Before-after analyses compare population metrics (spawner abundance, NORs, and productivity) before supplementation to those during supplementation. In this case, data collected before supplementation represent the reference condition. The assumption is that population trajectories measured during the pre-supplementation period would continue in the absence of supplementation. We compared trends in abundance and productivity, mean abundance and productivity, and stock-recruitment relationships before and after supplementation.

Trend Analysis

Comparing trends before and after supplementation can be used to assess the effects of supplementation. Here, we compared the slopes of trends of spawner abundance, NORs, and productivity before and during supplementation using t-tests. If the hatchery program is successfully supplementing the natural spring Chinook population, the trend for spawner abundance and NORs during supplementation should be greater than the slope during the pre-supplementation period. For productivity, the slope during the supplementation period should increase or remain the same as that during the pre-supplementation period.

Visual examination of trends of Chiwawa data indicates that spawner abundance, NORs, and productivity decreased during the pre-supplementation period, but increased during the supplementation period (Figure 22). Only the changes in NOR trends were significant (Figure 22). This was true for both transformed and untransformed data.

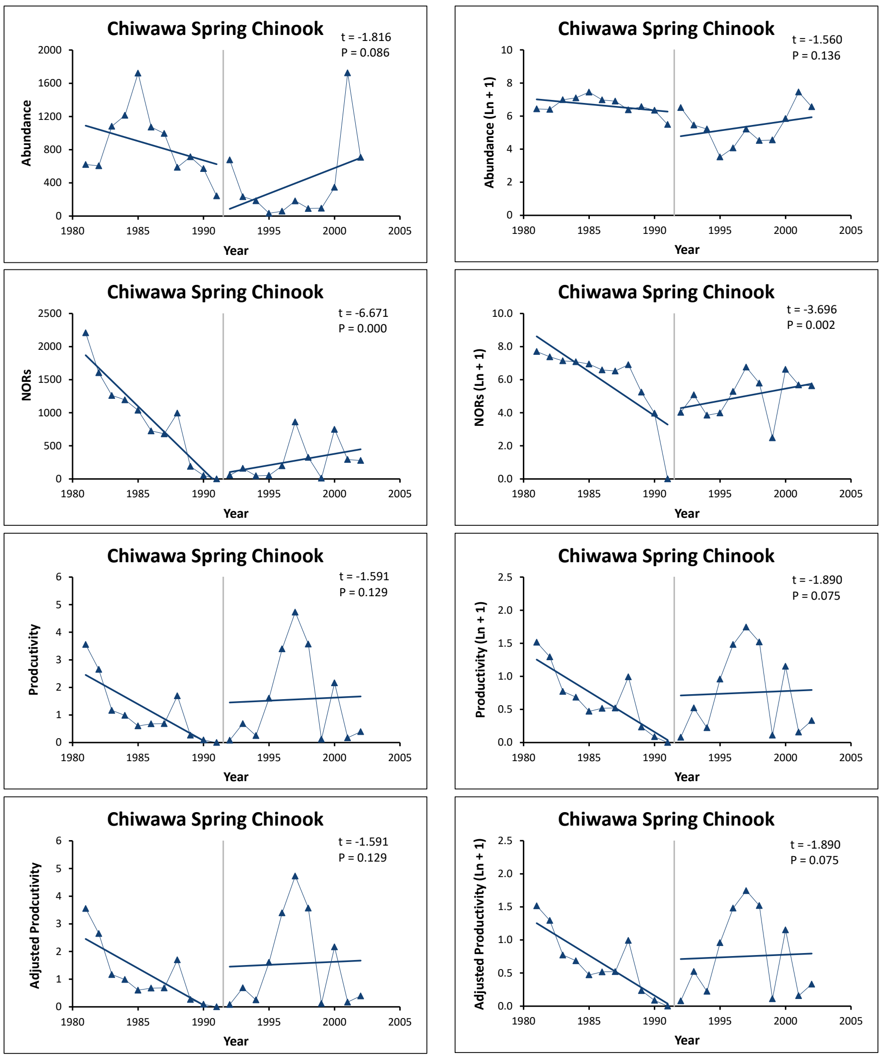

Figure 22. Trends in Chiwawa spring Chinook spawner abundance, natural-origin recruits (NORs), productivity (adults recruits per spawner), and adjusted productivity (adjusted for density dependence) before and during supplementation. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left show untransformed data; figures on the right include natural-log transformed data. Figures include results of t-tests comparing slope of trends before and during supplementation.

Analysis of Mean Scores

We also compared mean spawner abundance, NORs, and productivity data before and after supplementation. If the hatchery program is successfully supplementing the natural spring Chinook population, mean spawner abundance and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean productivity during the supplementation period should be equal to or higher than the pre-supplementation period. We tested the following statistical hypotheses.

Spawner Abundance and NORs:

Ho: Mean spawner abundance and NORs before supplementation ≥ Mean spawner abundance and NORs during supplementation.

Ha: Mean spawner abundance and NORs before supplementation < Mean spawner abundance and NORs during supplementation.

Productivity (Recruits/Spawner):

Ho: Mean productivity before supplementation ≤ Mean productivity during supplementation.

Ha: Mean productivity before supplementation > Mean productivity during supplementation.

We tested before-after supplementation effects using a one-tailed Aspin-Welch unequal-variance test. We also used a randomization test, based on 10,000 Monte Carlo simulations, to assess differences in spawner abundance and productivity before and during supplementation. The randomization procedure only allowed the testing of two-tailed hypotheses. Therefore, we generated 95% confidence intervals on the mean difference (μ_{pre} - μ_{post}) using bootstrapping methods to determine if the significant result from the randomization test was in the right direction. We generated 5,000 bootstrap samples to calculate confidence intervals.

Mean spawner abundance during the supplementation period was significantly less than the pre-supplementation spawner abundance (Table 33). Mean spawner abundance decreased 46% between the pre- and post-supplementation periods. Likewise, mean NORs decreased significantly between the two periods (Table 33). On the other hand, productivity increased slightly, but not significantly, between the pre- and post-supplementation periods (Table 33). This was true for both adjusted and transformed productivity data.

Table 33. Statistical results comparing mean scores of spawner abundance, natural-origin recruits (NORs), and productivity (using both untransformed and natural-log transformed) before and during supplementation of Chiwawa spring Chinook. Randomization tests were based on 10,000 Monte Carlo samples and 95% CI were based on 5,000 bootstrap samples.

Population metric	Mean scores		Test on means			
			Aspin-Welch test		Random test P-value	Bootstrap 95% CI
	Before	During	t-value	P-value		
Abundance	856	393	2.383	0.986	0.028	112 - 843
LN Abundance	6.6	5.4	3.304	0.997	0.004	0.56 – 1.99
NORs	905	275	2.846	0.993	0.009	214 – 1034
LN NORs	6.0	5.0	1.197	0.876	0.250	-0.40 – 2.54
Productivity	1.13	1.56	-0.721	0.759	0.479	-1.55 – 0.73
LN Productivity	0.64	0.75	-0.450	0.671	0.649	-0.55 – 0.35
Adj Productivity	1.12	1.56	-0.721	0.759	0.477	-1.54 – 0.71
LN Adj Productivity	0.64	0.75	-0.450	0.671	0.652	-0.57 – 0.34

Analysis of Stock-Recruitment Curves

The third method compared stock-recruitment curves of the Chiwawa population during supplementation with those generated before supplementation. Specifically, we tested whether the regression parameters were equal between the pre- and post-supplementation periods, and whether the fitted curves coincided between the two time periods. We used the methods described earlier to fit the Ricker, Beverton-Holt, and smooth hockey stick curves to the two data sets. We tested the following hypotheses.

Parameter equivalence:

Ho: Stock-recruitment parameters (α and β) of the pre-supplementation period = Stock-recruitment parameters of the supplementation period.

Ha: Stock-recruitment parameters (α and β) of the pre-supplementation period ≠ Stock-recruitment parameters of the supplementation period.

Curve equivalence:

Ho: Modeled stock-recruitment curves from the pre-supplementation period = Modeled stock-recruitment curves from the pre-supplementation period.

Ha: Modeled stock-recruitment curves from the pre-supplementation period ≠ Modeled stock-recruitment curves from the pre-supplementation period.

We were only able to fit stock-recruitment curves to the post-supplementation data. Non-linear regression was unable to converge on a solution using only pre-supplementation data. Therefore, we were unable to use this method to test supplementation effects on the Chiwawa spring Chinook population. If we could have fit curves to both the pre- and post-supplementation periods, we would have used two-sided randomization tests to evaluate the null hypotheses of equal model parameters and that fitted curves coincided.

Before describing correlation approaches, it is important to note that comparing before-after data can sometimes be misleading. For example, the spawner abundance, NORs, and productivity data presented in Figure 22 suggest that supplementation is increasing the abundance and productivity of spring Chinook in the Chiwawa Basin. However, when we compared these trends to those from reference populations during the same time periods (Figures 9-11), it becomes clear that supplementation was not responsible for increasing the trends in spawner abundance, NORs, and productivity of the Chiwawa population. Thus, whenever possible, it is wise to compare before-after data with a reference population.

Correlation Analyses

A simple way to see if the supplementation program is increasing or decreasing productivity is to assess the association between the proportion of adult spawners that are made up of hatchery adults (pHOS) and productivity (recruits/spawner). If the supplementation program is working as planned, the increase in hatchery fish spawning naturally should increase the productivity of the population. It should not decrease the productivity of the population.

We tested the association between pHOS and adult productivity[22] using Pearson correlation. During the pre-supplementation period, productivity averaged 1.13 recruits/spawner; during the supplementation period, productivity averaged 1.39 recruits/spawner. This increase in productivity did not appear to be strongly correlated to pHOS (Figure 23). Correlation analysis showed that there was no significant association between pHOS and productivity, even though productivity increased with increasing pHOS.

22 Note that the analysis could also include juvenile productivity (e.g., smolts/spawner).

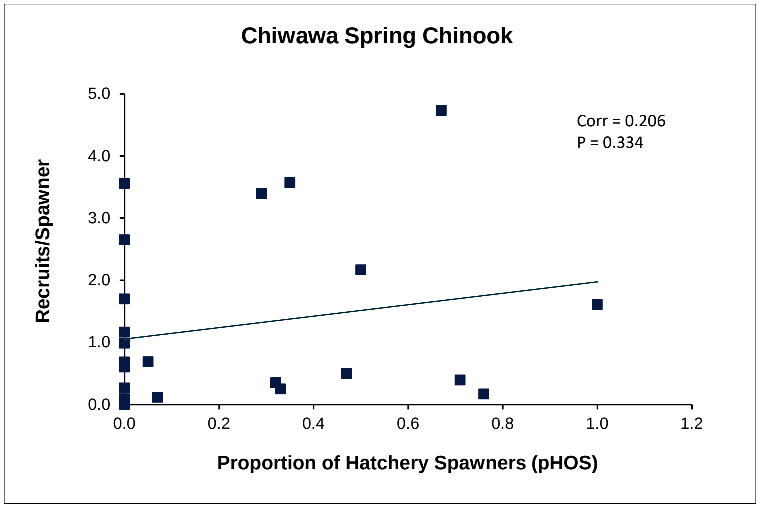

Figure 23. Association between the proportion of spawners that are made up of hatchery adults (pHOS) and the number of natural-origin recruits. The Pearson correlation coefficient (Corr) and its P-value (P) are shown in the figure.

The association between pHOS and productivity can also be assessed by testing the correlation between pHOS and the residuals from stock-recruitment curves fitted to the Chiwawa spawner and natural-origin recruitment data. This approach removes the effects of density dependence on the relationship between pHOS and productivity. A significant negative association provides evidence that hatchery-origin spawners may not be as productive as natural-origin spawners.

The Ricker, Beverton-Holt, and smooth hockey stick models were fit to the Chiwawa stock and recruitment data (including {S, R} data from both the pre- and post-supplementation period, 1981-2004) using methods described earlier. Residuals were calculated by subtracting the predicted recruitment values from the observed (modeled) values. Pearson correlation then tested the association between pHOS and the residuals from each model.

Although there was a negative trend in residuals with increasing pHOS, suggesting that hatchery-origin spawners may not be as productive as natural-origin spawners, the association was not significant (Figure 24). Thus, based on these analyses, there is no strong evidence that the supplementation program has significantly benefited or harmed the natural spring Chinook population.

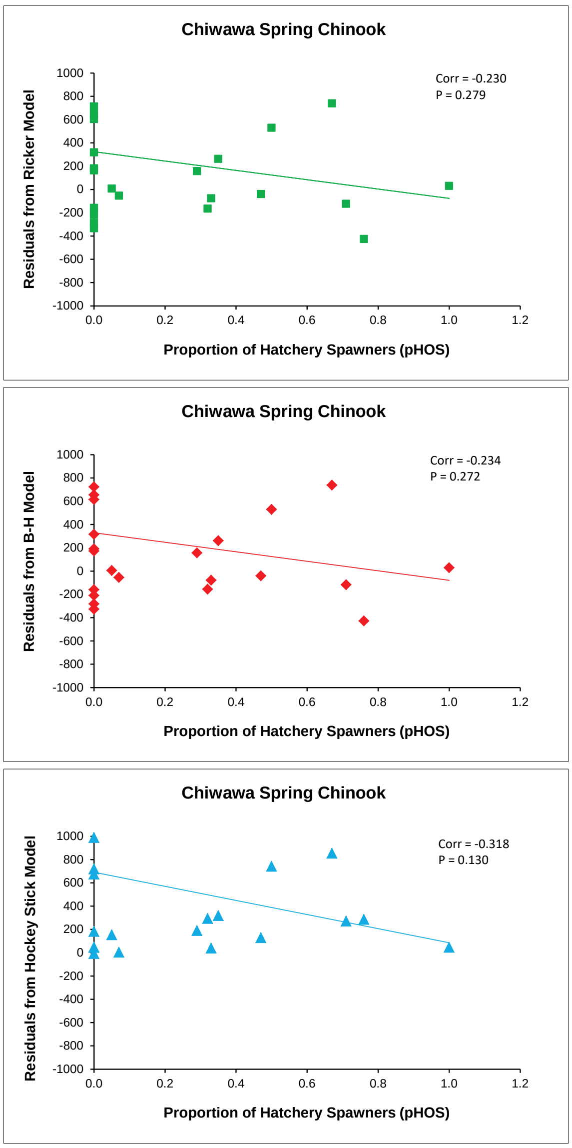

Figure 24. Association between the proportion of spawners that are made up of hatchery adults (pHOS) and the residuals from Ricker, Beverton-Holt (B-H), and smooth hockey stick stock-recruitment models. The Pearson correlation coefficient (Corr) and its P-value (P) are shown in the figures.

Comparison to Standards

In those cases in which suitable reference populations are not available and there are no pre-supplementation data, the investigator is left with comparing population parameters to relevant standards. Standards can include performance of natural-origin fish in similar environments (a type of reference condition), mitigation requirements, quantitative objectives of the program, Biological Assessment and Management Plan (BAMP) values, or other appropriate standards. An example of a statistical hypothesis would be:

Ho: Productivity (Recruits/Spawner) of the supplemented population $\geq$ standard productivity.

Ha: Productivity (Recruits/Spawner) of the supplemented population $<$ standard productivity.

For these analyses to be useful, the standards must be based on biological reality.

Conclusions and Recommendations

Hatcheries are an important component of fish production within the Upper Columbia Basin. The goal of some of these programs is to supplement natural production in declining populations. The supplementation programs generally use both hatchery and natural (spawned and reared in nature from either wild or hatchery parents) adults for hatchery broodstock. These programs are designed to supplement natural populations by increasing natural reproduction while preventing the establishment of a domesticated hatchery stock. Thus, the programs should increase total spawning escapement and NORs, and not reduce the productivity of the natural population. Measuring the success of these programs is challenging and expensive.

In this paper, we described methods that can be used to determine if supplementation programs are achieving some of their goals. This paper focused on the use of reference populations to determine if the supplementation programs increase total spawning escapement, NORs, and maintain or increase productivities. In some cases, suitable reference populations may not be available (e.g., we found no suitable reference populations for Upper Columbia steelhead and sockeye). In these cases, alternative methods are needed to assess supplementation effects. We also described these alternative methods in this paper.

Identification of Reference Populations

Finding suitable reference populations that match well with supplemented populations is a difficult and time-consuming process. Our three-step selection process included identification of populations with similar life-history characteristics, few or no hatchery spawners, a long time series of accurate abundance and productivity estimates, and similar freshwater habitat impairments and out-of-basin effects. Those populations that met these criteria were then examined for their relationship with the supplemented population (in this case, the Chiwawa spring Chinook population). Several criteria were scored, including pNOS, correlation, trend, and effect size. Reference populations with total weighed scores of 81 or greater were selected as suitable reference populations.

