in the data and time series. Graf said he has anecdotally noticed natural breakpoints in the data, which may or may not be associated with program changes. Hillman said he would work with Pearsons to draft revised language for Section 8.

In Appendix 5, Hillman said he added release numbers to the table. Gale requested adding a footnote that Chief Joseph 10j spring Chinook salmon come from Winthrop NFH (as Methow Composite fish).

Hillman said he will make all the requested edits and provide a revised version for Hatchery Committees review.

IV. HCP Administration

A. Next Meetings

The next Hatchery Committees meetings are on September 20, 2017 (Grant PUD), October 18, 2017 (Grant PUD), and November 15, 2017 (Grant PUD).

Rocky Reach and Rock Island HCP Hatchery Committees
DRAFT Statement of Agreement
Regarding District's Coho Obligation
August 16, 2017

Statement

The Rocky Reach and Rock Island HCP Hatchery Committees (hereafter "Committees") agree that Chelan PUD shall provide coho compensation for the Methow River and Wenatchee River sub-basins at a rate equivalent to 7.0% at each project to meet Chelan PUD's No Net Impact hatchery obligations for brood years 2017 to 2021 (release years 2019 to 2023); therefore, 7.0% will be used as the coho hatchery compensation rate until the next scheduled hatchery compensation recalculation (2023). Methodology described in the SOA Regarding the 2013 No Net Impact Recalculation Methodology (dated July 20th, 2011) will be used to calculate hatchery compensation levels for coho.

In order to meet this obligation, Chelan PUD and the Yakama Nation intend to enter into an agreement where Chelan PUD will provide funding for the Mid-Columbia Coho Reintroduction Project (facility use may be included as part of the agreement). As long as Chelan PUD is meeting the terms of the agreement with the Yakama Nation, and remains consistent with any future recalculated hatchery compensation obligations, the Committees agree that Chelan PUD is fulfilling its coho hatchery obligation for the term of the Rocky Reach and Rock Island Habitat Conservation Plans.

Background

On June 20, 2007, the Committees agreed to implement coho hatchery compensation as detailed in Section 8.4.3.a of the Rocky Reach and Rock Island HCPs and agreed that the District shall begin providing hatchery compensation no later than October 1, 2007. On March 28, 2017, the Rocky Reach and Rock Island Coordinating Committees agreed to use Chelan PUD's yearling Chinook acoustic tag survival estimates and coho PIT-tag based survival estimates to estimate juvenile coho survival of 93.98% at Rock Island and 92.94% at Rocky Reach (Skalski and Townsend 2017) which culminated in a 93% survival value at both projects.

Calculations for Rocky Reach Coho Obligation

Compensation for **hatchery-origin smolts** will be determined by multiplying the Program's annual release targets from the Methow sub-basin hatchery program by the unavoidable project mortality (1-(0.93 x 0.93)) for Rocky Reach and Rock Island.

Compensation for **natural-origin smolts** produced is determined by:

- Mean NOR[1] to Rocky Reach (return years 2008 to 2011 and 2013 to 2015) = 43
- Mean NOR in absence of project mortality: 43/0.9300 = 46
- Adult equivalents to meet NNI: 46-43=3
- Mean 8 year SAR (release years 2008-2015 Methow sub-basin hatchery program) = 0.59%
- Compensation for natural-origin smolts: 3/0.0059 = 508 smolts

Calculations for Rock Island Coho Obligation

Compensation for **hatchery-origin smolts** will be determined by multiplying the Program's annual release targets from the Wenatchee sub-basin hatchery program by the unavoidable project mortality (1-0.93) for Rock Island.

Compensation for **natural-origin smolts** is determined by:

- Mean NOR to Rock Island (return years 2007-2016) = 529
- Mean NOR in absence of project mortality: 529/0.9300 = 569
- Adult equivalents to meet NNI: 569-529 = 40
- Mean 10 year SAR[2] (release years 2006-2015 Wenatchee sub-basin hatchery program) = 0.75%
- Compensation for natural-origin smolts: 40/0.0075 = 5,333 smolts

[1]Natural-origin return=NOR
[2]SAR=releases from the Wenatchee hatchery programs and returns to Priest Rapids Dam (versus Rock Island Dam due to historic variable PIT tag detection efficiency at the adult ladders).

1. Introduction

The Habitat Conservation Plan (HCP) specifies that a monitoring and evaluation plan will be developed for the hatchery program. The approach to monitoring the hatchery programs was guided by the "*Monitoring and Evaluation Plan for PUD Hatchery Programs: 2013 Update"* (Hillman et al. 2013) and the "*Conceptual Approach to Monitoring and Evaluating the Chelan County Public Utility District Programs*" (Murdoch and Peven 2005).

The purpose of this document is to define the tasks associated with the approved scope of work to implement Chelan PUD's (CPUD's) hatchery monitoring and evaluation (M&E) plan for 2018. Additionally, monitoring and evaluation activities for Lake Wenatchee sockeye in 2018 are included in this document. As monitoring tasks are completed in 2017 and are evaluated for their efficacy, methodologies to accomplish the tasks defined in the 2018 Implementation Plan may be modified [with Habitat Conservation Plan's Hatchery Committee (HCP-HC) approval].

Deleted: 2017

The work described in this plan has Endangered Species Act (ESA) coverage provided by NFMS Section 10(a)(1)(A) permits 18121 and 1395 and Section 10(a)(1)(B) permit 1347. All activities conducted under this Implementation Plan shall adhere to all terms and conditions as specified in the referenced permits. These permits allow for changes to monitoring or research protocols with the caveat that such modifications are approved by NMFS prior to implementing those changes. Terms and conditions relevant to monitoring and evaluating the hatchery programs have been used to inform the various measurements below and associated scopes of work with entities performing the work. A report summarizing compliance with the terms and conditions set forth under the above-references permits is required for submittal to NMFS; a copy of this completed report will be provided to the HCP HC.

The Implementation Plan includes all four components of the hatchery M&E Program including: (1) aquaculture monitoring; (2) juvenile monitoring; (3) adult monitoring; and (4) data, analysis and reporting. Under each component are study design elements that will be used to inform the overarching program components. Figure 1 illustrates the relationship of the components and study design elements used to address each component. Table 1 depicts which study design element is being performed by entity, and the associated objectives for each study design element as referred to in Hillman et al. 2013. For Lake Wenatchee sockeye salmon, the proposed M&E activities cover juvenile and adult life history stages and provide the data necessary to track or estimate viable salmonid population parameters (VSP) and is described in Section 6.0.

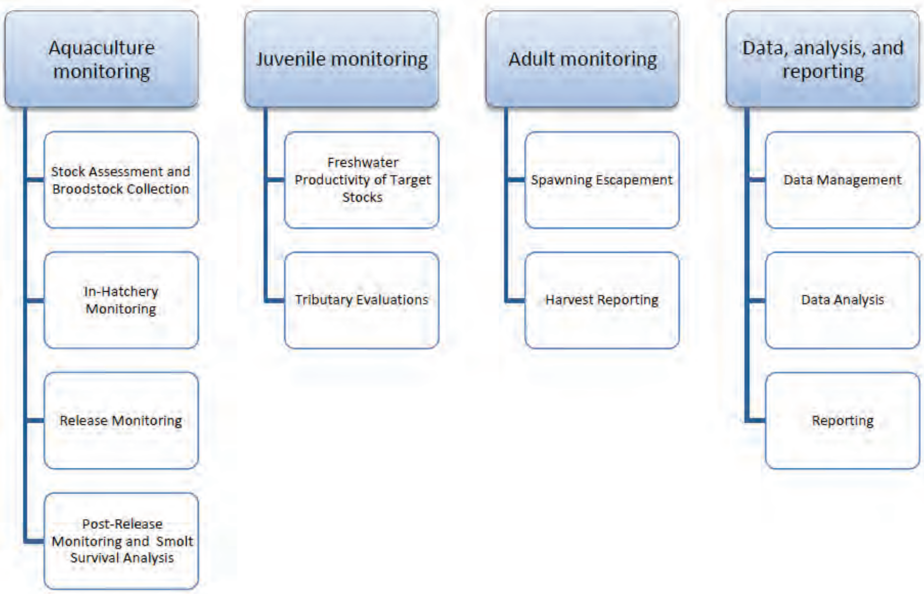

Figure 1. The four components of the hatchery monitoring and evaluation program and the study design elements within each component.

Table 1. Study design elements performed by entity, and the associated objectives for each study design element as referred to in Hillman et al. 2013.

Monitoring and evaluation component	Objectives[1]	Study Design Elements	Chiwawa spring Chinook	Wenatchee summer Chinook	Methow spring Chinook[4]	Chelan Falls summer Chinook[5]	Wenatchee Steelhead

[1] Monitoring questions relative to Objective 7 will be addressed at the next 10 year HCP check-in.
[2]CPUD crews will PIT tag in-hatchery fish.
[3]Biomark will PIT tag in-hatchery fish.
[4]In 2018, monitoring and evaluation for the Methow spring Chinook program is described in "Implementation of Comprehensive Monitoring and Evaluation of Wells Hatchery Complex Programs".
[5]Because the Chelan summer Chinook program is primarily an augmentation program, monitoring and evaluation efforts focus on straying, release characteristics, and harvest.

Deleted: 2017

2. Aquaculture Monitoring

The aquaculture monitoring component is comprised of two basic elements: (1) stock assessment and broodstock collection at adult trapping locations and (2) in-hatchery monitoring including spawning, rearing, and release of juveniles. Data collected during these elements primarily support monitoring questions 5.1.1, 5.2.1, 8.1.1, 8.2.1, 8.3.1, 8.3.2, 8.4.1, 9.1.1, 9.2.1, 9.3.1 and 9.4.1, but also contribute data to monitoring questions 3.2.1, and 3.2.2 (Hillman et al. 2013). Table 2 below provides a summary of the variables to be measured in 2018 under the aquaculture monitoring component and what objective the measure(s) supports. The text that follows in this section further describes the activities.

Deleted: 2017

Table 2. Monitoring and Evaluation Plan (Hillman et al. 2013) objectives and the associated measured variables for the aquaculture monitoring component.

Objectives	**Measured Variables** *(Applicable Study Component(s))*
Objective 3: Determine if the hatchery adult-to adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.	• Number of hatchery and naturally produced fish collected for broodstock (*Broodstock Collection and Stock Assessment*) • Number of broodstock used by brood year (hatchery and naturally produced fish) (*Broodstock Collection and Stock Assessment*)
Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.	• Ages of hatchery and naturally produced fish sampled via PIT tags or stock assessment monitoring (*Broodstock Collection and Stock Assessment*) • Time (Julian date) of ripeness of hatchery and natural origin steelhead captured for broodstock (*Broodstock Collection and Stock Assessment*)
Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of the natural populations.	• Size (length), gender, and total/salt age of broodstock (*Broodstock Collection and Stock Assessment*) • Assess age of fish (*Broodstock Collection and Stock Assessment*) • Length, weight, and age (covariate) of hatchery and natural-origin broodstock after eggs have been removed (*Broodstock Collection and Stock Assessment*) • Number and weight of eggs (*Broodstock Collection and Stock Assessment*)
Objective 9: Determine if hatchery fish were released at the programmed size and number.	• Fork length and weights of random samples of hatchery juveniles at release (*Release Monitoring*) • Monthly individual lengths and weights of random samples of hatchery juveniles (*In-Hatchery Monitoring*) • Numbers of smolts released from the hatchery (*Release Monitoring*)

Deleted: 2017

2.1 Broodstock Collection and Stock Assessment

Broodstock collection and stock assessment for Wenatchee summer steelhead, Wenatchee summer Chinook, Methow spring Chinook, Chelan Falls summer Chinook, and Chiwawa River spring Chinook, hatchery programs will, in most instances, occur concurrent to and consistent with the Broodstock Collection Protocol approved annually by the HCP-HC and relevant permits. Data collection during broodstock collection will be consistent with Murdoch and Peven (2005). A representative sample of fish trapped throughout the entire run, either collected for broodstock or released back to the river, will be sampled for origin, age, sex, size, and migration timing. Biological sampling of all fish trapped will include presence of internal (CWT or PIT) and external (VIE) tags or marks, scales, length, and sex (determined by ultrasound). PIT tags will be injected into all target species (Chinook and steelhead), whether collected for broodstock or released back to the river to monitor for potential fallbacks. All non-target species will be enumerated daily. Measures of central tendency and spread will be calculated and reported for each metric.

2.2 In-Hatchery Monitoring

The in-hatchery monitoring component will begin when adult fish are collected and retained for broodstock and ends when juvenile fish are released. Life stage specific in-hatchery survival and growth rates, disease monitoring, and an estimate of the number of fish released will be collected and analyzed according to Murdoch and Peven (2005). Additional data to be collected includes individual lengths and weights of juveniles during monthly sampling, and the weight of gonadal mass and body of spawned broodstock. Measures of the central tendency and spread will be calculated and reported for each metric.

Fish Marking

All of Chelan PUD's hatchery fish will be coded-wire tagged (CWT) and externally marked or marked as otherwise agreed to by the HCP HC. A comprehensive marking strategy will be developed by the HCP-HC and included as an Addendum to this Plan. The identification of these hatchery-produced fish is needed for a suite of adult metrics and may be used for adult management and/or fisheries as contemplated by the co-managers.

Using methods described in Keller and Murauskas (2012), hatchery fish will be PIT-tagged (Table 3) at Eastbank Hatchery approximately two to four weeks before the fish are transferred to acclimation ponds or in the spring prior to release. Additional PIT-tagging may occur for program specific studies/comparisons as approved by the HCP-HC. The data collected from the PIT-tags will assist in release monitoring, migration timing, juvenile survival, and smolt-to-adult survival. For all fish marking, quality control check will be performed during and immediately following tagging and prior to release.

Deleted: 2017

Table 3. Chelan PUD's hatchery program release goals and recommended number of fish PIT tagged.

Program	Release goals	Number of fish PIT tagged[1]	PIT tag rate (%)
Chiwawa spring Chinook	144,026	10,000	6.9
Wenatchee steelhead	247,300	20,000	8.0
Wenatchee summer Chinook	318,816 (CPUD Program) 181,184 (GPUD Program)	20,600	4.1
Methow spring Chinook	60,156	5,000	8.3
Chelan Falls summer Chinook	576,000	10,000	1.7

[1] Additional PIT tagging may take place for Chelan PUD approved studies and/or comparisons.

2.3 Release Monitoring

Hatchery fish will be released during smoltification in the spring, typically between 15 April and 1 June. Whenever possible, the exact release dates will coincide with environmental conditions that promote a rapid emigration that minimizes both the potential negative ecological interactions of hatchery fish with naturally produced fish and predation on hatchery fish by avian or other predators. The default release method will incorporate a volitional approach, as approved by the HCP HC, unless it can be demonstrated other approaches are better. The monitoring data collected for each stock are described below.

Chiwawa and Methow Spring Chinook

Pre-release sampling data will be conducted consistent with Murdoch and Peven (2005), including individual weights to the nearest 0.1 gram. Data collected will support monitoring questions 9.1, 9.2, 9.3 and 9.4 in the updated monitoring and evaluation plan (Hillman et al. 2013). PIT tag monitoring of spring Chinook released in the Chiwawa River will occur during the release period (April). Juvenile Chinook will pass through two 92-cm diameter PIT-tag antennas connected to Allflex 310 readers and Quantitative Sampling Technologies (QST) QuBE data logger. The release location and type (i.e., volitional, forced, or trucked) are recorded for each observation file created and uploaded to the PTAGIS database maintained by the Pacific States Marine Fisheries Commission after each year of release. PIT-tagged fish in each observation (release) file are assumed to represent untagged fish. Observation files contain the PIT tags associated with the original tag files and will be used for analysis (see Post-release Monitoring Section). The total number of fish released will be based on the population size at CWT tagging (100%), subtracting mortality enumerated by hatchery staff that occurred from tagging to release.

Deleted: 2017

Wenatchee Summer Steelhead–
Pre-release sampling will be conducted consistent with Murdoch and Peven (2005), including individual weights to the nearest 0.1 gram. Data collected will support monitoring questions 9.1, 9.2, 9.3 and 9.4 in the updated monitoring and evaluation plan. Monitoring of steelhead released in the Wenatchee River sub-basin will occur during loading of fish into transport trucks, unless fish are released directly into the Chiwawa River. Steelhead will pass through a series of PIT-tag antennas, each connected to a data logger, thereby allowing the creation of a PIT-tag observation file for each truckload of steelhead consisting of unique tag records. The release location (stream and rkm), release type (volitional or forced), and hatchery group (HxH or WxW) will be recorded for each tag file created. PIT-tagged fish in each observation (release) file are assumed to represent untagged fish. However, because PIT-detection efficiency during loading will not be 100%, the number of fish in each truckload will be estimated using volumetric displacement. Observation files contain the PIT tags associated with the original tag files and will be used for analysis (see Post-release Monitoring Section). The total number of fish released will be based on the population size at CWT tagging (100%), subtracting mortality enumerated by hatchery staff that occurred from tagging to release.

Wenatchee and Chelan Falls Summer Chinook
Pre-release sampling will be conducted consistent with Murdoch and Peven (2005), including individual weights to the nearest 0.1 gram. Data collected will support monitoring questions 9.1, 9.2, 9.3 and 9.4 in the updated monitoring and evaluation plan. Should PIT tagging occur, a monitored release strategy consistent with other Chinook stocks (i.e., Chiwawa Spring Chinook) will be implemented. The total number of fish released will be based on the population size at CWT tagging (100%), subtracting mortality enumerated by hatchery staff that occurred from tagging to release.

2.4 Post-Release Monitoring and Survival Analysis
Data will be collected during rearing, acclimation, release, and the emigration period that may prove valuable in explaining variability in adult survival (Murdoch and Peven 2005). Rearing densities have been reported to influence the survival of hatchery fish (Martin and Wertheimer 1989; Banks 1994) and may also be linked to disease prevalence during rearing (Banks 1994; Ogut and Reno 2004). Acclimation of hatchery fish before release has been found to increase survival and reduce stray rates when the duration of the acclimation period is sufficient (Clarke et al. 2010, 2012; Rosenberger et al. 2013). These metrics (i.e., rearing density and acclimation period) will be collected annually to determine their influence on fish survival.

PIT-tagged groups of hatchery fish will be used to estimate survival during their emigration. Variation in survival during the emigration period may also inform observed adult survival rates. Survival during emigration and travel will be estimated using interrogation or release files and the standard Cormack-Jolly-Seber (CJS) estimator. CJS estimates are termed apparent survival estimates because it is unknown whether fish suffered mortality (e.g., size or time of release) or simply failed to emigrate (i.e., residualized or were precocial males). In the latter case, the proportion of PIT-tagged fish detected in the Methow sub-basin, Wenatchee or Columbia rivers after the emigration period is complete may explain variation in smolt survival rates. The post-release performance of PIT-tag groups will be estimated and monitored annually, consistent

Deleted: 2017

with methods in Murdoch and Peven (2005). Additionally, precocity of hatchery releases will be evaluated by examining the proportion of PIT tag releases detected in adult fish ladders and tributaries within the same year as release.

3. Juvenile Monitoring

Data collected during these elements primarily support monitoring questions 2.1.1 and 2.2.1. and the monitoring objectives described in Table 4 (Hillman et al. 2013). Table 4 below provides a summary of the variables to be measured in 2018 under the juvenile monitoring component and what objective the measure supports. The text that follows in this section further describes the activities.

Deleted: 2017

Table 4. Monitoring and Evaluation Plan (Hillman et al. 2013) objectives and the associated measured variables for the juvenile monitoring component.

Objective	Measured Variables *(Applicable Study Component(s))*
Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.	• Number of juveniles (smolts, parr [where appropriate], and emigrants) (*Freshwater Productivity of Supplemented Stocks*)

3.1 Freshwater productivity of Supplemented Stocks

Steelhead, Spring Chinook, and Summer Chinook

The freshwater productivity of supplemented stocks in the Wenatchee sub-basin will be monitored using smolt traps in the Chiwawa River and the lower Wenatchee River consistent with historical trapping efforts. Additionally, a newly derived analytical method which uses PIT-tag mark-recapture data will be utilized that reduces bias and increases precision by including estimates of emigration during the winter non-trapping periods. Up to 3,000 parr will be PIT tagged in the Chiwawa River in the fall, based on the spatial distribution and abundance estimated during parr snorkel surveys, to generate estimates of migration during the non-trapping periods. A random sample of a minimum of 10 percent of fish per remote site will be held in a live box for 24 hours to evaluate tag loss and delayed mortality. Using PIT tagged parr detections at the lower Chiwawa PIT array during the non-trapping period, the total number of PIT-tagged parr that emigrated will be estimated, and then expanded by the tag rate. Overwinter mortality of PIT-tagged parr is assumed to be the same as non-PIT-tagged parr. Overwinter survival estimates of Chiwawa River parr will be derived by estimating survival to the lower Wenatchee PIT tag array and analyses with the TribPit Survival software program and/or estimating survival of fall parr and spring smolts to McNary. PIT-tag mark-recapture trials conducted during the trapping period in the fall will also be used to estimate detection probabilities of the PIT-tag array at a given discharge level. Abundance and variance will be estimated using the same methods as those used in the smolt trap estimate. The estimated abundance and variance from each method and time period (trapping and non-trapping

Deleted: 2017

periods) will be summed to estimate a total production estimate. Under the proposed methodology, unbiased estimates of abundance during the entire migration period will be generated with relatively high precision (PSE < 15%), which is consistent with NOAA Fisheries' recommendations (Crawford and Rumsey 2011). Historical estimates will be revised using the new estimation techniques.

Specific actions to monitor the freshwater productivity of supplemented spring Chinook salmon in the Methow sub-basin have yet to be determined. As these become available, the plan will be amended and presented to the HC by December.

3.2 Tributary Evaluations

Chiwawa River

Snorkel surveys will be utilized to estimate parr abundance within the Chiwawa subwatershed during the summer. This approach has been used in the Chiwawa subwatershed since 1992. In parallel to addressing Objective 2, additional juvenile data can help to assess the habitat carrying capacity in each tributary. This information can add value to the overall M&E plans and help inform management decisions.

Sampling will follow a stratified random sampling design. Landscape classification will be used to stratify streams in the Chiwawa subwatershed that support juvenile Chinook salmon. In the Chiwawa subwatershed, WDFW found that classification "explained" most of the variability in fish numbers caused by geology, land type, valley bottom type, stream state condition, and habitat type (Hillman 2013). The same classification method was used to identify sections of the Little Wenatchee River (reference area) that corresponded to discrete reaches in the supplemented subwatersheds, but that had no release of hatchery Chinook. Consistent with previous efforts, habitat types within each land-class or reach will be identified and quantified annually. At least three units of each habitat type within each reach will be randomly selected for estimating densities of salmon and trout. Thus, overall sampling consists of a stratified- random sampling design, which increases the accuracy and precision of population estimates.

Densities of salmon and trout will be estimated in August and September by direct underwater observation within the randomly-selected habitat units. Underwater methods will follow those described by Thurow (1994), Dolloff et al. (1996), and O'Neal (2007). Habitat surface areas and volumes will be estimated during fish sampling. Numbers of fish counted will be adjusted for detection probabilities using the models published in Hillman et al. (1992). For each habitat type within a state type and reach stratum, the mean density of salmon and trout will be calculated as the ratio of mean numbers to mean area or volume sampled (Cochran 1977). Total numbers of fish will be estimated per habitat type within a state type and reach stratum as the product of mean density of fish in a given habitat type, times total area or volume of that habitat type within the stratum (Cochran 1977). Total numbers of fish within the supplemented subwatershed will be estimated as the sum of all population numbers per habitat type in state type/reach strata. Bootstrapping methods will be utilized to estimate variance and percent errors (based on 95% confidence interval) for total numbers of fish.

Deleted: 2017

4. Adult Monitoring

The adult monitoring component is comprised of two basic elements: (1) estimating spawning escapement and (2) harvest monitoring. Data collected during these elements primarily support monitoring questions 1.1.1, 1.2.1, 2.1.1, 2.2.1, 3.2.1, 3.2.2, 4.1.1, 5.1.1, 5.2.1, 5.3.1, 5.3.2, 6.3.1, but also contribute data to monitoring questions 6.1.1, 6.2.1, 8.1.1, 8.2.1, 8.4.1, 10.1.1, 10.1.2, 10.1.3 and 10.1.4. Table 5 below provides a summary of the variables to be measured in 2018 under the adult monitoring component and what objective the measure(s) supports. The text that follows in this section further describes the activities.

Deleted: 2017under

Table 5. Monitoring and Evaluation Plan (Hillman et al. 2013) objectives and the associated measured variables for the adult monitoring component.

Objective	Measured Variables *(Applicable Study Component(s))*
Objective 1: Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.	• Number of hatchery and naturally produced fish on spawning grounds *(Spawning Escapement Estimates)* • Number of hatchery and naturally produced fish taken for broodstock (*Broodstock Collection and Stock Assessment*) • Number of hatchery and naturally produced fish taken in harvest (if recruitment is to the Columbia) *(Harvest Reporting)*
Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.	• Number of hatchery and naturally produced fish on the spawning grounds (*Spawning Escapement Estimates*) • Number of redds *(Spawning Escapement Estimates)*
Objective 3: Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.	• Number of hatchery and naturally produced fish on spawning grounds *(Spawning Escapement Estimates)* • Number of hatchery and naturally produced fish harvested *(Harvest Reporting)*
Objective 4: Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.	• Number of hatchery and naturally produced fish on spawning grounds *(Spawning Escapement Estimates)*
Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.	• Time (Julian date) of hatchery and naturally produced salmon carcasses or marked steelhead detected on spawning grounds within defined reaches *(Spawning Escapement Estimates)* • Time (Julian date) of arrival at mainstem projects and within tributaries (e.g., traps, PIT arrays) with

Deleted: 2017

Objective	Measured Variables *(Applicable Study Component(s))*
	the intent to identify biologically significant differences *(Spawning Escapement Estimates)* • Location (GPS coordinates) of female salmon carcasses observed on spawning grounds *(Spawning Escapement Estimates)*
Objective 6: Determine if stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.	• Number of hatchery fish collected for broodstock (*Broodstock Collection and Stock Assessment*) • Number of hatchery fish taken in fishery (*Harvest Reporting*) • Locations of live and dead strays (used to tease out overshoot) *(Spawning Escapement Estimates)* • Number of hatchery carcasses (PIT-tagged and/or CWT) found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas (stray data into the Entiat sub-basin will be obtained from USFWS Fisheries Resource Office-Leavenworth) *(Spawning Escapement Estimates)*
Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.	• Total and salt (ocean) age and gender of hatchery and naturally produced salmon carcasses collected on spawning grounds *(Spawning Escapement Estimates)* • Whenever possible, age at maturity and sex ratio will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling or ultrasound on live fish) *(Spawning Escapement Estimates)* • Assess age of fish, including harvested fish *(Spawning Escapement Estimates and Harvest Reporting)*
Objective 10: Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.	• Numbers of hatchery fish taken in harvest *(Harvest Reporting)* • Numbers of natural-origin fish taken in harvest *(Harvest Reporting)*

Deleted: 2017

4.1 Spawning Escapement Estimates

Chelan Summer/Fall Chinook

Chinook spawning ground surveys will be conducted in the Chelan River and (see Appendix A for survey reaches). Spawning ground surveys will be conducted via foot or raft beginning late September and continuing until spawning has ended (usually mid-November). Frequency of surveys will vary depending on method.

Summer Chinook carcass surveys will be conducted in the Chelan River beginning in September and ending in November consistent with methods described in Murdoch and Peven (2005). A representative sample (i.e., 20%) of spawners as determined by spawner abundance and distribution (typically 100% of the carcasses encountered in the Chelan River) will be sampled. Biological data will include collection of scale samples for age analysis, length measurements (POH and FKL), gender, egg voidance, and a check for tags or marks. DNA samples (five-hole punches from operculum) will be collected as needed to address different objectives. These data will be used to assess length-at-age, size-at-age, egg voidance, origin (hatchery or naturally produced), stray rates, and genetics. All carcass surveys will be conducted within the historical reaches.

Wenatchee Steelhead

The number of hatchery and naturally produced steelhead returning to the Wenatchee sub- basin will be estimated using a PIT tag mark recapture model. The estimated spawner abundance for the Wenatchee steelhead population will be a combination of PIT tag-based tributary and redd-based mainstem Wenatchee River estimates. Steelhead redd counts will be conducted weekly in all major spawning areas in the mainstem Wenatchee River (see Appendix A for survey reaches); minor spawning areas in the mainstem Wenatchee River will be surveyed once, based on the spawn timing in adjacent major spawning areas, to estimate redd abundance at peak spawning. The estimated total number of redds in the Wenatchee River mainstem will be expanded by the sex ratio of the population to estimate spawner abundance. Spawner abundance in tributaries of the Wenatchee River will be estimated using a PIT tag mark recapture model.