This selection process provided a valuable framework for selecting suitable reference populations for supplemented populations. Interestingly, we found that a given reference population may match well with one parameter of the supplemented population (e.g., spawning escapement), but not for all parameters (e.g., not NORs or productivity). The reason for this may be related to errors

in the estimation of population parameters and/or differential factors limiting population parameters of supplemented and reference populations. Therefore, depending on the parameter analyzed, a different suite of reference populations may be needed.

An important assumption in the use of reference populations is that the supplemented and reference populations that tracked each other before supplementation would continue to track each other in the absence of supplementation. Given that the reference populations did not match the Chiwawa population on all criteria examined, and some reference populations tracked the Chiwawa population more poorly than others, there may be some uncertainty as to whether differences observed between the supplemented and reference populations during the supplementation period are associated with the hatchery program, or other unaccounted factors. For example, any large-scale change (man-made or natural) within the reference or supplemented population could affect our ability to assess the effectiveness of the supplementation program.

To account for some of these uncontrollable factors, we recommend the use of a "causal-comparative" approach to strengthen the certainty of our inferences. This approach relies on correlative data to try and make a case for causal inference. We recommend that the following state variables be measured and tracked within the supplemented and reference populations: mean annual precipitation, total and riparian forest cover, road density, impervious surface, and alluvium. These variables can be used to describe differences in water temperatures at different life stages (pre-spawning, egg incubation, and summer rearing) and substrate characteristics, including fine sediments and embeddedness. These state variables can be used to help explain possible changes in spawner abundance, NORs, and productivity that are independent of supplementation. In addition, the use of multiple reference streams reduces the possibility that man-made changes to a single reference stream will influence the interpretation of the results.

Analyses with Reference Populations

Using reference populations, we evaluated the effects of supplementation on natural-log transformed and untransformed total spawning escapement, NORs, and productivity by comparing trends, analyzing mean differences, ratios, and rates, and comparing stock-recruitment curves and their parameters. For trend analysis, we compared the slopes of the trends between each supplemented/reference pair before and during supplementation. If the hatchery program is successfully supplementing the natural population, trends in spawner abundance and NORs should deviate significantly during the supplementation period (i.e., the slope of the supplemented population should be greater than the slopes of the reference populations during the supplementation period), but not during the pre-supplementation period. For productivity, the slope of the supplemented population, relative to the reference population, should increase or remain the same.

Because trend analysis only tests the slopes of the trend lines, it does not test for differences in elevations of the trend lines, additional analyses were needed to determine if supplementation increased spawner abundance, NORs, and productivity of the target population without changing the slopes of the trend lines. To do this, we derived three different response variables using natural-log transformed and untransformed spawner abundance, NORs, and productivity data. The first derived variable included difference scores, which were calculated as the difference between paired treatment and reference data (T-R). The second included ratios, which were calculated as the ratio of paired treatment and reference data (T/R). Finally, we calculated the differences in annual changes in paired treatment and reference population data (ΔT-ΔR). If the hatchery

program is successfully supplementing the natural population, the mean difference or ratio score of paired spawner abundance data and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean difference or ratio score during the supplementation period should be equal to or higher than the pre-supplementation period.

As a final set of analyses, we compared the stock-recruitment curves of the supplemented population (using stock and recruitment data only from the supplementation period) to the reference populations (using all available stock and recruitment data). Specifically, we tested whether the regression parameters were equal between the supplemented population and the reference populations, and whether the fitted curves coincided between populations. Here, we were most interested in comparing the productivity parameters in the models.

Surprisingly, these different analyses yielded similar results when they were applied to the Chiwawa spring Chinook and reference population data. Trend analysis was unable to detect a significant difference in trends between the supplemented and reference populations during the supplementation period. Even though we measured an increasing trend in spawner abundance, NORs, and productivity in the supplemented population during the supplementation period, these same parameters trended upward in the reference populations. Likewise, we were unable to detect a significant supplementation effect using difference scores, ratios, and differences in annual changes. However, we found the results from analysis of mean differences of annual change difficult to interpret and they may be insensitive to treatment effects. A simpler analysis, which is also easier to interpret, is to use trend analysis. Finally, comparing stock-recruitment curves and their parameters did not provide strong evidence that supplementation has affected the productivity of the natural population.

Based on these results, we do not recommend using difference scores of annual change (ΔT-ΔR), nor do we recommend comparing stock-recruitment curves and their parameters. As noted above, difference scores of annual change are difficult to interpret and may be redundant with trend analysis. Testing stock-recruitment curves and their parameters appears redundant with testing differences in productivity using difference scores or ratios. In addition, the analyses are computer intensive and do not appear to be very sensitive to changes.

There was little difference in results using difference scores and ratios. It appears that ratios may be more sensitive to change than difference scores (e.g., we found significant differences in some comparisons using ratios but not with difference scores), but ratios can be more difficult to interpret than difference scores. Nevertheless, we recommend the use of ratios in future analyses.

Correcting for Density Dependence and Carrying Capacity

The analyses described so far assumed that the density of spawners or recruits did not affect the survival and productivity of fish. However, without controlling for density effects, productivity of the population would continue to decline with increasing abundance. This scenario could occur in supplementation programs that increase the number of spawners, and could result in lower productivities relative to reference populations. In addition, lower productivities may be caused by differential environmental carrying capacities rather than the capacity of the supplemented fish to produce offspring. Therefore, we described two different methods for deriving density-corrected estimates of productivity. The first controlled the effects of density on productivity by partitioning observed productivities into density-independent and density-dependent productivity. These productivities were then combined in a single test. The second method corrected for differences in carrying capacities between the supplemented and reference populations. This was accomplished

by calculating the percent saturation of NORs, which was estimated as the ratio of observed NORs to the maximum number of NORs that the habitat could support.

We fit Ricker, Beverton-Holt, and smooth hockey stick models to stock and recruitment data to estimate the maximum number of NORs (NORs at carrying capacity) and the maximum number of spawners needed to produce maximum NORs. We fit models to the supplemented and reference populations. Using information-theoretic criterion and evaluating the precision of estimated parameters, we found that the smooth hockey stick model provided the best estimates of maximum NORs and spawners. We used these modeled values to estimate density-independent and density-dependent productivities, and saturation of NORs.

Statistical analyses, using difference scores and ratios of adjusted Chiwawa spring Chinook productivity data, found no significant effects of supplementation on the productivity of the supplemented population. Indeed, the results from correcting for density dependence were similar to those without correcting for density dependence. This is in part because the abundance of the supplemented and reference populations has been below their respective carrying capacities in most years. This was clearly demonstrated in the analyses of NORs corrected for carrying capacity. In the supplemented population, the mean fraction of the carrying capacity filled with NORs decreased significantly during the supplementation period. In other words, the carrying capacity was filled with more NORs during the pre-supplementation period than during the supplementation period, which is contrary to the goal of supplementation. By comparison, two of the reference populations showed a similar decrease in saturation, while the other two reference populations actually increased in saturation. Analyzing the saturation scores using BACI-design analyses indicated that two of the four pairings differed significantly. That is, the percent saturation of the supplemented population decreased significantly relative to two reference populations.

Because productivity can be affected by the abundance of spawners and recruits, we recommend that future analyses comparing supplemented and reference populations adjust for density-dependent effects and differential carrying capacities. Although we detected only slight differences between adjusted and unadjusted results, as supplemented stocks recover, it will become more important to adjust productivities to account for density dependence. Importantly, the analyses using percent saturation placed NORs in the context of the carrying capacity of the environment. This will help managers determine if supplementation programs are filling or over-filling the capacity of the habitat with NORs.

As we noted earlier, analyses using productivities adjusted for density dependence assume that there is a spawner abundance at which density-independent effects end and density-dependent effects begin. In reality, density-dependent effects occur at low spawning abundance and intensify as spawning abundance increases. We did not account for these increasing density-dependent effects at lower spawner abundances. This is an area that needs additional attention.

Analyses without Reference Populations

Because of the rigorous criteria we used to select reference populations, it is likely that reference populations may not exist for making comparisons with supplemented populations. For example, we used the criteria described in this paper to identify reference populations for supplemented steelhead and sockeye populations in the Upper Columbia Basin. We were unsuccessful in identifying any suitable reference populations. Therefore, in the absence of suitable reference populations, it is important to have alternative methods for assessing supplementation effects. We described three different types of analyses one can use to assess supplementation effects in the

absence of reference populations. They include before-after comparisons, correlation analysis, and comparisons to standards.

Before-after analyses compare population metrics before supplementation with those during supplementation. In this case, data collected before supplementation represent the reference condition. The assumption is that population trajectories measured during the pre-supplementation period would continue in the absence of supplementation. We compared trends in spawner abundance, NORs, and productivity before and after supplementation. In addition, we compared mean scores in these three parameters before and after supplementation. Finally, we attempted to compare stock-recruitment parameters before and after supplementation. The hypotheses examined were that the spawner abundance and NORs would be greater during the supplementation period, and that productivities would not decline during the supplementation period.

Trend analysis indicated that the all three Chiwawa spring Chinook population parameters trended downward during the pre-supplementation period, but trended upward during supplementation. On the other hand, mean spawner abundance and NORs were lower during the supplementation period than during the pre-supplementation period. Mean productivities increased, but not significantly, during the supplementation period. We were unable to compare pre- and post-supplementation stock-recruitment curves because we were unable to fit stock-recruitment models to the pre-supplementation data.

We used correlation analyses to determine if the proportion of hatchery-origin fish that spawn naturally on the spawning grounds (pHOS) increased productivity. In addition, we used correlation to assess the association between pHOS and the residuals from stock-recruitment relationships. A significant negative association provides evidence that hatchery-origin spawners may not be as productive as natural-origin spawners. The analysis indicated that the productivity of Chiwawa spring Chinook increased with increasing pHOS, but the association was not significant. In contrast, there was a negative association between pHOS and the stock-recruitment residuals, but again the association was not significant. The latter analysis accounts for density-dependent effects.

In concert, the before-after comparisons and correlation analyses do not provide conclusive evidence that the supplementation program has increased spawner abundance and NORs, or that it has significantly reduced the productivity of the supplemented population. Although increasing the number of hatchery fish on the spawning grounds appears to reduce NORs and productivity, mean productivity actually increased during the supplementation period compared to the pre-supplementation period.

It is important to note that relying on only one set of analysis could result in drawing a wrong conclusion. For example, if we had only conducted trend analysis, we may have concluded wrongly that the Chiwawa spring Chinook supplementation program significantly increased spawner abundance, NORs, and productivity in the supplemented population. The analysis of mean scores and correlations indicates that the supplementation program has not increased spawner abundance or NORs in the supplemented population. Therefore, in the absence of suitable reference populations, we recommend that analyses include the evaluation of trends, means scores, and correlations. By conducting more than one set of analyses, one can use weight-of-evidence to assess the effects of supplementation programs.

Under the scenario that there are no reference populations or pre-supplementation data, one is left with comparing population parameters to relevant standards. These standards could come from mitigation requirements, quantitative objectives, or published or unpublished standards. One could also use correlation to evaluate the association between productivity and pHOS, but this requires a wide range in pHOS values to be most effective. A more extreme approach, which probably would not gain much traction with managers, is to shutoff the supplementation program for some time and then evaluate the effects of the program in a before-after design. The Entiat spring Chinook hatchery program provides a unique opportunity to evaluate this type of management decision.

Some Concerns and Limitations

No matter how hard we try to explain different sources of variation in population data, we are limited by the quality of the data. Teasing out the effects of supplementation requires long time series of population data. Because funding levels and methods change over time, the quality (i.e., accuracy and precision) of the data also changes over time. Importantly, the population parameters examined in this paper (spawner abundance, NORs, and productivity) are rarely measured directly in the field. That is, other population metrics, such as numbers of redds, number of fish counted at weirs or dams, scales, tags, etc., are sampled in the field. These metrics are then used to calculate spawner abundance[23], NORs, and productivity, often based on assumptions about fish/redd, pre-spawning loss, marking rates, and sampling rates. This has a tendency to increase the variability in the data independent of supplementation programs. In our studies, we can only control sampling within the supplemented populations, and even that is limited by available funding. We have no control over the sampling within reference populations. Thus, we have to assume that sampling within the reference populations will continue and that sampling effort will remain comparable to that in the supplemented populations.

In our analyses, we included both the Entiat and Little Wenatchee populations as references for the Chiwawa population. In the analyses, we treated them as equivalent to the other reference populations. That is, the statistical procedures used to compare the supplemented population to each reference population were identical. This is appropriate. However, the interpretation of the results must be different when comparing the Entiat and Little Wenatchee to the supplemented population, because they are populations that were influenced by hatchery fish. As noted earlier, the Entiat spring Chinook hatchery program has been discontinued. Therefore, it provides a unique type of reference where the comparison changes from both populations being supplemented to only one population being supplemented. For the Little Wenatchee, nearly all the strays came from the Chiwawa program. Straying should stop or be greatly reduced with the change in water supply to the Chiwawa Rearing Ponds. In sum, one must be careful in how they interpret these test-reference results.

Finally, it is important to point out that for this paper, we conducted 463 statistical tests. Because we set our Type I error rate at 0.05, by random chance alone, we may have incorrectly rejected about 23 null hypotheses. Inasmuch as this work was designed to evaluate different ways to analyze test-reference data, the number of future analyses will be greatly reduced based on the results from this work. However, if the Type I error rate is a concern to managers, researchers can

---

23 The smooth hockey stick model, which we used to estimate density-dependent correction factors for productivity and NORs, is sensitive to errors in spawner escapement estimates. Therefore, it is important to use accurate and precise estimates of spawner escapement.

use a lower error rate, such as α = 0.01. Another option is to analyze test-reference data graphically. Although this is subjective, there are no statistical analyses and therefore no concerns with violating assumptions of statistical tests, including temporal correlation. We believe researchers should use the statistical procedures recommended in this report to support graphic analysis.

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Hatchery Committees

Date: October 19, 2017

From: Tracy Hillman, HCP Hatchery Committees Chairman

cc: Sarah Montgomery, Anchor QEA, LLC

Re: Final Minutes of the September 20, 2017 HCP Hatchery Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Hatchery Committees meeting was held at the Grant PUD office in Wenatchee, Washington, on Wednesday, September 20, 2017, from 9:00 a.m. to 12:00 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A). *(Note: this item is ongoing.)*
- Mike Tonseth will coordinate with Todd Seamons (WDFW) to produce an outline or recommended approach for genetic monitoring (Item I-A). *(Note: this item is ongoing.)*
- Tracy Hillman will distribute the Upper Columbia Salmon Recovery Board's (UCSRB) discussion draft Hatchery Report to the Hatchery Committees when he receives it (Item I-A). *(Note: Hillman sent the report to Montgomery, who distributed it to the Hatchery Committees on October 13, 2017.)*
- Tracy Hillman will invite Greer Meier (UCSRB) to an upcoming Hatchery Committees meeting to discuss the Hatchery Report (Item I-A). *(Note: Meier plans to attend the November 15, 2017 Hatchery Committees meeting.)*
- Kirk Truscott will discuss internally and coordinate with Keely Murdoch on potential edits to Chelan PUD's *Draft Statement of Agreement Regarding the District's Coho Obligation* (Item II-A).
- Tom Kahler will send Douglas PUD's Transition Plan Outline to Sarah Montgomery for distribution to the Hatchery Committees (Item III-A). *(Note: Montgomery distributed the outline following the meeting on September 20, 2017.)*
- Douglas PUD will provide their Transition Plan to the Hatchery Committees for review (Item III-A). *(Note: Tom Kahler sent the plan to Montgomery, which she forwarded to the Hatchery Committees on October 16, 2017.)*

- Hatchery Committees representatives will review the revised monitoring and evaluation (M&E) Plan for PUD Hatchery Programs and discuss it during the October 18, 2017 Hatchery Committees meeting (Item IV-D). *(Note: Montgomery distributed the latest version of the plan on October 10, 2017.)*
- Tracy Hillman will invite Barry Berejikian (Northwest Fisheries Science Center) to the October 18, 2017 Hatchery Committees meeting to discuss steelhead in the Twisp River (Item V-A). *(Note: Berejikian plans to attend the October 18, 2017 meeting.)*

Decision Summary

- There were no decisions approved during today's meeting.

Agreements

- There were no agreements discussed during today's meeting.

Review Items

- Sarah Montgomery sent an email to the Rocky Reach and Rock Island Hatchery Committees on August 15, 2017, notifying them that the Chelan PUD *Draft Statement of Agreement Regarding the District's Coho Obligation* is available for a 30-day review, with comments due to Catherine Willard by September 14, 2017. Chelan PUD indicated they will request approval of the Statement of Agreement (SOA) at the Hatchery Committees September 20, 2017 meeting. *(Note: this item will be discussed at the November 15, 2017 Hatchery Committees meeting.)*
- Sarah Montgomery sent an email to the Hatchery Committees on September 1, 2017, notifying them that the Draft 2016 Douglas PUD and Grant PUD M&E Annual Report is available for a 60-day review, with edits and comments due to Greg Mackey by October 31, 2017. *(Note: Douglas PUD requested comments in 30 days if possible, which would be October 2, 2017.)*
- Sarah Montgomery sent an email to the Hatchery Committees on October 16, 2017 notifying them that the draft plan, Implementation of Comprehensive Monitoring and Evaluation of Wells Hatchery Complex Programs in 2018, is available for review with edits and comments due to Greg Mackey by December 1, 2017.

Finalized Documents

- Sarah Montgomery sent an email to the Hatchery Committees on September 15, 2017, notifying them the Chelan PUD and Grant PUD 2016 Final M&E Annual Report and Appendices is now available for download from the Hatchery Committees Extranet site.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the August 16, 2017, Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the Hatchery Committees and asked for any additions or changes to the agenda. Hillman added agenda items for annual and monthly M&E reports. Keely Murdoch requested that Douglas PUD discuss the transition plan for the Wells Program hatcheries. Greg Mackey agreed and also added an item for Wells Fish Hatchery Modernization.

The Hatchery Committees representatives reviewed the revised draft August 16, 2017 meeting minutes. Sarah Montgomery said there are a few outstanding comments in the notes, and representatives revised the meeting minutes. Hatchery Committees representatives present approved the draft August 16, 2017 meeting minutes, as revised.

Action items from the Hatchery Committees meeting on August 16, 2017, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meeting on August 16, 2017)*:

- *Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A).*
  Mike Tonseth said this item is ongoing.
- *Sarah Montgomery will clarify the review period for the Chelan PUD Draft Statement of Agreement (SOA) Regarding the District's Coho Obligation and provide an update to the Hatchery Committees (Item II-A).*
  This item is complete.
- *Mike Tonseth will coordinate with Todd Seamons (WDFW) to produce an outline or recommended approach for genetic monitoring (Item III-E).*
  Tonseth said he began coordinating with Seamons and this item is ongoing.
- *Mike Tonseth will send the revised Table 3 of the Hatchery Monitoring and Evaluation (M&E) Plan to Tracy Hillman for inclusion in the 2017 Update (Item III-G).*
  This item is complete. Tonseth provided the table to Hillman on August 17, 2017.

- *Sarah Montgomery will send SOAs regarding Non-target Taxa of Concern (NTTOC) study results to Tracy Hillman (Item III-G).*
  This item is complete.
- *Tracy Hillman and Todd Pearsons will revise NTTOC and adaptive management language in the Draft 2017 Update to the M&E Plan for PUD Hatchery Programs and provide a revised version for Hatchery Committees review (Item III-G).*
  Hillman revised the plan and Sarah Montgomery distributed a revised version for review on September 2, 2017, which will be discussed today.

II. Chelan PUD

A. Draft Coho Salmon Mitigation SOA (Catherine Willard)

Catherine Willard shared the document titled *Draft Statement of Agreement Regarding the District's Coho Obligation*, which Sarah Montgomery distributed to the Hatchery Committees on September 6, 2017 (Attachment B). Willard said the revised version includes clarifications regarding which calculations apply to which coho reintroduction projects (i.e. Methow sub-basin or Wenatchee sub-basin). She asked if there are any comments or questions.

Kirk Truscott said the Colville Confederated Tribes (CCT) need to discuss this internally before approving it, and asked to coordinate discussions with the Yakama Nation (YN). Keely Murdoch agreed and said YN and CCT will coordinate any proposed revisions to the SOA and provide an update to the Hatchery Committees at the October 18, 2017 Hatchery Committees meeting.

B. Tumwater Feasibility Study for Lamprey Update (Catherine Willard)

Catherine Willard said Chelan PUD has been working on a feasibility study for lamprey passage at Tumwater Dam. She said an updated version of the study will be available for review soon. Bill Gale asked if the study needs to be reviewed by Chelan PUD management again. Alene Underwood said no and it will likely be distributed in October 2017. Gale asked if the draft will be available for the Rocky Reach Fish Forum (RRFF) to review. Underwood said Chelan PUD will ask the RRFF to review the document and provide comments.

Willard said the YN has been introducing lamprey into the Wenatchee River in 2016 and 2017, above and below Tumwater Dam, and lamprey have been counted at the Tumwater Dam observation window. Gale asked how many lamprey have been counted at the window and Willard said during the times trapping was not occurring, 14 lamprey were counted passing by the observation window at night. She said between July 16 to August 31, limited trapping occurs at Tumwater for up to 16 hours per day (versus 24 hours/7 days/week). Additionally, from August 31 to September 6, 2017, trapping was not occurring at Tumwater Dam to evaluate lamprey passage in the fishway after the August 31st lamprey release. She said when the trap is not operating, the denil is not operating, and lamprey are using the fishway to ascend the dam. However, she did note that a lamprey was observed ascending the denil, which was captured on video by WDFW technicians. She said PIT-tag detection data have not been uploaded to PTAGIS yet, but it appears that 24 unique detections in the Tumwater Dam fish ladder are likely the lamprey most recently released by the YN. She said PIT-tag detections have occurred previously in the fish ladder at Tumwater Dam.

III. Douglas PUD

A. Wells Transition Plan (Greg Mackey)

Greg Mackey said Douglas PUD terminated their contract with WDFW to operate the Wells and Methow fish hatcheries. He said this decision was precipitated by complaints, investigations, and firings at Wells Fish Hatchery, covered heavily by media. He said the Douglas PUD General Manager and commissioners have been working to determine a path forward and directed the PUD to terminate the WDFW contract. Mackey said the termination includes a contractually-determined 90-day transition period, which may or may not be extended pending higher-level discussions.

Mackey said Steve Parker (YN) contacted Douglas PUD with concerns, mostly about the transition period, and Shane Bickford (Douglas PUD) discussed the transition period with him. Mackey said no determination has been made yet to extend the transition period, but Douglas PUD is not opposed to a longer period such as 120 days.

Mackey said Douglas PUD is drafting a transition plan and shared hard-copies of the Transition Plan Outline to meeting attendees (Attachment C). Tom Kahler said he would send an electronic copy to Sarah Montgomery to distribute to the Hatchery Committees. Mackey said Douglas PUD intends to distribute the Transition Plan for the Hatchery Committees to review soon, as it is nearly complete. He said it will be important to receive input from representatives about any missing pieces or program details. Mackey said Douglas PUD has posted approximately 10 positions, which they intend to fill very soon. He said the fish health position, if not filled by Douglas PUD, would be contracted to the U.S. Fish and Wildlife Service (USFWS), WDFW, or other qualified sources.

Keely Murdoch thanked Mackey for the update and agreed with his summary of Parker's feedback that YN would prefer a longer transition period. She said 90 days may be too short of a time to discuss and cover all items and tasks. She said jointly held permits, roles and responsibilities, National Pollutant Discharge Elimination System permits, marking, staffing, operation of Carlton Pond, and adult management and surplusing are just a few of the complex management actions that need to be worked out during the transition. She suggested not just a longer transition period, but also a more collaborative transition plan. She said the Wells and Methow fish hatcheries are central to Douglas PUD's hatchery mitigation requirements and communication and involvement with others who make related management decisions is necessary to ensure a smooth transition. Mackey said Douglas PUD intends to keep the M&E contract with WDFW in place, as there are no performance issues with those tasks. He said it also conceptually makes sense to have the M&E contract separate from the hatchery operations so that oversight can be performed separate from operations. He said it would not make sense for Douglas PUD to monitor their own programs, even though this has not been an issue in the past with WDFW having both contracts

Tonseth said a detailed transition plan is the most necessary piece of this transition to make sure nothing gets missed. He said parties will not understand if the transition is working unless a plan is being followed. He said he hopes to see a full transition plan available for review soon, as Bickford indicated. Mackey said Douglas PUD will distribute the draft soon and asked for representatives to provide feedback on the outline so Douglas PUD can adjust the plan as needed.

Brett Farman said the National Marine Fisheries Service (NMFS) has similar concerns regarding the transition period and making sure nothing is missed. He said NMFS is working to understand how to transfer and renew permits with Douglas PUD as the hatchery operator. He said, for example, NMFS needs to ensure the operating party meets qualifications and has a demonstrated track record of hatchery performance in order to transfer permits. He said NMFS is working to interpret this regulatory language and will provide a letter with their concerns soon.

Bill Gale said this is a big change in hatchery operations and the policy aspects of the termination are outside many Hatchery Committees representatives' control. He said as agency representatives, Hatchery Committees representatives are responsible for oversight of hatchery mitigation related to the Rock Island, Rocky Reach, and Wells projects. He said he is pleased that Douglas PUD is hiring staff and working on a transition plan, but urged Douglas PUD to make the transition plan collaborative within the Hatchery Committees because representatives are charged with overseeing mitigation related to these programs. He said representatives have the responsibility and obligation to ensure that mitigation and plans for transition are going to be implemented. He said the USFWS is working to understand some of the regulatory aspects of this transition, and would prefer a more deliberate and collaborative transition process over a longer period. He also voiced frustration with the lack of communication about the transition and asked for Hatchery Committees representatives to be kept better informed of these sorts of changes in the future.

Kahler agreed that the luxury of better communication regarding the contract termination would have been ideal, but was not an option. Tonseth agreed and said better communication on all sides could have reduced stress and surprises associated with the transition.

Kirk Truscott said he also urges Douglas PUD to communicate with the Hatchery Committees regarding the transition and asked that the Hatchery Committees review the transition plan.

Kahler summarized that Douglas PUD will provide a transition plan soon for the Hatchery Committees to review and thanked everyone for their input, expertise, and offers of help during the transition.

B. Wells Fish Hatchery Modernization (Greg Mackey)

Greg Mackey said the Wells Fish Hatchery Modernization project is nearly complete. He said Douglas PUD extended the contract end date past August 31, 2017, to finish minor items such as grating and fixed ladder designs, but the building is operational and essentially complete as scheduled. He invited Hatchery Committees representatives to visit and said he plans to schedule a tour or perhaps an upcoming Hatchery Committees meeting there this fall.

IV. Joint HCP-HC/PRCC HSC

A. USFWS Bull Trout Consultation Update (Bill Gale)

Bill Gale said he does not have an update from Karl Halupka (USFWS) regarding bull trout consultations. Mike Tonseth said WDFW met with National Oceanic and Atmospheric Administration and USFWS staff earlier this week and said they discussed strategies and outstanding items for bull trout consultation. Tonseth said Halupka finished making edits and responding to comments on the Biological Opinion for the batch of Wenatchee subbasin programs and Sierra Franks (USFWS) is currently reviewing the document. He said Franks indicated there are no major red flags in the document and it will go through a more senior review and then back to Halupka for revisions. Tonseth said the Wenatchee steelhead permit will likely be the only remaining permit issued in 2017, because it only needs Section 7 consultation and signatures.

B. NMFS Consultation Update (Brett Farman)

Brett Farman said Emi Kondo (NMFS) intends to finish the proposed action for the upper Columbia River unlisted summer Chinook salmon programs next week and is incorporating edits and comments from reviewers. He said Chuck Peven (Peven Consulting Inc.) is working on the Biological Opinion for the upper Columbia River unlisted programs and may contact people for information.

C. Wenatchee Spring Chinook Salmon Lifecycle Modeling (Jeff Jorgensen)

Tracy Hillman introduced Jeff Jorgensen (Ocean Associates, Inc.), who shared a presentation titled *Lifecycle modeling in the Wenatchee River Basin* (Attachment D). Hillman said he and Andrew Murdoch have also participated in developing this model and Jorgensen leads one of several lifecycle modeling teams. Jorgensen said the different teams share ideas and code and, while models may be driven by different factors, most of the work is directed to inform biological opinions and recovery planning. He said today he will describe the Wenatchee spring Chinook salmon lifecycle model.

Roots and basics of the model (slides 1-4)

Jorgensen said the Wenatchee lifecycle model is a population dynamics model that addresses how the population changes relative to natural factors or demographic rates and has its roots in a matrix-type model. He said the Independent Scientific Advisory Board (ISAB) reviewed the Wenatchee model in 2013 and again in 2017. He said to determine how many fish move to the next step of the model, you multiply the number of fish by difference equations. This allows for applying different demographic parameters to different production areas, such as management areas in the Wenatchee basin (e.g., Chiwawa River or White River).

Running the model and using modules (slides 5-13)

Running the model starting with spawner abundance produces different outcomes, which can be summarized and characterized to determine tendencies and variation. Jorgensen said there are a lot of data in the Wenatchee basin that help inform this model. Estimates of spawner abundance and juvenile production are particularly useful to fit a fish production function within the model based on observations. Numbers of spawners, numbers of smolts, and hatchery relative reproductive success are all used to calibrate and parameterize the model. Additionally, smolt-to-adult survival rates, harvest rates, fish passage rates, and pre-spawn mortality are all factored into the model. In the Wenatchee basin, different production areas account for different production levels.

Jorgensen said the model is separated into different modules and one of those is the hatchery module, which considers broodstock, conservation, and mitigation elements to hatchery programs in the Chiwawa River and Nason Creek. He said hatchery fish are allowed to spawn in the wild based on percent natural influence (PNI) targets and percentage of hatchery origin spawners (pHOS), which set the baseline for natural-origin returns in the model. He said recent PNI estimates for the Chiwawa River, for example, are used in the model because hatchery fish are less productive than natural fish, so their spawning success is discounted. Kirk Truscott asked if the model accounts for hatchery fish spawning in the wild in separate areas. Jorgensen said hatchery fish tend to choose marginal habitat compared to wild fish, and that difference is still being discussed for incorporation in the model. Andrew Murdoch said the lifecycle modeling team will incorporate as much detail as possible to the model, especially in specific basins. Bill Gale asked if the model should consider three- or four-population estimates for PNI. Jorgensen said each area could be considered separately if enough data are available. Hillman asked if the same function is being used for both the Chiwawa River and Nason Creek. Jorgensen said yes. Hillman said for example, in the Chiwawa River, hatchery fish spawn mostly in the lower part of the river, so the Chiwawa River could be written into the model as having two separate spawning aggregates.

Jorgensen emphasized that the lifecycle model evolves as more information becomes available and the hatchery module operates within the lifecycle model. He said at low natural-origin return abundance, hatchery managers have more flexibility for hatchery fish to spawn in the wild. He said the model sets a hatchery-origin return ceiling at very low natural-origin return abundance. In the Chiwawa River, for example, the pHOS line is a function of natural-origin returns.

Evaluating hatchery programs (slides 14-16)

Jorgensen said there are different scenarios for evaluating hatchery management. Broodstock collection levels, smolt releases, and domestication can change, which would all affect the number of hatchery-origin spawners spawning in the wild.

Scenarios and outputs (slides 17-30)

Jorgensen said hatcheries, habitat, hydropower projects, avian predation, ocean conditions, harvest, and pinniped predation are all factors included in the model that can change. In addition, Lake Wenatchee and toxics can be included in the model, but those will not be discussed today. Jorgensen said, for example, some potential changes to the habitat variable include improving juvenile rearing capacity by reconnecting side channels and converting rangeland to floodplain.

The model can be run by changing multiple scenarios at a time, and the output is a graph of natural-origin spawners vs. each scenario. The model also allows for referencing recruits back to brood year, so quasi-extinction risk and viable salmon population scores can be considered.

Jorgensen said sensitivity analyses help identify the big drivers in the lifecycle model. Jorgensen said Lake Wenatchee is one area where it is difficult to understand how to parameterize the lifecycle model. He said there are opportunities and challenges when considering Lake Wenatchee, but the effects of changing habitat or other actions pertaining to the lake are currently unclear. Some of the scenarios for the lake consider changes in habitat for eggs, habitat for parr, and lake survival under different hatchery scenarios, with the output being a change in the number of smolts leaving Lake Wenatchee, a change in natural origin spawners, or other factors.

Next steps and acknowledgments (slides 31-33)

Jorgensen said the lifecycle modeling team is working on incorporating pre-spawn mortality and the early migrant juvenile-life-history strategy into the model. He said they will consider the results of spatially continuous, long-term time-series stream-temperature data, and perhaps incorporate it into fish-habitat relationships. Jorgensen acknowledged his funding sources and collaborators and asked for any questions or comments.

Questions and comments

Greg Mackey asked if Jorgensen ever encountered populations going extinct during model runs and asked if adjustments had to be made for calibration to reasonably represent current conditions. Jorgensen said they did not run into an extinction situation when running the model, likely because in the Wenatchee basin there are two life-history stages to calibrate the model and keep it within reasonable bounds.

Hillman asked how important was the hatchery component to overall abundance? Jorgensen said the hatchery component is very important to abundance especially compared to habitat or harvest. He said the lifecycle modeling team can run more scenarios to further isolate the hatchery component and determine its influence.