Chiwawa Spring Chinook

Chiwawa spring Chinook spawning escapement will be estimated based on the total number of redds found in each tributary (Murdoch et al. 2010) using methods described in Murdoch and Peven (2005). Weekly redd and carcass surveys will be conducted simultaneously from the first week of August through September (see Appendix A for survey reaches). Redd-based estimates assume that each female constructs one redd, which WDFW has found to be appropriate for this population (Murdoch et al. 2009). The total number of redds in each reach will be estimated using methods described in Millar et al. (2012) and using the observer efficiency model currently under development by WDFW. Redd counts will be expanded and the number of hatchery and naturally produced fish will be estimated using methods in Murdoch et al. (2010). Carcasses encountered during surveys will be sampled according to methods outlined in Murdoch and Peven (2005). All CWTs (i.e., snout or adipose) from carcasses will be read and the data entered into the Regional Mark Processing Center database within one year of collection.

Deleted: 2017

Additionally, all redds and female carcasses will be geo-referenced using hand-held GPS devices. Carcass recovery bias has been detected in the Chiwawa spring Chinook population (Murdoch et al. 2010) and if not corrected will bias estimates of hatchery and naturally produced fish on the spawning grounds. While it may be appropriate to correct for carcass recovery bias for some monitoring questions (e.g., 2.2), when comparisons to reference populations are made in monitoring questions 1.1.and 1.2, carcass bias will not be corrected because other monitoring programs have not corrected for a similar bias.

Wenatchee Summer Chinook

Wenatchee summer Chinook spawning ground counts will begin the first week in September and continue through the end of spawning in November (see Appendix A for survey reaches). Total census redd counts will be conducted by foot or raft depending on stream size, flow, and density of spawners within the stream reach (see Appendix A for survey reaches). All stream reaches will be surveyed once per week. Redd data will be collected using methods described in Murdoch and Peven (2005). The total number of redds in each reach will be estimated using methods described in Millar et al. (2012) and using the observer efficiency model currently under development by WDFW. Weekly ground-based census counts and the true number of redds (determined via intensive surveys) will be compared in order to generate observer efficiency. River characteristics (e.g., channel width, water depth, discharge, visibility, and habitat complexity), observer experience, and survey effort will be incorporated into a model to predict observer efficiency in all river reaches. Predicted redd generate observer efficiency for each river reach will be used to adjust ground-based redd counts to estimate the total reach redd count. Ground-based surveys will also be used to estimate redd life for each river reach. The estimated spawner abundance in the Wenatchee River and an associated level of precision will be calculated using the estimated total redd count for each reach, mean redd life, and the sex ratio of the population similar to methods described in Millar et al. (2012). Salmon carcass data collected during spawning ground surveys will be consistent with Murdoch and Peven (2005). All CWTs (i.e., snout or adipose) from carcasses will be sent to the WDFW lab in Olympia. The CWT lab will extract and read CWTs and submit all required information to RMIS within one year of collection.

4.2 Harvest Reporting

In years when the expected hatchery adult returns are in excess of the levels needed to meet the hatchery program goals (i.e., broodstock and/or escapement), surplus fish may be available for harvest. Harvesting or removal of surplus hatchery fish may have benefits to the natural populations by reducing potential negative ecological and genetic impacts (e.g., density dependent effects, loss of fitness, and loss of genetic variation). The contribution of hatchery fish to fisheries will be monitored using CWT recoveries on a brood-year basis supporting Objective 10.

To obtain the necessary data to determine if the harvest rates are meeting objectives, a statistically valid creel program will be designed and implemented for all sport and/or conservation fisheries in the Upper Columbia River to estimate harvest of hatchery fish from

Deleted: 2017

both Chelan and Grant County PUD funded hatchery programs (Murdoch and Peven 2005). Information collected during creel surveys are an integral component to calculating the HRR (Objective 3), particularly given most CWT recoveries for PUD mitigation programs occur in the Upper Columbia River and its tributaries, with the exception of summer Chinook where most CWT recoveries occur in ocean fisheries. Because of considerable time lags in reporting of CWT's to the Regional Marking Information System (RMIS) database, it requires an ongoing query of recovery data until the number of estimated fish does not change.

5. Data Management , Analysis, and Reporting

5.1 Data Management

A Microsoft Access database maintained by WDFW will contain all the monitoring data collected for hatchery evaluations. The database will contain and manage all data associated with aquaculture monitoring, juvenile monitoring, and adult monitoring.

All data entered into the database are evaluated for quality control and quality assurance by WDFW. Quality control checks using analyses such as modified Z-scores, boxplots, and the Generalized Extreme Studentized Deviate Procedure (Iglewicz and Hoaglin 1993) will be conducted for all data entry. In the event outliers are identified, discussion will occur on whether identified outliers are true data points or transcription errors. This process ensures that the data used to test statistical hypotheses are correct and accurate.

5.2 Data Analysis

The analyses proposed are consistent with the Monitoring and Evaluation Plan for PUD Hatchery Programs: 2013 Update (Hillman et al. 2013). Each of the objectives will be addressed using the appropriate statistical tests, as well as graphic analyses that convey relevant information.

5.3 Reporting

An annual M&E report will be generated following the completion of each calendar year and will be available for HCP-HC review by June 1 of the following year. Additionally, monthly progress reports will be made available to the HCP-HC.

6. Lake Wenatchee Sockeye Salmon

The Chelan PUD will conduct monitoring and evaluation (M&E) activities to track key population attributes related to Lake Wenatchee sockeye salmon in 2018(Table 6). In the absence of a sockeye hatchery program, M&E activities are no longer rooted in the context of evaluating the effects of sockeye salmon supplementation, but instead focus directly on the performance of the natural population, which is a unique departure from historic monitoring obligations. Broadly, the proposed M&E activities cover juvenile and adult life history stages and provide the data necessary to track or estimate viable salmonid population parameters (VSP): abundance, productivity, spatial structure and diversity (McElhaney et al. 2000). The data collected may also have utility in future hatchery compensation recalculation efforts.

Chelan PUD is conducting these M&E activities to support commitments made under the 2011 hatchery recalculation effort, which also included a steelhead production commitment for a sockeye species swap (SOA 2011). This section of the implementation plan describes the specific commitments by juvenile and adult life history stages.

6.1 Juvenile Monitoring

Chelan PUD will conduct or fund activities to monitor and evaluate the temporal distribution and age/size of out-migrating smolts, and estimate smolt production (Table 6). Smolt production will be estimated from data collected at the lower Wenatchee smolt trap and via back calculations based on collected adult return data (i.e., age-at-return estimates, SARs, and adult escapement to the tributaries). Collectively, these activities include: (1) funding of the lower Wenatchee River smolt trap concurrent with efforts aimed at evaluating Chelan PUD funded supplemented populations in the Wenatchee River sub-basin; (2) tagging up to 5,000 PIT tags for natural-origin juveniles encountered during smolt trapping activities and collecting scale samples at this location; and (3) estimating adult escapement estimates to the tributaries, and collection of adult return data at Tumwater (see the *Adult Monitoring* section for details) to back-calculate smolt production.

The monitoring data obtained will provide a useful set of tools for evaluating the performance of natural origin sockeye salmon within the sub-basin and downstream and also support the evaluation of VSP parameters [e.g., outmigration timing and size (diversity); and PIT tagging juveniles for SAR estimates (productivity)].

6.2 Adult Monitoring

Several M&E activities associated with adult returns of Lake Wenatchee sockeye salmon will be conducted and/or funded by Chelan PUD (Table 6). These efforts include (1) continuation of accurate adult counts at Rock Island, Rocky Reach, and Tumwater dams; (2) sampling of scales for age distribution, sex ratio determination, and returns of PIT-tagged adults at Tumwater Dam; (3) reach-specific conversion estimates between Rock Island Dam and spawning grounds in the White and Little Wenatchee rivers (i.e., Rock Island to Tumwater Dam to spawning tributaries); and (4) providing between 250 to 1,000 PIT tags to estimate adult spawning escapement in the Little Wenatchee and White rivers utilizing PIT tags and mark-recapture techniques (the software program Sample Size 2.0.7, developed by the University of Washington School of Aquatic and Fisheries Science (P. Westhagen, J. Lady, and J. Skalski) was used to determine the minimum number of tags required (i.e., 250) to estimate adult sockeye escapement at a +/- 7 percent confidence interval). Chelan PUD will adjust the number of PIT-tagged individuals in order to maintain precision in estimates at the lowest rate of interference to migrating populations, if it is warranted due to annual changes in escapement and detection probabilities. In an effort to PIT tag the run at large, adults will be PIT tagged at Tumwater consistent with the Tumwater Operations Protocol, daily throughout the run.

Collectively, these data will provide reliable metrics of adult returns and spawning escapement (abundance), recruits-per-spawner (productivity), distribution of spawners among tributaries (spatial structure), and run-timing and age structure for adult immigrants (diversity).

Table 6. Chelan PUD's proposed Lake Wenatchee sockeye salmon monitoring and evaluation activities.

Life History Stage	M&E Activity	Entity Performing the Activity	Related analysis	VSP parameter addressed
Juvenile	Concurrent operation of the lower Wenatchee smolt trap to collect juvenile outmigration data	WDFW	Generate distribution of outmigration timing, estimate smolt production and determine average smolt size.	Diversity and productivity
Juvenile	PIT tagging smolts at lower Wenatchee smolt trap (up to 5,000 fish annually) and collecting/aging scale samples	WDFW	Estimate smolt-to-adult returns.	Productivity
Juvenile	Develop adult return based smolt production estimates	WDFW	Use collected data (i.e., adult age-at-return data, SARs, adult escapement to the tributaries) to back-calculate smolt production.	Productivity
Adult	Rock Island and Rocky Reach Dam adult counts	CPUD	Initial spawner abundance (Okanogan stock separation)	Abundance and spatial structure
Adult	PIT tag subsample (250 adults) of returning adults at Tumwater Dam to support mark-recapture evaluation	WDFW	Calculate spawner abundance and relative distribution among ~~in~~ tributaries	Abundance and spatial structure
Adult	Collect and age scales[1] and determine sex via ultrasound from returning adults at Tumwater Dam	WDFW	Estimate age-at-return, sex ratio, and relative productivity of contributing spawner cohorts	Productivity and diversity
Adult	Tumwater Dam adult counts	WDFW	Estimate potential spawner abundance (pre Lake-Wenatchee harvest), potential productivity (recruits/spawner), and run timing distribution	Abundance and diversity
Adult	Operate PIT detection arrays on Little Wenatchee and White River	WDFW	Calculate spawner abundance (post-Lake Wenatchee harvest and other mortality), actual productivity (recruits/spawner), and entry-to-spawning-habitat timing distribution, and spatial spawner distribution among tributaries	Abundance, productivity, spatial structure, and diversity
All	Data management, analysis, and reporting	BioAnalysts CPUD	------	NA

[1] Scales would be collected concurrently from adults that are PIT tagged at Tumwater Dam.

Subject: Update - Hatchery M + E Genetic Monitoring Objectives

---

The “Monitoring and Evaluation Plan for PUD Hatchery Programs 2013 Update,” describes investigating population genetics to monitor and evaluate hatchery programs. Specifically, Objective 7 details three monitoring indicators (‘Allele Frequency’, ‘Genetic Distances between Populations’, and ‘Effective Spawning Population’) used to examine the potential for changes in genetic diversity of natural populations as a result of hatchery programs. These investigations are scheduled to be conducted at ten year intervals, with samples for each stock and species being gathered on separate timelines (based on the completion year of the previous analyses).

Beginning in January of 2016, WDFW began preparing to investigate these genetic indicators, through a series of requests made by co-managers and the HC. These requests led to defined tasks that include: (1) Update the inventory of existing genetic samples for UC hatchery programs, (2) Gather all relevant previous reports pertinent to genetic investigations in the Upper Columbia, (3) Develop a timeline for sample collection, analyses, and reporting to meet the monitoring objectives outlined above, and, (4) Investigate a potential analyses with geneticists, this investigation would inform an updated sample interval for conducting future genetic investigations outlined in the monitoring and evaluation plan.

Below, you will find each task with a completion summary. Genetic sampling is slated to begin taking place in 2017 (spring Chinook Salmon and summer steelhead). Further, pertinent notes and questions for the future of genetic sampling are outlined beneath each summary. Attached with this document, you will find an Excel file that contains the updated inventory and upcoming sampling timeline (see tab labeled “Guide”).

(1) *Update the inventory of existing genetic samples for UC hatchery programs*.

During April and May of 2016, the WDFW Genetics lab catalogued its collection of genetic samples stowed in their temperature controlled storage room. During this effort, WDFW cross referenced and updated an existing inventory previously developed in 2010. Further, WDFW included additional stocks/samples at the request of co-managers. The additional stocks/samples were included in the inventory despite not being stored at the WDFW Genetics Lab in Olympia. These included samples from the USFWS, YN and GCPUD. The inventory is attached to the memo electronically (Tabs 1 through Tab 18 in attached file).

Notes to HC – During the development of this updated inventory, questions arose as to the future of historic samples. The inventory provides insight of what questions are possible to ask, and the historic samples will be relevant to those questions. Will historic samples be used in upcoming analyses? If so, which samples? There may be limitations to the amount and condition of genetic material available in some cases. Further, advancements (SNP markers) in genetic profiling would make historic samples more informative, but the historic samples would need to be extracted and analyzed to use these new developed markers. Currently, samples from USFWS programs are included in the inventory, but are not included in the timeline. Is there a desire to include USFWS programs need to be included in the timeline? They report on a different schedule, and samples are stored in a separate lab (Abernathy).

(2) *Gather all relevant previous reports pertinent to genetic investigations in the Upper Columbia*.

During June and July of 2016, WDFW conducted a review of the literature and assembled a report list. This activity involved a series of meetings with co-managers and the Genetics Lab. A list of relevant reports and literature is included with the inventory and timeline file attached electronically (Tab “Guide”, Column E).

Notes to HC – As previous research/reports were being gathered, it was clear that many hatchery programs have evolved (e.g. differing broodstock, release locations, mating crosses) since the inception the programs. Previous analyses may not be comparable to upcoming analyses. The availability and quantity of historic samples will shape what analyses can be performed. Do upcoming analyses need to be comparable to previous analyses? How will program changes influence the scope of the analyses?

(3) *Develop a timeline for sample collection, analyses, and reporting to meet the monitoring objectives*.

From July through November of 2016, WDFW met with co-managers and the Genetics Lab on several occasions to discuss time frame and logistics (e.g., manpower, sample location, sample frequency, sample amount, analyses timeframe, etc.). Stocks/programs were also added to the timeline at request of co-managers (e.g., CCT). Attached electronically is the timeline (with collection and reporting schedule, on Tab 19).

Notes to HC – SNP markers/panels have been developed for many of the stocks/species to be examined in the timeline. However, there may be further refinement of SNP panels for some stocks/species, which may add time (and cost) to the analyses. Do we need to use SNP's for all programs? Other labs or groups may have SNP panels that could be borrowed and used, but that will take more coordination. Also, the timeline spreads the genetic work over a five year period. This allows for two years of collection, a year of analyses, and a different species to be examined annually. This may lengthen the sampling interval for some programs to greater than ten years. Is this acceptable? Finally, how do conservation programs fit into monitoring and evaluation analyses? Would there be different criteria in evaluating whether there are hatchery impacts (as opposed to safety net or harvest programs)?

(4) *Investigate potential analyses with geneticists, this investigation would inform an updated sample interval for conducting future genetic investigations outlined in the monitoring and evaluation plan.*

During February of 2017, WDFW consulted with two specialists (Scott Blankenship at Cramer Fish Sciences and Todd Seamons at WDFW Genetics Lab) to explore the potential of conducting an analyses to derive an adequate sample interval for genetic investigations. There comments are quoted below:

<u>From Todd Seamons</u>:

"The first thing we would need to do for a power analysis is decide on the specific statistical tests that we would be using for the analysis. There is some guidance in the Upper C M&E plan, but we typically tackle the question from a lot of different angles. The more statistical analyses we choose at the beginning, the more effort for the power analysis. We could focus on one or two tests with the caveat that the power analysis is only relevant for those tests.

The power of the statistical tests relies on both the genetic power (i.e., the type and number of markers) and sample sizes, and we would necessarily cover several different time periods or some continuous range of time, since that's the question driving the request for the power analysis in the first place. Covering a lot of that sample space would take a lot of time. We would evaluate SNP markers only. In order to reduce the time, we could focus on one or two different numbers of markers and one or two sample sizes, again with caveats.

We would probably tackle this with both simulated and empirical data.

Hatchery production can have a number of effects on wild fish, thus modeling the effects (e.g., with simulated data) could involve any number of covariates and would necessarily involve simplifying assumptions. Each covariate increases the complexity of the model and the time needed to evaluate it. To do it right, we'd likely want to do some sort of sensitivity analysis to violation of assumptions, which could add substantial amount of time."

From Scott Blankenship:

"Yes, I agree with Todd, the more metrics folks care to look at the more effort it will take to configure and implement.

As I mentioned, the analyses done by NMFS regarding recovery planning (specifically population viability) may provide you a starting place to discuss the logic and underlying issues of evaluating population on the 2-3 generation time frame.

Some more food for thought. On the whole, the couple decades of hatchery evaluations appears to have landed on a few topics to consider. Very broadly these are: 1) Reproductive Success; 2) Life history traits alterations; 3) Hatcheries goals; 4) Co-existence. I am not suggesting it is appropriate to bring these issues up to various hatchery committees, but some of these issues may be floating around. Taking a more restricted genetics only view, some standard topics to consider are loss of within-population genetic diversity, homogenization, reduction in effective population size (N_e), and domestication selection. Interestingly, Peven and Murdoch 2005 attempted to deal with all those except domestication. Although, I acknowledge what would be considered an evaluation of diversity probably has changed in the past 10 years."

Please let me know if you have any questions.

Best,

McLain Johnson

Appendix 6: **Identifying and Analyzing Reference Populations.**

GLOSSARY

Adult-to-Adult survival (Ratio)	The number of parent broodstock relative to the number of returning adults.
Age at maturity	The age of fish at the time of spawning (hatchery or naturally)
Augmentation	A hatchery strategy where fish are released for the sole purpose of providing harvest opportunities.
Broodstock	Adult salmon and steelhead collected for hatchery fish egg harvest and fertilization.
Donor population	The source population for supplementation programs before hatchery fish spawned naturally.
Effective population size (Ne)	The number of reproducing individuals in an ideal population (i.e., Ne = N) that would lose genetic variation due to genetic drift or inbreeding at the same rate as the number of reproducing adults in the real population under consideration (Hallerman 2003).
ESA	Endangered Species Act passed in 1973. The ESA-listed species refers to fish species added to the ESA list of endangered or threatened species and are covered by the ESA.
Expected value	The number of smolts or adults derived from survival rates agreed to in the Biological Assessment and Management Plan (BAMP 1998).
Extraction rate	The proportion of the spawning population collected for broodstock.
Genetic diversity	All the genetic variation within a species of interest, including both within and between population components.
Genetic stock structure	A type of assortative mating, in which the gene pool of a species is composed of a group of subpopulations, or stocks, that mate panmictically within themselves.
Genetic variation	All the variation due to different alleles and genes in an individual, population, or species.
HCP	Habitat Conservation Plan is a plan that enables an individual or organization to obtain a Section 10 Permit which outlines what will be done to “minimize and mitigate” the impact of the permitted take on a listed species.
HCP-HC	Habitat Conservation Plan Hatchery Committee is the committee that directs actions under the hatchery program section of the HCP’s for Chelan and Douglas PUDs.
HRR	Hatchery Replacement Rate is the ratio of the number of returning hatchery adults relative to the number of adults taken as broodstock, both hatchery and naturally produced fish (i.e., adult-to-adult replacement rate).
Long-term fitness	Long-term fitness is the ability of a population to self-perpetuate over successive generation.
Naturally produced	Progeny of fish that spawned in the natural environment, regardless of the origin of the parents.

Mean Ratio	The ratio between a treatment and control population, with the mean taken across a time period, such as years. Used in analysis in Before-After-Control-Impact studies.
Ne	Effective population size
Non-target taxa of concern (NTTOC)	Species, stocks, or components of a stock with high value (e.g., stewardship or utilization) that may suffer negative impacts as a result of a hatchery program.
NRR	Natural replacement rate is the ratio of the number of returning naturally produced adults relative to the number of adults that naturally spawned, both hatchery and naturally produced.
NTTOC	Non-target taxa of concern.
pHOS	Proportion of Hatchery Origin Spawners
PNI	Proportionate Natural Influence
pNOB	Proportion of Natural Origin Broodstock
Productivity	The capacity in which juvenile fish or adults can be produced.
Reference population	A population in which no directed artificial propagation is currently directed, although may have occurred in the past. Reference populations are used to monitor the natural variability in survival rates and out of basin impacts on survival.
SAR	Smolt-to-adult survival rate
SAR Smolt-to-adult survival rate (SAR)	Smolt-to-adult survival rate is a measure of the number of adults that return from a given smolt population.
Segregated	A type of hatchery program in which returning adults are spatially or temporally isolated from other populations.
Size-at-maturity	The length or weight of a fish at a point in time during the year in which spawning will occur.
Smolts per redd	The total number of smolts produced from a stream divided by the total number of redds from which they were produced.
Spawning Escapement	The number of adult fish that survive to spawn.
Stray rate	The rate at which fish spawn outside of natal rivers or the stream in which they were released.
Supplementation	A hatchery strategy where the main purpose is to increase the relative abundance of natural spawning fish without reducing the long-term fitness of the population.
Target population	A specific population in which management actions are directed (e.g., artificial propagation, harvest, or conservation).

SECTION 1: INTRODUCTION

This document is an update of the monitoring and evaluation (M&E) plan of the salmon and steelhead hatchery programs funded by Douglas, Chelan, and Grant County Public Utility Districts (PUDs). Programmatic changes, evaluation of data collection methods, and M&E results from the past several years, along with shifting management paradigms affect M&E needs, all of which have occurred under advancing fish culture and monitoring techniques. As required by the programs, this document is a result of a five-year review intended to expand on and coalesce previous M&E documents (BAMP 1998; Cates et al. 2005; Murdoch and Peven 2005; Hays et al. 2006; Pearsons and Langshaw 2009a, 2009b; Hillman et al. 2013) with inclusion of new information.

Fishery management agencies developed the following general goal statements for hatchery programs, which were adopted by the HCPs Hatchery Committees and PRCC Hatchery Sub-Committee (hereafter, Hatchery Committees):

1. Support the recovery of ESA-listed species by increasing the abundance of the natural adult population, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity.
2. Increase the abundance of the natural adult population of unlisted plan species, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity. In addition, provide harvest opportunities in years when spawning escapement is sufficient to support harvest.
3. Provide salmon for harvest and increase harvest opportunities, while segregating returning adults from natural tributary spawning populations.

Following the development of Hatchery and Genetic Management Plans (HGMPs), artificial supplementation programs are now characterized into three categories. The first type, integrated conservation programs, are intended to support or restore natural populations. These programs focus on increasing the natural production of targeted fish populations. A fundamental assumption of this strategy is that hatchery fish returning to the spawning grounds are reproductively similar to naturally produced fish. The second type, safety-net programs, are extensions of conservation programs, but are intended to function as reserve capacity for conservation programs in years of low returns. The safety-net provides a demographic and genetic reserve for the natural population. That is, in years of abundant returns they function like segregated programs, and in low return years they can be managed as conservation programs. Lastly harvest augmentation programs are intended to increase harvest opportunities while limiting interactions with wild-origin counterparts.

Monitoring is needed to determine if the hatchery programs are meeting the intended management objectives of conservation, safety-net, or harvest augmentation programs. Objectives for hatchery programs are generally grouped into three categories of performance indicators:

1. In-Hatchery: Is the program meeting the hatchery production objectives?
2. In-Nature: How do fish from the program perform after release?
    a. Conservation Program:

- How does the program affect target population abundance and productivity?
- How does the program affect target population long-term fitness?

b. Safety-Net Program:

- How does the program affect target population long-term fitness?

c. Harvest Augmentation Program:

- Does the program provide harvest opportunities?

3. Risk Assessment: Does the program pose risks to other populations?

Objectives in this plan have been organized in a hierarchy where productivity indicators are the primary metrics used to assess if conservation and safety-net program goals have been met; harvest rates and effects on non-targeted populations are used for harvest programs. In cases where productivity indicators are not available or results are equivocal, monitoring indicators may be used to help evaluate the performance of the program. Evaluations of monitoring indicators may not provide sufficiently powerful conclusions on which to base management actions, although they may provide insight as to why a productivity indicator did or did not meet the program goal. Therefore, the relationship between hatchery programs and indicators can be viewed in a chain-of-causation: management actions within the hatchery programs affect the status of monitoring indicators, which in turn influence productivity indicators (Figure 1).

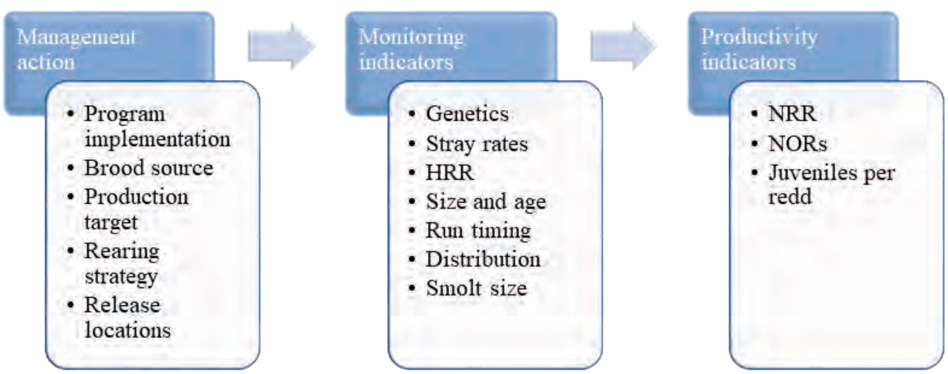

Figure 1. **Relationship of indicators to the assessment of supplementation programs. Management actions affect monitoring indicators, which influence productivity indicators. Monitoring indicators may be used to hypothesize the magnitude of influence on productivity.**

The primary goal of a conservation program is to contribute to the rebuilding and recovery of naturally reproducing populations within their native habitat. In this plan, natural replacement rates (NRR), recruitment of naturally-produced fish (NOR), and juvenile productivity (juveniles per redd) are important indicators for assessing the success of supplementation. These indicators are difficult to measure precisely and are quite variable in space and time. Therefore, monitoring indicators can be evaluated to help assess if productivity was related to the hatchery programs or other factors (Table 1).

Table 1. Program objectives, indicators, and goals for conservation hatchery programs including productivity and monitoring indicators (also applies to safety-net programs when used to support a conservation program).

	Objective	Indicator	Target	Program goals: Rebuild natural populations	Program goals: Maintain genetic diversity	Program goals: Opportunity for harvest
Productivity indicators	Determine if the program has increased the number of naturally spawning adults	Abundance of natural spawners	Increase	✓		✓
		Adult productivity (NRR)	No decrease	✓		
	Determine if the proportion of hatchery fish affects freshwater productivity	Residuals vs. pHOS	No relationship	✓		
		Juveniles per redd vs. pHOS	No relationship	✓		
Monitoring indicators	Determine if run timing and distribution meets objectives	Migration timing	No difference	✓	✓	
		Spawn timing[1]	No difference	✓	✓	
		Redd distribution[2]	No difference	✓	✓	
	Determine if program has affected genetic diversity and population structure	Allele frequency (hatchery vs. wild)	No difference		✓	
		Genetic distance between populations	No difference		✓	
		Effective population size	Increase		✓	
		Age and size at maturity	No difference		✓	
	Determine if hatchery survival meets expectations	HRR	HRR > NRR	✓		
		HRR	HRR ≥ Goal[3]	✓		
	Determine if recipient stray rate of hatchery fish is acceptable	Out of basin	≤ 5%	✓	✓	
		Within basin	≤ 10%	✓	✓	
	Determine if hatchery fish were released at program targets	Size and number	= Target[4]	✓		
	Provide harvest opportunities when appropriate	Harvest	Escapement goals			✓

[1] Hatchery and natural-origin fish should spawn at the same time across the range of elevations within the spawning distribution of each stock.

[2] Hatchery and natural-origin fish should spawn in the same locations. Exceptions are the Carlton and Dryden Summer Chinook programs (see Appendix 4).