Peter Graf asked if the alternative hatchery scenario, which reduced pHOS, included commensurate changes in linked parameters, such as reduced broodstock collected or reduced juvenile releases. Jorgenson said that in this case the parameters were not linked and that only pHOS reduced, but those variables could be linked in the model. Tom Kahler commented that those parameters should be linked for a proper evaluation of hatcheries.

Peter Graf asked why adult survival to Bonneville Dam is described as an unknown quantity in the model and included in the calibration process. Jorgensen said it is used as a test case to see if the model fits, and used to help calibrate the model. Jorgensen noted that since discussing this further with the ISAB, the lifecycle modeling team has taken a more approximate approach to calibrating the model in order to account for natural variability and covariability. Graf asked if Lake Wenatchee survival could be treated similarly to the other less certain variables like year-1 ocean survival and be included in the calibration process. Jorgensen said it could but some prior knowledge or data is needed to create bounds around the vairaible otherwise the variable will not have an effect on the model. Mackey asked about the end product of the model. That is, will the model be available so anyone can run the model? Jorgensen said it would be difficult to train people to run the model themselves, but the modeling team may run all possible combinations and then create something like a Shiny application to display the results. Mike Tonseth asked if the Hatchery Committees identified a suite of questions or scenarios to evaluate, would the modeling team be able to run those. Jorgensen said yes. Andrew Murdoch said the model will change over time and data currently being collected will further inform the model.

Jorgensen summarized that the model is intended to be useful for managers and asked for representatives present to consider improvements to the model.

Tom Kahler asked about including water transport time, plume size, and the timing and duration of the spring freshet in the model. Jorgensen said these were considered when the model was being developed, but ultimately were not included because they correlate with model inputs that are already included. Additionally, the time series for those data is not as lengthy as other parameters like ocean regimes. Jorgensen said the lifecycle modeling team will be developing a revised module for ocean survival (currently under development for modeling for the Snake River), which includes more variables. He said water and travel time do not end up having a large influence on the model, but when included with ocean survival the variables are similar. Jorgensen said the model can be forced to run with bad ocean conditions to simulate a bad ocean sample, and a very visible relationship is seen between ocean conditions and decreased fish numbers.

Hatchery Committees representatives present thanked Jorgensen for presenting the model and expressed interest in future developments in the model and potentially running certain hatchery scenarios.

D. M&E Plan for PUD Hatchery Programs 2017 Update (All)

Tracy Hillman said he revised the M&E Plan for PUD Hatchery Programs to reflect changes discussed during the August 16, 2017 Hatchery Committees meeting. Sarah Montgomery distributed a revised version of the plan for review on September 2, 2017 (Attachment E). Hillman reviewed the edits in the document, and questions and comments were discussed.

Hillman said language in Section 7.2 (Non-target Taxa of Concern) is new and asked if anyone had comments. There were no immediate questions, but representatives indicated they would like more time to review it.

Hillman said he added language to Section 8 (Adaptive Management) regarding analyzing major program changes. He said in order to complete theses analyses, the Hatchery Committees will need to identify major program changes in fish culture or M&E for each program and suggested that the Hatchery Committees start by identifying program changes with spring Chinook salmon during the October 18, 2017 Hatchery Committees meeting.

Hillman said he is still drafting Appendix 1, Carrying Capacity, and it will be available for review soon. He summarized that Hatchery Committees representatives will review the revisions to the plan and discuss it again at the Hatchery Committees October 18, 2017 meeting.

E. 2016 Chelan PUD and Grant PUD M&E Annual Report (Tracy Hillman)

Tracy Hillman reminded the Hatchery Committees that the Chelan PUD and Grant PUD 2016 Final M&E Annual Report and Appendices are now available for download from the Hatchery Committees Extranet site (note: Sarah Montgomery sent this information to the Hatchery Committees on September 15, 2017).

F. Chelan PUD and Grant PUD Hatchery Programs M&E Progress Report – August 2017 (Tracy Hillman)

Hillman shared the document, Chelan PUD and Grant PUD Hatchery Programs M&E Progress Report – August 2017 (Attachment F), which Sarah Montgomery distributed to the Hatchery Committees on September 19, 2017. He said in the section discussing 2016 Brood Nason Spring Chinook Salmon, there was an action that needs to be clarified. He said there was an over-production of both wild-by-wild (WxW) and hatchery-by-hatchery (HxH) spring Chinook salmon. As a result, a surplus of 41,263 HxH spring Chinook were released into Banks Lake. He said the remaining HxH Chinook salmon totals about 76,135 fish, which is below the production goal for this program (goal = 98,760 HxH fish). He said the over-production of WxW fish were marked as part of the safety-net program; thus, the safety-net program will meet its release target.

Keely Murdoch asked why the overage and subsequent release were not discussed with the Hatchery Committees before decisions were made. She said decisions to release fish to Banks Lake and to mark WxW fish as if they are HxH (ad-clip+coded wire tag [CWT]) does not reflect the purpose and spirit of the Hatchery Committees. Catherine Willard asked if there is a Hatchery Committees agreed-to policy for moving and tagging fish outside of what is described in broodstock collection protocols. Murdoch said the precedent is to discuss where and how to release excess fish as a committee. Mike Tonseth said some surplus management decisions and prioritizations are included in the broodstock collection protocols for steelhead, but not juvenile spring Chinook. He said an additional item to consider is that fish could not be transferred to the Chiwawa program because progeny of fish that would have had the highest assignments to the Chiwawa (from the composite brood collected at Tumwater for the Nason program) had already been comimingled with the rest of the Nason program which precluded being able to transfer those progeny to the Chiwawa program because Nason Creek is a composite program and Chiwawa is not. Tonseth said this should be discussed, so that if a surplus occurs again, particularly with WxW progeny, fish can be moved between programs to satisfy conservation targets. Peter Graf said protocols and permits should be reviewed and discussed to determine how to manage overages and balance conservation programs. He said Grant PUD has concerns about WxW fish being marked as ad-clip+CWT, and asked what the venue is for discussing these concerns.

Bill Gale said this should be discussed in both the Hatchery Committees and Priest Rapids Coordinating Committee Hatchery Sub-Committee meetings. Tonseth said presently, utilizing WxW overages in the Nason Creek program for the Chiwawa program would be inconsistent with current permits. He said pending consultation with NOAA and discussion with the Hatchery Committees and Hatchery Sub-Committee, surplus WxW fish in the Nason program may be able to be prioritized for the Chiwawa program if a deficit occurs and the ability to keep progeny of fish with the highest assignments to the Chiwawa can be reared separately until an overage or insufficiency can be identified. Tonseth suggested additional alternatives and stated that further discussion is required with NOAA and other agencies.

Keely Murdoch said she is not certain the outcome of this overage (transfer to Banks Lake) would have been the same if it were discussed with the Hatchery Committees. She said she is not sure whether YN would have supported marking WxW fish with HxH fish, or the transfer to Banks Lake. She said the Hatchery Committees should discuss the protocol and decision-making standards for this type of decision in the future, especially for transferring fish as it may influence contracting and mitigation credit.

Tonseth said each program has individual and total release targets, and he had to make an immediate decision regarding this overage. He said the issue that forced this decision was capacity. He said there are two points at which staff can estimate numbers of fish on hand—the eyed-egg stage and during tagging. He said during the eyed-egg stage, it appeared that there might be an overage, but not more than the acceptable 110% limit. He apologized for the lack in communication about the transfer and decision, and suggested that as many management caveats and options should be included in agreed-to protocols as possible. He said decisions like this can be avoided in the future if program prioritization is built into protocols. He said, for example, if there is a known group of fish with very high assignment rates, that group could be kept separate from rearing to tagging then potentially could be transferred to a different program. He summarized that better communication and building more options and caveats into agreed-to protocols will help prevent something like this from occurring again.

V. HCP Administration

A. Next Meetings

The next Hatchery Committees meetings are on October 18, 2017 (to be decided; perhaps Wells Fish Hatchery or Grant PUD), November 15, 2017 (Grant PUD), and December 20, 2017 (Grant PUD).

Rocky Reach and Rock Island HCP Hatchery Committees
DRAFT Statement of Agreement
Regarding District's Coho Obligation
September 20th, 2017

Deleted: August 16

Statement

The Rocky Reach and Rock Island HCP Hatchery Committees (hereafter "Committees") agree that Chelan PUD shall provide coho compensation for the Methow River and Wenatchee River sub-basins at a rate equivalent to 7.0% at each project to meet Chelan PUD's No Net Impact hatchery obligations for brood years 2017 to 2021 (release years 2019 to 2023); therefore, 7.0% will be used as the coho hatchery compensation rate until the next scheduled hatchery compensation recalculation (2023). Methodology described in the SOA Regarding the 2013 No Net Impact Recalculation Methodology (dated July 20th, 2011) will be used to calculate hatchery compensation levels for coho.

In order to meet this obligation, Chelan PUD and the Yakama Nation intend to enter into an agreement where Chelan PUD will provide funding for the Mid-Columbia Coho Reintroduction Project (facility use may be included as part of the agreement). As long as Chelan PUD is meeting the terms of the agreement with the Yakama Nation, and remains consistent with any future recalculated hatchery compensation obligations, the Committees agree that Chelan PUD is fulfilling its coho hatchery obligation for the term of the Rocky Reach and Rock Island Habitat Conservation Plans.

Background

On June 20, 2007, the Committees agreed to implement coho hatchery compensation as detailed in Section 8.4.3.a of the Rocky Reach and Rock Island HCPs and agreed that the District shall begin providing hatchery compensation no later than October 1, 2007. On March 28, 2017, the Rocky Reach and Rock Island Coordinating Committees agreed to use Chelan PUD's yearling Chinook acoustic tag survival estimates and coho PIT-tag based survival estimates to estimate juvenile coho survival of 93.98% at Rock Island and 92.94% at Rocky Reach (Skalski and Townsend 2017) which culminated in a 93% survival value at both projects.

Deleted: Obligation
Deleted: hatchery program

Compensation for **hatchery-origin smolts** will be determined by multiplying the Program's annual release targets from the Methow sub-basin coho reintroduction project by the unavoidable project mortality (1-(0.93 x 0.93)) for Rocky Reach and Rock Island.

Compensation for **natural-origin smolts** produced is determined by:

- Mean NOR[1] to Rocky Reach (return years 2008 to 2011 and 2013 to 2015) = 43
- Mean NOR in absence of project mortality: 43/0.9300 = 46
- Adult equivalents to meet NNI: 46-43=3
- Mean 8 year SAR (release years 2008-2015 Methow sub-basin hatchery program) = 0.59%
- Compensation for natural-origin smolts: 3/0.0059 = 508 smolts

Calculations for the Wenatchee Sub-basin Coho Reintroduction Project

Deleted: Rock Island
Deleted: Obligation
Deleted: hatchery program

Compensation for **hatchery-origin smolts** will be determined by multiplying the Program's annual release targets from the Wenatchee sub-basin coho reintroduction project by the unavoidable project mortality (1-0.93) for Rock Island.

Compensation for **natural-origin smolts** is determined by:

- Mean NOR to Rock Island (return years 2007-2016) = 529
- Mean NOR in absence of project mortality: 529/0.9300 = 569
- Adult equivalents to meet NNI: 569-529 = 40
- Mean 10 year SAR[2] (release years 2006-2015 Wenatchee sub-basin hatchery program) = 0.75%
- Compensation for natural-origin smolts: 40/0.0075 = 5,333 smolts

[1]Natural-origin return=NOR
[2]SAR=releases from the Wenatchee hatchery programs and returns to Priest Rapids Dam (versus Rock Island Dam due to historic variable PIT tag detection efficiency at the adult ladders).

SECTION 1: INTRODUCTION

This document is an update of the monitoring and evaluation (M&E) plan of the salmon and steelhead hatchery programs funded by Douglas, Chelan, and Grant County Public Utility Districts (PUDs). Programmatic changes, evaluation of data collection methods, and M&E results from the past several years, along with shifting management paradigms affect M&E needs, all of which have occurred under advancing fish culture and monitoring techniques. As required by the programs, this document is a result of a five-year review intended to expand on and coalesce previous M&E documents (BAMP 1998; Cates et al. 2005; Murdoch and Peven 2005; Hays et al. 2006; Pearsons and Langshaw 2009a, 2009b; Hillman et al. 2013) with inclusion of new information.

Fishery management agencies developed the following general goal statements for hatchery programs, which were adopted by the HCPs Hatchery Committees and PRCC Hatchery Sub-Committee (hereafter, Hatchery Committees):

1. Support the recovery of ESA-listed species by increasing the abundance of the natural adult population, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity.
2. Increase the abundance of the natural adult population of unlisted plan species, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity. In addition, provide harvest opportunities in years when spawning escapement is sufficient to support harvest.
3. Provide salmon for harvest and increase harvest opportunities, while segregating returning adults from natural tributary spawning populations.

Following the development of Hatchery and Genetic Management Plans (HGMPs), artificial supplementation programs are now characterized into three categories. The first type, integrated conservation programs, are intended to support or restore natural populations. These programs focus on increasing the natural production of targeted fish populations. A fundamental assumption of this strategy is that hatchery fish returning to the spawning grounds are reproductively similar to naturally produced fish. The second type, safety-net programs, are extensions of conservation programs, but are intended to function as reserve capacity for conservation programs in years of low returns. The safety-net provides a demographic and genetic reserve for the natural population. That is, in years of abundant returns they function like segregated programs, and in low return years they can be managed as conservation programs. Lastly harvest augmentation programs are intended to increase harvest opportunities while limiting interactions with wild-origin counterparts.

Monitoring is needed to determine if the hatchery programs are meeting the intended management objectives of conservation, safety-net, or harvest augmentation programs. Objectives for hatchery programs are generally grouped into three categories of performance indicators:

1. In-Hatchery: Is the program meeting the hatchery production objectives?
2. In-Nature: How do fish from the program perform after release?
    a. Conservation Program:

- How does the program affect target population abundance and productivity?
- How does the program affect target population long-term fitness?

b. Safety-Net Program:
   - How does the program affect target population long-term fitness?

c. Harvest Augmentation Program:
   - Does the program provide harvest opportunities?

3. Risk Assessment: Does the program pose risks to other populations?

Objectives in this plan have been organized in a hierarchy where productivity indicators are the primary metrics used to assess if conservation and safety-net program goals have been met; harvest rates and effects on non-targeted populations are used for harvest programs. In cases where productivity indicators are not available or results are equivocal, monitoring indicators may be used to help evaluate the performance of the program. Evaluations of monitoring indicators may not provide sufficiently powerful conclusions on which to base management actions, although they may provide insight as to why a productivity indicator did or did not meet the program goal. Therefore, the relationship between hatchery programs and indicators can be viewed in a chain-of-causation: management actions within the hatchery programs affect the status of monitoring indicators, which in turn influence productivity indicators (Figure 1).

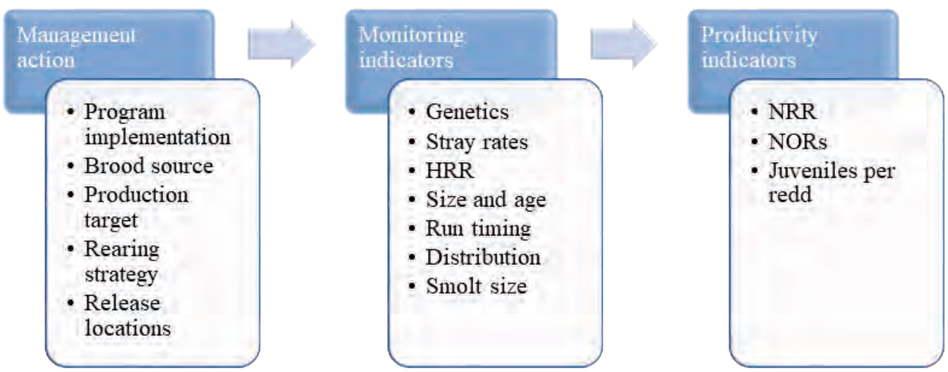

Figure 1. Relationship of indicators to the assessment of supplementation programs. Management actions affect monitoring indicators, which influence productivity indicators. Monitoring indicators may be used to hypothesize the magnitude of influence on productivity.

The primary goal of a conservation program is to contribute to the rebuilding and recovery of naturally reproducing populations within their native habitat. In this plan, natural replacement rates (NRR), recruitment of naturally-produced fish (NOR), and juvenile productivity (juveniles per redd) are important indicators for assessing the success of supplementation. These indicators are difficult to measure precisely and are quite variable in space and time. Therefore, monitoring indicators can be evaluated to help assess if productivity was related to the hatchery programs or other factors (Table 1).

Table 1. Program objectives, indicators, and goals for conservation hatchery programs including productivity and monitoring indicators (also applies to safety-net programs when used to support a conservation program).