[3] HRR targets are identified in Appendix 2.

[4] Number and size targets are identified in Table 3 and Appendix 5.

A flow of information following sequential, logical steps will be employed to evaluate supplementation programs, consistent with the indicators described in Table 1. For example, a hatchery program, at a minimum, must be able to produce more adults per spawner than would occur in the natural environment. Should the program fail this test, hatchery operations should be evaluated to determine if improvements can correct the problem. If a program successfully replaces the required number of adults, it is then evaluated against a reference population or condition, if available, to determine if it has increased the overall number of naturally spawning fish (including both hatchery- and natural-origin adults), increased the number of natural-origin spawners, and to test if productivity of the natural population has changed. When these goals are met, the program is considered successful. When these goals are not met, monitoring indicators may infer why the program is not achieving its goals

If suitable reference populations are not available, other comparisons can be used to help evaluate treatment responses. Evaluation of programs may pursue the following approaches:

- Comparison to reference population(s) that do not contain pre-treatment data.
- Before treatment and after treatment comparisons.
- Comparison to standard(s).
- Comparison to other suitable reference conditions.

Methodologies for selecting reference streams, analyzing data from treatment and reference stream comparisons, and other comparisons are presented in Hillman et al. (2012) (see Appendix 6).

The primary goals of a safety-net program are to provide demographic and genetic reserves for a population that is supplemented by a conservation program (Table 2). Harvest and adult management may be used to control escapement of spawners when appropriate. Monitoring focuses on estimating the number of fish that escape to spawn naturally and stray rates and in-hatchery performance evaluation.

Table 2. Program objectives, indicators, and goals for segregated harvest augmentation hatchery programs including monitoring indicators.

				Program goals		
	Objective	**Indicator**	**Target**	**Rebuild natural populations**	**Maintain genetic diversity**	**Opportunity for harvest**
Monitoring indicators	Determine if hatchery survival meets expectations	HRR	HRR > NRR			✓
		HRR	HRR ≥ Goal[1]			✓
	Determine if stray rate of hatchery fish is acceptable	Out of basin	≤ 5%		✓	
		Within basin	≤ 10%		✓	
	Determine if hatchery fish were released at program targets	Size and number	= Target[2]			✓
	Provide harvest opportunities when appropriate	Harvest	Escapement goals			✓

[1] HRR targets are identified in Appendix 2.
[2] Number and size targets are identified in Table 3 and Appendix 5.

The primary goal of a harvest augmentation program is to increase harvest opportunities, while segregating adults from natural spawning populations. In this plan, harvest opportunity, survival rates, and stray rates are important indicators for assessing the success of harvest augmentation. These indicators are more readily quantified compared to productivity indicators (Table 2). A flow of information will be employed to evaluate harvest augmentation programs. Since harvest augmentation programs are typically segregated, monitoring indicators will be used to determine the success of a program.

Both monitoring and productivity indicators will be used to evaluate the success of hatchery programs. In the event that the statistical power of tests that involve productivity indicators is insufficient to inform sound management decisions, some of the monitoring indicators may be used to guide management. Figure 2 show the categories of indicators associated with each component of monitoring.

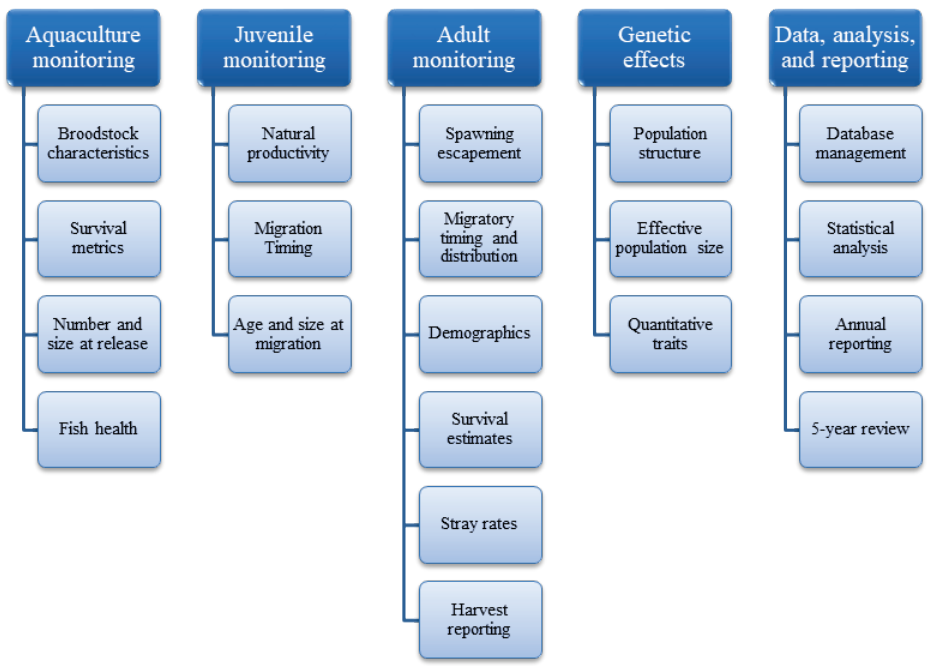

Figure 2. Overview of Monitoring and Evaluation Plan Categories and Components (not including regional objectives).

The overarching goals of conservation, safety-net, and harvest augmentation programs, as described above, are shown in detail in Figure 3. The flow chart (Figure 3) shows the relationship of overarching program goals, the strategies used to meet the goals, the monitoring and evaluation objectives used to evaluate the strategies and determine if goals are being met, and the adaptive management cycle associated with the programs (see Tables 1 and 2 for the indicators under each objective). The logic depicted in this flow chart shall be used to assess M&E results and apply

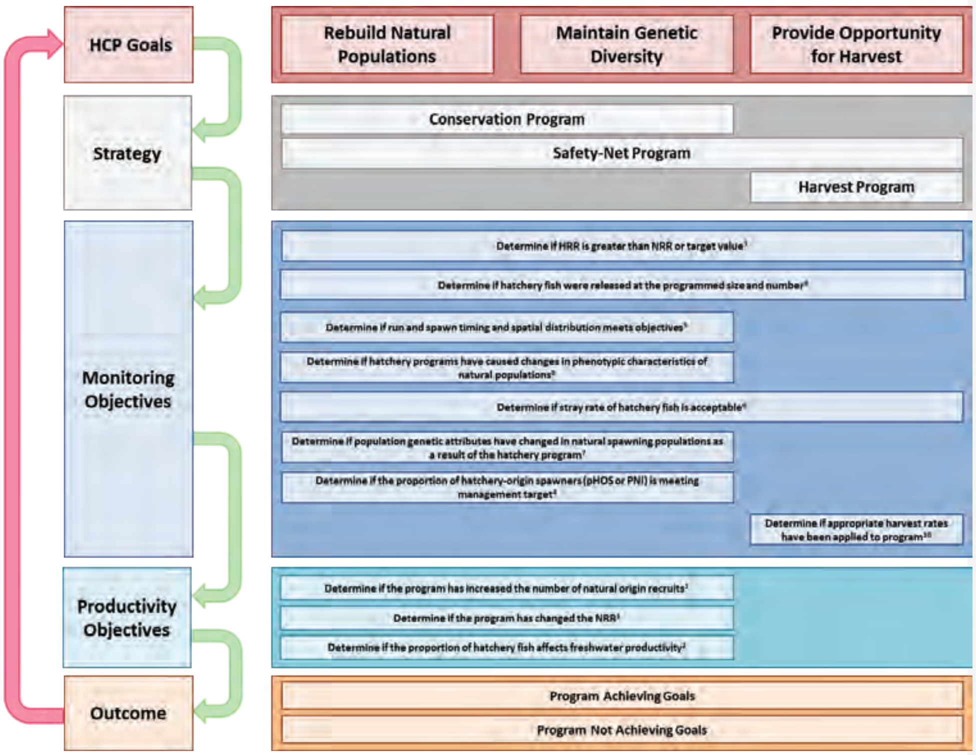

Figure 3. Adaptive management flow chart depicting HCP goals, associated strategies to meet the goals, the monitoring and evaluation objectives (indicated in superscript), and the adaptive management feedback cycle. The strategies, objectives, and outcomes are aligned vertically under the corresponding goals.

Table 3. Hatchery programs in the mid-Columbia River Basin, 2012. Funding entities included Douglas PUD (D), Chelan PUD (C), Grant PUD (G), Bonneville Power Administration (B), Bureau of Reclamation (O), and Army Corps of Engineers (A) and are listed in order of contribution. Total artificial production targets in the mid-Columbia River exceeds 20 million juveniles annually.

Program	Species	Basin	Purpose	Funding Entity	Production
Methow[5]	Spring Chinook [1]	Methow	NNI/Conservation	G, C, D	223,765

[6] Program also partially covered by CCT M&E Plan.
[7] Program affects PUD-funded programs covered by this plan.
[8] Planned to increase within the next 5 years.

SECTION 2: ADULT PRODUCTIVITY

2.1 Natural Replacement Rates of Supplemented Populations[1]

Objective 1: Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.

At the core of a conservation program is the objective of increasing the number of spawning adults (i.e., the combined number of naturally produced and hatchery fish) in order to affect a subsequent increase in the number of returning naturally produced fish or natural-origin recruits (NOR). In order for the natural population to remain stable or to increase, the Natural Replacement Rate (NRR), or the ratio of NORs to the parent spawning population, must be at a level where parents are being replaced by their offspring as spawners in the next generation. It is possible to affect an increase in natural-origin spawners through supplementation with a stable or decreasing NRR. However, if the NRR is below replacement (NRR<1.0), termination of the supplementation program will result in a declining natural population should that state of NRR persist. The proportion of the hatchery-origin spawners (pHOS) that will increase natural production without creating adverse effects to the genetic diversity or reproductive success rate of the natural population is unknown, and may be dependent on how individual hatchery programs are operated, as well as available spawning and rearing habitat. Some programs may restrict pHOS to reduce the risk to the natural population with the intent of optimizing productivity, concomitantly reducing the overall number of spawners. All other objectives of the M&E Plan either directly support this objective or seek to minimize negative effects of the conservation programs on non-target stocks of concern.

Differences in carrying capacities of supplemented and non-supplemented streams can confound the analysis of the effects of supplementation on total number of spawners returning to the streams. For example, if the supplemented population is at carrying capacity and the non-supplemented population is not, the total number of spawners returning to the non-supplemented population may show an increasing trend over time, while the supplemented population would show no increasing trend. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on total spawners, density corrections should be included in the analyses. Hypotheses that may require density corrections are noted under each monitoring question. Appendix 1 describes methods for estimating carrying capacities.

Monitoring Questions:

Q1.1.1 Has the supplementation program changed the adult productivity (NRRs) of the supplemented populations?[2]

Target Species/Populations:

[1] Supplementation programs may include a safety-net component.

[2] Because adult productivity is affected by the abundance of the population (i.e., productivity decreases with increasing abundance), the goal of supplementation is to increase or maintain productivity, but not decrease it.

- Q1.1.1 applies to all conservation and safety-net stocks.

Statistical Hypotheses 1.1.1[3]:

- $Ho_{1.1.1.1}$: Slope in NRRs before supplementation ≤ slope in NRRs after supplementation.
- $Ho_{1.1.1.2}$: Differences in slopes in NRRs between supplemented and reference populations before supplementation ≤ differences in slopes in NRRs between supplemented and reference populations after supplementation.
- $Ho_{1.1.1.3}$: Mean NRRs before supplementation ≤ mean NRRs after supplementation.
- $Ho_{1.1.1.4}$: Mean ratio scores in NRRs before supplementation ≤ Mean ratio scores in NRRs during supplementation.
- $Ho_{1.1.1.5}$: Mean ratio scores in NRRs (adjusted for density dependence) before supplementation ≤ Mean ratio scores in NRRs (adjusted for density dependence) during supplementation. [This hypothesis adjusts NRRs for density-dependent effects (see Hillman et al. 2012 for details; Appendix 6).]
- $Ho_{1.1.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds
- Number of naturally produced fish harvested

Derived Variables:

- Number of naturally produced recruits by brood year for both naturally produced parents and hatchery parents (≥age-3).
- NRRs (calculated as NORs/spawner).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NRRs (requires reference population[s]).
- Includes calculation of ratios NORs (requires reference population).
- Appendix 1: Spawning escapement and carrying capacity information (as applicable)

Spatial/Temporal Scale:

- Calculated annually based on brood year.
- Time series.

Possible Statistical Analysis:

[3] Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 6) for details.

- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 6). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NRRs.
- On a five-year period, correlate productivity with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

2.2 Natural-Origin Recruits of Supplemented Populations

Monitoring Questions:

Q1.2.1: Has the supplementation program changed the abundance of NORs within the supplemented population?

Target Species/Populations:

- Q1.2.1 applies to all supplemented or safety net stocks.

Statistical Hypotheses 1.2.1[4]:

- $Ho_{1.2.1.1}$: Slope in NORs[5] before supplementation ≥ slope in NORs after supplementation.
- $Ho_{1.2.1.2}$: Differences in slopes in NORs between supplemented and reference populations before supplementation ≥ differences in slopes in NORs between supplemented and reference populations after supplementation.
- $Ho_{1.2.1.3}$: Mean NORs before supplementation ≥ mean NORs after supplementation.
- $Ho_{1.2.1.4}$: Mean ratio scores in NORs before supplementation ≥ Mean ratio scores in NORs during supplementation.
- $Ho_{1.2.1.5}$: Mean ratio scores in NORs/Maximum Recruitment before supplementation ≥ Mean ratio scores in NORs/Maximum Recruitment during supplementation. [This hypothesis adjusts NORs for the capacity of the habitat; it tests the fraction of the habitat saturated with NORs (see Hillman et al. 2012 for details).]
- $Ho_{1.2.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and NORs; rho = 0. [If there is a significant negative association between

[4] Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 7) for details.

[5] "Slope in NORS" refers to abundance of NORs across time (years).

pHOS and NORs, then hatchery fish may be reducing the reproductive success of the wild population.]

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish taken for broodstock.
- Number of hatchery and naturally produced fish taken in harvest (if recruitment is to the Columbia).

Derived Variables:

- NORs (number of naturally produced recruits (total recruits) by brood year for both naturally produced parents and hatchery parents [≥age-3]).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NORs (requires reference population[s]).
- Estimates of carrying capacity (see Appendix 1).

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NORs.
- On a five-year period, correlate NORs with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

SECTION 3: JUVENILE PRODUCTIVITY

3.1 Freshwater Juvenile Productivity

Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.

Out-of-basin effects (e.g., smolt passage through the hydro system, harvest, and ocean productivity, etc.) influence the survival of smolts after they migrate from the tributaries. These effects introduce substantial variability into the adult-to-adult survival rates (NRRs and HRRs) and may mask in-basin effects (e.g., habitat quality, density-dependent mortality, and differential reproductive success of hatchery and naturally produced fish). Therefore, an estimate of freshwater productivity may help inform the performance of hatchery and natural-origin spawners.

The objective of estimating freshwater productivity in the Upper Columbia ESU/DPS is to estimate the survival from egg to a critical juvenile life stage(s) of target stocks. Smolt or juvenile production models generated from the information obtained through these programs will provide a level of predictability with greater sensitivity to in-basin effects than spawner-recruitment models that consider all effects.

Differences in the current carrying capacities of supplemented and non-supplemented streams can confound the effects of supplementation on numbers of juveniles per redd. For example, if the supplemented population is at or above carrying capacity and the non-supplemented population is not, numbers of juveniles per redd in the non-supplemented population may be significantly greater than the number of juveniles per redd in the supplemented population. In addition, pHOS may be correlated with overall spawner abundance. In these cases, it is difficult or impossible to separate density-dependent effects from the influence of pHOS on freshwater productivity. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on juveniles per redd, the capacity of the habitats must be included in the analyses. The Supplementary Hypotheses presented below are designed to address the confounding effects of different densities on the analyses.

Monitoring Questions:

Q2.1.1: Has the supplementation program changed the number of juveniles (smolts, parr, and/or emigrants) per redd within the supplemented population?

Q2.2.1: Does the number of juveniles per redd decrease as the proportion of hatchery spawners increases?[6]

Target Species/Populations:

- Both Q2.1.1 and Q2.2.1 apply to all conservation stocks.

Statistical Hypotheses for 2.1.1[7]:

6 Information is needed to estimate the effects of density dependence on these questions. Consider spatial distribution of redds.

7 Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. (2012) for details.

- $Ho_{2.1.1.1}$: Slope in juveniles/redd before supplementation ≤ slope in juveniles/redd after supplementation.
- $Ho_{2.1.1.2}$: Differences in slopes in juveniles/redd between supplemented and reference populations before supplementation ≤ differences in slopes in juveniles/redd between supplemented and reference populations after supplementation.
- $Ho_{2.1.1.3}$: Mean juveniles/redd before supplementation ≤ mean juveniles/redd after supplementation.
- $Ho_{2.1.1.4}$: Mean ratio scores in juveniles/redd before supplementation ≤ Mean ratio scores in juveniles/redd during supplementation.
- $Ho_{2.1.1.5}$: Mean ratio scores in juveniles/redd (adjusted for density dependence) before supplementation ≤ Mean ratio scores in juveniles/redd (adjusted for density dependence) during supplementation. [This hypothesis adjusts juveniles/redd for density-dependent effects (see Hillman et al. 2012 for details; Appendix 6).]
- $Ho_{2.1.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

Statistical Hypotheses for 2.2.1:

- $Ho_{2.2.1.1}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]
- $Ho_{2.2.1.2}$: The slope between proportion of hatchery spawners and juveniles/redd is ≥ 0.

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Numbers of redds.
- Number of juveniles (smolts, parr [where appropriate], and emigrants).

Derived Variables:

- Number of juveniles per spawner.
- Number of juveniles per redd.
- Carrying capacity (see Appendix 1).

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- These analyses shall be performed every five-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 6). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and juveniles/redd.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

SECTION 4: NATURAL ENVIRONMENT MONITORING INDICATORS

4.1 Hatchery Replacement Rates (HRRs)

<u>Objective 3</u>: **Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.**

The survival advantage from the hatchery (i.e., egg-to-smolt) must be sufficient to produce a greater number of returning adults than if broodstock were left to spawn naturally. If a hatchery program cannot produce a greater number of adults than naturally spawning fish, then the program should be modified or discontinued. Production levels were initially developed using historical run sizes and smolt-to-adult survival rates (BAMP 1998). Using the stock specific NRR and agreed upon target values (see Appendix 2), comparisons to actual survival rates will be made to ensure the expected level of survival has been achieved.

Deleted: e.g. values listed in the BAMP or derived from other sources

Monitoring Questions:

Q3.2.1: Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the adult-to-adult survival rate (NRR) of naturally produced fish?

Q3.2.2: Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the Target Value identified in Appendix 2[8]?

Target Species/Populations:

- Q3.2.1 applies to all conservation stocks.
- Q3.2.2 applies to all stocks.

Statistical Hypothesis 3.2.1:

- $Ho_{3.2.1.1}$: $HRR_{\text{Year } x} \geq NRR_{\text{Year } x}$

Statistical Hypothesis 3.2.2:

- $Ho_{3.2.2.1}$: HRR ≥ Target Value identified in Appendix 2

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish harvested.
- Number of hatchery and naturally produced fish collected for broodstock.
- Number of broodstock used by brood year (hatchery and naturally produced fish).

Derived Variables:

- Number of hatchery and naturally produced adults by brood year (≥age-3).

[8] Target values may be adjusted by the hatchery committees.

- HRR (number of returning adults per brood year/broodstock)
- NRR (from Objective 1)
- Appendix 2: HRR targets identified in Appendix 2

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- For Q3.2.1 use graphic analysis and paired-sample quantile tests to compare HRR to NRR
- For Q3.2.2 use graphic analysis and one-sample quantile tests to compare HRR to the target value.
- On a five-year period, correlate HRRs with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.2 Proportion of Hatchery-Origin Spawners (pHOS or PNI)

Objective 4: Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.

Certain hatchery programs have pHOS or PNI targets, while other do not. HGMPs and permits inform the selection of targets, which are identified in Appendix 3.

Monitoring Questions:

Q4.1.1: Is the estimated proportion of hatchery-origin spawners (pHOS) less than or equal to the management target, and/or, is the estimated Percent Natural Influence (PNI) greater than or equal to the management target identified in Appendix 3?

Target Species/Populations:

- Q4.1.1 applies to all conservation and safety-net stocks that have a defined pHOS or PNI target or sliding scale (see Appendix 3).

Statistical Hypothesis 4.1.1:

- $Ho_{4.1.1.1}$: pHOS > target value or $PNI_{Supplemented\ population}$ < target value identified in Appendix 3

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds

Derived Variables:

- pHOS or PNI
- Appendix 3: PNI and pHOS targets and sliding scales identified in Appendix 3

Spatial/Temporal Scale:

- Calculate annually.
- Analyzed as time series.

Possible Statistical Analysis:

- Use graphic analysis and summary statistics to compare pHOS or PNI to the target value in Appendix 3.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

4.3 Run Timing, Spawn Timing, and Spawning Distribution

Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.

Strategies for conservation programs typically intend that hatchery and natural-origin fish spawn together and in similar locations. However, in some cases, strategies may differ from this paradigm (e.g., summer Chinook salmon in the Wenatchee and Methow rivers; see Appendix 4). Phenotypic plasticity or selection resulting from the hatchery environment (i.e., domestication) may affect run (migration) timing, spawn timing, and spawning distribution. If conservation programs do not adequately represent the genetic diversity of the natural population, and if phenotypic traits in supplementation fish related to fitness deviate from the naturally produced spawning population, the goals of supplementation may not be achieved. Hatchery adults that migrate and/or spawn at different times or are spatially segregated from natural-origin fish may be subject to reduced fitness. Hatchery adults that spawn at different times or locations than natural-origin fish would be reproductively isolated from the natural population. The extent of such isolation, ranging from no isolation to substantial isolation, may be exploited for management purposes in some cases.

Migration Timing

Monitoring Questions:

Q5.1.1: Is the migration timing of hatchery and natural-origin fish from the same age class similar?

Target Species/Populations:

- Q5.1.1 applies to all conservation stocks.

Statistical Hypotheses 5.1.1:

- $Ho_{5.1.1.1}$: Migration timing $_{\text{Hatchery Age X}}$ = Migration timing $_{\text{Naturally produced Age X}}$

- $Ho_{5.1.1.2}$: The cumulative frequency of migration timing of hatchery-origin fish = the cumulative frequency of migration timing of natural-origin fish.
- $Ho_{5.1.1.3}$: The 10th percentile, 50th percentile (mode), 90th percentile, and mean migration timing of hatchery-origin fish = the 10th percentile, 50th percentile (median), 90th percentile, and mean migration timing of natural-origin fish.

Measured Variables:

- Ages of hatchery and natural-origin fish sampled via pit tags or stock assessment monitoring.
- Time (Julian date) of arrival at mainstem projects and within tributaries (e.g., traps, PIT arrays) with the intent to identify biologically significant differences.

Derived Variables:

- Mean Julian date for a given age class.

Spatial/Temporal Scale:

- Calculate annually based on return year and age class.
- Time series.

Possible Statistical Analysis:

- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Spawn Timing

Monitoring Questions:

Q5.2.1: Is the timing of spawning similar for conservation hatchery and natural-origin fish?

Deleted: ly produced

Target Species/Populations:

- Q5.2.1: Applies to all semelparous species and populations supplemented by conservation programs. Steelhead can only be assessed for natural spawning in situations where hatchery and natural-origin fish can be appropriately marked and detected.

Deleted:

Statistical Hypotheses 5.2.1:

- $Ho_{5.2.1.1}$: The cumulative frequency of spawn timing of hatchery-origin fish = the cumulative frequency of spawn timing of natural-origin fish.
- $Ho_{5.2.1.2}$: The 10th percentile, 50th percentile (mode), 90th percentile, and mean spawn timing of hatchery-origin fish = the 10th percentile, 50th percentile (mode), 90th percentile, and mean spawn timing of natural-origin fish.

- Ho$_{5.2.1.3}$: The relationship between elevation and spawn timing of hatchery-origin fish = the relationship between elevation and spawn timing of natural-origin fish.

Measured Variables:

- Time (Julian date) and elevation (m) of hatchery and natural-origin salmon carcasses or marked steelhead detected on spawning grounds within defined reaches.
- Time (Julian date) of ripeness of hatchery and natural-origin steelhead captured for broodstock.

Deleted: ly produced

Deleted:

Derived Variables:

- Mean Julian date.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.
- Use graphic analyses, ANCOVA, and regression analysis to assess relationships between elevation and spawn timing.

Deleted: ANCOVA with elevation as a covariate

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Spatial Distribution of Redds

Monitoring Questions:

Q5.3.1: Is the distribution of redds similar for conservation hatchery and natural-origin fish?

Q5.3.2: Is the distribution of redds similar to defined management targets (see Appendix 4)?

Target Species/Populations:

- Q5.3.1 applies to all conservation program stocks.
- Q5.3.2 applies only to conservation program stocks with specific spawning distribution targets (Carlton and Dryden summer Chinook programs; Appendix 4).

Deleted: Table 5.3.1

Statistical Hypothesis 5.3.1:

- Ho$_{5.3.1.1}$: The distribution of hatchery-origin redds (hatchery females) = the distribution of natural-origin redds (natural-origin females).

Statistical Hypothesis 5.3.2:

- $Ho_{5.3.2.1}$: The distribution of hatchery-origin redds (hatchery females) = the target distribution identified in Appendix 4.

Measured Variables:

- Location (GPS coordinate) of female salmon carcasses observed on spawning grounds. The distribution of hatchery and naturally produced steelhead redds may be evaluated if marking or tagging efforts provide reasonable results.

Derived Variables:

- Location of female salmon carcass at the historic reach scale and at the 0.1 km scale.
- Calculate percent overlap in distribution across available spawning habitat or historical reaches.
- Appendix 4: Management targets for spatial distribution of spawners or redds (as applicable).

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates' Chi-square analysis for both Q5.3.1 and Q5.3.2.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.4 Stray Rates

Objective 6: Determine if the recipient stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.

Maintaining locally adapted traits among independent fish populations requires that returning hatchery fish have a high rate of site fidelity to the target population or stream. Hatchery practices (e.g., imprinting on water sources at key life history stages, release methodology, release location, age at return, and environmental conditions) are the main variables thought to affect stray rates. Regardless of the magnitude of homing of adult returns, if adult hatchery fish do not contribute to the natural population, the program will not meet the basic condition of a supplementation program.

Independent populations are populations that are genetically differentiated from other populations. In some cases, genetic differentiation may be assumed based on phenotypic traits or geographic isolation when molecular genetics analyses are not available. When populations are not independent, straying among them does not pose a risk of genetic homogenization. In addition, stray rates of hatchery-origin fish cannot be expected to be lower than for natural-origin fish. When estimates of stray rates for natural-origin fish are available and if they exceed the 5% among population stray rate or 10% within population stray rate thresholds identified in this plan, analysis

and interpretation of stray rates must take into account the concept that hatchery programs may be held to unattainable standards based on the natural stray rate. Current criteria established by the ICBTRT (2005) and the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) indicate that fish that do stray to other non-target populations should not comprise greater than 5% of the non-target spawning population. Likewise, fish that stray into non-target spawning areas within an independent population should not comprise greater than 10% of the non-target spawning aggregate (see Tables 6.1 and 6.2).

This plan identifies three stray rate metrics; brood-year stray rate, among population return-year stray rate, and within population return-year stray rate. The return-year stray rates have specific targets that are from the ICBTRT (2005) and Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007), and are linked to extinction risk. That is, hatchery strays from other populations cannot make up more than 5% of the spawning escapement within a non-target, recipient population. In addition, hatchery strays from other spawning aggregations within a population (e.g., Chiwawa spring Chinook) cannot make up more than 10% of the spawning escapement within a non-target, recipient spawning aggregate (e.g., Peshastin Creek). Brood-year stray rate, on the other hand, is not discussed in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) or ICBTRT (2005) and therefore has no specific target. Nevertheless, it is important to track brood-year stray rates to determine if hatchery operations affect the homing and straying of specific brood years. These data support the return-year stray metrics and are used to explain possible changes in genetic variation among stocks.

Brood-Year Stray Rates

Monitoring Questions:

Q6.1.1: What is the brood-year stray rate of hatchery fish?

Deleted: I

Deleted: less than 5% for the total brood return

Target Species/Populations:

- Q6.1.1 applies to all hatchery stocks.

Statistical Hypothesis 6.1.1:

- $Ho_{6.1.1.1}$: None.

Deleted: Stray rate of hatchery fish ≥ 5% of total hatchery brood return

Measured Variables:

- Number of hatchery carcasses found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.
- Number of hatchery fish collected for broodstock.
- Number of hatchery fish taken in fishery.
- Locations of live and dead strays (used to tease out overshoot).

Derived Variables:

- Total number of hatchery carcasses and take in fishery estimated from expansion analysis.
- Percent of the total brood return that strays.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphical analysis to track brood-year stray rates over time.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Among-Population Return-Year Stray Rates

Monitoring Questions:

Q6.2.1: Do hatchery strays make up less than 5% of the spawning escapement within ther non-target independent populations?

Target Species/Populations:

- Q6.2.1 applies to all hatchery stocks.

Statistical Hypothesis 6.2.1:

- $Ho_{6.2.1.1}$: Stray hatchery fish make up ≥ 5% of the spawning escapement (based on run year) within other independent populations [9]

Measured Variables:

- Number of hatchery carcasses (PIT-tagged steelhead) found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

Derived Variables:

- Total number of hatchery salmon carcasses (PIT-tagged steelhead, spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target population that is made up of hatchery strays.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

[9] This stray rate is suggested based on a literature review and recommendations by the ICBTRT (2005) and is identified in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007). It can be re-evaluated as more information on naturally-produced Upper Columbia salmonids becomes available. This will be evaluated on a species and program specific basis and decisions made by the HCP HC. It is important to understand the actual spawner composition of the population to determine the potential effect of straying.

Deleted: <#>Appendix 5: Reciprocal stray rates¶

Deleted: and one-sample quantile tests to compare the estimated stray rate with the target (5%) stray rate.

Deleted: <#>Type I Error of 0.05.¶

- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (5%) stray rate.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Within-Population Return-Year Stray Rates

Monitoring Questions:

Q6.3.1: Do hatchery strays make up less than 10% of the spawning aggregate within non-target spawning areas within the target population?[10]

Target Species/Populations:

- Q6.3.1 applies to all hatchery stocks.

Statistical Hypothesis 6.3.1:

- $Ho_{6.3.1}$: Stray hatchery fish make up ≥ 10% of spawning escapement (based on run year) within non-target spawning areas within the target population

Measured Variables:

- Number of hatchery carcasses (possibly PIT-tagged steelhead) found in non-target and target spawning aggregates or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

Derived Variables:

- Total number of hatchery salmon carcasses (possibly PIT-tagged steelhead or spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target spawning aggregate that is made up of hatchery strays.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (10%) stray rate.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

[10] The value of 10% should be reviewed by the Hatchery Committee. See footnote 3 for additional information.

4.5 Population Genetics

Objective 7: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.

The genetic component of the M&E Plan specifically addresses the potential for changes in genetic diversity in natural populations as a result of a hatchery program(s). The long-term fitness of populations is assumed to be related to maintaining the genetic diversity of natural populations. However, hatchery programs select a subset of individuals from the population to pass on genetic material to the next generation. This is often a relatively small number of individuals that produce a large number of offspring, and can result in changes in allele frequencies and reductions of effective population size. Therefore, it is important to monitor the genetic status of the natural populations to determine if there are signs of changes in genetic distance among populations, changes in allele frequencies, and to estimate effective population size. Assessing the genetic effects of the hatchery program does not require annual sampling. Meeting stray-rate targets (hypotheses tested under Objective 5) should reduce significant changes in population genetics. Stray rates may inform population genetic analyses. Testing statistical hypotheses associated with genetic components (Hypotheses 3.1, 3.2, and 3.3) should be conducted every ten years or two generations.

Allele Frequency

Monitoring Questions:

Q7.1.1: Is the allele frequency of hatchery fish similar to the allele frequency of naturally produced and donor fish?

Target Species/Populations:

- Q7.1.1 applies to all conservation stocks.

Statiscial Hypotheses 7.1.1:

- $Ho_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ = Allele frequency $_{\text{Naturally produced}}$ = Allele frequency $_{\text{Donor pop.}}$
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ ≠ Allele frequency $_{\text{Naturally produced}}$ = Allele frequency $_{\text{Donor pop.}}$ or
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ = Allele frequency $_{\text{Naturally produced}}$ ≠ Allele frequency $_{\text{Donor pop.}}$ or
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ ≠ Allele frequency $_{\text{Naturally produced}}$ ≠ Allele frequency $_{\text{Donor pop.}}$

Measured Variables:

- Microsatellite genotypes or SNP genotypes, as appropriate

Derived Variables:

- Allele frequency

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples within drainages.

Possible Statistical Analysis:

- Population differentiation tests, analysis of molecular variance (AMOVA), and relative genetic distances.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Genetic Distance Between Populations

Monitoring Questions:

Q7.2.1: Does the genetic distance among subpopulations within a supplemented population remain the same over time?

Target Species/Populations:

- Q7.2.1 applies to all conservation and safety-net stocks.

Statistical Hypothesis 7.2.1:

- $Ho_{7.2.1.1}$: Genetic distance between subpopulations $_{\text{Year x}}$ = Genetic distance between subpopulations $_{\text{Year y}}$

Measured Variables:

- Microsatellite genotypes or SNP genotypes

Derived Variables:

- Allele frequencies

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples among spawning aggregates.

Possible Statistical Analysis:

- Population differentiation tests, AMOVA, and relative genetic distances.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Effective Spawning Population

Monitoring Questions:

Q7.3.1: Is the ratio of effective population size (N_e) to spawning population size (N) constant over time?

Target Species/Populations:

- Q7.3.1 applies to all supplemented stocks.

Statistical Hypothesis 3.3:

- $Ho_{7.3.1.1}$: $(N_e/N)_{t0} = (N_e/N)_{t1}$ for each population

Measured Variables:

- Microsatellite genotypes or SNP genotypes

Derived Variables:

- Allele frequencies

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.

Possible Statistical Analysis:

- Population differentiation tests, relative genetic distances, statistics to calculate effective population size (e.g., harmonic means).

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.6 Phenotypic Traits

Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

Fitness, or the ability of individuals to survive and pass on their genes to the next generation in a given environment, includes genetic, physiological, and behavioral components.[11] Maintaining the long-term fitness of supplemented populations requires a comprehensive evaluation of genetic and phenotypic characteristics. Evaluation of some phenotypic traits (i.e., run timing, spawn timing, spawning location, and stray rates) is addressed under Objective 5. Objective 8 assess the potential effects of domestication, including size at maturity, age at maturity, sex ratio, and fecundity. Age and size at maturity shall be assessed for both fish arriving in the Columbia system, and those recovered on the spawning grounds. Size (or age) selective mortality during migration through the Columbia system, such as through fisheries, could alter the age and size of fish on the spawning grounds.

[11] These metrics are difficult to measure, and phenotypic expression of these traits may be all we can measure and evaluate.

Age at Maturity

Monitoring Questions:

Q8.1.1: Is the age at maturity of hatchery and natural-origin fish similar at the time they enter the Columbia River and when they spawn?

Target Species/Populations:

- Q8.1.1 applies to all conservation program stocks.

Statistical Hypotheses 8.1.1:

- $Ho_{8.1.1.1}$: Age at Maturity $_{\text{Hatchery produced spawners Gender X}}$ = Age at Maturity $_{\text{Naturally produced spawners Gender X}}$
- $Ho_{8.1.1.2}$: Age at Maturity $_{\text{All hatchery produced adults Gender X}}$ = Age at Maturity $_{\text{All naturally produced adults Gender X}}$

Measured Variables:

- Total and salt (ocean) age of hatchery and natural-origin salmon carcasses collected on spawning grounds.
- Total and salt age of broodstock.
- Total and salt age of fish at stock assessment locations (e.g., Dryden, Tumwater, Wells, Priest Rapids).
- Whenever possible, age at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).
- Assess age of fish, including harvested fish.

Derived Variables:

- Total age and saltwater age
- Age of fish entering the Columbia River.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates' Chi-square.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Size at Maturity

Monitoring Questions:

Q8.2.1: Is the size (length) at maturity of a given age and sex of hatchery fish similar to the size at maturity of a given age and sex of natural-origin fish?

Target Species/Populations:

- Q8.2.1 applies to all conservation and safety-net stocks.

Statistical Hypothesis 8.2.1:

- $Ho_{8.2.1.1}$: Size (length) at Maturity $_{\text{Hatchery Age X and Gender Y}}$ = Size (length) at Maturity $_{\text{Naturally produced Age X and Gender Y}}$
- $Ho_{8.2.1.2}$: Size (length) at Maturity $_{\text{All hatchery adults Gender X}}$ = Size (length) at Maturity $_{\text{All naturally produced adults Gender X}}$

Measured Variables:

- Size (length), age, and gender of hatchery and natural-origin salmon carcasses collected on spawning grounds.
- Size (length), age, and gender of broodstock.
- Size (length), age, and gender of fish at stock assessment locations (e.g., Priest Rapids, Dryden, Tumwater, Wells, Twisp Weir).
- Whenever possible size at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).

Derived Variables:

- Total age and saltwater age

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and three-way ANOVA by origin, gender, and age

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Fecundity at Size[12]

Monitoring Questions:

Q8.3.1: Is the fecundity vs. size relationship of hatchery and natural-origin fish similar?

---

12 May not apply to all programs.

Q8.3.2: Is the gonadal mass vs. size relationship of hatchery and natural-origin fish similar?

Target Species/Populations:

- Both Q8.3.1 and Q8.3.2 apply to all conservation stocks using both natural- and hatchery-origin broodstock.

Statistical Hypothesis 8.3.1:

- $Ho_{8.3.1.1}$: Slope of Fecundity vs. Size $_{\text{Hatchery}}$ = Slope of Fecundity vs. Size $_{\text{Naturally produced}}$

Statistical Hypothesis 8.3.2:

- $Ho_{8.3.2.1}$: Gonadal Mass vs. Size $_{\text{Hatchery}}$ = Gonadal Mass vs. Size $_{\text{Naturally produced}}$

Measured Variables:

- Length, weight, and age (covariate) of hatchery and natural-origin broodstock after eggs have been removed.
- Number and weight of eggs

Derived Variables:

- Total age and saltwater age.
- Mean weight per egg.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis, regression, t-test, and ANCOVA.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Sex Ratio

Monitoring Questions:

Q8.4.1: Is the sex ratio of hatchery and natural-origin fish similar?

Target Species/Populations:

- Q8.4.1 applies to all conservation stocks.

Statistical Hypothesis 8.4.1:

- $Ho_{8.4.1.1}$: Sex Ratio $_{\text{Hatchery}}$ = Sex Ratio $_{\text{Naturally produced}}$

Measured Variables:

- Age and sex of hatchery and natural-origin salmon carcasses collected on spawning grounds or sampled at dams or weirs.
- Whenever possible sex ratio will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling or ultrasound on live fish).

Derived Variables:

- Ratio of sexes based on brood year returns

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates'Chi-square.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 5: HATCHERY ENVIRONMENT MONITORING INDICATORS

5.1 Release Targets

Objective 9: **Determine if hatchery fish were released at the programmed size and number.**

The HCP outlines the number and size of fish that are to be released to meet NNI and inundation compensation levels. The size of the fish at release may be altered according to an adaptive management process in the Hatchery Committee(s), and the number of fish can be altered by survival study results and adjustment of hatchery production for population dynamics. Size of fish at release can affect survival, sex ratios, age at return, stray rate, and fecundity. In addition, the variation in size at release may affect performance of the fish.

The coefficient of variation (CV) will be evaluated to ascertain if program performance is related to variation in size at release. Note also that variation in a population is a natural condition and striving to control this variation could result in directional or stabilizing artificial selection that could have unforeseen long-term consequences. Attaining uniform or multi-modal growth in a hatchery environment may not be adaptive for fitness in the wild. Therefore, pursuit of a CV target should be seen as an informative exercise, but is not in itself indicative of success or failure of a hatchery program. Furthermore, growth regimes may prove to be important in affecting adult returns and age structure. Although many factors can influence both the size and number of fish released, past hatchery cultural experience with these stocks should assist in meeting program production levels. Appendix 5 presents the target size at release and CVs for the programs. These targets shall be assessed annually to ensure they are optimized to inform management decisions.

Size at Release of Hatchery Fish

Monitoring Questions:

Q9.1.1: Is the size (fish per pound; fpp) of hatchery fish released equal to the program goal identified in Appendix 5?

Deleted: length and weight

Target Species/Populations:

- Q9.1.1 applies to all hatchery stocks.

Statistical Hypothesis 9.1.1:

- $Ho_{9.1.1}$: Hatchery fish $fpp_{\text{at release}}$ = Programmed $fpp_{\text{at release}}$ (see Appendix 5)

Deleted: Size

Deleted: Size

Measured Variables:

- Fork length and weights of random samples of hatchery juveniles at release.

Derived Variables:

- Mean length (FL), mean weight, and fish per pound
- Appendix 5: Rearing targets

Deleted: and

Deleted: 6

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated fpp of hatchery fish at time of release with the program goal.

Deleted: size

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Coefficient of Variation (CV) of Hatchery Fish Released

Monitoring Questions:

Q9.2.1: Is the CV of hatchery fish released equal to the program target identified in Appendix 5?

Target Species/Populations:

- Q9.2.1 applies to all hatchery stocks.

Statistical Hypothesis 9.2.1:

- $Ho_{9.2.1.1}$: Hatchery fish $CV_{\text{at release}}$ = Programmed CV in Appendix 5

Measured Variables:

- Length and weights of random samples of hatchery smolts.

Derived Variables:

- Coefficient of Variation: $cv = (1 + 1/4n) \times (s/x)$ (where s = standard deviation, x = estimated mean, n = sample size)
- Appendix 5: Rearing targets

Deleted: 6

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated CV of size of hatchery fish released with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Condition Factor (K) of Hatchery Fish Released

Monitoring Questions:

Q9.3.1: Is the K of hatchery fish released equal to the program target identified in Appendix 5?

Target Species/Populations:

- Q9.3.1 applies to all hatchery stocks.

Statistical Hypothesis 9.3.1:

- $Ho_{9.3.1.1}$: Hatchery fish $K_{\text{at release}}$ = Programmed K identified in Appendix 5

Measured Variables:

- Monthly individual lengths and weights of random samples of hatchery juveniles.

Derived Variables:

- Condition Factor: $K = W/L^3 \times 10^5$

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated K of released hatchery fish with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Number of Hatchery Fish Released

Monitoring Questions:

Q9.4.1: Is the number of hatchery fish released equal to the program goal identified in Appendix 5?

Target Species/Populations:

- Q9.4.1 applies to all hatchery stocks.

Statistical Hypothesis 9.4.1:

- $Ho_{9.4.1.1}$: Hatchery Fish Number = Programmed Number identified in Appendix 5

Measured Variables:

- Numbers of smolts released from the hatchery.

Derived Variables:

- Appendix 5: Rearing targets

Deleted: 6

Spatial/Temporal Scale:

- Calculate annually.

- Time series.

Possible Statistical Analysis:

- Use graphic analysis and one-sample quantile tests to compare the estimated number of hatchery fish released with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 6: HARVEST MONITORING INDICATORS

6.1 Harvest Rates

<u>Objective 10</u>: Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.

Harvest will be applied to different types of programs in an effort to achieve the management objectives of those programs. Programs designed to augment harvest should routinely contribute to harvest at a rate that greatly reduces the incidence of straying to natural spawning grounds, but also allows the program to be sustained. Safety-net programs may be harvested as part of an adult management strategy to minimize excessive escapement of hatchery-origin fish to spawning grounds. Similarly, conservation programs may undergo harvest to manage returning adults, but the emphasis for these programs should be to achieve escapement goals. In all cases, harvest effort should not have the unintended consequence of removing excessive numbers of conservation or natural-origin fish. In years when the expected returns of hatchery adults are above the level required to meet program goals (i.e., supplementation of spawning populations and/or brood stock requirements), surplus fish may be available for harvest. The M&E Plan specifically addresses harvest and harvest opportunities upstream of Priest Rapids Dam. Harvest or removal of surplus hatchery fish from the spawning grounds may assist in reducing potential adverse ecological and genetic impacts to natural populations (e.g., loss of genetic variation within and between populations, loss of fitness, reduced effective population size, and density-dependent effects).

Monitoring Questions:

Q10.1.1: Conservation Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of conservation hatchery fish but low enough to sustain the hatchery program?

Q10.1.2: Safety-Net Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of safety-net hatchery fish but low enough to sustain the hatchery program?

Q10.1.3: Is the harvest on hatchery fish produced from harvest-augmentation programs high enough to manage natural spawning but low enough to sustain the hatchery program?

Q10.1.4: Is the escapement of fish from conservation and safety-net programs in excess of broodstock and natural production[13] needs to provide opportunities for terminal harvest?

Target Species/Populations:

- Q10.1.1 applies to conservation programs.
- Q10.1.2 applies to safety-net programs.

[13] The current best estimates of carrying capacity (maximum recruits) will be used, as available.

- Q10.1.3 applies harvest augmentation programs.
- Q10.1.4 applies to conservation and safety-net programs.

Statistical Hypothesis 10.1.1:

- $Ho_{10.1.1.1}$: Harvest rate ≤ Maximum level to meet program goals

Statistical Hypothesis 10.1.2:

- $Ho_{10.1.2.1}$: Harvest rate ≤ Maximum level to meet program goals

Statistical Hypothesis 10.1.3:

- $Ho_{10.1.3.1}$: Escapement ≤ Maximum level to meet supplementation goals

Statistical Hypothesis 10.1.4:

- $Ho_{10.1.4.1}$: Harvest rate ≤ Maximum level to meet program goals

Measured Variables:

- Numbers of hatchery fish taken in harvest.
- Numbers of natural-origin fish taken in harvest.

Derived Variables:

- Total harvest by fishery estimated from expansion analysis.

Spatial/Temporal Scale:

- Calculated annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and one-sample quantile tests to compare the estimated harvest of hatchery fish with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 7: REGIONAL OBJECTIVES

Hatchery programs have the potential to increase diseases that typically occur at low levels in the natural environment (Objective 9). In addition, hatchery fish can reduce the abundance, size, or distribution of non-target taxa through ecological interactions (Objective 10). These are important objectives that will be monitored at a later time. Analytical rules will be established for these objectives before monitoring activities begin.

7.1 Incidence of Disease

Objective 11: Determine if the incidence of disease has increased in the natural and hatchery populations.

The hatchery environment has the potential to amplify diseases that are typically found at low levels in the natural environment. Amplification could occur within the hatchery population (i.e., vertical and horizontal transmission) or indirectly from the hatchery effluent or commingling between infected and non-infected fish (i.e., horizontal transmission). Potential impacts to natural populations have not been extensively studied, but should be considered for programs in which the hatchery fish are expected to commingle with natural fish. This is particularly important for supplementation type programs. Specifically, the causative agent of bacterial kidney disease (BKD), *Renibacterium salmoninarum* (Rs), could be monitored at selected acclimation ponds, both in the water and fish, in which the risk and potential for transmission from the hatchery is highest. Although it is technologically possible to measure the amount of Rs in water or Rs DNA in smolts and adults non-lethally sampled, the biological meaning of these data are uncertain. Currently, the only metric available for M & E purposes is measuring the antigen level from kidney/spleen samples (i.e., ELISA, PCR). When available, non-lethal sampling may replace or be used in concert with lethal sampling.

Implementation of this objective will be conducted in a coordinated approach within the hatchery and natural environment. BKD management within the hatchery population (e.g., broodstock or juveniles) has the potential to reduce the prevalence of disease through various actions (e.g., culling or reduced rearing densities). BKD management must also take into account and support other relevant objectives of the M & E program (e.g., Hatchery Return Rate [HRR], number of smolts released). Hence, the goal of BKD management is to decrease the prevalence of disease and maintain hatchery production objectives (i.e., number and HRR).

As previously discussed, disease transmission from hatchery to naturally produced fish may occur at various life stages and locations. Of these, horizontal transmission from hatchery effluent, vertical transmission on the spawning grounds, and horizontal transmission in the migration corridor have been identified as disease interactions that could be examined under this objective, although others may also be relevant. Experimental designs addressing this objective may require technology not yet available, although in some instances samples may be collected, but not analyzed until a link can be established between bacteria levels in samples and disease prevalence.

Developing a complete set of questions and hypotheses statements for this objective may not be practical at this time, because there is currently no BKD Management Plan. However, while developing experimental designs for this objective, it may be feasible to incorporate both hatchery and natural environment monitoring under a single study design. Integration of the different aspects of the objective would likely result in a more robust approach into understanding the effectiveness of disease management strategies.

Proposed Tasks:

T1: Assemble fish health data for fish used as brood (e.g., ELISA results).

T2: Conduct data exploration exercise to identify potential relationships between pathogen profiles and likely causative variables (e.g., rearing conditions and management actions).

T3: Develop hypotheses for potential testing to meet objective.

7.2 Non-Target Taxa of Concern (NTTOC)

<u>Objective 12</u>: Determine if the release of hatchery fish affects non-target taxa of concern (NTTOC) within acceptable limits.

Ecological risks of Pacific salmon (spring, summer, and fall run Chinook, coho, and sockeye salmon) and steelhead trout hatchery programs operated between 2013 and 2023 in the Upper Columbia Watershed will be assessed using Delphi and modeling approaches. Committees composed of resource managers and public utility districts identified non-target taxa of concern (i.e., taxa that are not the target of supplementation), and acceptable hatchery impacts (i.e., change in population status) to those taxa. Biologists assembled information about hatchery programs, non-target taxa, and ecological interactions and this information will be provided to expert panelists in the Delphi process to facilitate assessment of risks and also used to populate the Predation, Competition, and Disease (PCD) Risk 1 model. Delphi panelists will independently estimate the proportion of a non-target taxa population that will be affected by each individual hatchery program. Estimates from each of the two approaches will be independently averaged, a measure of dispersion calculated (e.g., standard deviation), and subsequently compared to the acceptable hatchery impact levels that were determined previously by committees of resource managers and public utility districts. Measures of dispersion will be used to estimate the scientific uncertainty associated with risk estimates. Delphi and model results will be compared to evaluate the qualities of the two approaches. Furthermore, estimates of impacts from each hatchery program will be combined together to generate an estimate of cumulative impact to each non-target taxa.

The Hatchery Evaluation Technical Team (HETT) is currently addressing this objective. Work has been underway for several years. The study is expected to provide risk assessment using both an ecological modeling approach and a panel of expert opinion. These two methods will be compared to establish the potential to use modeling in place of expert panels to conduct such risk assessments in the future.

SECTION 8: ADAPTIVE MANAGEMENT

Because of naturally large variation in productivity indicators, several years of data may be required before statistical inferences can be made regarding the effects of hatchery fish on productivity of naturally produced fish. Furthermore, given the large natural variation of productivity indicators, productivity could increase or decrease as a result of the hatchery programs before a difference is detected statistically. In the interim, risk associated with supplementation programs and the productivity of naturally produced fish can be quantified based on observed natural variation in the indicator of interest (Table 1). If large differences in rates of change between supplemented and reference populations are observed, management actions may be required.

Assuming hatchery programs do not negatively affect the productivity of naturally produced fish, the observed difference in rates of change between the supplemented and reference populations should decrease over time as more of the natural variation within and between populations is incorporated into these data. More simply, as the number of years increases, the acceptable observed difference in the indicator(s) decreases. The value of the difference at any point in time would determine if management actions are warranted.

APPENDIX 1: ESTIMATION OF CARRYING CAPACITY

APPENDIX 2: HATCHERY REPLACEMENT RATES

Based on ideas developed by the HETT, in February 2016, the HCP Hatchery Committees and PRCC Hatchery Subcommittee agreed to the following rules and HRR targets:

1. Use the estimated 40% HRR Target during 5-year statistical evaluation periods.
2. Use varying degrees of action depending on the numbers of years that annual HRR deviates from Target.
   a. Green Light (below Target for ≤ 2 years.
   b. Red Light (below Target for > 2 years.
3. Each program will have its own HRR target with the following exceptions.
   a. Nason Creek spring Chinook will use the Chiwawa Target (there are currently no data to calculate a target for Nason Creek spring Chinook).
   b. Methow and Chewuch spring Chinook will use the greater of their two Targets (they are MetComp stock and evaluated similarly).

Table 1. Release numbers and 5-year hatchery replacement rates (HRR) targets for Upper Columbia River Hatchery Programs.

Species	Owner	Program (Hatchery)	Basin (Purpose)	Smolts released[1]	5-Year HRR[2]
Steelhead	CPUD	Eastbank (Chiwawa)	Wenatchee (Conservation)	123,650	6.9
Steelhead	CPUD	Eastbank (Chiwawa)	Wenatchee (Safety Net)	123,650	6.9
Steelhead	DPUD	Wells (Wells)	Columbia (Safety Net)	160,000	26.5
Steelhead	DPUD	Wells (Wells)	Methow (Safety Net)	100,000	26.5
Steelhead	DPUD	Wells (Wells)	Twisp (Conservation)	48,000	26.5
Steelhead	GPUD	Wells (Omak)	Okanogan (Conservation)	100,000	7.3 [3]
SUM Chinook	CPUD	Eastbank (Chelan Falls)	Chelan (Conservation)	176,000	5.7
SUM Chinook	CPUD	Eastbank (Chelan Falls)	Chelan (Harvest)	400,000	5.7
SUM Chinook	CPUD, GPUD	Eastbank (Dryden)	Wenatchee (Conservation)	500,000	5.7
SUM Chinook	DPUD	Wells (Wells)	Columbia (Harvest)	320,000	3.0
SUM Chinook	GPUD	Eastbank (Carlton)	Methow (Conservation)	200,000	3.0
SUM Chinook	CCT	Chief Joseph	Okanogan (Harvest)	1,100,000	8.6
SPR Chinook	CPUD	Eastbank (Chiwawa)	Wenatchee (Conservation)	144,026	6.7
SPR Chinook	CPUD, DPUD, GPUD	Wells (Methow)	Methow (Conservation)	193,765	3.8
SPR Chinook	DPUD, GPUD	Wells (Twisp)	Methow (Conservation)	30,000	2.7
SPR Chinook	GPUD	Eastbank (Nason)	Wenatchee (Conservation)	149,114	6.7

[1] Release goal established by HCPs and adjusted by HC.
[2] Derived from Annual Reports.
[3] Harvest not included.

APPENDIX 3: PNI and pHOS Targets and Sliding Scales

Select CPUD, DPUD, and GPUD funded hatchery mitigation programs have PNI management targets, while others do not. Table 1 summarizes management strategies by species and population. Detailed information can be found in the sections that follow. Descriptions provided in the following sections are taken directly from HGMPs and/or issued and draft permits.

Table 1. Summary of management strategies by species and population.

Species	Population	Management Strategy	Comments
Spring Chinook	Wenatchee	Sliding Scale of PNI management	Details can be found in Section 2.0
	Methow	Two—population sliding scale PNI management	Details can be found in Section 3.0
	Okanogan	None Currently	Details can be found in Section 4.0
Steelhead	Wenatchee	Two-zone management.	Details can be found in 5.0
	Methow	In-development	Details forthcoming; Section 6.0
	Okanogan	None Currently	Details can be found in Section 7.0
Summer Chinook	Wenatchee	None Currently	Details can be found in Section 9.0
	Methow	None Currently	Details can be found in Section 10.0
	Okanogan	0.67; pHOS 0.30	Details can be found in Section 11.0
	Upper Columbia River	None Currently	Details can be found in Section 12.0
Fall Chinook	Hanford Reach	0.67	Details can be found in Section 13.0

2.0 Wenatchee Spring Chinook

Wenatchee spring Chinook will be managed according to the sliding scale identified in the Wenatchee Spring Chinook Management Plan (2010) and Permit Numbers 18118 and 18121. The sliding scale is based upon the estimated number of natural origin spring Chinook over Tumwater Dam. As more information becomes available the sliding scale may be adjusted as a result of gaining a better understanding of the pre-spawn mortality rate and carrying capacity.

Table 2. Sliding scale of PNI goals based on natural origin spring Chinook run size expected to the Wenatchee River basin. Percentiles are based on adult returns observed between 1999 and 2008.

Percentile	NOR Run Size				PNI
	Chiwawa	Nason Creek	White	Wenatchee River (above TWD)	
>75th	>372	>350	>87	>910	≥ 0.80
50% - 75%	278-372	259-349	68-86	631-909	≥ 0.67
25% - 50%	209-277	176-258	41-67	525-630	≥ 0.50
10%-25%	176-208	80-175	20-40	400-524	≥ 0.40
<10th	<175	<80	<20	<400	Any PNI

3.0 Methow/ Chewuch Spring Chinook

The following sliding scale (Table 3) is presented in the April 14, 2016 draft Methow Hatchery Spring Chinook Section 10-Draft. It is anticipated that no further changes will be made to the sliding scale prior to issuance of the final permits.