	Objective	Indicator	Target	Program goals: Rebuild natural populations	Program goals: Maintain genetic diversity	Program goals: Opportunity for harvest
Productivity indicators	Determine if the program has increased the number of naturally spawning adults	Abundance of natural spawners	Increase	✓		✓
		Adult productivity (NRR)	No decrease	✓		
	Determine if the proportion of hatchery fish affects freshwater productivity	Residuals vs. pHOS	No relationship	✓		
		Juveniles per redd vs. pHOS	No relationship	✓		
Monitoring indicators	Determine if run timing and distribution meets objectives	Migration timing	No difference	✓	✓	
		Spawn timing[1]	No difference	✓	✓	
		Redd distribution[2]	No difference	✓	✓	
	Determine if program has affected genetic diversity and population structure	Allele frequency (hatchery vs. wild)	No difference		✓	
		Genetic distance between populations	No difference		✓	
		Effective population size	Increase		✓	
		Age and size at maturity	No difference		✓	
	Determine if hatchery survival meets expectations	HRR	HRR > NRR	✓		
		HRR	HRR ≥ Goal[3]	✓		
	Determine if recipient stray rate of hatchery fish is acceptable	Out of basin	≤ 5%	✓	✓	
		Within basin	≤ 10%	✓	✓	
	Determine if hatchery fish were released at program targets	Size and number	= Target[4]	✓		
	Provide harvest opportunities when appropriate	Harvest	Escapement goals			✓

[1] Hatchery and natural-origin fish should spawn at the same time across the range of elevations within the spawning distribution of each stock.

[2] Hatchery and natural-origin fish should spawn in the same locations. Exceptions are the Carlton and Dryden Summer Chinook programs (see Appendix 4).

[3] HRR targets are identified in Appendix 2.

[4] Number and size targets are identified in Table 3 and Appendix 5.

A flow of information following sequential, logical steps will be employed to evaluate supplementation programs, consistent with the indicators described in Table 1. For example, a hatchery program, at a minimum, must be able to produce more adults per spawner than would occur in the natural environment. Should the program fail this test, hatchery operations should be evaluated to determine if improvements can correct the problem. If a program successfully replaces the required number of adults, it is then evaluated against a reference population or condition, if available, to determine if it has increased the overall number of naturally spawning fish (including both hatchery- and natural-origin adults), increased the number of natural-origin spawners, and to test if productivity of the natural population has changed. When these goals are met, the program is considered successful. When these goals are not met, monitoring indicators may infer why the program is not achieving its goals

If suitable reference populations are not available, other comparisons can be used to help evaluate treatment responses. Evaluation of programs may pursue the following approaches:

- Comparison to reference population(s) that do not contain pre-treatment data.
- Before treatment and after treatment comparisons.
- Comparison to standard(s).
- Comparison to other suitable reference conditions.

Methodologies for selecting reference streams, analyzing data from treatment and reference stream comparisons, and other comparisons are presented in Hillman et al. (2012) (see Appendix 6).

The primary goals of a safety-net program are to provide demographic and genetic reserves for a population that is supplemented by a conservation program (Table 2). Harvest and adult management may be used to control escapement of spawners when appropriate. Monitoring focuses on estimating the number of fish that escape to spawn naturally and stray rates and in-hatchery performance evaluation.

Table 2. Program objectives, indicators, and goals for segregated harvest augmentation hatchery programs including monitoring indicators.

	Objective	Indicator	Target	Program goals: Rebuild natural populations	Program goals: Maintain genetic diversity	Program goals: Opportunity for harvest
Monitoring indicators	Determine if hatchery survival meets expectations	HRR	HRR > NRR			✓
		HRR	HRR ≥ Goal[1]			✓
	Determine if stray rate of hatchery fish is acceptable	Out of basin	≤ 5%		✓	
		Within basin	≤ 10%		✓	
	Determine if hatchery fish were released at program targets	Size and number	= Target[2]			✓
	Provide harvest opportunities when appropriate	Harvest	When greater than escapement goals			✓

[1] HRR targets are identified in Appendix 2.

[2] Number and size targets are identified in Table 3 and Appendix 5.

The primary goal of a harvest augmentation program is to increase harvest opportunities, while segregating adults from natural spawning populations. In this plan, harvest opportunity, survival rates, and stray rates are important indicators for assessing the success of harvest augmentation. These indicators are more readily quantified compared to productivity indicators (Table 2). A flow of information will be employed to evaluate harvest augmentation programs. Since harvest augmentation programs are typically segregated, monitoring indicators will be used to determine the success of a program.

Both monitoring and productivity indicators will be used to evaluate the success of hatchery programs. In the event that the statistical power of tests that involve productivity indicators is insufficient to inform sound management decisions, some of the monitoring indicators may be used to guide management. Figure 2 show the categories of indicators associated with each component of monitoring.

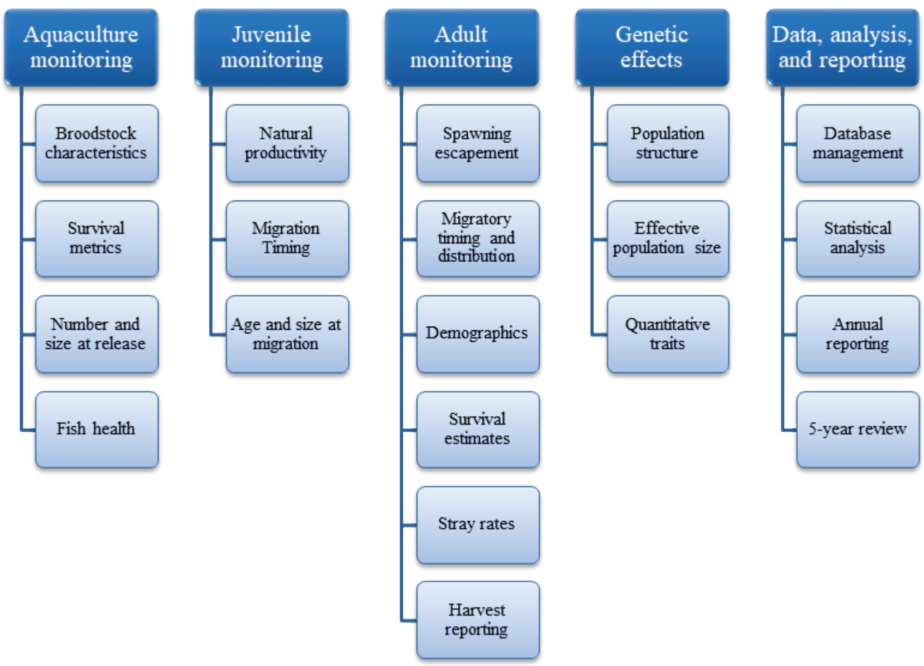

Figure 2. Overview of Monitoring and Evaluation Plan Categories and Components (not including regional objectives).

The overarching goals of conservation, safety-net, and harvest augmentation programs, as described above, are shown in detail in Figure 3. The flow chart (Figure 3) shows the relationship of overarching program goals, the strategies used to meet the goals, the monitoring and evaluation objectives used to evaluate the strategies and determine if goals are being met, and the adaptive

management cycle associated with the programs (see Tables 1 and 2 for the indicators under each objective). The logic depicted in this flow chart shall be used to assess M&E results and apply those results to management decisions. Table 3 presents the current hatchery programs releasing fish in the Upper Columbia Basin.

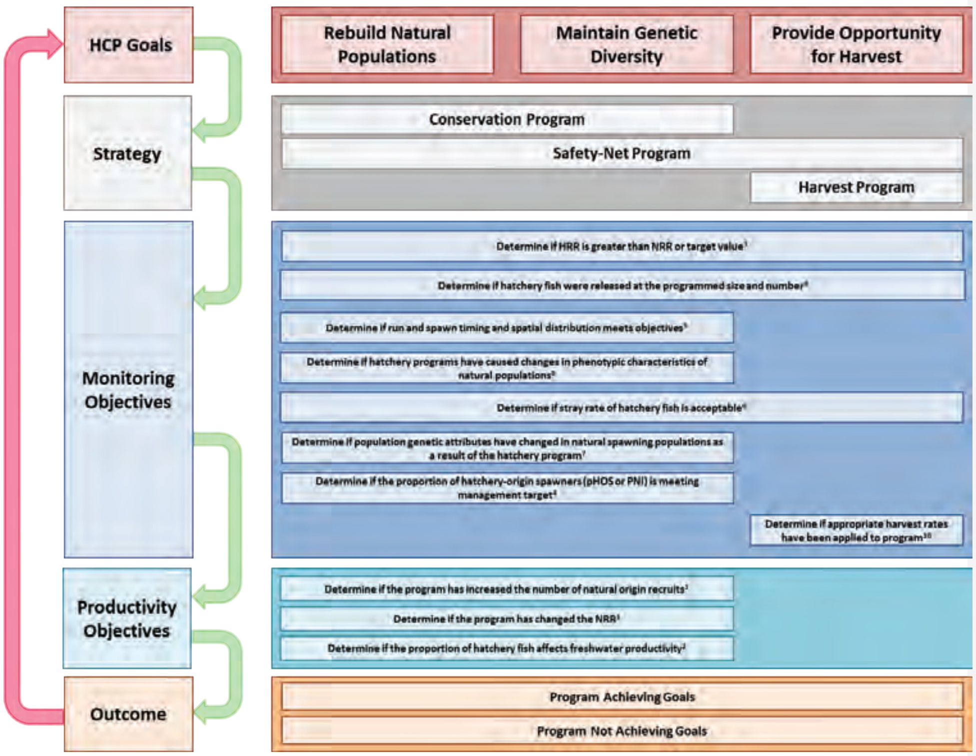

Figure 3. Adaptive management flow chart depicting HCP goals, associated strategies to meet the goals, the monitoring and evaluation objectives (indicated in superscript), and the adaptive management feedback cycle. The strategies, objectives, and outcomes are aligned vertically under the corresponding goals.

Table 3. Hatchery programs in the mid-Columbia River Basin, 2012. Funding entities included Douglas PUD (D), Chelan PUD (C), Grant PUD (G), Bonneville Power Administration (B), Bureau of Reclamation (O), and Army Corps of Engineers (A) and are listed in order of contribution. Total artificial production targets in the mid-Columbia River exceeds 20 million juveniles annually.

SECTION 2: ADULT PRODUCTIVITY

2.1 Natural Replacement Rates of Supplemented Populations[1]

Objective 1: Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.

At the core of a conservation program is the objective of increasing the number of spawning adults (i.e., the combined number of naturally produced and hatchery fish) in order to affect a subsequent increase in the number of returning naturally produced fish or natural-origin recruits (NOR). In order for the natural population to remain stable or to increase, the Natural Replacement Rate (NRR), or the ratio of NORs to the parent spawning population, must be at a level where parents are being replaced by their offspring as spawners in the next generation. It is possible to affect an increase in natural-origin spawners through supplementation with a stable or decreasing NRR. However, if the NRR is below replacement (NRR<1.0), termination of the supplementation program will result in a declining natural population should that state of NRR persist. The proportion of the hatchery-origin spawners (pHOS) that will increase natural production without creating adverse effects to the genetic diversity or reproductive success rate of the natural population is unknown, and may be dependent on how individual hatchery programs are operated, as well as available spawning and rearing habitat. Some programs restrict pHOS to reduce the risk to the natural population with the intent of optimizing productivity, concomitantly reducing the overall number of spawners. All other objectives of the M&E Plan either directly support this objective or seek to minimize negative effects of the conservation programs on non-target stocks of concern.

Differences in carrying capacities of supplemented and non-supplemented streams can confound the analysis of the effects of supplementation on total number of spawners returning to the streams. For example, if the supplemented population is at carrying capacity and the non-supplemented population is not, the total number of spawners returning to the non-supplemented population may show an increasing trend over time, while the supplemented population would show no increasing trend. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on total spawners, density corrections should be included in the analyses. Hypotheses that may require density corrections are noted under each monitoring question. Appendix 1 describes methods for estimating carrying capacities.

Monitoring Questions:

Q1.1.1 Has the supplementation program changed the adult productivity (NRRs) of the supplemented populations?[2]

Target Species/Populations:

[1] Supplementation programs may include a safety-net component.

[2] Because adult productivity is affected by the abundance of the population (i.e., productivity decreases with increasing abundance), the goal of supplementation is to increase or maintain productivity, but not decrease it.

- Q1.1.1 applies to all conservation and safety-net stocks.

Statistical Hypotheses 1.1.1[3]:

- $Ho_{1.1.1.1}$: Slope in NRRs before supplementation ≤ slope in NRRs after supplementation.
- $Ho_{1.1.1.2}$: Differences in slopes in NRRs between supplemented and reference populations before supplementation ≤ differences in slopes in NRRs between supplemented and reference populations after supplementation.
- $Ho_{1.1.1.3}$: Mean NRRs before supplementation ≤ mean NRRs after supplementation.
- $Ho_{1.1.1.4}$: Mean ratio scores in NRRs before supplementation ≤ Mean ratio scores in NRRs during supplementation.
- $Ho_{1.1.1.5}$: Mean ratio scores in NRRs (adjusted for density dependence) before supplementation ≤ Mean ratio scores in NRRs (adjusted for density dependence) during supplementation. [This hypothesis adjusts NRRs for density-dependent effects (see Hillman et al. 2012 for details; Appendix 6).]
- $Ho_{1.1.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds
- Number of naturally produced fish harvested

Derived Variables:

- Number of naturally produced recruits by brood year for both naturally produced parents and hatchery parents (≥age-3).
- NRRs (calculated as NORs/spawner).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NRRs (requires reference population[s]).
- Includes calculation of ratios NORs (requires reference population).
- Appendix 1: Spawning escapement and carrying capacity information (as applicable)

Spatial/Temporal Scale:

- Calculated annually based on brood year.
- Time series.

Possible Statistical Analysis:

[3] Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 6) for details.

- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 6). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NRRs.
- On a five-year period, correlate productivity with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

2.2 Natural-Origin Recruits of Supplemented Populations

Monitoring Questions:

Q1.2.1: Has the supplementation program changed the abundance of NORs within the supplemented population?

Target Species/Populations:

- Q1.2.1 applies to all supplemented or safety net stocks.

Statistical Hypotheses 1.2.1[4]:

- $Ho_{1.2.1.1}$: Slope in NORs[5] before supplementation ≥ slope in NORs after supplementation.
- $Ho_{1.2.1.2}$: Differences in slopes in NORs between supplemented and reference populations before supplementation ≥ differences in slopes in NORs between supplemented and reference populations after supplementation.
- $Ho_{1.2.1.3}$: Mean NORs before supplementation ≥ mean NORs after supplementation.
- $Ho_{1.2.1.4}$: Mean ratio scores in NORs before supplementation ≥ Mean ratio scores in NORs during supplementation.
- $Ho_{1.2.1.5}$: Mean ratio scores in NORs/Maximum Recruitment before supplementation ≥ Mean ratio scores in NORs/Maximum Recruitment during supplementation. [This hypothesis adjusts NORs for the capacity of the habitat; it tests the fraction of the habitat saturated with NORs (see Hillman et al. 2012 for details).]
- $Ho_{1.2.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and NORs; rho = 0. [If there is a significant negative association between

[4] Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 7) for details.

[5] "Slope in NORS" refers to abundance of NORs across time (years).

pHOS and NORs, then hatchery fish may be reducing the reproductive success of the wild population.]

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish taken for broodstock.
- Number of hatchery and naturally produced fish taken in harvest (if recruitment is to the Columbia).

Derived Variables:

- NORs (number of naturally produced recruits (total recruits) by brood year for both naturally produced parents and hatchery parents [≥age-3]).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NORs (requires reference population[s]).
- Estimates of carrying capacity (see Appendix 1).

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NORs.
- On a five-year period, correlate NORs with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

SECTION 3: JUVENILE PRODUCTIVITY

3.1 Freshwater Juvenile Productivity

Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.

Out-of-basin effects (e.g., smolt passage through the hydro system, harvest, and ocean productivity, etc.) influence the survival of smolts after they migrate from the tributaries. These effects introduce substantial variability into the adult-to-adult survival rates (NRRs and HRRs) and may mask in-basin effects (e.g., habitat quality, density-dependent mortality, and differential reproductive success of hatchery and naturally produced fish). Therefore, an estimate of freshwater productivity may help inform the performance of hatchery and natural-origin spawners.

The objective of estimating freshwater productivity in the Upper Columbia ESU/DPS is to estimate the survival from egg to a critical juvenile life stage(s) of target stocks. Smolt or juvenile production models generated from the information obtained through these programs will provide a level of predictability with greater sensitivity to in-basin effects than spawner-recruitment models that consider all effects.

Differences in the current carrying capacities of supplemented and non-supplemented streams can confound the effects of supplementation on numbers of juveniles per redd. For example, if the supplemented population is at or above carrying capacity and the non-supplemented population is not, numbers of juveniles per redd in the non-supplemented population may be significantly greater than the number of juveniles per redd in the supplemented population. In addition, pHOS may be correlated with overall spawner abundance. In these cases, it is difficult or impossible to separate density-dependent effects from the influence of pHOS on freshwater productivity. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on juveniles per redd, the capacity of the habitats must be included in the analyses. The Supplementary Hypotheses presented below are designed to address the confounding effects of different densities on the analyses.