Table 3. PUD PNI sliding scale calculations for a range of natural run sizes.

Natural Origin Returns	PUD pHOS	WNFH pHOS	PUD pNOB	2-pop PNI	PUD PNI (equation)
<300	Ensure minimum of 500 total spawners				
300	0.40	0.2	0.75	0.67	0.67
500	0.40	0.2	0.80	0.68	0.76
900	0.30	0.15	1.00	0.78	0.80
1500	0.25	0.1	1.00	0.8	0.80
2000	0.25	0.1	1.00	0.8	0.80
2500	0.25	0.1	1.00	0.8	0.80

4.0 Okanogan Spring Chinook

The Okanogan spring Chinook program is a re-introduction effort implemented as a non-essential experimental population under ESA Section 10j to re-introduced spring Chinook into the Okanogan River. As a non-essential experimental population targeting re-introduction and establishment of a local population of spring Chinook, the Okanogan spring Chinook program will not conduct adult management actions to reduce the proportion of 10j hatchery fish on the spawning grounds or conduct broodstocking efforts in the Okanogan for a 10-year period (2014 – 2023), as such, no PNI or pHOS objectives have been identified for this program in this 10-year period.

CJH Program segregated production released into the mainstem Columbia River are non-listed Leavenworth stock released reared/acclimated/released at CJH. Although no PNI or pHOS targets are identified for the Okanogan 10j population, minimizing strays from the CJH segregated spring Chinook program is a program objective, as such, returning segregated program fish will be subject to directed harvest and aggressive adult surplusing at CJH to minimize straying to the Okanogan River Basin as well as other extant upper Columbia River spring Chinook populations. Stray targets for the segregated program are 5% or less stray rate (i.e. spawning contribution to other upper Columbia River spring Chinook populations).

5.0 Wenatchee Steelhead

Interim escapement goal for Wenatchee River steelhead will be 1,500 spawners with an additional goal of attaining an average PNI of 0.67 for the Wenatchee River basin population as a whole. To achieve the stated goal, the Wenatchee steelhead program will use a two-zone management approach wherein the upper basin (above TWD) will be managed for recovery using an integrated recovery program, a separate spawning escapement goal, and a PNI standard to achieve the overall basin goal of an average PNI over time of 0.67 (Table 4). Areas below TWD will be managed to minimize hatchery supplementation with a pHOS goal of < 0.10.

Steelhead returning upstream of TWD will be managed as an integrated recovery program with a pNOB goal of 1.0. The above TWD escapement goal will be 1,094 spawners. Working within this framework, pNOB will be maximized above TWD while pHOS will be minimized.

Table 4. Wenatchee steelhead two-zone management and PNI targets.

Location	Run Escapement Goal	pNOB Conservation Program	pNOB Safety Net Program	pHOS	PNI
Above TWD	1,094	1.0	0.0	Varies	Varies
Below TWD	406	N/A	N/A	< 0.10	< 0.67
Basin Total	1,500	N/A	N/A	Minimal	Average = 0.67

6.0 Methow Steelhead

Methow steelhead PNI targets are currently in development.

7.0 Okanogan Steelhead

Current program has no PNI goal. CTCR submitted an Okanogan steelhead HGMP to NOAA Fisheries on February 4, 2014. Within the HGMP provisions were included to allow a greater collection of natural-origin broodstock and multiple adult management strategies to address over-escapement of hatchery-origin steelhead to the spawning grounds. The HGMP also identified a near-term (1-4 years) and a long-term PNI objectives of 0.50 and > 0.67, respectively. Once NOAA has completed the consultation and issued a new permit, providing the opportunity to increase the proportion of natural-origin fish in the broodstock and additional adult management strategies, the program will adopt the PNI objectives and this Appendix can be amended accordingly.

8.0 Wells Columbia Mainstem Safety-net Steelhead

The Safety-Net Mainstem Columbia component released below Wells Dam will be managed primarily at the Wells Hatchery volunteer channel. The objective of the adult management of the Safety-Net Mainstem Columbia component is to prevent runs of this component from moving into natural spawning areas. This will be accomplished through in-river harvest and removal of volunteers at the Wells Hatchery outfall. There are no PNI goals for this component.

9.0 Wenatchee Summer Chinook

No PNI goals are established.

10.0 Methow Summer Chinook

No PNI goals are established.

11.0 Okanogan Summer Chinook

Okanogan summer/fall Chinook will be managed to achieve a 5-year rolling average PNI of 0.67 and pHOS of 0.30. Strategies to achieve that PNI target include up to 100% pNOB, aggressive removal of hatchery-origin Chinook in selective fisheries, at the Okanogan weir, and during surplusing at CJH ladder. Reduction in the number of juveniles released in the Okanogan River Basin (integrated program) is also a management option, should adult management actions be unable to control the proportion of hatchery fish on the spawning grounds to achieve that PNI target.

CJH segregated summer/fall Chinook program rears/acclimates/releases smolts into the mainstem Columbia River at CJH. Broodstock are 100% hatchery-origin, as such no PNI target for this production component. Stray rate (i.e. contribution to upper Columbia summer/fall Chinook

populations) is 5% or less. Adult management on returning adults from the segregated program include fisheries, removal at the Okanogan weir, and removal at the CJH ladder.

12.0 Upper Columbia Summer Chinook (Chelan Falls and Wells) Summer Chinook

No PNI goals are established. Chelan Falls and Wells FH summer Chinook programs are segregated harvest programs designed to provide opportunity for harvest. Adult returns are not intended to spawn naturally; therefore, there is no escapement goal for natural spawning areas. Adult returns will be managed to meet program objectives. Chelan Falls and Wells Hatchery summer Chinook are available for harvest in the ocean and Columbia River commercial, tribal, and recreational fisheries.

13.0 Priest Rapids Fall Chinook

The Hanford Reach fall Chinook population is intentionally supplemented by Grant PUD at the Priest Rapids Hatchery and the ACOE at the Priest Rapids and Ringold Springs hatcheries. Managers desire to achieve a population level PNI that includes all hatchery programs of $\geq$0.67. Grant PUD and the HSC do not have control over operation or expansion of the ACOE program and therefore will strive to operate the Priest Rapids Hatchery fall Chinook program in a way that does its fair share of achieving a population level PNI of 0.67.

APPENDIX 4: SPATIAL DISTRIBUTION OF SPAWNERS OR REDDS

Strategies for conservation programs typically intend that hatchery and naturally produced fish spawn together and in similar locations. However, in some cases, strategies may differ from this paradigm. In Table 1, conservation programs that have a spatial distribution management plan that deviates from similar to the natural spawning spatial distributions are presented. Otherwise, conservation programs are intended to have a spawning distribution similar to the natural origin spawning spatial distributions, as described by M&E Objective 5.3.

Table 1. Management targets for the spatial distribution of hatchery-origin redds for conservation programs that deviate from Objective 5.3.

Program	Target	Rational	Source
Carlton Summer Chinook	The observed spawning distribution of hatchery origin Methow summer Chinook from 2005-2010 represents the base-line spawner distribution for evaluating the performance of the hatchery program (i.e., M&E plan check-ins). It is acknowledged that this distribution is lower in the River than the spawning distribution of natural origin summer Chinook salmon.	Based upon an assessment of summer Chinook and ESA-listed spring Chinook abundance and spawner distribution, it was determined that an increase in summer Chinook spawning abundance in the upper most range of natural origin summer Chinook distribution or potentially above the current range may pose an unknown and potentially adverse impact to ESA listed spring Chinook. Due to the concern for spring Chinook, the HSC has endorsed an acclimation site in the Methow Basin that is lower in the basin than may be required to attain exact replication of natural and hatchery origin summer Chinook spawner distribution.	SOA 2011-02 Priest Rapids Coordinating Committee Hatchery Subcommittee Statement of Agreement on Monitoring & Evaluation (M&E) Objective for Spawning Distribution of Hatchery-Origin Summer Chinook
Dryden Summer Chinook	The observed spawning distribution of hatchery origin Wenatchee summer Chinook from 2008-2013 (previous 5 years to the current M&E check-in cycle) represents the base-line spawner distribution for evaluating the performance of the hatchery program (i.e., M&E plan check-ins).	The primary site endorsed by the HSC for Grant PUD overwinter acclimation of summer Chinook is the Dryden Pond, and is the current acclimation and release site for the existing summer Chinook supplementation program funded and owned by Chelan PUD. Because current data indicates that spawning distribution of hatchery summer Chinook from the existing program is lower in the Wenatchee River than natural origin spawners, expectations are that acclimation of Grant PUD's summer Chinook at Dryden Pond would continue to return hatchery origin summer Chinook that result in different spawning distributions for hatchery and natural summer Chinook.	Adapted from SOA 2011-02 Priest Rapids Coordinating Committee Hatchery Subcommittee Statement of Agreement on Monitoring & Evaluation (M&E) Objective for Spawning Distribution of Hatchery-Origin Summer Chinook

APPENDIX 5: WITHIN HATCHERY REARING TARGETS

Rearing Targets for Upper Columbia River Hatchery Programs. K-factor or fork length targets will be determined based on data from the pending "Five-Year Report."

Table 1. Numbers, fish per pound (fpp), coefficient of variation (CV), and condition factor (K) targets at release of Upper Columbia River Hatchery Programs.

Hatchery	Species	Life Stage	Basin	Release number	FPP	CV	K-factor
Methow	Spring Chinook	Yearling	Methow	193,765[1]	15	<10	TBD
Methow	Spring Chinook	Yearling	Twisp	30,000	15	<10	TBD

Chelan Falls	Summer Chinook	Yearling	Chelan	576,000	13	9.0	TBD
Entiat	Summer Chinook	Yearling	Entiat		17	<10	TBD
Carlton	Summer Chinook	Yearling	Methow	200,000	13-17	<12	TBD
Chief Joseph	Summer Chinook	Yearling	Columbia	500,000	10	<7	TBD
Chief Joseph	Summer Chinook	Yearling	Okanogan	799,998[6]	10	<7	TBD
Dryden	Summer Chinook	Yearling	Wenatchee	500,001	18	9.0	TBD
Priest	Fall Chinook	Subyearling	Columbia	7.3 M[7]	50	<10	TBD
Ringold	Fall Chinook	Subyearling	Columbia	3.5 M	50	<10	TBD

[1] The total release includes the release of 108,249 into the Methow River at the Methow Fish Hatchery, 25,000 into the Methow River at the Goat Wall site, and 60,516 into the Chewuch River at the Chewuch Acclimation Facility.

[2] The total release includes 125,000 conservation fish and 98,670 safety net fish.

[3] The combined Okanogan and Omak steelhead release number is 100,000.

[4] The total release includes 66,771 fish into Nason Creek, 53,170 into the Chiwawa River, 102,359 into the Wenatchee River, and 25,000 into Blackbird Pond.

[5] The Wells subyearling Chinook are not reared to achieve a specific size target. The fish are released on a date to optimize survival and are grown to the largest size possible before release.

[6] The total release is divided equally among the Omak, Riverside, and Similkameen Acclimation Ponds.

[7] The total release consists of 5.6 m fall Chinook for the Grant PUD program and 1.7 M fall Chinook for the Army Corps of Engineers program.

APPENDIX 6: IDENTIFYING AND ANALYZING REFERENCE POPULATIONS

An important goal of supplementation is to increase spawning abundance and natural-origin recruitment of the supplemented population, and not reduce the productivity of the supplemented population. Indeed, a successful supplementation program must increase spawning abundance and natural-origin recruitment to levels above those that would have occurred without supplementation. There are several methods that can be used to test the effects of supplementation programs on these population metrics. One important method is to compare the performance of population metrics (e.g., spawning abundance, natural-origin recruitment, and productivity) in the supplemented population to those in un-supplemented (reference) populations. By comparing supplemented populations to reference populations, one can determine if the supplementation programs benefit, harm, or have no effect on the supplemented populations. These comparisons, however, are only valid if the performance of the reference populations is similar to the performance of the supplemented population prior to the period of supplementation. If the performance of the two populations differs significantly before any supplementation occurs, then any results from comparing the two populations after supplementation will be suspect. It is therefore important to select reference populations that are as similar as possible to the supplemented populations.

One of the goals of the Conceptual Approach to Monitoring and Evaluating the Chelan County PUD Hatchery Programs (Murdoch and Peven 2005) is to use reference populations to analyze the potential effects of hatchery supplementation programs on natural-origin salmon and steelhead spawner abundance and productivity[14]. Murdoch and Peven (2005) identified specific objectives to evaluate the performance of the program. For example, Objective 1 determines if the supplementation programs have increased the number of naturally spawning and naturally produced adults of the target population (supplemented population) relative to a reference population. Objective 7 determines if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity (e.g., number of juveniles per redd) of supplemented streams when compared to reference streams. The relevant questions tested under each objective are as follows:

Objective 1:

- Is the annual change in the number of natural-origin recruits produced from the supplemented populations greater than or equal to the annual change in natural-origin recruits in an un-supplemented population?
- Is the change in natural replacement rates within the supplemented population greater than or equal to the change in natural replacement rates in an un-supplemented population?

Objective 7:

[14] Productivity is defined as adult recruits per spawner, where recruits are the number of adults produced from a given brood year (i.e., spawners plus adults harvested).

- Is the change in numbers of juveniles (smolts, parr, or emigrants) per redd in the supplemented population greater than or equal to that in an un-supplemented population?[15]

In this paper, we describe methods used to identify suitable reference streams and statistical techniques that can be used to compare reference populations with supplemented populations. Although we apply the methods described in this paper to Chiwawa spring Chinook salmon (hereafter referred to as Chinook), the methods should also apply to steelhead and other supplemented salmon stocks in the Upper Columbia Basin.

Identification of Reference Populations

Reference populations are an important component of an effectiveness monitoring design because they provide the standard by which treatment conditions are compared (ISRP and ISAB 2005; Murdoch and Peven 2005; Galbreath et al. 2008). Selecting appropriate reference areas and maintaining them over long periods of time is needed to establish the effectiveness of supplementation programs.

We developed a three-step process for identifying suitable reference populations (Figure 1). Each step serves as a filter. That is, potential reference populations are evaluated based on specific criteria under each step. Populations that pass through each step are considered suitable reference populations for a specific supplemented population.

[15] In this paper we only address adult recruits, not juvenile recruits. This is because we were unable to find suitable reference populations for analysis of juveniles. However, the methods described in this paper would also apply to juveniles.

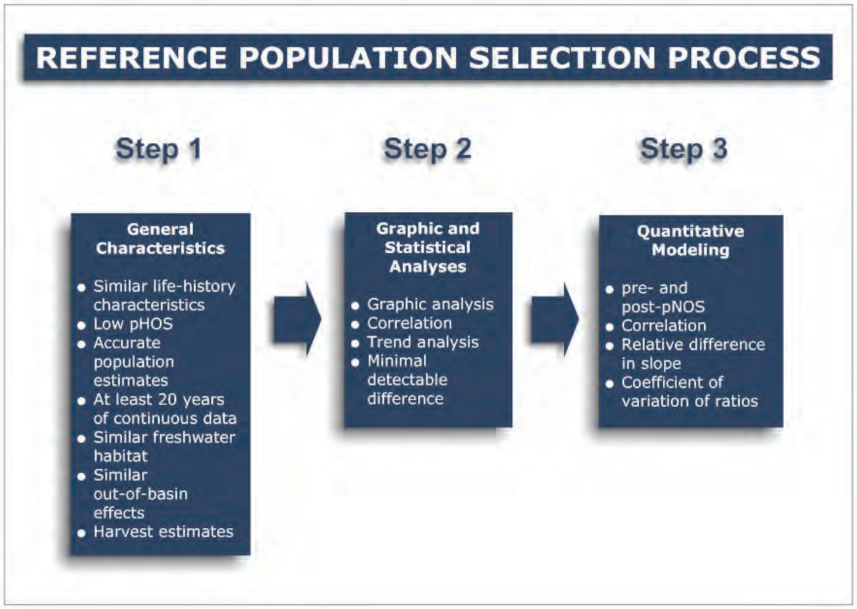

Figure 1. Criteria evaluated during each step in the process of identifying suitable reference populations.

Step 1: General Characteristics

Under step 1, potential reference populations are evaluated based on several general criteria. When compared to the supplemented population, potential reference populations should have:

- Similar life-history characteristics (e.g., run timing, migration characteristics, etc.).
- No or few hatchery fish in the reference area (pHOS < 10%).
- Accurate abundance estimates.
- Long time series of natural-origin abundance and productivity estimates (at least 20 years of continuous data).
- Similar trends in freshwater habitat.
- Similar out-of-basin effects (i.e., similar migration and ocean survivals).
- Harvest estimates for adjusting escapement estimates.

We used these criteria to begin the process of selecting suitable reference populations for the Chiwawa spring Chinook program. We began by identifying stream-type Chinook populations within the Columbia Basin. Galbreath et al. (2008; their Table 1) identified stream-type Chinook populations within the Columbia River Basin that may serve as suitable reference populations for hatchery programs. Supplementing their work with data from the NOAA Fisheries Salmon Population Summary Database, we identified 18 candidate stream-type Chinook populations that may serve as reference populations for the Chiwawa supplementation program (Table 1).

Table 1. Populations of stream-type Chinook salmon and their comparison to Chiwawa spring Chinook.

Population	Similar life-history	No or few hatchery fish	Accurate abundance estimates	Long time series (at least 20 years)	Similar freshwater habitat impairments	Similar out-of-basin effects	Comments
Deschutes River	Yes	Yes	Yes	Yes	No	No	
John Day mainstem	Yes	Yes	Yes	Yes	No	No	
Middle Fk John Day	Yes	Yes	Yes	Yes	No	No	
North Fk John Day	Yes	Yes	Yes	Yes	No	No	
Granite Creek	Yes	Yes	Yes	Yes	No	No	
Wenaha River	Yes	No	Yes	Yes	Yes	No	Hatchery strays (>10%)
Minam River	Yes	No	Yes	Yes	Yes	No	Hatchery strays (>10%)
Slate Creek	Yes	Yes	Yes	No	No	No	
Secesh River	Yes	Yes	Yes	Yes	Yes	No	
Middle Fk Salmon River	Yes	Yes	Yes	No	No	No	Fair productivity est.
Big Creek	Yes	Yes	Yes	Yes	No	No	
Camas Creek	Yes	Yes	Yes	Yes	No	No	Fair productivity est.
Loon Creek	Yes	Yes	Yes	Yes	No	No	Fair productivity est.
Sulphur Creek	Yes	Yes	Yes	Yes	No	No	
Bear Valley Creek	Yes	Yes	Yes	Yes	No	No	
Marsh Creek	Yes	Yes	Yes	Yes	Yes	No	
North Fk Salmon River	Yes	Yes	No	No	Yes	No	
Lemhi River	Yes	Yes	Yes	Yes	No	No	
East Fk Salmon River	Yes	No	Yes	Yes	No	No	Hatchery strays (>10%)
Valley Creek	Yes	No	Yes	Yes	No	No	Hatchery strays (>10%)
Chamberlain Creek	Yes	Yes	Yes	No	Yes	No	
Naches River	Yes	Yes	Yes	Yes	Yes	No	
Little Wenatchee River	Yes	No	Yes	Yes	Yes	Yes	Hatchery strays (>10%)
Entiat River	Yes	No	Yes	Yes	No	No	Hatchery release ending

We then assessed the accuracy and length of the series of abundance estimates. We assumed that abundance estimates generated from expanded redd counts or adjusted weir counts would compare well with estimates in the Chiwawa Basin, which were based on expanded redd counts. In addition, we looked for populations that had an abundance data series that extended from at least 1981 to present. Based on this analysis, we identified 18 populations with abundance estimates that could be compared to those from the Chiwawa Basin (Table 1).

Next, we determined if the potential reference populations came from watersheds with habitat conditions similar to those in the Chiwawa Basin. For this exercise, we searched recovery plans and draft recovery plans to identify tributary factors that limit Chinook abundance, productivity, and survival within the reference populations. We compared these factors with those limiting

Chinook salmon in the Chiwawa Basin. Based on this analysis, we identified eight populations with habitat impairments similar to those in the Chiwawa Basin (Table 1).

Finally, we examined the potential reference populations to see if they experienced out-of-basin effects similar to spring Chinook from the Chiwawa Basin. In this case, we compared the number of mainstem dams that each potential reference population passes during migration. Six of the potential reference populations pass less than six mainstem dams; the other populations pass eight mainstem dams (Table 1). Only the Little Wenatchee population passes seven dams, similar to the Chiwawa population.

In sum, there were no reference populations that matched the Chiwawa spring Chinook population on all the criteria identified above. Differential out-of-basin effects and freshwater habitat conditions prevented most reference populations from matching with Chiwawa spring Chinook. However, some of the potential reference populations were similar to the Chiwawa population on several criteria and warranted further investigation. We selected the following populations for further investigation: Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River.

We included the Little Wenatchee because it is within the Wenatchee River basin and experiences similar out-of-basin effects and has the same climatic and environmental conditions as the Chiwawa. A confounding effect with the Little Wenatchee is that Chiwawa hatchery fish have strayed into the Little Wenatchee. However, straying of Chiwawa hatchery fish should decrease with the change in source water to the Chiwawa acclimation ponds in 2006. We also included the Entiat River because it is an adjacent basin to the Chiwawa and experiences similar climatic and environmental conditions. The spring Chinook hatchery program that has operated in the Entiat since 1975 has been discontinued. Therefore, this population offers a unique opportunity to compare the Chiwawa population to a population in which the hatchery program has been discontinued.

Step 2: Graphic and Statistical Analysis

Graphic Analysis

Although we were unable to find potential reference populations that matched with the Chiwawa population on all criteria considered under Step 1, spawner abundance, natural-origin recruits (NORs), and productivity of some of the potential reference populations may nevertheless track closely with the Chiwawa population. If the time series of abundance, NORs, and productivity of a potential reference population tracks closely with the abundance, NORs, and productivity of the Chiwawa population, the reference population may provide a reasonable reference condition for testing the effects of supplementation on the Chiwawa population.

Under Step 2, we used graphing techniques to examine the relationship of abundance, NORs, and productivity between the Chiwawa population and the five reference populations (Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River). We compiled spawner abundance, NORs, and productivity data from local biologists and the NOAA Fisheries Salmon Population Summary Database. We then compared time series plots of spawner abundance, NORs, and productivity data of potential reference populations with the Chiwawa population (Figures 2, 3, and 4; plots on the left side of figures). The time series only included the period 1981 to 1992, which represented the period before supplementation of the Chiwawa population (pre-treatment period). We also plotted the relationship between the abundance, NORs, and productivity of each

potential reference population to the Chiwawa population (Figures 2, 3, and 4; plots on right side of figures). These plots show whether the reference populations closely tracked the Chiwawa population. As a point of reference, data points that fall along the dashed line would represent a perfect relationship between the two populations (i.e., both populations have identical abundance, NORs, and productivity estimates). While a perfect relationship between two independent populations is unrealistic, a strong linear relationship between the two populations indicates populations with similar trends.

Based on analysis of spawner abundance, the Naches River time series tracked more closely with the abundance of Chiwawa spring Chinook than did the other potential reference populations. The poor relationship with the other potential reference streams was largely because of the relatively high abundance of Chiwawa spring Chinook during the mid-1980s. As with spawner abundance, analyses of NORs indicated a close relationship between the Naches and Chiwawa populations. The other potential reference populations tracked poorly with the Chiwawa. The analyses of productivity indicated close relationships between potential reference populations and the Chiwawa population. The Naches, Sesech, and Little Wenatchee populations tracked the closest with the Chiwawa population.

When analyzing the potential effects of a supplementation program on fish performance, it is common to transform the data to meet various assumptions of statistical analysis. The most common transformation used to adjust abundance, NORs, and productivity data is the natural logarithm (LN or $\log_e$). We therefore transformed the spawner abundance, NORs, and productivity data using LN and re-plotted the relationships between the potential reference populations and the Chiwawa population (Figures 5, 6, and 7). We added 1 to each observation before taking its logarithm to avoid taking the logarithm of 0, which is undefined (note that the LN of 1 is 0).

By transforming spawner abundance, NORs, and productivity data, most of the potential reference populations tracked more closely with the Chiwawa population. The Naches, Entiat, and Little Wenatchee abundance data tracked the closest with the Chiwawa abundance data (Figure 5). For NORs, Marsh Creek and the Little Wenatchee populations tracked the closest with the Chiwawa (Figure 6). For productivity, the Naches, Sesech, and Little Wenatchee tracked the closest with the Chiwawa (Figure 7).