Monitoring Questions:

Q2.1.1: Has the supplementation program changed the number of juveniles (smolts, parr, and/or emigrants) per redd within the supplemented population?

Q2.2.1: Does the number of juveniles per redd decrease as the proportion of hatchery spawners increases?[6]

Target Species/Populations:

- Both Q2.1.1 and Q2.2.1 apply to all conservation stocks.

Statistical Hypotheses for 2.1.1[7]:

[6] Information is needed to estimate the effects of density dependence on these questions. Consider spatial distribution of redds.

[7] Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. (2012) for details.

- $Ho_{2.1.1.1}$: Slope in juveniles/redd before supplementation ≤ slope in juveniles/redd after supplementation.
- $Ho_{2.1.1.2}$: Differences in slopes in juveniles/redd between supplemented and reference populations before supplementation ≤ differences in slopes in juveniles/redd between supplemented and reference populations after supplementation.
- $Ho_{2.1.1.3}$: Mean juveniles/redd before supplementation ≤ mean juveniles/redd after supplementation.
- $Ho_{2.1.1.4}$: Mean ratio scores in juveniles/redd before supplementation ≤ Mean ratio scores in juveniles/redd during supplementation.
- $Ho_{2.1.1.5}$: Mean ratio scores in juveniles/redd (adjusted for density dependence) before supplementation ≤ Mean ratio scores in juveniles/redd (adjusted for density dependence) during supplementation. [This hypothesis adjusts juveniles/redd for density-dependent effects (see Hillman et al. 2012 for details; Appendix 6).]
- $Ho_{2.1.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

Statistical Hypotheses for 2.2.1:

- $Ho_{2.2.1.1}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]
- $Ho_{2.2.1.2}$: The slope between proportion of hatchery spawners and juveniles/redd is ≥ 0.

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Numbers of redds.
- Number of juveniles (smolts, parr [where appropriate], and emigrants).

Derived Variables:

- Number of juveniles per spawner.
- Number of juveniles per redd.
- Carrying capacity (see Appendix 1).

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- These analyses shall be performed every five-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 6). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and juveniles/redd.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

SECTION 4: NATURAL ENVIRONMENT MONITORING INDICATORS

4.1 Hatchery Replacement Rates (HRRs)

Objective 3: **Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.**

The survival advantage from the hatchery (i.e., egg-to-smolt) must be sufficient to produce a greater number of returning adults than if broodstock were left to spawn naturally. If a hatchery program cannot produce a greater number of adults than naturally spawning fish, then the program should be modified or discontinued. Production levels were initially developed using historical run sizes and smolt-to-adult survival rates (BAMP 1998). Using the stock specific NRR and agreed upon target values (see Appendix 2), comparisons to actual survival rates will be made to ensure the expected level of survival has been achieved.

Monitoring Questions:

Q3.2.1: Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the adult-to-adult survival rate (NRR) of naturally produced fish?

Q3.2.2: Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the Target Value identified in Appendix 2[8]?

Target Species/Populations:

- Q3.2.1 applies to all conservation stocks.
- Q3.2.2 applies to all stocks.

Statistical Hypothesis 3.2.1:

- $Ho_{3.2.1.1}$: $HRR_{\text{Year x}} \geq NRR_{\text{Year x}}$

Statistical Hypothesis 3.2.2:

- $Ho_{3.2.2.1}$: HRR ≥ Target Value identified in Appendix 2

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish harvested.
- Number of hatchery and naturally produced fish collected for broodstock.
- Number of broodstock used by brood year (hatchery and naturally produced fish).

Derived Variables:

- Number of hatchery and naturally produced adults by brood year (≥age-3).

[8] Target values may be adjusted by the hatchery committees.

- HRR (number of returning adults per brood year/broodstock)
- NRR (from Objective 1)
- Appendix 2: HRR targets identified in Appendix 2

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- For Q3.2.1 use graphic analysis and paired-sample quantile tests to compare HRR to NRR
- For Q3.2.2 use graphic analysis and one-sample quantile tests to compare HRR to the target value.
- On a five-year period, correlate HRRs with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.2 Proportion of Hatchery-Origin Spawners (pHOS or PNI)

<u>**Objective 4**</u>**: Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.**

Certain hatchery programs have pHOS or PNI targets, while other do not. HGMPs and permits inform the selection of targets, which are identified in Appendix 3.

Monitoring Questions:

Q4.1.1: Is the estimated proportion of hatchery-origin spawners (pHOS) less than or equal to the management target, and/or, is the estimated Percent Natural Influence (PNI) greater than or equal to the management target identified in Appendix 3?

Target Species/Populations:

- Q4.1.1 applies to all conservation and safety-net stocks that have a defined pHOS or PNI target or sliding scale (see Appendix 3).

Statistical Hypothesis 4.1.1:

- $Ho_{4.1.1.1}$: pHOS > target value or $PNI_{\text{Supplemented population}}$ < target value identified in Appendix 3

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds

Derived Variables:

- pHOS or PNI
- Appendix 3: PNI and pHOS targets and sliding scales identified in Appendix 3

Spatial/Temporal Scale:

- Calculate annually.
- Analyzed as time series.

Possible Statistical Analysis:

- Use graphic analysis and summary statistics to compare pHOS or PNI to the target value in Appendix 3.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

4.3 Run Timing, Spawn Timing, and Spawning Distribution

Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.

Strategies for conservation programs typically intend that hatchery and natural-origin fish spawn together and in similar locations. However, in some cases, strategies may differ from this paradigm (e.g., summer Chinook salmon in the Wenatchee and Methow rivers; see Appendix 4). Phenotypic plasticity or selection resulting from the hatchery environment (i.e., domestication) may affect run (migration) timing, spawn timing, and spawning distribution. If conservation programs do not adequately represent the genetic diversity of the natural population, and if phenotypic traits in supplementation fish related to fitness deviate from the naturally produced spawning population, the goals of supplementation may not be achieved. Hatchery adults that migrate and/or spawn at different times or are spatially segregated from natural-origin fish may be subject to reduced fitness. Hatchery adults that spawn at different times or locations than natural-origin fish would be reproductively isolated from the natural population. The extent of such isolation, ranging from no isolation to substantial isolation, may be exploited for management purposes in some cases.

Migration Timing

Monitoring Questions:

Q5.1.1: Is the migration timing of hatchery and natural-origin fish from the same age class similar?

Target Species/Populations:

- Q5.1.1 applies to all conservation stocks.

Statistical Hypotheses 5.1.1:

- $Ho_{5.1.1.1}$: Migration timing $_{\text{Hatchery Age X}}$ = Migration timing $_{\text{Naturally produced Age X}}$

- $Ho_{5.1.1.2}$: The cumulative frequency of migration timing of hatchery-origin fish = the cumulative frequency of migration timing of natural-origin fish.
- $Ho_{5.1.1.3}$: The 10th percentile, 50th percentile (mode), 90th percentile, and mean migration timing of hatchery-origin fish = the 10th percentile, 50th percentile (median), 90th percentile, and mean migration timing of natural-origin fish.

Measured Variables:

- Ages of hatchery and natural-origin fish sampled via PIT tags or stock assessment monitoring.
- Time (Julian date) of arrival at mainstem projects and within tributaries (e.g., traps, PIT arrays) with the intent to identify biologically significant differences.

Derived Variables:

- Mean Julian date for a given age class.

Spatial/Temporal Scale:

- Calculate annually based on return year and age class.
- Time series.

Possible Statistical Analysis:

- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Spawn Timing

Monitoring Questions:

Q5.2.1: Is the timing of spawning similar for conservation hatchery and natural-origin fish?

Target Species/Populations:

- Q5.2.1: Applies to all semelparous species and populations supplemented by conservation programs. Steelhead can only be assessed for natural spawning in situations where hatchery and natural-origin fish can be appropriately marked and detected.

Statistical Hypotheses 5.2.1:

- $Ho_{5.2.1.1}$: The cumulative frequency of spawn timing of hatchery-origin fish = the cumulative frequency of spawn timing of natural-origin fish.
- $Ho_{5.2.1.2}$: The 10th percentile, 50th percentile (mode), 90th percentile, and mean spawn timing of hatchery-origin fish = the 10th percentile, 50th percentile (mode), 90th percentile, and mean spawn timing of natural-origin fish.

- $Ho_{5.2.1.3}$: The relationship between elevation and spawn timing of hatchery-origin fish = the relationship between elevation and spawn timing of natural-origin fish.

Measured Variables:

- Time (Julian date) and elevation (m) of hatchery and natural-origin salmon carcasses or marked steelhead detected on spawning grounds within defined reaches.
- Time (Julian date) of ripeness of hatchery and natural-origin steelhead captured for broodstock.

Derived Variables:

- Mean Julian date.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.
- Use graphic analyses, ANCOVA, and/or regression analysis to assess relationships between elevation and spawn timing.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Spatial Distribution of Redds

Monitoring Questions:

Q5.3.1: Is the distribution of redds similar for conservation hatchery and natural-origin fish?

Q5.3.2: Is the distribution of redds similar to defined management targets (see Appendix 4)?

Target Species/Populations:

- Q5.3.1 applies to all conservation program stocks.
- Q5.3.2 applies only to conservation program stocks with specific spawning distribution targets (Carlton and Dryden summer Chinook programs; Appendix 4).

Statistical Hypothesis 5.3.1:

- $Ho_{5.3.1.1}$: The distribution of hatchery-origin redds (hatchery females) = the distribution of natural-origin redds (natural-origin females).

Statistical Hypothesis 5.3.2:

- $Ho_{5.3.2.1}$: The distribution of hatchery-origin redds (hatchery females) = the target distribution identified in Appendix 4.

Measured Variables:

- Location (GPS coordinate) of female salmon carcasses observed on spawning grounds. The distribution of hatchery and naturally produced steelhead redds may be evaluated if marking or tagging efforts provide reasonable results.

Derived Variables:

- Location of female salmon carcass at the historic reach scale and at the 0.1 km scale.
- Calculate percent overlap in distribution across available spawning habitat or historical reaches.
- Appendix 4: Management targets for spatial distribution of spawners or redds (as applicable).

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates' Chi-square analysis for both Q5.3.1 and Q5.3.2.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.4 Stray Rates

<u>Objective 6</u>: Determine if the recipient stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.

Maintaining locally adapted traits among independent fish populations requires that returning hatchery fish have a high rate of site fidelity to the target population or stream. Hatchery practices (e.g., imprinting on water sources at key life history stages, release methodology, release location, age at return, broodstock used, spawner density, spawning habitat quality and access, and environmental conditions) are the main variables thought to affect stray rates. Regardless of the magnitude of homing of adult returns, if adult hatchery fish do not contribute to the natural population, the program will not meet the basic condition of a supplementation program.

Independent populations are populations that are genetically differentiated from other populations. In some cases, genetic differentiation may be assumed based on phenotypic traits or geographic isolation when molecular genetics analyses are not available. When populations are not independent, straying among them does not pose a risk of genetic homogenization. In addition, stray rates of hatchery-origin fish cannot be expected to be lower than for natural-origin fish. When estimates of stray rates for natural-origin fish are available and if they exceed the 5% among population stray rate or 10% within population stray rate thresholds identified in this plan, analysis

and interpretation of stray rates must take into account the concept that hatchery programs may be held to unattainable standards based on the natural stray rate. Current criteria established by the ICBTRT (2005) and the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) indicate that fish that do stray to other non-target populations should not comprise greater than 5% of the non-target spawning population. Likewise, fish that stray into non-target spawning areas within an independent population should not comprise greater than 10% of the non-target spawning aggregate (see Tables 6.1 and 6.2).

This plan identifies three stray rate metrics; brood-year stray rate, among population return-year stray rate, and within population return-year stray rate. The return-year stray rates have specific targets that are from the ICBTRT (2005) and Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007), and are linked to extinction risk. That is, hatchery strays from other populations cannot make up more than 5% of the spawning escapement within a non-target, recipient population. In addition, hatchery strays from other spawning aggregations within a population (e.g., Chiwawa spring Chinook) cannot make up more than 10% of the spawning escapement within a non-target, recipient spawning aggregate (e.g., White River). Brood-year stray rate, on the other hand, is not discussed in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) or ICBTRT (2005) and therefore has no specific target. Nevertheless, it is important to track brood-year stray rates to determine if hatchery operations affect the homing and straying of specific brood years. These data support the return-year stray metrics and are used to inform possible changes in genetic variation among stocks.

Brood-Year Stray Rates

Monitoring Questions:

Q6.1.1: What is the brood-year stray rate of hatchery fish?

Target Species/Populations:

- Q6.1.1 applies to all hatchery stocks.

Statistical Hypothesis 6.1.1:

- $Ho_{6.1.1.1}$: None.

Measured Variables:

- Number of hatchery carcasses found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.
- Number of hatchery fish collected for broodstock.
- Number of hatchery fish taken in fishery.
- Locations of live and dead strays (used to tease out overshoot).

Derived Variables:

- Total number of hatchery carcasses and take in fishery estimated from expansion analysis.
- Percent of the total brood return that strays.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphical analysis to track brood-year stray rates over time.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Among-Population Return-Year Stray Rates

Monitoring Questions:

Q6.2.1: Do hatchery strays make up less than 5% of the spawning escapement within their non-target independent populations?

Target Species/Populations:

- Q6.2.1 applies to all hatchery stocks.

Statistical Hypothesis 6.2.1:

- $Ho_{6.2.1.1}$: Stray hatchery fish make up ≥ 5% of the spawning escapement (based on run year) within other independent populations [9]

Measured Variables:

- Number of hatchery carcasses (PIT-tagged steelhead) found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

Derived Variables:

- Total number of hatchery salmon carcasses (PIT-tagged steelhead, spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target population that is made up of hatchery strays.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

[9] This stray rate is suggested based on a literature review and recommendations by the ICBTRT (2005) and is identified in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007). It can be re-evaluated as more information on naturally-produced Upper Columbia salmonids becomes available. This will be evaluated on a species and program specific basis and decisions made by the HCP HC and PRCC HSC. It is important to understand the actual spawner composition of the population to determine the potential effect of straying.

- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (5%) stray rate.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Within-Population Return-Year Stray Rates

Monitoring Questions:

Q6.3.1: Do hatchery strays make up less than 10% of the spawning aggregate within non-target spawning areas within the target population?

Target Species/Populations:

- Q6.3.1 applies to all hatchery stocks.

Statistical Hypothesis 6.3.1:

- $Ho_{6.3.1}$: Stray hatchery fish make up ≥ 10% of spawning escapement (based on run year) within non-target spawning areas within the target population

Measured Variables:

- Number of hatchery carcasses (possibly PIT-tagged steelhead) found in non-target and target spawning aggregates or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

Derived Variables:

- Total number of hatchery salmon carcasses (possibly PIT-tagged steelhead or spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target spawning aggregate that is made up of hatchery strays.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (10%) stray rate.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.5 Population Genetics

<u>Objective 7</u>: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.

The genetic component of the M&E Plan specifically addresses the potential for changes in genetic diversity in natural populations as a result of a hatchery program(s). The long-term fitness of populations is assumed to be related to maintaining the genetic diversity of natural populations. However, hatchery programs select a subset of individuals from the population to pass on genetic material to the next generation. This is often a relatively small number of individuals that produce a large number of offspring, and can result in changes in allele frequencies and reductions of effective population size. Therefore, it is important to monitor the genetic status of the natural populations to determine if there are signs of changes in genetic distance among populations, changes in allele frequencies, and to estimate effective population size. Assessing the genetic effects of the hatchery program does not require annual sampling, but does require regular sampling at generational scales. Meeting stray-rate targets (hypotheses tested under Objective 5) should reduce significant changes in population genetics. Stray rates may inform population genetic analyses. Testing statistical hypotheses associated with genetic components (Hypotheses 3.1, 3.2, and 3.3) should be conducted every ten years or two generations.

Allele Frequency

Monitoring Questions:

Q7.1.1: Is the allele frequency of hatchery fish similar to the allele frequency of naturally produced and donor (broodstock) fish?

Target Species/Populations:

- Q7.1.1 applies to all conservation stocks.

Statiscial Hypotheses 7.1.1:

- $Ho_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ = Allele frequency $_{\text{Naturally produced}}$ = Allele frequency $_{\text{Donor pop.}}$
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ ≠ Allele frequency $_{\text{Naturally produced}}$ = Allele frequency $_{\text{Donor pop.}}$ or
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ = Allele frequency $_{\text{Naturally produced}}$ ≠ Allele frequency $_{\text{Donor pop.}}$ or
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ ≠ Allele frequency $_{\text{Naturally produced}}$ ≠ Allele frequency $_{\text{Donor pop.}}$

Measured Variables:

- SNP genotypes

Derived Variables:

- Allele frequency

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples within drainages.