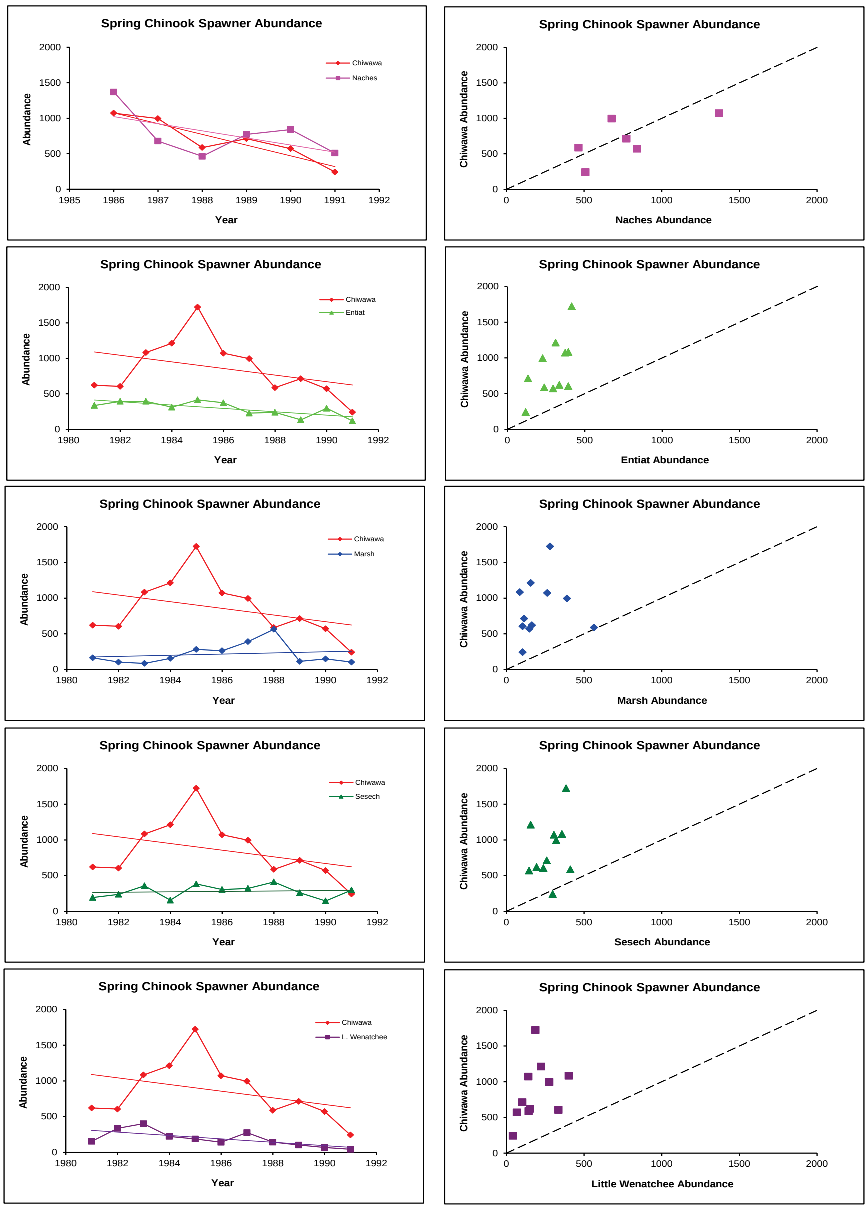

Figure 2. Time series of spawner abundance of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

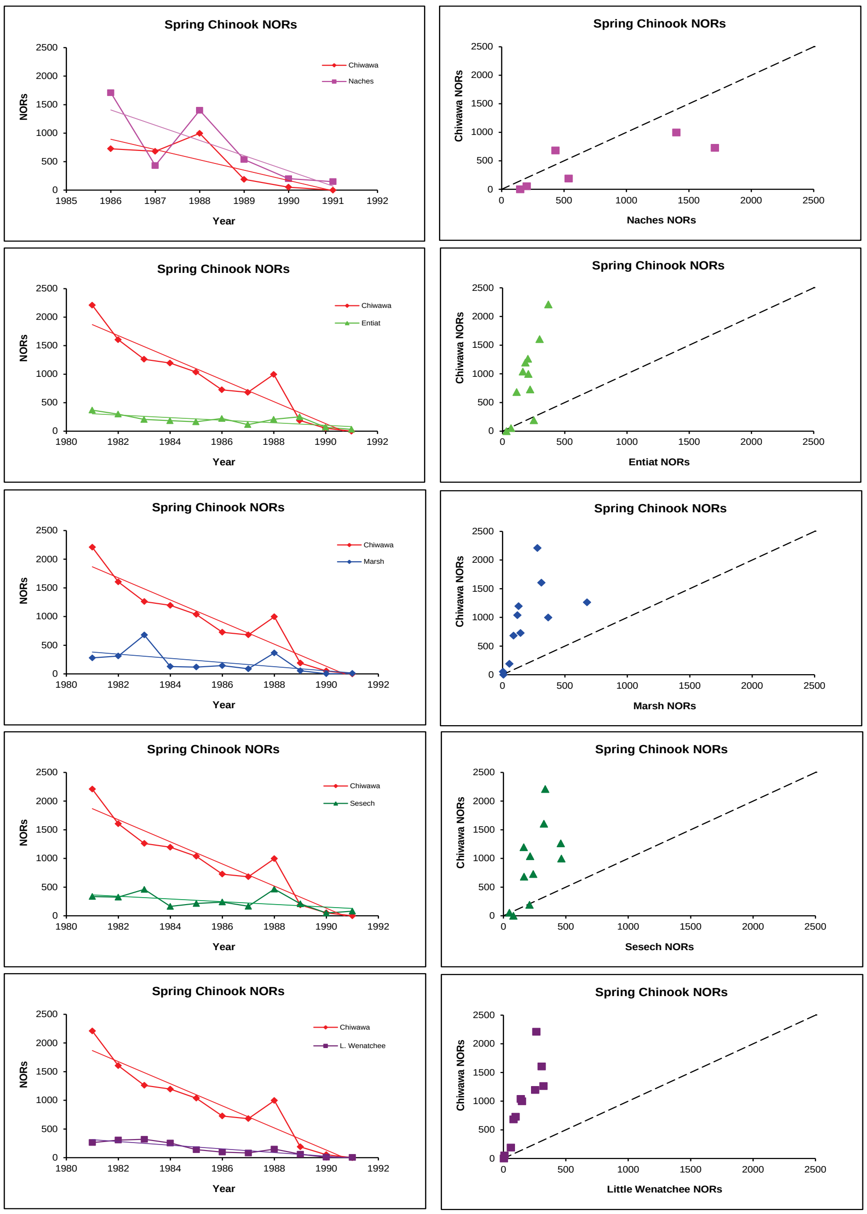

Figure 3. Time series of natural-origin recruits (NORs) of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

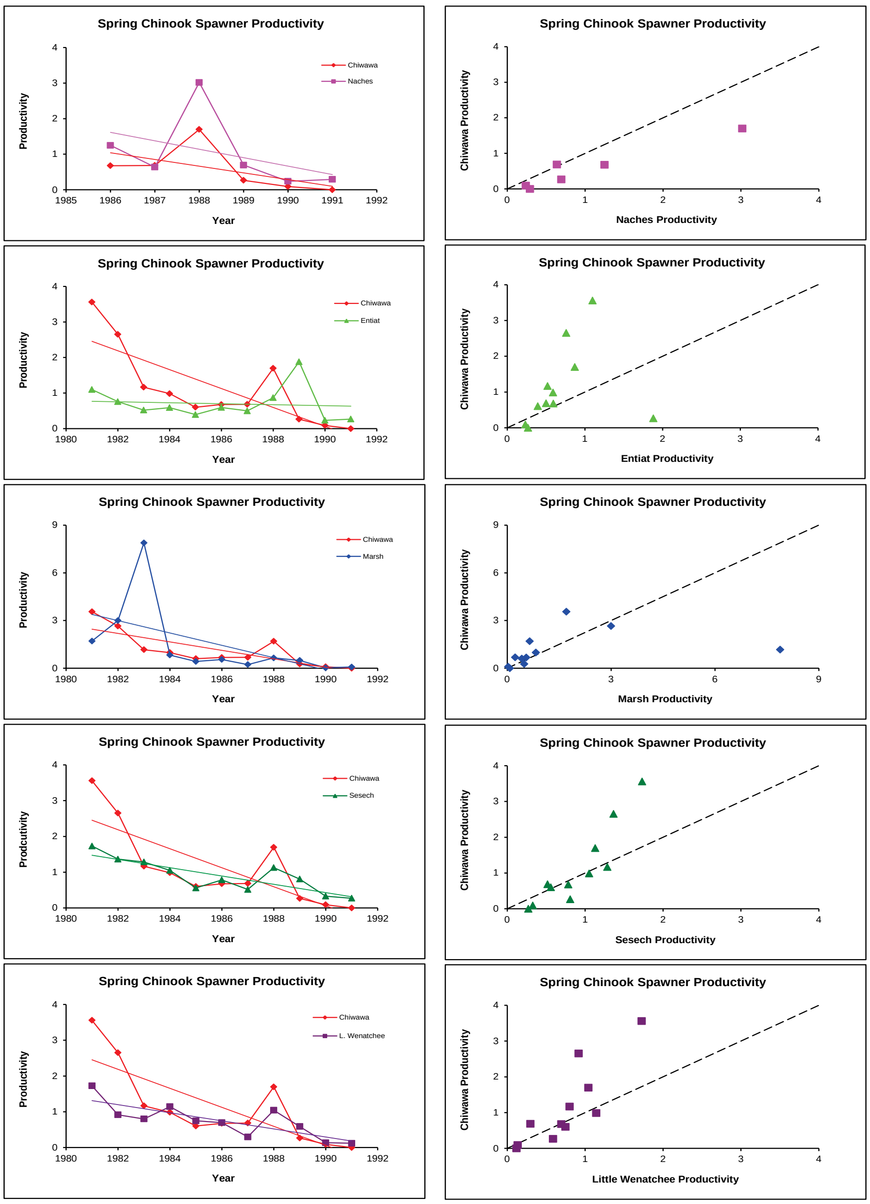

Figure 4. Time series of adult productivity of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

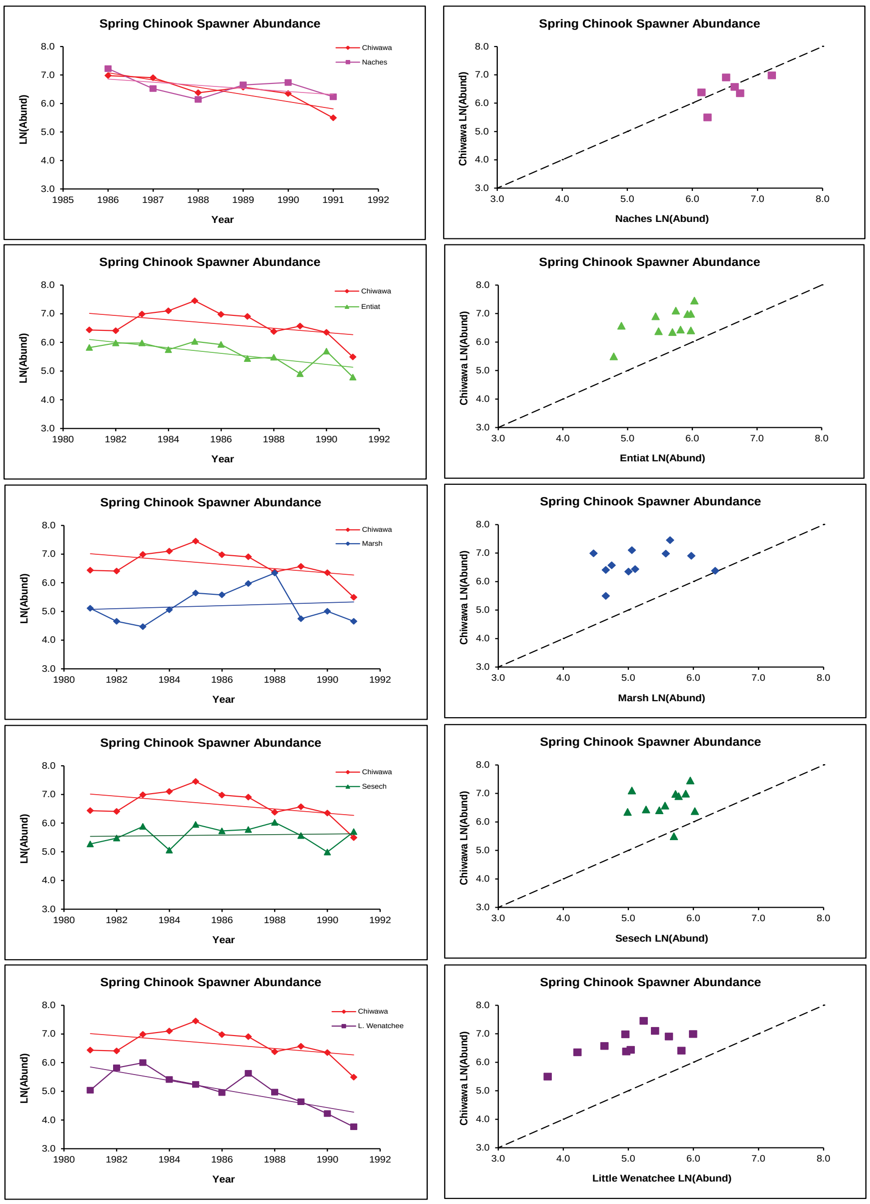

Figure 5. Time series of natural log spawner abundance of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

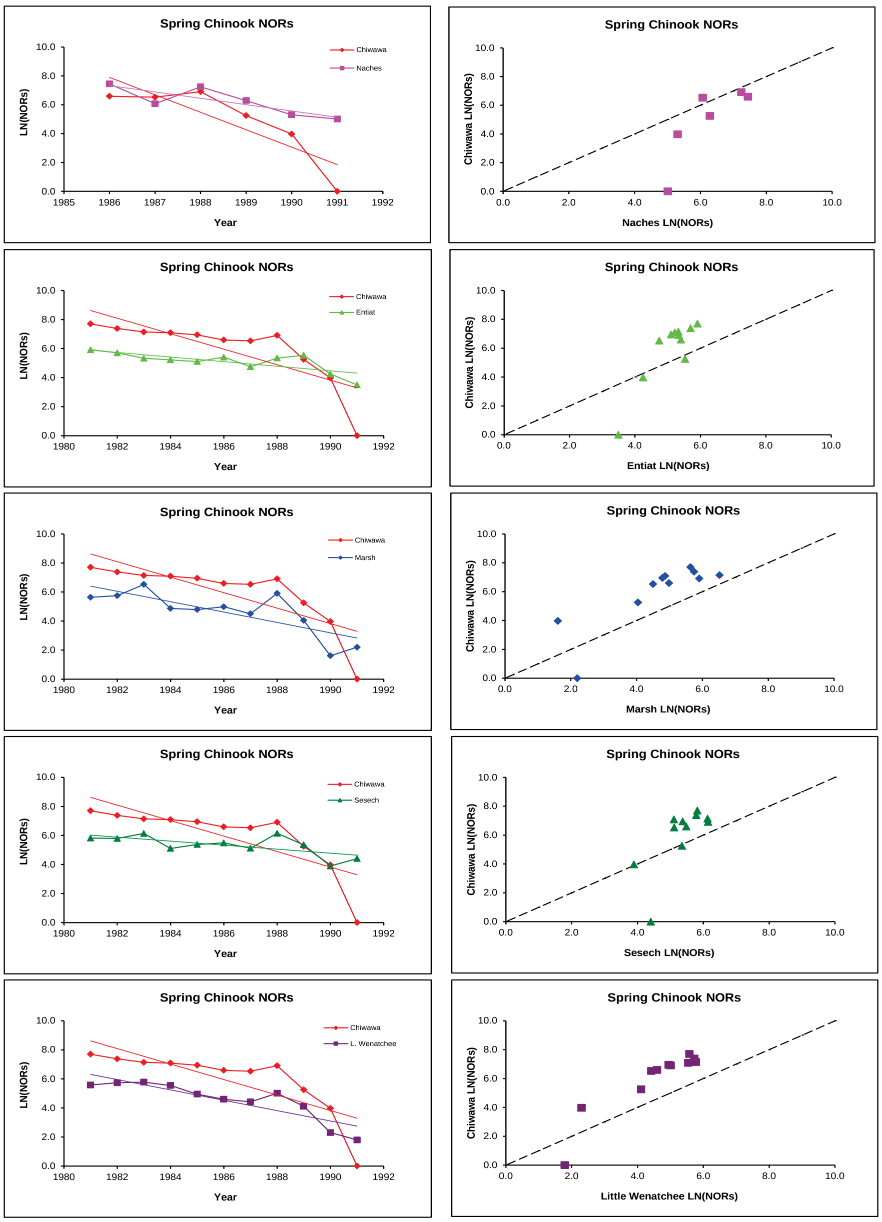

Figure 6. Time series of natural log natural-origin recruits (NORs) of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

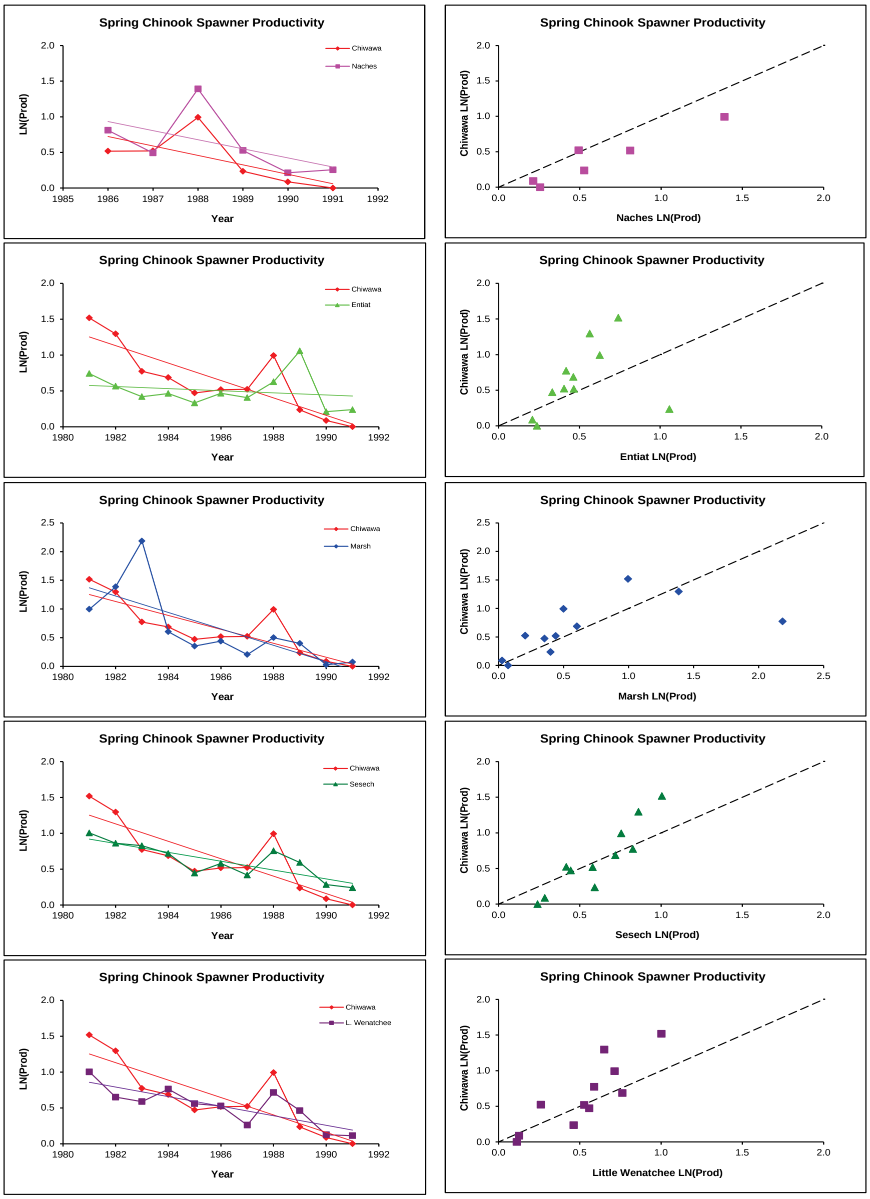

Figure 7. Time series of natural log adult productivity of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

Correlations and Trends

Other methods for evaluating the suitability of potential reference populations under Step 2 include correlation and trend analyses. For correlation analysis, we simply calculated the Pearson correlation coefficient, which is an index of the strength of the association between the potential reference populations and the Chiwawa population. The coefficient ranges from -1 to 1, where a value near 1 or -1 represents that strongest association between the populations. A value of 0 means no association. We used only spawner abundance, NORs, and productivity data during the pre-treatment period (1981-1992). We assumed that populations with coefficients greater than 0.6 represented reasonable reference conditions.

For trend analyses, we used least squares techniques to compute a straight-line trend through the spawner abundance and productivity data for the potential reference populations and the Chiwawa population. Trends were fit to the pre-treatment time series data (1981-1992). We then used t-tests to determine if the slopes of the trends between potential reference populations and the Chiwawa population differed significantly.

It is important to note that time-series trend analyses are susceptible to temporal correlations in the data. Autoregressive integrated moving average (ARIMA) models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). However, these models require a long time series (N > 40) and therefore we could not use them to model the spring Chinook data. As such, we were unable to correct for any temporal correlation that may exist within the time series.

Tests of correlation with spawner abundance data indicated that the Naches River closely correlated with the Chiwawa population (Table 2). There was no difference in abundance trends between the potential reference populations and the Chiwawa population (Table 2; Figure 2). For NORs, all potential reference populations correlated with the Chiwawa population (Table 2). However, trends in NORs of all reference populations, except Naches, differed significantly from the Chiwawa population (Table 2; Figure 3). For productivity, the Naches, Sesech, and Little Wenatchee correlated with the Chiwawa population (Table 2). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 2; Figure 4).

Table 2. Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (*) indicates significance at P < 0.05.

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Spawner Abundance Data				
Naches	0.684*	-0.659	8	0.528
Entiat	0.598*	-0.596	18	0.559
Marsh	0.147	-1.341	18	0.197
Sesech	0.274	-1.265	18	0.222
Little Wenatchee	0.399	-0.591	18	0.562
Natural-Origin Recruits				
Naches	0.803*	0.666	8	0.524
Entiat	0.795*	-7.495	18	0.000

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Marsh	0.605*	-5.786	18	0.000
Sesech	0.648*	-6.874	18	0.000
Little Wenatchee	0.880*	-7.206	18	0.000
Productivity Data				
Naches	0.960*	0.169	8	0.870
Entiat	0.272	-3.057	18	0.007
Marsh	0.320	0.605	18	0.553
Sesech	0.903*	-2.059	18	0.054
Little Wenatchee	0.848*	-2.065	18	0.054

We also ran correlation and trend analyses on natural-log transformed spawner abundance, NORs, and productivity data. These analyses indicated that the Naches, Entiat, and Little Wenatchee abundance data correlated with the Chiwawa population data (Table 3). None of the abundance trends of the potential reference populations differed significantly from the Chiwawa population trend (Table 3; Figure 5). For NORs, all potential reference populations correlated with the Chiwawa population (Table 3). Only trends in NORs of the Entiat and Sesech differed significantly from the Chiwawa population (Table 2; Figure 6). For productivity, the Naches, Marsh, Sesech, and Little Wenatchee correlated with the Chiwawa population data (Table 3). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 3; Figure 7).

Table 3. Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (*) indicates significance at $P < 0.05$. Analyses were conducted on natural-log transformed abundance and productivity data.

LN Productivity Data				

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Naches	0.944*	-0.042	8	0.968
Entiat	0.373	-3.043	18	0.007
Marsh	0.610*	0.428	18	0.674
Sesech	0.913*	-2.050	18	0.055
Little Wenatchee	0.862*	-1.811	18	0.087

In summary, based on correlation, trend, and graphic analyses, the Naches, Entiat, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. For NORs, the Naches, Marsh, and Little Wenatchee appear to be reasonable reference populations. For productivity, the Naches, Marsh, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for the Chiwawa population.

Minimal Detectable Differences (MDD)

Given a suite of potential reference populations, it is important to conduct power analyses to determine the minimum differences that can be detected when comparing the reference populations to the supplemented population. As a final exercise under Step 2, we examined potential reference populations for the smallest minimal detectable differences. Before conducting power analyses, several decisions needed to be made, including what statistical procedures will be used to analyze the data, the desired level of statistical power (probability of rejecting a false null hypothesis), the size of the type-I error (the probability of rejecting a true null hypothesis of no difference), and the number of samples (i.e., years) included in the analysis. In this case, the number of samples represents the number of treatment (supplementation) years. The number of pre-treatment years (1981-1992) was based on the number of years of quality data available for Chiwawa spring Chinook and potential reference populations.

We designed the study as a modified BACI (Before-After, Control-Impact) design, which includes replication before and after supplementation in both the treated (T) population and the reference (R) populations. A common approach used to analyze data from BACI designs includes analysis of difference scores (Stewart-Oaten et al. 1992; Smith et al. 1993). Differences are calculated between paired treatment and reference population scores (i.e., T-R). Another approach is to calculate ratios (treatment/reference; T/R) for paired treatment and reference population scores (Skalski and Robson 1992). Finally, differences in annual changes in paired treatment and reference population scores can be calculated (i.e., ΔT-ΔR) (Murdoch and Peven 2005; Hays et al. 2006).[16] These derived difference and ratio scores are then analyzed for a before-after treatment effect with a two-sample t-test, Aspin-Welch modification of the t-test, or a randomization test. For power analyses, we calculated minimal detectable differences assuming the use of an independent two-sample t-test with a type-I error rate of 0.05, power of 0.80 (beta or type-II error rate of 0.20), and sample sizes (treatment years) of 5, 10, 15, 20, 25, and 50 years.

16 The difference of annual difference scores was estimated by first subtracting the population parameter (e.g., spawner abundance) in year 2 from year 1. This continues for all years in the data series for both treatment ($T_{t+1} - T_t$) and reference populations ($R_{t+1} - R_t$). We then calculated differences between paired treatment and reference annual difference scores [$(T_{t+1} - T_t) - (R_{t+1} - R_t) = \Delta T - \Delta R$].

The power analysis calculated the minimal detectable difference between mean difference or ratio scores before and during supplementation. We used existing data to calculate variances for the pre-supplementation and supplementation periods. Thus, variances were known and unequal. For both spawner abundance and NORs, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was less than the mean difference during supplementation (one-tail test; Difference < 0). For productivity, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was greater than the mean difference during supplementation (one-tail test; Difference > 0).

Based on spawner abundance data, power analysis indicated that the Sesech-Chiwawa pairing consistently produced the smallest detectable differences (Table 4). However, when the abundance data were transformed using natural logs, the Entiat-Chiwawa pairing produced the smallest detectable difference (Table 5). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 334 to 394 adult spawners; transformed data ranged from 0.479 to 1.010. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

Table 4. Minimal detectable differences between mean difference and ratio scores before and during supplementation. Analyses were conducted on spawner abundance data.

Based on NORs, power analysis indicated that the Entiat-Chiwawa, Marsh-Chiwawa, and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 6). When NORs were transformed using natural logs, the Little Wenatchee-Chiwawa pairing produced the smallest detectable difference (Table 7). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 483 to 640 NORs; transformed data ranged from 0.958 to 2.262. These analyses indicate that the Entiat, Marsh, and Little Wenatchee populations appear to be reasonable reference populations for comparing NORs with Chiwawa data.

Using untransformed productivity data, power analysis indicated that the Little Wenatchee-Chiwawa pairing consistently produced the smallest detectable differences (Table 8). The Marsh-Chiwawa pairings produced the largest detectable differences. When we analyzed natural-log transformed productivity data, the Naches-Chiwawa and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 9). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 0.754 to 1.839; transformed data ranged from 0.277 to 0.477. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing productivity data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

Step 3: Quantitative Method for Ranking Selection Criteria

Not surprisingly, different selection criteria produced different results (Table 10). Determining whether a given population is or is not a suitable reference population based on selection criteria such as graphic analysis can be subjective. In addition, treating each selection criterion as equally important may not be appropriate. For example, using the information in Table 10, is it appropriate to select a reference population that has two or three "Yes" entries, or should only populations with four "Yes" entries be selected as suitable reference populations? This approach does not allow certain selection criteria to carry more weight in the overall selection process. That is, correlation may be more important than graphic analysis in the overall selection process. In order to reduce

subjectivity, we developed a method of scoring and weighting each selection criterion. This method allows a more quantitative process for selecting suitable reference populations.

Table 10. Summary of results from graphic analysis, correlations, trend analysis, and power analysis (minimal detectable differences). “Yes” indicates that the population is a suitable reference population for the Chiwawa population; “No” indicates that it may not be a suitable reference population.

Potential reference populations	Graphic analysis	Correlation	Trends	Minimal detectable differences
Spawner Abundance				
Naches	Yes	Yes	Yes	Yes
Entiat	Yes	Yes	Yes	Yes
Marsh	No	No	Yes	No
Sesech	No	No	Yes	Yes
Little Wenatchee	Yes	Yes	Yes	Yes
Natural-Origin Recruits				
Naches	Yes	Yes	Yes	No
Entiat	No	Yes	No	Yes
Marsh	Yes	Yes	Yes	Yes
Sesech	No	Yes	No	No
Little Wenatchee	Yes	Yes	Yes	Yes
Productivity				
Naches	Yes	Yes	Yes	Yes
Entiat	No	No	No	Yes
Marsh	No	Yes	Yes	No
Sesech	Yes	Yes	Yes	Yes
Little Wenatchee	Yes	Yes	Yes	Yes

We developed scoring methods for each of the following five selection criteria:

(1) The proportion of natural-origin spawners (pNOS) in the reference population for the period before supplementation (pre-pNOS);

(2) pNOS in the reference population for the period following supplementation (post-pNOS);

(3) The correlation between the reference and supplemented populations before supplementation;

(4) The relative difference in slopes between the reference and supplemented populations before supplementation; and

(5) The coefficient of variation (CV) of the ratio of supplemented to reference populations before the period of supplementation.

Each selection criteria was scored from 0 to 1, with 0 being the worst possible score and 1 being the best.

The pre- and post-pNOS values were calculated as the average pNOS values before and after supplementation, respectively. Because pNOS values range from 0-1, we did not need to rescale

these values. When using reference populations to evaluate the effects of supplementation programs, it is important that the reference populations maintain high values of pNOS throughout the life of the monitoring program. Therefore, we heavily weighted the mean pNOS scores. We assigned weights of 30 and 40 to the mean pre- and post-pNOS scores, respectively. The relatively larger weight for the post-supplementation period is to reduce the likelihood of retaining a reference population that becomes influenced by hatchery fish during the supplementation period.

We assessed the association between the reference and supplemented populations during the pre-supplementation period by calculating the Pearson correlation coefficient, which ranges from -1 to 1. To scale the coefficient between 0 and 1, we took the absolute value of the coefficient. Thus, a coefficient of -0.92 would be reported as 0.92. For our analyses, we were not concerned with the direction of the relationship, only the strength of the relationship. The correlation coefficient was given a weight of 12.5.

As noted earlier, we used least squares to fit a linear trend to each of the reference populations and the supplemented population during the pre-supplementation period. Using the slope estimates for each trend line, we calculated the relative difference in slopes as the slope of the supplemented population minus the slope of the reference population, divided by the slope of the reference population. To scale this value between 0 and 1, we used absolute values, and depending on the direction of the slopes, we subtracted the relative difference from 1. The latter was needed to make sure a larger relative difference value indicated a small difference in slopes between the supplemented and reference populations. The relative difference score was given a weight of 7.5.

Finally, as a means to score effect size, we calculated the CV of the ratio of supplemented to reference population parameters (i.e., T/R). The CV was calculated as the standard deviation of the ratios divided by the absolute value of the mean ratios. The CV was subtracted from 1. This scaled the value from 0 to 1 with larger values representing the best condition. The CV was given a weight of 10, which is greater than the weight for trend, but less than the weight for correlation.

The total score for a reference population was calculated by multiplying the estimated value, which ranged from 0 to 1, by its weight. The sum of the five weighted values provided a total score, which ranged from 0 to 100. Based on several simulations, we set the cut-off score at 81. That is, if the total score for a given reference population equaled or exceeded 81, the population was included as a suitable reference population. If the total score fell below 81, the population was not considered a suitable reference. Based on the distribution of all scores possible, a score of 81 or greater represented only 3% of the total distribution. Thus, a cut-off of 81 is quite conservative.