Possible Statistical Analysis:

- Population differentiation tests, analysis of molecular variance (AMOVA), and relative genetic distances.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Genetic Distance Between Populations

Monitoring Questions:

Q7.2.1: Does the genetic distance among subpopulations within a supplemented population remain the same over time?

Target Species/Populations:

- Q7.2.1 applies to all conservation and safety-net stocks.

Statistical Hypothesis 7.2.1:

- $Ho_{7.2.1.1}$: Genetic distance between subpopulations $_{\text{Year } x}$ = Genetic distance between subpopulations $_{\text{Year } y}$

Measured Variables:

- SNP genotypes

Derived Variables:

- Allele frequencies

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples among spawning aggregates.

Possible Statistical Analysis:

- Population differentiation tests, AMOVA, and relative genetic distances.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Effective Spawning Population

Monitoring Questions:

Q7.3.1: Is the ratio of effective population size (N_e) to spawning population size (N) constant over time?

Target Species/Populations:

- Q7.3.1 applies to all supplemented stocks.

Statistical Hypothesis 3.3:

- $Ho_{7.3.1.1}$: $(N_e/N)_{t0} = (N_e/N)_{t1}$ for each population

Measured Variables:

- SNP genotypes

Derived Variables:

- Allele frequencies

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.

Possible Statistical Analysis:

- Population differentiation tests, relative genetic distances, statistics to calculate effective population size (e.g., harmonic means).

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.6 Phenotypic Traits

Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

Fitness, or the ability of individuals to survive and pass on their genes to the next generation in a given environment, includes genetic, physiological, and behavioral components.[10] Maintaining the long-term fitness of supplemented populations requires a comprehensive evaluation of genetic and phenotypic characteristics. Evaluation of some phenotypic traits (i.e., run timing, spawn timing, spawning location, and stray rates) is addressed under Objective 5. Objective 8 assess the potential effects of domestication, including size at maturity, age at maturity, sex ratio, and fecundity. Age and size at maturity shall be assessed for both fish arriving in the Columbia system, and those recovered on the spawning grounds. Size (or age) selective mortality during migration through the Columbia system, such as through fisheries, could alter the age and size of fish on the spawning grounds.

[10] These metrics are difficult to measure, and phenotypic expression of these traits may be all we can measure and evaluate.

Age at Maturity

Monitoring Questions:

Q8.1.1: Is the age at maturity of hatchery and natural-origin fish similar at the time they enter the Columbia River and when they spawn?

Target Species/Populations:

- Q8.1.1 applies to all conservation program stocks.

Statistical Hypotheses 8.1.1:

- $Ho_{8.1.1.1}$: Age at Maturity $_{\text{Hatchery produced spawners Gender X}}$ = Age at Maturity $_{\text{Naturally produced spawners Gender X}}$
- $Ho_{8.1.1.2}$: Age at Maturity $_{\text{All hatchery produced adults Gender X}}$ = Age at Maturity $_{\text{All naturally produced adults Gender X}}$

Measured Variables:

- Total and salt (ocean) age of hatchery and natural-origin salmon carcasses collected on spawning grounds.
- Total and salt age of broodstock.
- Total and salt age of fish at stock assessment locations (e.g., Dryden, Tumwater, Wells, Priest Rapids).
- Whenever possible, age at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).
- Assess age of fish, including harvested fish.

Derived Variables:

- Total age and saltwater age
- Age of fish entering the Columbia River.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates' Chi-square.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Size at Maturity

Monitoring Questions:

Q8.2.1: Is the size (length) at maturity of a given age and sex of hatchery fish similar to the size at maturity of a given age and sex of natural-origin fish?

Target Species/Populations:

- Q8.2.1 applies to all conservation and safety-net stocks.

Statistical Hypothesis 8.2.1:

- $Ho_{8.2.1.1}$: Size (length) at Maturity $_{\text{Hatchery Age X and Gender Y}}$ = Size (length) at Maturity $_{\text{Naturally produced Age X and Gender Y}}$
- $Ho_{8.2.1.2}$: Size (length) at Maturity $_{\text{All hatchery adults Gender X}}$ = Size (length) at Maturity $_{\text{All naturally produced adults Gender X}}$

Measured Variables:

- Size (length), age, and gender of hatchery and natural-origin salmon carcasses collected on spawning grounds.
- Size (length), age, and gender of broodstock.
- Size (length), age, and gender of fish at stock assessment locations (e.g., Priest Rapids, Dryden, Tumwater, Wells, Twisp Weir).
- Whenever possible, size at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).

Derived Variables:

- Total age and saltwater age

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and three-way ANOVA by origin, gender, and age

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Fecundity at Size[11]

Monitoring Questions:

Q8.3.1: Is the fecundity vs. size relationship of hatchery and natural-origin fish similar?

[11] May not apply to all programs.

Q8.3.2: Is the gonadal mass vs. size relationship of hatchery and natural-origin fish similar?

Target Species/Populations:

- Both Q8.3.1 and Q8.3.2 apply to all conservation stocks using both natural- and hatchery-origin broodstock.

Statistical Hypothesis 8.3.1:

- $Ho_{8.3.1.1}$: Slope of Fecundity vs. Size $_{\text{Hatchery}}$ = Slope of Fecundity vs. Size $_{\text{Naturally produced}}$

Statistical Hypothesis 8.3.2:

- $Ho_{8.3.2.1}$: Gonadal Mass vs. Size $_{\text{Hatchery}}$ = Gonadal Mass vs. Size $_{\text{Naturally produced}}$

Measured Variables:

- Length, weight, and age (covariate) of hatchery and natural-origin broodstock after eggs have been removed.
- Number and weight of eggs

Derived Variables:

- Total age and saltwater age.
- Mean weight per egg.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis, regression, t-test, and ANCOVA.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Sex Ratio

Monitoring Questions:

Q8.4.1: Is the sex ratio of hatchery and natural-origin fish similar?

Target Species/Populations:

- Q8.4.1 applies to all conservation stocks.

Statistical Hypothesis 8.4.1:

- $Ho_{8.4.1.1}$: Sex Ratio $_{\text{Hatchery}}$ = Sex Ratio $_{\text{Naturally produced}}$

Measured Variables:

- Age and sex of hatchery and natural-origin salmon carcasses collected on spawning grounds or sampled at dams or weirs.
- Whenever possible sex ratio will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling or ultrasound on live fish).

Derived Variables:

- Ratio of sexes based on brood year returns

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates'Chi-square.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 5: HATCHERY ENVIRONMENT MONITORING INDICATORS

5.1 Release Targets

Objective 9: Determine if hatchery fish were released at the programmed size and number.

The HCP outlines the number and size of fish that are to be released to meet NNI and inundation compensation levels. The size of the fish at release may be altered according to an adaptive management process in the Hatchery Committee(s), and the number of fish can be altered by survival study results and adjustment of hatchery production for population dynamics. Size of fish at release can affect survival, sex ratios, age at return, stray rate, and fecundity. In addition, the variation in size at release may affect performance of the fish.

The coefficient of variation (CV) will be evaluated to ascertain if program performance is related to variation in size at release. Note also that variation in a population is a natural condition and striving to control this variation could result in directional or stabilizing artificial selection that could have unforeseen long-term consequences. Attaining uniform or multi-modal growth in a hatchery environment may not be adaptive for fitness in the wild. Therefore, pursuit of a CV target should be seen as an informative exercise, but is not in itself indicative of success or failure of a hatchery program. Furthermore, growth regimes may prove to be important in affecting adult returns and age structure. Although many factors can influence both the size and number of fish released, past hatchery cultural experience with these stocks should assist in meeting program production levels. Appendix 5 presents the target size at release and CVs for the programs. These targets shall be assessed annually to ensure they are optimized to inform management decisions.

Size at Release of Hatchery Fish

Monitoring Questions:

Q9.1.1: Is the size (fish per pound; fpp) of hatchery fish released equal to the program goal identified in Appendix 5?

Target Species/Populations:

- Q9.1.1 applies to all hatchery stocks.

Statistical Hypothesis 9.1.1:

- $Ho_{9.1.1.1}$: Hatchery fish $_{\text{fpp at release}}$ = Programmed $_{\text{fpp at release}}$ (see Appendix 5)

Measured Variables:

- Fork length and weights of random samples of hatchery juveniles at release.

Derived Variables:

- Mean length (FL), mean weight, and fish per pound
- Appendix 5: Rearing targets

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated fpp of hatchery fish at time of release with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Coefficient of Variation (CV) of Hatchery Fish Released

Monitoring Questions:

Q9.2.1: Is the CV of hatchery fish released equal to the program target identified in Appendix 5?

Target Species/Populations:

- Q9.2.1 applies to all hatchery stocks.

Statistical Hypothesis 9.2.1:

- $Ho_{9.2.1.1}$: Hatchery fish $CV_{\text{at release}}$ = Programmed CV in Appendix 5

Measured Variables:

- Length and weights of random samples of hatchery smolts.

Derived Variables:

- Coefficient of Variation: $cv = (1 + 1/4n) \times (s/x)$ (where s = standard deviation, x = estimated mean, n = sample size)
- Appendix 5: Rearing targets

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated CV of size of hatchery fish released with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Condition Factor (K) of Hatchery Fish Released

Monitoring Questions:

Q9.3.1: Is the K of hatchery fish released equal to the program target identified in Appendix 5?

Target Species/Populations:

- Q9.3.1 applies to all hatchery stocks.

Statistical Hypothesis 9.3.1:

- $Ho_{9.3.1.1}$: Hatchery fish $K_{\text{at release}}$ = Programmed K identified in Appendix 5

Measured Variables:

- Monthly individual lengths and weights of random samples of hatchery juveniles.

Derived Variables:

- Condition Factor: $K = W/L^3 \times 10^5$

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated K of released hatchery fish with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Number of Hatchery Fish Released

Monitoring Questions:

Q9.4.1: Is the number of hatchery fish released equal to the program goal identified in Appendix 5?

Target Species/Populations:

- Q9.4.1 applies to all hatchery stocks.

Statistical Hypothesis 9.4.1:

- $Ho_{9.4.1.1}$: Hatchery Fish Number = Programmed Number identified in Appendix 5

Measured Variables:

- Numbers of smolts released from the hatchery.

Derived Variables:

- Appendix 5: Rearing targets

Spatial/Temporal Scale:

- Calculate annually.

- Time series.

Possible Statistical Analysis:

- Use graphic analysis and one-sample quantile tests to compare the estimated number of hatchery fish released with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 6: HARVEST MONITORING INDICATORS

6.1 Harvest Rates

Objective 10: Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.

Harvest will be applied to different types of programs in an effort to achieve the management objectives of those programs. Programs designed to augment harvest should routinely contribute to harvest at a rate that greatly reduces the incidence of straying to natural spawning grounds, but also allows the program to be sustained. Safety-net programs may be harvested as part of an adult management strategy to minimize excessive escapement of hatchery-origin fish to spawning grounds. Similarly, conservation programs may undergo harvest to manage returning adults, but the emphasis for these programs should be to achieve escapement goals. In all cases, harvest effort should not have the unintended consequence of removing excessive numbers of conservation or natural-origin fish. In years when the expected returns of hatchery adults are above the level required to meet program goals (i.e., supplementation of spawning populations and/or brood stock requirements), surplus fish may be available for harvest. The M&E Plan specifically addresses harvest and harvest opportunities upstream of Priest Rapids Dam. Harvest or removal of surplus hatchery fish from the spawning grounds may assist in reducing potential adverse ecological and genetic impacts to natural populations (e.g., loss of genetic variation within and between populations, loss of fitness, reduced effective population size, and density-dependent effects).

Monitoring Questions:

Q10.1.1: Conservation Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of conservation hatchery fish but low enough to sustain the hatchery program?

Q10.1.2: Safety-Net Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of safety-net hatchery fish but low enough to sustain the hatchery program?

Q10.1.3: Is the harvest on hatchery fish produced from harvest-augmentation programs high enough to manage natural spawning but low enough to sustain the hatchery program?

Q10.1.4: Is the escapement of fish from conservation and safety-net programs in excess of broodstock and natural production[12] needs to provide opportunities for terminal harvest?

Target Species/Populations:

- Q10.1.1 applies to conservation programs.
- Q10.1.2 applies to safety-net programs.

[12] The current best estimates of carrying capacity (maximum recruits) will be used, as available.

- Q10.1.3 applies harvest augmentation programs.
- Q10.1.4 applies to conservation and safety-net programs.

Statistical Hypothesis 10.1.1:

- $Ho_{10.1.1.1}$: Harvest rate ≤ Maximum level to meet program goals

Statistical Hypothesis 10.1.2:

- $Ho_{10.1.2.1}$: Harvest rate ≤ Maximum level to meet program goals

Statistical Hypothesis 10.1.3:

- $Ho_{10.1.3.1}$: Escapement ≤ Maximum level to meet supplementation goals

Statistical Hypothesis 10.1.4:

- $Ho_{10.1.4.1}$: Harvest rate ≤ Maximum level to meet program goals

Measured Variables:

- Numbers of hatchery fish taken in harvest.
- Numbers of natural-origin fish taken in harvest.

Derived Variables:

- Total harvest by fishery estimated from expansion analysis.

Spatial/Temporal Scale:

- Calculated annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and one-sample quantile tests to compare the estimated harvest of hatchery fish with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 7: REGIONAL OBJECTIVES

Hatchery programs have the potential to increase diseases that typically occur at low levels in the natural environment (Objective 9). In addition, hatchery fish can reduce the abundance, size, or distribution of non-target taxa through ecological interactions (Objective 10). In this section, we address incidence of disease and non-target taxa of concern.

7.1 Incidence of Disease

Objective 11: Determine if the incidence of disease has increased in the natural and hatchery populations.

The hatchery environment has the potential to amplify diseases that are typically found at low levels in the natural environment. Amplification could occur within the hatchery population (i.e., vertical and horizontal transmission) or indirectly from the hatchery effluent or commingling between infected and non-infected fish (i.e., horizontal transmission). Potential impacts to natural populations have not been extensively studied, but should be considered for programs in which the hatchery fish are expected to commingle with natural fish. This is particularly important for supplementation type programs. Specifically, the causative agent of bacterial kidney disease (BKD), *Renibacterium salmoninarum* (Rs), could be monitored at selected acclimation ponds, both in the water and fish, in which the risk and potential for transmission from the hatchery is highest. Although it is technologically possible to measure the amount of Rs in water or Rs DNA in smolts and adults non-lethally sampled, the biological meaning of these data are uncertain. Currently, the only metric available for M & E purposes is measuring the antigen level from kidney/spleen samples (i.e., ELISA, PCR). When available, non-lethal sampling may replace or be used in concert with lethal sampling.

Implementation of this objective will be conducted in a coordinated approach within the hatchery and natural environment. BKD management within the hatchery population (e.g., broodstock or juveniles) has the potential to reduce the prevalence of disease through various actions (e.g., culling or reduced rearing densities). BKD management must also take into account and support other relevant objectives of the M & E program (e.g., Hatchery Return Rate [HRR], number of smolts released). Hence, the goal of BKD management is to decrease the prevalence of disease and maintain hatchery production objectives (i.e., number and HRR).

As previously discussed, disease transmission from hatchery to naturally produced fish may occur at various life stages and locations. Of these, horizontal transmission from hatchery effluent, vertical transmission on the spawning grounds, and horizontal transmission in the migration corridor have been identified as disease interactions that could be examined under this objective, although others may also be relevant. Experimental designs addressing this objective may require technology not yet available, although in some instances samples may be collected, but not analyzed until a link can be established between bacteria levels in samples and disease prevalence.

Developing a complete set of questions and hypotheses statements for this objective may not be practical at this time, because there is currently no BKD Management Plan. However, while developing experimental designs for this objective, it may be feasible to incorporate both hatchery and natural environment monitoring under a single study design. Integration of the different

aspects of the objective would likely result in a more robust approach into understanding the effectiveness of disease management strategies.

Proposed Tasks:

T1: Assemble fish health data for fish used as brood (e.g., ELISA results).

T2: Conduct data exploration exercise to identify potential relationships between pathogen profiles and likely causative variables (e.g., rearing conditions and management actions).

T3: Develop hypotheses for potential testing to meet objective.

7.2 Non-Target Taxa of Concern (NTTOC)

Objective 12: Determine if the release of hatchery fish affects non-target taxa of concern (NTTOC) within acceptable limits.

Commented [TH1]: The text below is new.

Hatchery programs have the potential to affect non-target taxa through various types of interactions (e.g., competition and predation). These interactions can reduce the distribution, size, and abundance of non-target species. The non-target taxa of concern (NTTOC) ecological risk assessment was developed as a regional objective that would addressed ecological interactions on non-target taxa.