Under Step 3, we used this method to select the final suite of suitable reference populations. Table 11 shows results from scoring each of the reference populations using the quantitative method. Using the cut-off criterion of 81, only the Naches, Marsh, and Sesech populations would be considered suitable reference populations for the Chiwawa supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values).

Table 11. Results from scoring potential reference populations using the selection criteria (pNOS, correlation, trend, and effect size). Populations with scores less than 81 were considered unsuitable as reference populations. Populations with scores equal to or greater than 81 were considered suitable references. These results were based on natural-log transformed data.

Potential reference populations	Population metric		
	Abundance	NORs	Productivity
Naches	85	88	91
Entiat	23	21	16
Marsh	79	91	87
Sesech	84	85	88
Little Wenatchee	51	53	49

An important benefit from scoring the different selection criteria is that the total scores can be used to weight the outcome of differing statistical results. For example, analyses may show that when three suitable reference populations are compared to the supplemented population, two of the reference populations may indicate a significant treatment effect, while the third indicates no effect. Under this scenario it is not clear if the supplementation program has or has not affected the abundance or productivity of the supplemented population. If, however, the two reference populations that produced a significant result had higher total scores than the reference population that did not indicate a significant result, one can place more weight on the results from populations with higher total scores.

Conclusions

The purpose of this exercise was to develop a method for selecting suitable reference populations that could be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity. The selection process included a three-step process (Figure 8). Step 1 identified populations with similar life-history characteristics, few or no hatchery spawners, a long time series of accurate abundance and productivity estimates, and similar freshwater habitat impairments and out-of-basin effects. Populations that met these criteria were then examined for their graphical and statistical relationship with the supplemented population (Step 2). The statistical analysis under Step 2 were converted to a quantitative model (Step 3) that was used to generate a weighted score for pNOS, correlation, trends, and effect sizes for each potential reference population. Reference populations with total scores of 81 or greater were selected as suitable reference populations.

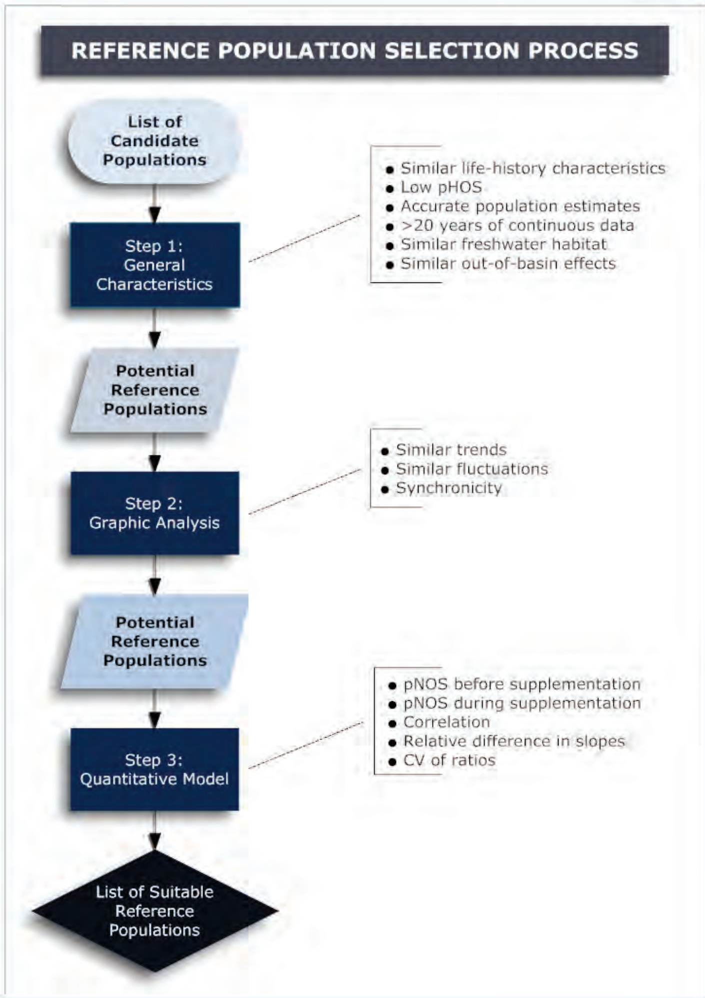

Figure 8. Three-step process for selecting suitable reference populations for supplemented populations.

We used this approach to select suitable reference populations for analyzing the effects of the Chiwawa spring Chinook supplementation program on fish abundance and productivity. The method indicated that the Naches, Marsh, and Sesech populations would serve as suitable reference populations for the Chiwawa spring Chinook supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values). However, because the presence of hatchery spring Chinook within those populations should decrease, they may serve as unique reference populations in which the comparisons change from all populations receiving

hatchery fish to only the Chiwawa population receiving hatchery fish. Therefore, we will continue to include both the Little Wenatchee and Entiat populations in future analyses.

An important assumption in the use of reference populations is that the supplemented and reference populations that tracked each other before supplementation would continue to track each other in the absence of supplementation. Given that the reference populations did not match the Chiwawa population on all criteria examined (Table 1) and some reference populations tracked the Chiwawa population more poorly than others (Figures 2-7; Tables 2-4), there may be some uncertainty as to whether differences observed between the Chiwawa and reference populations during the supplementation period are associated with the hatchery program, "nuisance" factors[17], or a combination of both. In addition, we have no ability to regulate or control activities in reference areas. Any large-scale change (man-made or natural) in reference areas could affect our ability to assess the effectiveness of the supplementation program.

Because we have no ability to maintain reference areas for long periods of time and may not be able to control all activities even within the supplemented populations, we propose the use of a "causal-comparative" approach to strengthen the certainty of our inferences (Pearsons and Temple 2010). The causal-comparative approach relies on correlative data to try and make a case for causal inference.[18] Correlation is used to rule out alternative hypotheses (note that we make our case as much if not more by disproving plausible alternatives as we do by showing that the data are consistent with a hypothesis). For example, large scale land-use activities or natural events can affect stream flows, fine sediment recruitment, and water temperatures. Changes in these factors can affect the freshwater survival and productivity of fish independently of supplementation programs. If changes in habitat, migratory, and ocean conditions do not affect reference and treatment populations similarly, inferences associated with supplementation programs may be confounded. By measuring and tracking these extraneous factors within reference and treatment areas, we can assess the effects of these state variables on population conditions independent of the supplementation programs. This allows us to more effectively assess the influence of supplementation programs on populations.

To that end, we recommend that the following state variables be measured and tracked within the Chiwawa Basin and each of the reference areas: mean annual precipitation, total and riparian forest cover, road density, impervious surface, and alluvium. These variables can be used to describe differences in water temperatures at different life stages (pre-spawning, egg incubation, and summer rearing) and substrate characteristics, including fine sediments and embeddedness (Jorgensen et al. 2009). They can be used to assess possible changes in spawner abundance, NORs, and productivity that are independent of supplementation.

17 A "nuisance" factor is any factor that is outside the control of the experimenter and can affect the response variable (spawner abundance or productivity). In this case, nuisance factors may include differences in freshwater habitat trends and conditions, out-of-basin effects (e.g., migration and ocean survival), and hatchery strays that affect the Chiwawa and reference populations differently.

18 It is important to point out that correlation does not demonstrate cause-and-effect. It only suggests a relationship between variables. Thus, inferences based on correlation lack the certainty that is associated with a design-based approach.

Analyses with Reference Populations

Once suitable reference populations are selected, methods for analyzing the supplemented and reference populations need to be identified. What follows is a description of different analyses that can be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity using reference populations. Later in this report we describe methods for assessing supplementation effects when reference populations are not available.

We used some of the reference populations selected for the Chiwawa program to illustrate the different methods for evaluating the effects of the supplementation program on spawner abundance, NORs, and productivity. For abundance, we selected the Naches, Entiat, Little Wenatchee, and Sesech populations as suitable references for the Chiwawa population. For NORs, we selected the Naches, Entiat, Marsh, and Little Wenatchee populations as suitable references. For productivity, we selected the Naches, Sesech, Little Wenatchee, and Marsh Creek as suitable references for the Chiwawa. As noted earlier, we included the Little Wenatchee and Entiat populations, even though they did not meet all the criteria for suitable reference populations.

Analysis of Trends

As a first step, we used trend analyses to assess the effects of the Chiwawa supplementation program on spring Chinook spawner abundance, NORs, and productivity. Here, we compared the slopes of the trends between each treatment/reference pair before and during supplementation using t-tests. If the hatchery program is successfully supplementing the natural spring Chinook population, trends in spawner abundance and NORs should deviate significantly (i.e., the slope of the supplemented population should be greater than the slopes of the reference populations during the supplementation period). For productivity, the slope of the supplemented population, relative to the reference population, should increase or remain the same.

Trend analysis indicated that the relationship of slopes of spawner abundance between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 9; Table 12). This was true for both transformed and untransformed abundance data. Before supplementation, spawner abundances trended down in both the Chiwawa and reference populations (Figure 9). During the period of supplementation, abundances in both the Chiwawa and reference populations trended upward. Interestingly, in nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the supplementation period than in the pre-supplementation period (Table 12). This was most evident in the transformed abundance data (Figure 9).

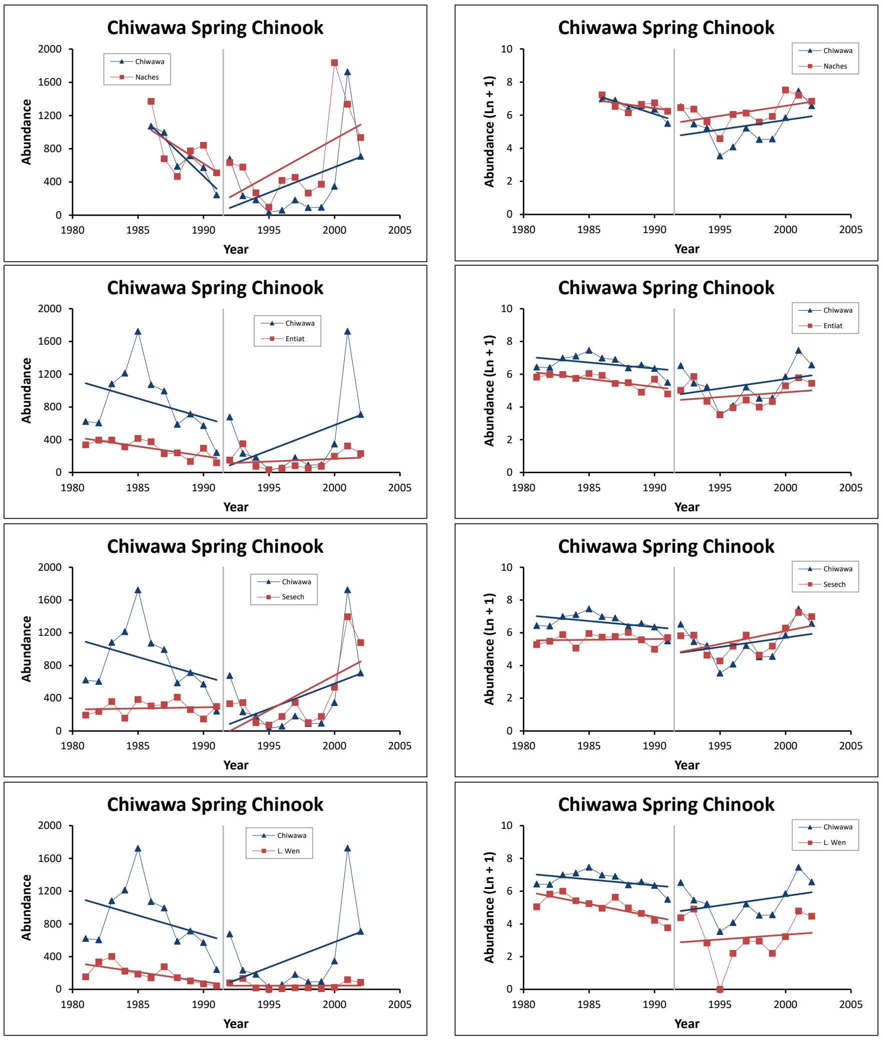

Figure 9. Trends in spring Chinook spawner abundance in the Chiwawa and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed spawner abundance data; those on the right include natural-log transformed data.

Table 12. Pearson correlation coefficients and t-test results comparing slopes of spawner abundance trends between reference populations and the Chiwawa spring Chinook population before and during the supplementation periods; for correlation coefficients, an asterisk (*) indicates significance at P < 0.05. Analyses include both untransformed and natural-log transformed spawner abundance data.

Reference population	Pearson correlation coefficient		Test on slopes

Trend analysis indicated that the relationship of slopes of NORs between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 10; Table 13). Before supplementation, Chiwawa NORs trended downward more strongly than the reference populations (Figure 10). However, during the supplementation period, both the Chiwawa and reference population NORs trended upward in parallel. In nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the pre-supplementation period than in the supplementation period (Table 13).

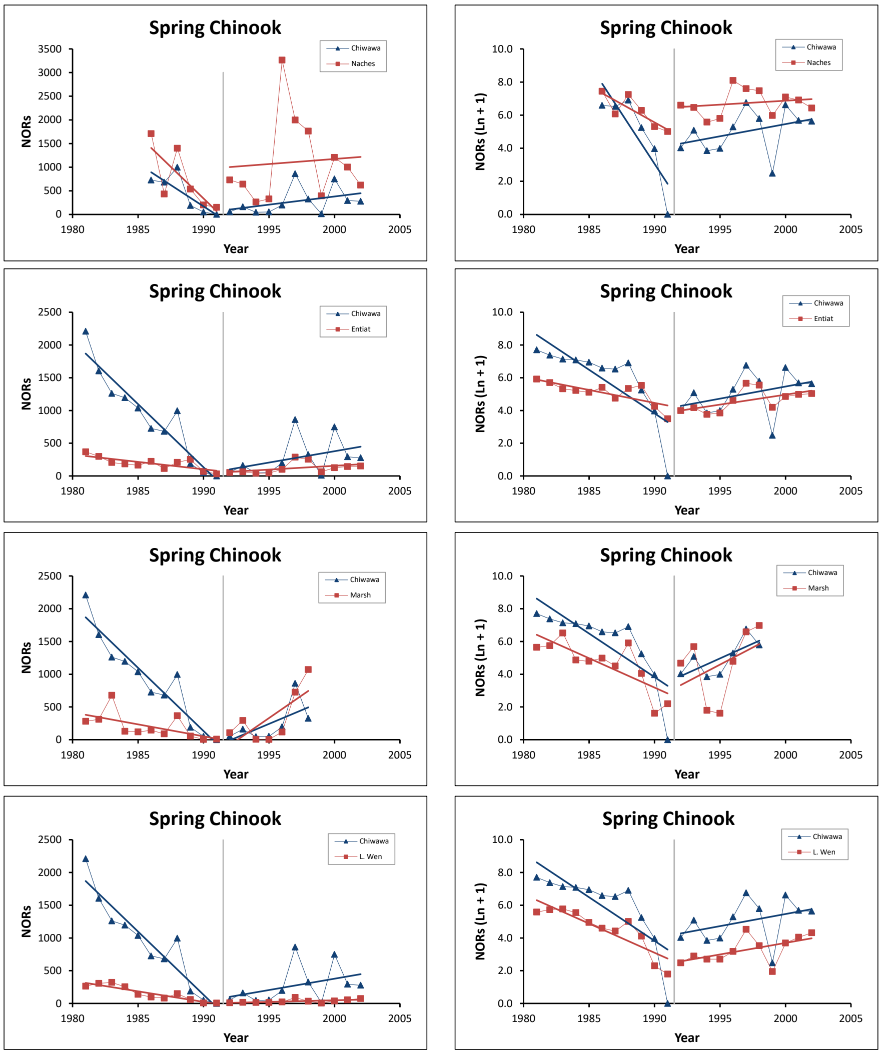

Figure 10. Trends in spring Chinook natural-origin recruits (NORs) in the Chiwawa and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed NORs; those on the right include natural-log transformed data.

Table 13. Pearson correlation coefficients and t-test results comparing slopes of natural-origin recruits trends between reference populations and the Chiwawa spring Chinook population before and during the supplementation periods; for correlation coefficients, an asterisk (*) indicates significance at $P < 0.05$. Analyses include both untransformed and natural-log transformed natural-origin recruits.

As with NORs and spawner abundance data, trend analysis indicated that the relationship of slopes of productivity (recruits/spawner) between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 11; Table 14). This was true for both transformed and untransformed productivity data. Before supplementation, productivities trended down in both the Chiwawa and reference populations (Figure 11). During the period of supplementation, productivities fluctuated widely in both the Chiwawa and reference populations. Nevertheless, during the supplementation period, productivities generally increased in both the reference and Chiwawa populations. Unlike with spawner abundance, the Pearson correlation coefficients resulting from analysis of productivity data were generally higher in the pre-supplementation period than during the supplementation period (Table 14).

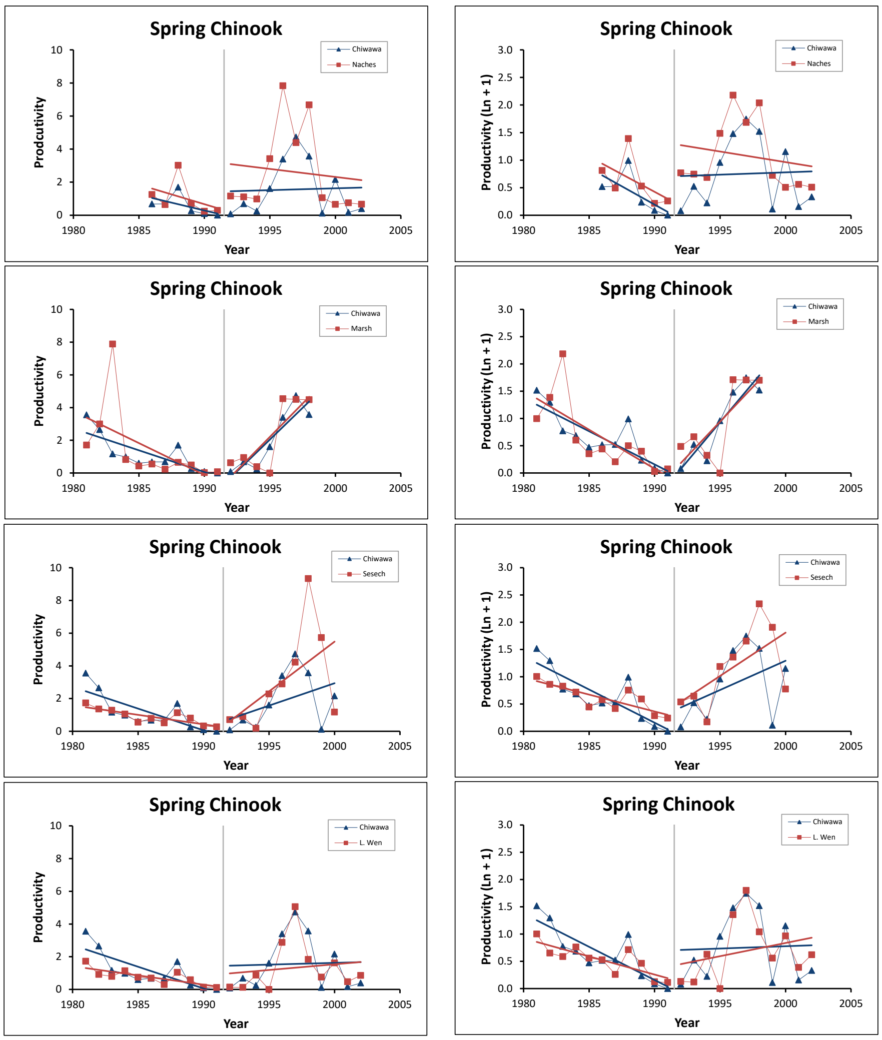

Figure 11. Trends in spring Chinook productivity (recruits/spawner) in the Chiwawa (supplemented) and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed productivity data; those on the right include natural-log transformed data.

Table 14. Using trend analysis, we found no evidence that the supplementation program has significantly increased the spawner abundance and NORs of spring Chinook in the Chiwawa Basin. Even though we documented an increasing trend in spawner abundance and NORs during the supplementation period, a similar increase in spawner abundance and NORs was observed in the reference populations. In addition, we found no evidence that the supplementation program has increased the productivity of spring Chinook in the Chiwawa Basin. Importantly, the productivity of spring Chinook in the Chiwawa Basin did not trend downward during the supplementation period. Thus, based on trend analysis, it appears that the supplementation program has not increased or decreased the abundance and productivity of spring Chinook in the Chiwawa Basin.

We note that this exercise only tests the slopes of the trend lines. It does not test for differences in elevations of the trend lines. A supplementation program could increase spawner abundance, NORs, and productivity of the target population without changing the slopes of the trend lines. That is, supplementation could cause the elevation of the trend line to be greater during the supplementation period than during the pre-supplementation period. In the next section we evaluate elevation differences by testing mean differences before and after supplementation.

Analysis of Mean Differences, Ratios, and Rates

For assessing mean differences between supplemented and reference populations, we derived three different response variables using transformed and untransformed spawner abundance, NORs, and productivity data. The first included difference scores, which were calculated as the difference between paired treatment and reference data (T-R). The second included ratios, which were calculated as the ratio of paired treatment and reference data (T/R). Finally, we calculated the differences in annual changes in paired treatment and reference population data (ΔT-ΔR; see footnote #2).

If the hatchery program is successfully supplementing the natural spring Chinook population, the mean difference or ratio score of paired spawner abundance data and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean difference or ratio score during the supplementation period should be equal to or higher than the pre-supplementation period. We tested the following statistical hypotheses.

Spawner Abundance and NORs:

> Ho: Mean Difference (or Ratio) before supplementation ≥ Mean Difference (or Ratio) during supplementation.
>
> Ha: Mean Difference (or Ratio) before supplementation < Mean Difference (or Ratio) during supplementation (i.e., $\mu_{pre} - \mu_{post} < 0$).

Productivity (Recruits/Spawner):

> Ho: Mean Difference (or Ratio) before supplementation ≤ Mean Difference (or Ratio) during supplementation.
>
> Ha: Mean Difference (or Ratio) before supplementation > Mean Difference (or Ratio) during supplementation (i.e., $\mu_{pre} - \mu_{post} > 0$).[19]

For each set of response variables, we tested before/after supplementation effects using a one-tailed Aspin-Welch unequal-variance test. We used the Aspin-Welch unequal-variance test instead of Student's t-test, because in nearly every case, the variances of response variables in the pre-treatment and supplementation periods were unequal.[20] This was true even for natural-log transformed variables. We used the modified Levene equal-variance test to assess the equality of variance. In some cases, the distributions of response variables were not normal (based on the Omnibus Normality test and examination of histograms, normal probability plots, and box plots). Therefore, we also used a randomization test, based on 10,000 Monte Carlo simulations, to assess differences in response variables before and during supplementation. The randomization procedure only allowed the testing of two-tailed hypotheses. Therefore, we generated 95% confidence intervals on the mean difference ($\mu_{pre} - \mu_{post}$) using bootstrapping methods to determine the direction of the difference. We generated 5,000 bootstrap samples to calculate confidence intervals.

All these statistical methods assume that the samples of derived difference or ratio scores from the pre-supplementation and supplementation periods were independent. However, BACI designs, like time-series trend analysis, are repeated-measures designs and therefore are susceptible to temporal correlations in the data. This means that the two samples of difference or ratio scores may not be independent. Under this scenario, ARIMA models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). ARIMA models can be fit individually to the reference and supplemented time series data, or to a derived data series created by taking the ratio or difference of the supplemented/reference data at each time step. ARIMA models, however, require a long time series (N > 40) and therefore we could not use them to model

19 Because of the logic of null hypothesis testing, the rejection of the null hypothesis of no difference in productivity would mean that the supplementation program has reduced the productivity of the target population (here rejection of the null indicates "harm"). Notice that the rejection of the null hypothesis of no difference in spawner abundance means that the supplementation program has improved the spawner abundance in the target population (here rejection of the null indicates "benefit").

20 In cases in which the variances were equal, both the Aspin-Welch test and Student's t-test gave the same result.

the spring Chinook data. Thus, we acknowledge that our analyses may be confounded if the samples are not independent.

Difference Scores (T-R)

Analysis of supplementation effects on spawner abundance using difference scores indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 15; Figure 12). Only the Little Wenatchee-Chiwawa pairing using transformed abundance data indicated a significant increase in spawning abundance following supplementation. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction (i.e., CIs > 0). That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 12).

Table 15. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed spawner abundance data. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

Reference population	Aspin-Welch unequal-variance test			Randomization test P-value	Bootstrap 95% CI

Analysis of supplementation effects on productivity (adult recruits/spawner) using difference scores indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 17; Figure 12). All tests, regardless of treatment-reference pairs, indicated that productivity did not change significantly during the supplementation period. These tests indicate that supplementation has not negatively affected the productivity of spring Chinook salmon in the Chiwawa Basin.

Table 17. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data. Tests determined if the mean difference scores during the supplementation period were less than mean difference scores during the pre-supplementation period.

Ratio Scores (T/R)

As with difference scores, analysis of supplementation effects on spawner abundance using ratios indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 18; Figure 13). Only the Little Wenatchee-Chiwawa pairing indicated a significant increase in spawning abundance following supplementation. Analysis with both transformed and untransformed Little Wenatchee-Chiwawa data indicated a significant effect. In contrast, only difference scores derived from transformed data indicated a significant effect. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction. That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 13).

Table 18. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed spawner abundance data. Tests determined if the mean ratios during the supplementation period were greater than mean ratios during the pre-supplementation period.

Analysis of supplementation effects on productivity (adult recruits/spawner) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 20; Figure 13). Although the Aspin-Welch test indicated a significant effect when comparing the Chiwawa to the Marsh Creek population, both the randomization test and the bootstrap CI did not indicate a significant effect. These tests indicate that supplementation has probably not negatively affected the productivity of spring Chinook salmon in the Chiwawa Basin.

Table 20. We believe results from analysis of mean differences of annual change (ΔT-ΔR) in spawning abundance, NORs, and productivity are difficult to interpret and may be insensitive to treatment effects. A simpler analysis, which is also easier to interpret, is the use of trend analysis. Therefore, we recommend that analyses using differences of annual change be replaced with trend analysis.

Corrections for Density Dependence and Carrying Capacity

The analyses described above assume that the density of spawners or recruits does not affect the survival and productivity of fish. However, it is well known that the density of fish can affect the number of recruits as well as the productivity of the population. This occurs through the relationship between density and mortality. Mortality of fish can be generally classified as density independent and density dependent. In general, when densities are low, the mortality is density independent, but as densities increase, the amount of density-dependent mortality increases. Monitoring programs can make use of this information to derive density-corrected estimates of productivity. In this section, we describe two different methods for deriving density-corrected estimates of productivity.

The first method controlled the effects of density on productivity (adult recruits/spawner; R/S) by partitioning observed productivities into density-independent and density-dependent productivity. When abundance is below the minimum number of spawners (S) needed to produce the maximum number of recruits (K_{sp}), the observed productivity is used in statistical tests. However, when the abundance is equal to or above K_{sp}, the modeled value of productivity (R/K_{sp}) is used in statistical tests.

$$\boldsymbol{Adj\ R/S} = \begin{cases} \boldsymbol{R/S,} & \boldsymbol{if\ S < K_{sp}} \\ \boldsymbol{R/K_{sp},} & \boldsymbol{if\ S \geq K_{sp}} \end{cases}$$

The density-independent and density-dependent productivities were then combined in a single test.

The second method was based on one of the goals of supplementation, which is to fill the capacity of the environment with fish. This method corrects for differences in carrying capacities between the supplemented and reference populations. We did this by calculating the percent saturation of NORs. That is, we calculated the fraction of the habitat (τ) that was filled with NORs by dividing the observed NOR by the modeled maximum number of NORs (K_R) that the habitat could support.

$$\boldsymbol{\tau = \frac{NOR_{obs}}{K_R}}$$

Note that 1-τ represents the unused portion of the carrying capacity and is the term that is multiplied by the exponential growth equation to derive the logistic growth equation. We included τ in the statistical analyses.

These two methods require the estimation of carrying capacity (K_R) and the spawning abundance that produces the maximum number of recruits (K_{sp}). We estimated these parameters for both reference populations and the supplemented population using Ricker, Beverton-Holt, and smooth hockey stick stock-recruitment models. We used only spawner abundance as a predictor of subsequent brood recruitment. We made the following assumptions in proceeding with the analysis:

- *Density-dependent mortality*—For some time period before recruitment, the brood instantaneous mortality rate is proportional to the number of parent spawners (Ricker 1954).
- *Lognormal variation*—At any particular spawning stock size, the variation in recruitment is log-normally distributed about its average, and acts multiplicatively (Quinn and Deriso 1999).
- *Measurement error*—Error in spawning stock size estimates (measurement error) is small relative to the range of spawning stock sizes observed (Hilborn and Walters 1992). Variation in realized recruitment at any particular spawning stock size (process error) dominates recruitment measurement error.
- *Stationarity*—The average stock-recruitment relationship is constant over time (Hilborn and Walters 1992). That is, environmental conditions randomly affect survival independent of stock size or time.

In general, the methods we used to fit the models to the data followed those outlined in Hilborn and Walters (1992) and Froese (2008). The Ricker model, which assumes that the number of recruits increases to a maximum and then declines as the number of spawners increases, takes the form:

$$E(R) = \alpha S e^{-\beta S}$$

where E(R) is the expected recruitment, S is spawner abundance, α is the number of recruits per spawner at low spawning levels, and β describes how quickly the recruits per spawner drop as the number of spawners increases. We estimated K_R as:

$$K_R = \left(\frac{\alpha}{\beta}\right) e^{-1}$$

and K_{sp} as:

$$K_{sp} = \frac{1}{\beta}$$

The Beverton-Holt model assumes that the number of recruits increases constantly toward an asymptote as the number of spawners increases. After the asymptote is reached, the number of recruits neither increases nor decreases. The asymptote represents the maximum number of recruits the system can support (i.e., carrying capacity for the system; K_R). The Beverton-Holt curve takes the form:

$$E(R) = \frac{(\alpha S)}{(\beta + S)}$$

where E(R) and S are as above, α is the maximum number of recruits produced (K_R), and β is the number of spawners needed to produce (on average) recruits equal to one-half the maximum number of recruits. Because $K_{sp} = \infty$ in the Beverton-Holt model, we estimated K_{sp} as the number of spawners needed to produce 0.99(K_R).

Like the Beverton-Holt model, the smooth hockey stick model assumes that the number of recruits increases toward an asymptote (carrying capacity; K_R) as the number of spawners increases. After the carrying capacity is reached, the number of recruits neither increases nor decreases. The carrying capacity represents the maximum number of recruits the system can support. This curve

takes the form (Froese 2008):

$$E(R) = R_\infty\left(1 - e^{-\left(\frac{\alpha}{R\infty}\right)S}\right)$$

where E(R) and S are as above, α is the slope at the origin of the spawner-recruitment curve, and R_∞ is the carrying capacity of recruits (note that $R_\infty = K_R$). As with the Beverton-Holt model, we estimated K_{sp} as the number of spawners needed to produce 0.99(K_R).

We used non-linear regression to fit the three models to spawner-recruitment data. Before fitting the models, we transformed recruitment data using natural logs. We estimated bias and uncertainty measures (95% CI) for the model parameters using bootstrap procedures, which assumed that the {R, S} sample represented or approximated the population. The number of bootstrap samples was 3,000. We computed and stored the non-linear regression results for each bootstrap sample. We then calculated the bootstrap 95% CI by arranging the 3,000 bootstrap parameter values in sorted order and selected the 2.5 and 97.5 percentiles from the list.

We used Akaike's Information Criterion for small sample size (AIC_c) to determine which model(s) best explained the relationship between spawners and recruitment in the supplemented and reference populations. AIC_c was estimated as:

$$AIC_c = -2log\left(£(\theta|data)\right) + 2K + \left(\frac{2K(K+1)}{n-K-1}\right)$$

where $log(£(\theta|data))$ is the maximum likelihood estimate, K is the number of estimable parameters (structural parameters plus the residual variance parameter), and n is the sample size (Burnham and Anderson 2002). We used least-squares methods to estimate $log(£(\theta|data))$, which was calculated as $log(\sigma^2)$, where σ^2 = residual sum of squares divided by the sample size ($\sigma^2 = RSS/n$). AIC_c assessed model fit in relation to model complexity (number of parameters). The model with the smallest AIC_c value represented the "best approximating" model within the model set. Remaining models were ranked relative to the best model using AIC_c difference scores (ΔAIC_c), Akaike weights (w_i), and evidence ratios. Models with ΔAIC_c values less than 2 indicated that there is substantial support for these models as being the best-fitting models within the set (Burnham and Anderson 2002). Models with values greater than 2 had less support. Akaike weights are probabilities estimating the strength of the evidence supporting a particular model as being the best model within the model set. Models with small w_i values are less plausible as competing models (Burnham and Anderson 2002). If no single model could be specified as the best model, a "best subset" of competing models was identified using (1) AIC_c differences to indicate the level of empirical support each model had as being the best model, (2) evidence ratios based on Akaike weights to indicate the relative probability that any model is the best model, and (3) coefficients of determination (R^2) assessing the explanatory power of each model.

Stock-Recruitment Analysis

We successfully fit stock-recruitment models to the Chiwawa and reference population data. The span of spawner data for the Chiwawa and reference populations was greater than 14 times the minimum observed spawners, which should provide sufficient contrast for estimation of model parameters. In addition, the span of recruitment data was greater than 12 times the minimum observed recruitment, again providing sufficient contrast for estimation of parameters. The relationship between natural log R/S and spawners indicated that some of the highest productivities occurred at the lower spawner levels and the lowest productivities generally occurred at the highest spawner levels (Figure 15). This is consistent with the assumption of density-dependent mortality.

Although model fits were generally poor, explaining less than 40% of the residual variation in natural-log recruitment data, we were able to estimate average maximum recruitment levels (K_R) and the spawning levels needed to produce maximum recruitment (K_{sp}) (Table 24; Figure 15). For all populations examined, Akaike information criterion was unable to identify a best approximating model (i.e., ΔAIC_c values were less than 2, indicating support for all three models). However, evaluation of 95% CIs and the asymptotic correlation coefficients indicated that the smooth hockey stick model may be the best approximating model for each population. Therefore, we used estimates of K_R and K_{sp} derived from the smooth hockey stick model to correct for density dependence and different carrying capacities in treatment-reference comparisons.

As part of the regression diagnostics, we examined the dependence of the model residuals on time and found a significant ($P < 0.05$), positive, one-year-lag autocorrelation for the Entiat (0.562), Marsh (0.551), Sesech (0.564), and Little Wenatchee (0.629) populations. For the purposes of our work here, we did not attempt to correct for this one-year-lag correlation in the residuals. Future analyses will explore the use of autoregressive models (e.g., AR1; Noakes et al. 1987) to correct for autocorrelation.

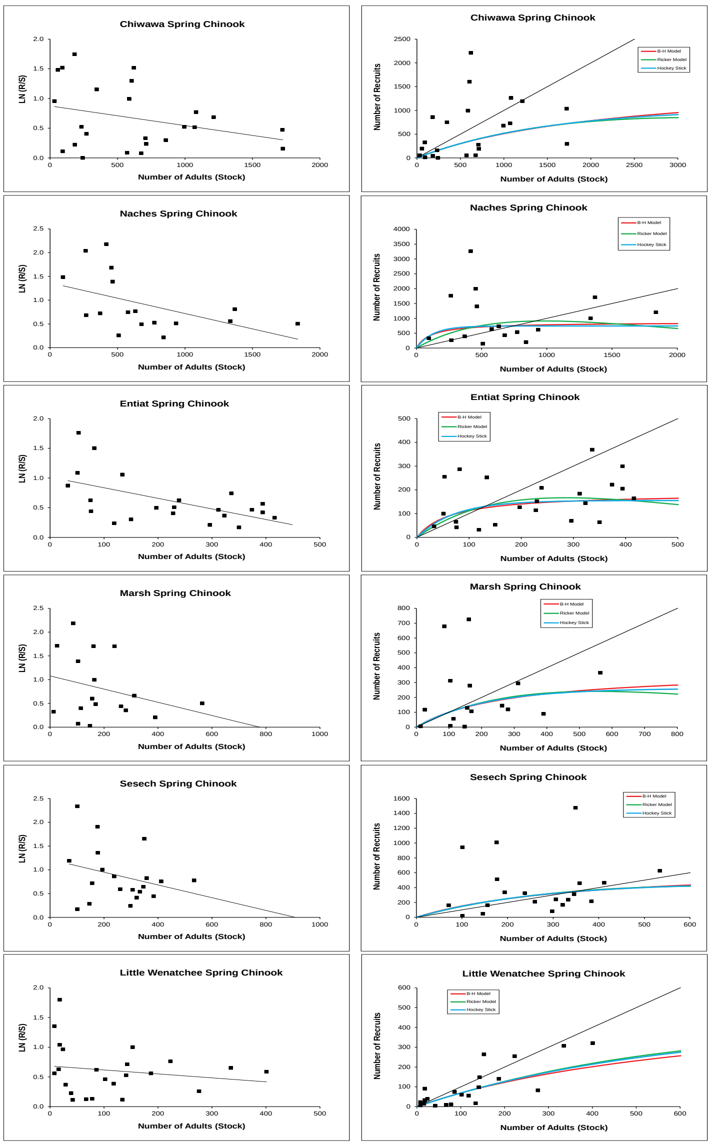

Figure 15. Relationships between natural log recruits/spawner (LN R/S) and spawners (Stock) in the Chiwawa and reference populations (figures on the left) and relationships between numbers of untransformed recruits and spawners in the Chiwawa and reference populations (figures on the right). Figures on the right also show the fit of the Ricker, Beverton-Holt, and the smooth hockey stick models to the data (black straight line represents R=S).

Table 24. Results from fitting Ricker, Beverton-Holt, and smooth hockey stick models to stock-recruitment data from the Chiwawa and reference populations. 95% CI on parameter estimates are based on 3,000 bootstrap trials; Corr coef = asymptotic correlation of the parameter estimates; K_R = maximum natural origin recruits (recruits at carrying capacity); K_{sp} = number of spawners needed to produce K_R; AICc = Akaike's Information Criterion for small sample size; Adj R^2 = coefficient of determination that is adjusted for the number of parameters in the model.

Method 1: Productivity Data Adjusted for Density Dependence

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects based on the smooth hockey stick model) using difference scores indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 25; Figure 16). All tests, regardless of treatment-reference pairs, indicated that productivity did not change significantly during the supplementation period, even though productivity did decrease during the supplementation period (Figure 16). These results are consistent with those based on unadjusted productivity data (Table 17). This is because most abundance estimates were below the level of assumed density dependence.

Table 25. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

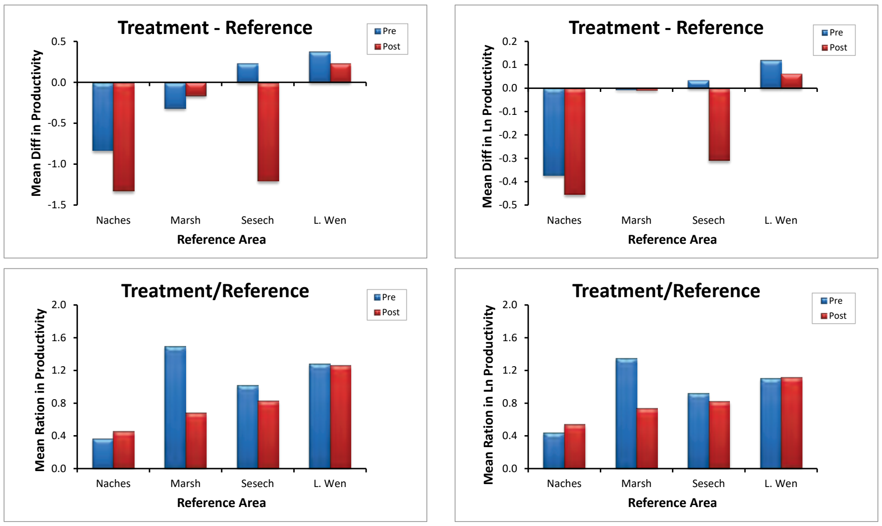

Figure 16. Mean differences (Treatment – Reference; figures on the top) and mean ratios (Treatment/Reference; figures on the bottom) of transformed and untransformed productivity data (adjusted for density dependence) before (pre) and after (post) spring Chinook supplementation in the Chiwawa Basin. Negative effects of supplementation on productivity are indicated when the pre-supplementation (blue) bars are greater than their corresponding post-supplementation (red) bars.

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 26; Figure 16). The Aspin-Welch test and the 95% CIs did indicate a significant effect when comparing the Chiwawa to the Marsh Creek population. These results are consistent with those using unadjusted productivity data (Table 20). Again, this is because most abundance estimates were below the level of assumed density dependence.

Table 26. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean ratios during the supplementation period were less than mean ratios during the pre-supplementation period.

Our analyses assume that there is a spawner abundance (K_{sp}) at which density-independent effects end and density-dependent effects begin. In reality, density-dependent effects occur at low spawning abundance and intensify as spawning abundance increases (evident in the changing slope of the three stock-recruitment curves used in our analyses). We did not account for these increasing density-dependent effects at spawner abundances less than K_{sp}. If we accounted for the increasing effects of density dependence at spawning abundances less than K_{sp}, the analysis with and without productivity adjustments may give different results.

Method 2: Fraction of Carrying Capacity Filled with NORs

We analyzed the effects of supplementation on filling the capacity of the habitat with natural-origin recruits. The smooth hockey stick model derived the carrying capacity (K_R) estimates for the Chiwawa and reference populations. The fraction of the carrying capacity filled with Chinook recruits before and during supplementation for the Chiwawa and reference populations is provided in Table 27. These data indicate that for the Chiwawa population, the mean fraction of the K_R filled with fish decreased significantly from the pre-supplementation period through the supplementation period (Table 27). Likewise, the Entiat and Little Wenatchee populations showed a significant decline in the mean fraction of K_R filled with adult recruits. In contrast, the mean fraction of K_R in the Naches and Marsh Creek populations increased during the same period (Table 27).[21] Interestingly, the fraction of K_R filled with adult recruits for all populations trended downward during the pre-supplementation period (Figure 17). During the supplementation period, however, the fraction of K_R filled with adult recruits trended upward for all populations. These results suggest that agents of mortality outside the Chiwawa and reference populations were reducing recruitment to the populations.

[21] Although we do not show the results here, statistical analysis of the mean fraction of carrying capacity filled by adult recruits using natural-log transformed data produced the same result as using untransformed data. This was true for all populations.

Table 27. Fraction of the carrying capacity that was filled with Chinook salmon adult recruits in the Chiwawa and reference populations before (pre) and during (post) supplementation in Chiwawa Basin. The smooth hockey stick model estimated carrying capacity for each population. Statistical results from comparing the pre and post mean scores using the Aspin-Welch unequal-variance test are provided at the bottom of the table.

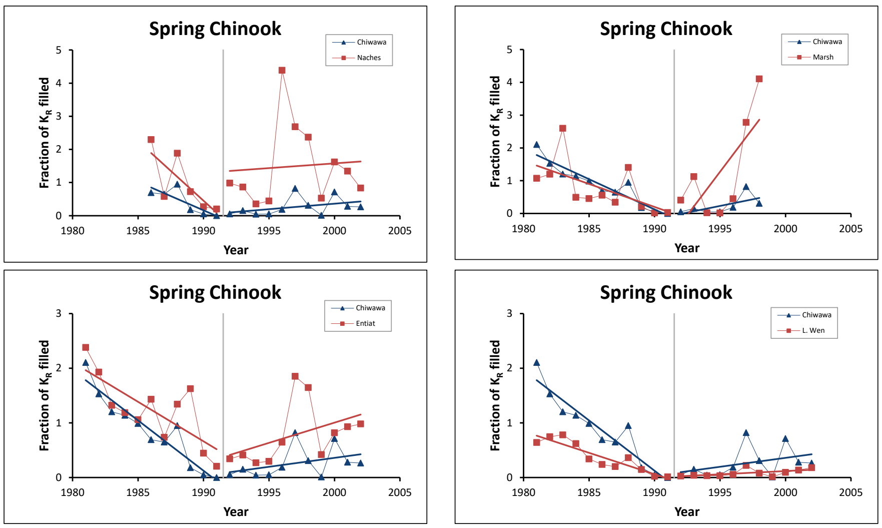

Figure 17. Trends in the fraction of the carrying capacity that was filled with Chinook salmon adult recruits in the Chiwawa and reference populations before (pre) and during (post) supplementation in Chiwawa Basin. The vertical lines in the figures separate the pre- and post-supplementation periods. The smooth hockey stick model estimated carrying capacity for each population.

We then compared the mean difference scores and ratios between the Chiwawa and reference populations before and during supplementation using data representing the fraction of K_R filled with adult recruits. In most of the Chiwawa-reference population comparisons, the absolute value of the mean difference between the fraction of K_R filled with recruits was greater in the supplementation period than during the pre-supplementation period; two of the four pairings were significant (Table 28; Figure 18). Analysis of difference scores using natural-log transformed data indicated that three of the four pairings were significant (Table 28).

Results from analyses using ratios were similar to results using difference scores. Mean ratio scores were generally smaller during the supplementation period than during the pre-supplementation period (Figure 18). This indicated that the mean fraction of K_R filled by adult recruits in most reference populations was greater during the supplementation period than during the pre-supplementation period (i.e., the denominator in the ratio increased between the pre- and post-supplementation periods). In contrast, the fraction of K_R filled by adult recruits in the Chiwawa decreased from the pre- to post-supplementation period (i.e., the numerator in the ratio decreased between the pre- and post-supplementation periods). Thus, unlike the Chiwawa population, the capacity of most reference populations was becoming more saturated during the period when the Chiwawa was being supplemented. Statistical analysis with mean ratios indicated that two of the four pairings were significant (Table 29).

Analyses comparing the Little Wenatchee with the Chiwawa indicate that adult recruits to the Little Wenatchee have been well below its carrying capacity. During the pre-supplementation period, the capacity of the Little Wenatchee was on average 37% saturated with adult recruits. During the supplementation period, the capacity of the Little Wenatchee declined to 8% saturation

with adult recruits (a 22% decline). The Chiwawa, during the pre-supplementation period, was on average 86% saturated. During the supplementation period, percent saturation in the Chiwawa decreased to 26% (a 30% decrease). During the same time periods, the capacity of the Entiat population, which until recently has been supplemented, declined from 124% to 78% saturation (a 63% decline).

Table 28. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on the fraction of the habitat capacity (K_R) that is filled with natural origin recruits. Analyses include both transformed and untransformed data. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

Comparing Stock-Recruitment Curves

As a final set of treatment and reference population comparisons, we compared the stock-recruitment curves of the Chiwawa population (using {R, S} data only from the supplementation period) to the reference populations (using all available {R, S} data). Specifically, we tested whether the regression parameters were equal between the Chiwawa population and the reference populations, and whether the fitted curves coincided between populations. Earlier in this report we described the data, methods, and results of fitting the Ricker, Beverton-Holt, and smooth hockey stick curves to the data. Because AIC_c was unable to identify a best approximating model, here we included all three models in our analyses. We tested the following hypotheses.

Parameter equivalence:

Ho: Stock-recruitment parameters (α and β) of the Chiwawa population = Stock-recruitment parameters of the reference populations.

Ha: Stock-recruitment parameters (α and β) of the Chiwawa population ≠ Stock-recruitment parameters of the reference populations.

Curve equivalence:

Ho: Modeled stock-recruitment curves of the Chiwawa population = Modeled stock-recruitment curves of the reference populations.

Ha: Modeled stock-recruitment curves of the Chiwawa population ≠ Modeled stock-recruitment curves of the reference populations.

We used two-sided randomization tests to test the null hypotheses of equal model parameters and that fitted curves coincided. Because the total number of permutations was in the millions, we used a Monte Carlo approach to randomly select 10,000 permutations. The test statistic for comparing the model parameters was formed by summing the difference between the population parameter estimates for each pair of populations. The test statistic for comparing the whole curve was formed by summing the difference between the estimated predicted values for each pair of populations at 500 equally spaced points along the curve.

Ricker Relationships

Ricker curves differed significantly between the Chiwawa and reference populations (Figure 19; Table 30). Interestingly, however, the parameters in the Ricker model did not differ significantly among most populations (Table 30). Only the β parameter differed significantly between the Chiwawa and Entiat populations.

In the Ricker model, the α parameter represents intrinsic productivity (i.e., recruits per spawner at low spawner densities). In this analysis, there was not enough evidence in the stock-recruitment data to reject the hypothesis of inequality in intrinsic productivity. Thus, this test was unable to demonstrate that supplementation, based on the Ricker curve, affected productivity in the Chiwawa population.

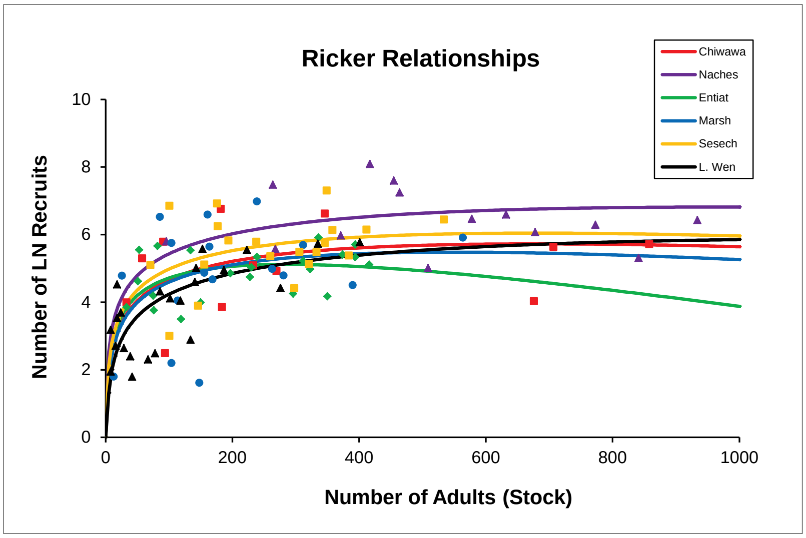

Figure 19. Scatter plot of the number of spawners and natural log adult recruits and fitted Ricker curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

Table 30. Randomization test results comparing the equality of Ricker curves and equality of parameter values (α and β). Randomization tests were based on 10,000 Monte Carlo samples. Equality or curves was based on 500 points along the x-axis (spawner abundance axis).

Curves tested	Curve inequality randomization P-value	Parameter inequality		
		Model Parameter		Randomization P-value
		Chiwawa	Reference	
Chiwawa v. Naches	0.008	α = 1.2247	α = 2.5267	0.236
		β = 0.0015	β = 0.0010	0.600

		β = 0.0015	β = 0.0008	0.203

Beverton-Holt Relationships

Beverton-Holt curves differed significantly only between the Chiwawa and Naches populations (Figure 20; Table 31). There was no significant difference in curves between the Chiwawa and the other reference populations. The parameters in the Beverton-Holt model did not differ significantly among any of the populations (Table 31). This was true even for the Chiwawa and Naches populations.

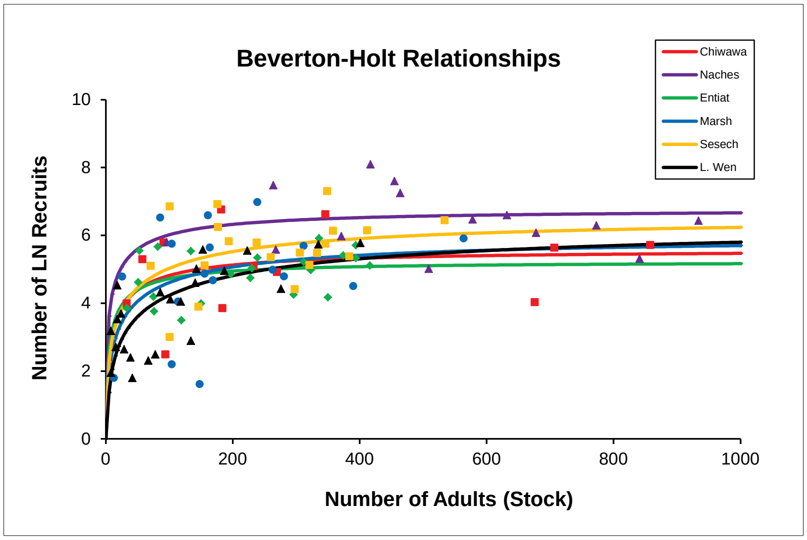

Figure 20. Scatter plot of the number of spawners and natural log adult recruits and fitted Beverton-Holt curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

Table 31. Randomization test results comparing the equality of Beverton-Holt curves and equality of parameter values (α and β). Randomization tests were based on 10,000 Monte Carlo samples. Equality or curves was based on 500 points along the x-axis (spawner abundance axis).

		β = 113.79	β = 351.59	0.869
Chiwawa v. L. Wenatchee	0.654	α = 264.25	α = 568.69	0.864
		β = 113.79	β = 725.87	0.751

Smooth Hockey Stick Relationships

Smooth hockey stick curves differed significantly between the Chiwawa and Naches populations and the Chiwawa and Sesech populations (Figure 21; Table 32). There was no significant difference in curves between the Chiwawa and the other reference populations. Most of the parameters in the smooth hockey stick model did not differ significantly among the populations (Table 32). However, the productivity parameter β did differ significantly between the Chiwawa and the Naches and the Chiwawa and Little Wenatchee populations. The β parameter for the Naches was significantly greater than the Chiwawa, while the β parameter for the Little Wenatchee was significantly less than the Chiwawa.

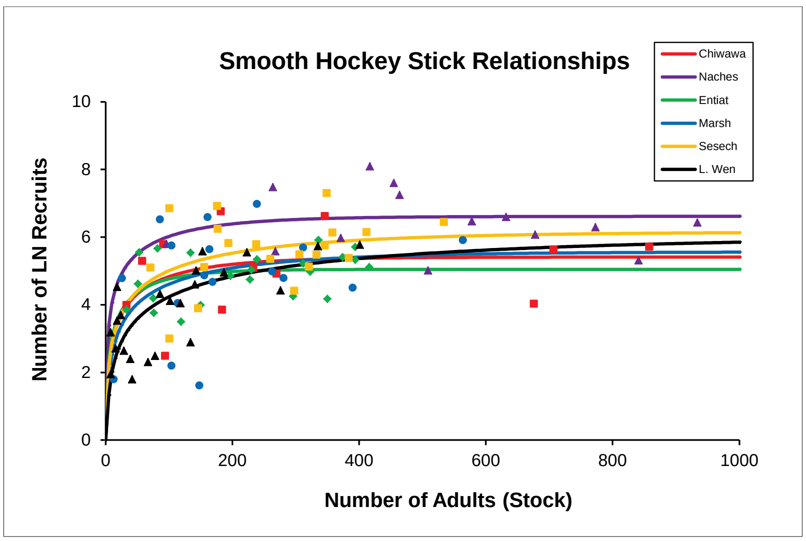

Figure 21. Scatter plot of the number of spawners and natural log adult recruits and fitted smooth hockey stick curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

Table 32. Randomization test results comparing the equality of smooth hockey stick curves and equality of parameter values (α and β). Randomization tests were based on 10,000 Monte Carlo samples. Equality or curves was based on 500 points along the x-axis (spawner abundance axis).

Curves tested	Curve inequality randomization P-value	Parameter inequality		
		Model Parameter		Randomization P-value
		Chiwawa	Reference	
Chiwawa v. Naches	0.000	α = 5.41	α = 6.61	0.000
		β = 1.84	β = 5.99	0.000
Chiwawa v. Entiat	0.999	α = 5.41	α = 5.05	0.999
		β = 1.84	β = 2.17	0.999
Chiwawa v. Marsh	0.999	α = 5.41	α = 5.56	0.999
		β = 1.84	β = 1.27	0.999
Chiwawa v. Sesech	0.000	α = 5.41	α = 6.15	0.000
		β = 1.84	β = 1.80	0.999
Chiwawa v. L. Wenatchee	0.990	α = 5.41	α = 6.02	0.999
		β = 1.84	β = 0.75	0.000

Comparing different stock-recruitment curves and their parameters did not provide strong evidence that the supplementation program has negatively affected the productivity of the Chiwawa population.

Analysis without Reference Populations

In some cases, suitable reference populations may not exist to compare with supplemented populations. It is therefore important to have alternative analyses to assess supplementation effects. In this section, we describe methods that can be used to assess supplementation effects when suitable reference populations are not available. We discuss before-after comparisons, correlation analysis, and comparisons to standards as alternatives when reference populations are unavailable.

Before-After Comparisons