In 2008, the Wells HCP, Rocky Reach HCP, Rock Island HCP Hatchery Committees, and the Priest Rapids Hatchery Sub-Committee agreed to an approach to evaluate the potential effects of hatchery programs on NTTOC. The committees originally planned to convene a panel of experts to conduct a preliminary evaluation of the potential effects of Plan supplemented species on NTTOC. At the 15 October 2008 Hatchery Committees meeting, the members agreed to convene an expert panel to conduct a preliminary evaluation of potential effects of supplemented Plan Species on non-target taxa using an approach similar to that used in the Yakima Basin (Pearsons and Hopley 1999; Ham and Pearsons, 2001). The Committees agreed to convene the panel in spring or early summer 2009, and focus this initial effort on HCP Plan Species and the two non-Plan Species, westslope cutthroat trout and lamprey. The Committees identified species interactions, containment objectives for non-target species, and fisheries professionals who possessed the expertise to contribute as panel members. However, this expert panel was never assembled. Instead, the Committees directed the Hatchery Evaluation Technical Team (HETT) to pursue assessment of the hatchery programs potential effects on NTTOC.

The HETT evaluated methods to conduct a risk assessment on NTTOC, and proposed using a combined modeling and a Delphi panel approach, whereby the modeling results would be compared and correlated with the Delphi panel results. The HETT identified the PCD Risk 1 model (Busack et al., 2005; Pearsons and Busack, 2012) to conduct the modeling evaluation. The PCD Risk 1 model is a data intensive, individual-based stochastic model. The HETT determined that the assembled data to be used as inputs for the PCD Risk 1 model would also serve to provide expert panelists the necessary data for them to conduct risk assessments. Hence, the HETT embarked on an extensive effort to gather, organize, and extract the required data from existing datasets, literature, and biologists familiar with the programs and/or particular NTTOC. Ultimately the input data were assembled in a relational database that allowed the data to be output in user-friendly formats for modeling or Delphi panel use. The database also served to hold the modeling results, which could be extracted and summarized as needed.

A report titled *Ecological Risk Assessment of Upper-Columbia Hatchery Programs on Non-Target Taxa of Concern* was drafted in 2013 and finalized in 2014, which included the modeling results to date. The results in the report represent a very extensive effort to model the risk of all the upper Columbia hatchery programs for the identified NTTOC for which data and model runs were available. Should new information become available, the Committees agreed to assess the suitability of the data as it relates to conducting future NTTOC evaluations as a regional objective.

SECTION 8: ADAPTIVE MANAGEMENT

Commented [TH2]: The text below is new.

One of the challenges of evaluating PUD hatchery programs is that hatchery programs are modified resulting in hatchery treatments that are uneven throughout the duration of the hatchery program. Modifications occur as a result of recalculating hatchery release numbers every 10 years and also through adaptive management. To solve this evaluation challenge, we propose to conduct two scales of analysis. First, the entire duration of the program will be analyzed using the entire data set. This evaluation will analyze whether the overall adaptively managed program achieved objectives. Second, where appropriate, analyses will be compared across periods or programs to determine if major program changes have resulted in hypothesized changes to key response variables. We acknowledged that partitioning data into shorter periods will likely result in reduced statistical power so only the biggest changes will be evaluated. In the future, the hatchery committees will develop a table or figure that identifies major program changes in fish culture or M&E.

In the past, hatchery programs have been evaluated at the hatchery program scale (e.g., Nason Creek, Carlton summer Chinook). In some cases, it may be worthwhile to evaluate supplementation programs at different spatial scales. For example, the Nason Creek spring Chinook salmon program can be evaluated at the scale of Nason Creek, the combined effects of spring Chinook hatchery programs in the Wenatchee basin at the Wenatchee basin scale, and then all of the spring Chinook programs in the upper Columbia at the upper Columbia basin scale.

Comparisons of supplemented populations (treatments) to in-basin reference populations are the best way to evaluate whether treatments have caused changes to variables such as natural-origin recruits or productivity. Many suitable out-of-basin references are available (see Appendix 6), but these references do not control for unique factors that may be happening in the upper Columbia or areas outside the upper Columbia. For example, large fires that occur in the Upper Columbia may not occur at similar times in areas outside of this area. Candidate in-basin reference populations are not ideal for spring Chinook salmon because they are small and are above a lake (e.g., Little Wenatchee River) or they have had a long history of hatchery stocking (e.g., Entiat River). Every population of upper Columbia summer and fall Chinook is supplemented so in-basin references are not currently available. Without a suitable number of in-basin reference populations that are similar in size and distribution to treated populations, it will be difficult to unambiguously assess hatchery effects on certain variables. Although not ideal, the only way to increase in-basin reference comparisons is to strategically reduce the number of places where hatchery fish are released such as was done for the Entiat River.

Previous stocking history will lessen the value of reference populations; however, they can still be of value. For instance, the Committees can still test whether NORs are increased under supplementation compared to periods when other populations are not supplemented (i.e., a reverse BACI analysis).

SECTION 10: GLOSSARY

Adult-to-Adult survival (Ratio)	The number of parent broodstock relative to the number of returning adults.
Age at maturity	The age of fish at the time of spawning (hatchery or naturally).
Augmentation	A hatchery strategy where fish are released for the sole purpose of providing harvest opportunities.
Broodstock	Adult salmon and steelhead collected for hatchery fish egg harvest and fertilization.
Donor population	The source population for supplementation programs before hatchery fish spawned naturally.
Effective population size (Ne)	The number of reproducing individuals in an ideal population (i.e., Ne = N) that would lose genetic variation due to genetic drift or inbreeding at the same rate as the number of reproducing adults in the real population under consideration (Hallerman 2003).
ESA	Endangered Species Act passed in 1973. The ESA-listed species refers to fish species added to the ESA list of endangered or threatened species and are covered by the ESA.
Expected value	The number of smolts or adults derived from survival rates agreed to in the Biological Assessment and Management Plan (BAMP 1998).
Extraction rate	The proportion of the spawning population collected for broodstock.
Genetic diversity	All the genetic variation within a species of interest, including both within and between population components.
Genetic stock structure	A type of assortative mating, in which the gene pool of a species is composed of a group of subpopulations, or stocks, that mate panmictically within themselves.
Genetic variation	All the variation due to different alleles and genes in an individual, population, or species.
HCP	Habitat Conservation Plan is a plan that enables an individual or organization to obtain a Section 10 Permit which outlines what will be done to “minimize and mitigate” the impact of the permitted take on a listed species.

HCP-HC	Habitat Conservation Plan Hatchery Committee is the committee that directs actions under the hatchery program section of the HCP's for Chelan and Douglas PUDs.
HRR	Hatchery Replacement Rate is the ratio of the number of returning hatchery adults relative to the number of adults taken as broodstock, both hatchery and naturally produced fish (i.e., adult-to-adult replacement rate).
Long-term fitness	Long-term fitness is the ability of a population to self-perpetuate over successive generation.
Naturally produced	Progeny of fish that spawned in the natural environment, regardless of the origin of the parents.
Mean Ratio	The ratio between a treatment and control population, with the mean taken across a time period, such as years. Used in analysis in Before-After-Control-Impact studies.
Ne	Effective population size.
Non-target taxa of concern (NTTOC)	Species, stocks, or components of a stock with high value (e.g., stewardship or utilization) that may suffer negative effects because of a hatchery program.
NRR	Natural replacement rate is the ratio of the number of returning naturally produced adults relative to the number of adults that naturally spawned, both hatchery and naturally produced.
NTTOC	Non-target taxa of concern.
pHOS	Proportion of Hatchery Origin Spawners.
PNI	Proportionate Natural Influence.
pNOB	Proportion of Natural Origin Broodstock.
PRCC HSC	Priest Rapids Coordinating Committee Hatchery Subcommittee.
Productivity	The capacity in which juvenile fish or adults can be produced.
Reference population	A population in which no directed artificial propagation is currently directed, although may have occurred in the past. Reference populations are used to monitor the natural variability in survival rates and out of basin impacts on survival.
Smolt-to-adult survival rate (SAR)	Smolt-to-adult survival rate is a measure of the number of adults that return from a given smolt population.
Segregated	A type of hatchery program in which returning adults are spatially or temporally isolated from other populations.

Size at maturity	The length or weight of a fish at a point in time during the year in which spawning will occur.
Smolts per redd	The total number of smolts produced from a stream divided by the total number of redds from which they were produced.
SNP or single-nucleotide polymorphism	A single-nucleotide polymorphism is a variation in a single nucleotide that occurs at a specific position in the genome, where each variation is present to some appreciable degree within a population.
Spawning Escapement	The number of adult fish that survive to spawn.
Stray rate	The rate at which fish spawn outside of natal rivers or the stream in which they were released.
Supplementation	A hatchery strategy where the main purpose is to increase the relative abundance of natural spawning fish without reducing the long-term fitness of the population.
Target population	A specific population in which management actions are directed (e.g., artificial propagation, harvest, or conservation).

APPENDIX 1: ESTIMATION OF CARRYING CAPACITY

APPENDIX 2: HATCHERY REPLACEMENT RATES

Based on ideas developed by the HETT, in February 2016, the HCP Hatchery Committees and PRCC Hatchery Subcommittee agreed to the following rules and HRR targets:

1. Use the estimated 40% HRR Target during 5-year statistical evaluation periods.
2. Use varying degrees of action depending on the numbers of years that annual HRR deviates from Target.
   a. Green Light (below Target for ≤ 2 years).
   b. Red Light (below Target for > 2 years).
3. Each program will have its own HRR target with the following exceptions.
   a. Nason Creek spring Chinook will use the Chiwawa Target (there are currently no data to calculate a target for Nason Creek spring Chinook).
   b. Methow and Chewuch spring Chinook will use the greater of their two Targets (they are MetComp stock and evaluated similarly).

Table 1. Release numbers and 5-year hatchery replacement rates (HRR) targets for Upper Columbia River Hatchery Programs.

Species	Owner	Program (Hatchery)	Basin (Purpose)	Smolts released[1]	5-Year HRR[2]
Steelhead	CPUD	Eastbank (Chiwawa)	Wenatchee (Conservation)	123,650	6.9
Steelhead	CPUD	Eastbank (Chiwawa)	Wenatchee (Safety Net)	123,650	6.9
Steelhead	DPUD	Wells (Wells)	Columbia (Safety Net)	160,000	26.5
Steelhead	DPUD	Wells (Wells)	Methow (Safety Net)	100,000	26.5
Steelhead	DPUD	Wells (Wells)	Twisp (Conservation)	48,000	26.5
Steelhead	GPUD	Wells (Omak)	Okanogan (Conservation)	100,000	7.3 [3]
SUM Chinook	CPUD	Eastbank (Chelan Falls)	Chelan (Conservation)	176,000	5.7
SUM Chinook	CPUD	Eastbank (Chelan Falls)	Chelan (Harvest)	400,000	5.7
SUM Chinook	CPUD, GPUD	Eastbank (Dryden)	Wenatchee (Conservation)	500,000	5.7
SUM Chinook	DPUD	Wells (Wells)	Columbia (Harvest)	320,000	3.0
SUM Chinook	GPUD	Eastbank (Carlton)	Methow (Conservation)	200,000	3.0
SUM Chinook	CCT	Chief Joseph	Okanogan (Harvest)	1,100,000	8.6
SPR Chinook	CPUD	Eastbank (Chiwawa)	Wenatchee (Conservation)	144,026	6.7
SPR Chinook	CPUD, DPUD, GPUD	Wells (Methow)	Methow (Conservation)	193,765	3.8
SPR Chinook	DPUD, GPUD	Wells (Twisp)	Methow (Conservation)	30,000	2.7
SPR Chinook	GPUD	Eastbank (Nason)	Wenatchee (Conservation)	223,670	6.7

[2] Derived from Annual Reports.
[3] Harvest not included.

Attachment E

APPENDIX 3: PNI and pHOS Targets and Sliding Scales

Select CPUD, DPUD, and GPUD funded hatchery mitigation programs have PNI management targets, while others do not. Table 1 summarizes management strategies by species and population. Detailed information can be found in the sections that follow. Descriptions provided in the following sections are taken directly from HGMPs and/or issued and draft permits.

Table 1. Summary of management strategies by species and population.

Species	Population	Management Strategy	Comments
Spring Chinook	Wenatchee	Sliding Scale of PNI management	Details can be found in Section 2.0
	Methow	Two—population sliding scale PNI management	Details can be found in Section 3.0
	Okanogan	None Currently	Details can be found in Section 4.0
Steelhead	Wenatchee	Two-zone management.	Details can be found in 5.0
	Methow	In-development	Details forthcoming; Section 6.0
	Okanogan	None Currently	Details can be found in Section 7.0
Summer Chinook	Wenatchee	None Currently	Details can be found in Section 9.0
	Methow	None Currently	Details can be found in Section 10.0
	Okanogan	0.67; pHOS 0.30	Details can be found in Section 11.0
	Upper Columbia River	None Currently	Details can be found in Section 12.0
Fall Chinook	Hanford Reach	0.67	Details can be found in Section 13.0

2.0 Wenatchee Spring Chinook

Wenatchee spring Chinook will be managed according to the sliding scale identified in the Wenatchee Spring Chinook Management Plan (2010) and Permit Numbers 18118 and 18121. The sliding scale is based upon the estimated number of natural origin spring Chinook over Tumwater Dam. As more information becomes available the sliding scale may be adjusted as a result of gaining a better understanding of the pre-spawn mortality rate and carrying capacity.

Table 2. Sliding scale of PNI goals based on natural origin spring Chinook run size expected to the Wenatchee River basin. Percentiles are based on adult returns observed between 1999 and 2008.

Percentile	NOR Run Size				PNI
	Chiwawa	Nason Creek	White	Wenatchee River (above TWD)	
>75th	>372	>350	>87	>910	≥ 0.80
50% - 75%	278-372	259-349	68-86	631-909	≥ 0.67
25% - 50%	209-277	176-258	41-67	525-630	≥ 0.50
10%-25%	176-208	80-175	20-40	400-524	≥ 0.40
<10th	<175	<80	<20	<400	Any PNI

3.0 Methow/ Chewuch Spring Chinook

The following sliding scale (Table 3) is presented in the April 14, 2016 draft Methow Hatchery Spring Chinook Section 10-Draft. It is anticipated that no further changes will be made to the sliding scale prior to issuance of the final permits.

Table 3. PUD PNI sliding scale calculations for a range of natural run sizes.

Natural Origin Returns	PUD pHOS	WNFH pHOS	PUD pNOB	2-Pop PNI	PUD PNI (equation)
<300	Ensure minimum of 500 total spawners				
300	0.40	0.2	0.75	0.67	0.67
500	0.40	0.2	0.80	0.68	0.76
900	0.30	0.15	1.00	0.78	0.80
1500	0.25	0.1	1.00	0.8	0.80
2000	0.25	0.1	1.00	0.8	0.80
2500	0.25	0.1	1.00	0.8	0.80

4.0 Okanogan Spring Chinook

The Okanogan spring Chinook program is a re-introduction effort implemented as a non-essential experimental population under ESA Section 10j to re-introduce spring Chinook into the Okanogan River. As a non-essential experimental population targeting re-introduction and establishment of a local population of spring Chinook, the Okanogan spring Chinook program will not conduct adult management actions to reduce the proportion of 10j hatchery fish on the spawning grounds or conduct broodstocking efforts in the Okanogan for a 10-year period (2014 – 2023), as such, no PNI or pHOS objectives have been identified for this program in this 10-year period.

CJH Program segregated production released into the mainstem Columbia River are non-listed Leavenworth stock released reared/acclimated/released at CJH. Although no PNI or pHOS targets are identified for the Okanogan 10j population, minimizing strays from the CJH segregated spring Chinook program is a program objective, as such, returning segregated program fish will be subject to directed harvest and aggressive adult surplusing at CJH to minimize straying to the Okanogan River Basin as well as other extant upper Columbia River spring Chinook populations. Stray targets for the segregated program are 5% or less stray rate (i.e. spawning contribution to other upper Columbia River spring Chinook populations).

5.0 Wenatchee Steelhead

Interim escapement goal for Wenatchee River steelhead will be 1,500 spawners with an additional goal of attaining an average PNI of 0.67 for the Wenatchee River basin population as a whole. To achieve the stated goal, the Wenatchee steelhead program will use a two-zone management approach wherein the upper basin (above TWD) will be managed for recovery using an integrated recovery program, a separate spawning escapement goal, and a PNI standard to achieve the overall basin goal of an average PNI over time of 0.67 (Table 4). Areas below TWD will be managed to minimize hatchery supplementation with a pHOS goal of < 0.10.

Steelhead returning upstream of TWD will be managed as an integrated recovery program with a pNOB goal of 1.0. The above TWD escapement goal will be 1,094 spawners. Working within this framework, pNOB will be maximized above TWD while pHOS will be minimized.

Table 4. Wenatchee steelhead two-zone management and PNI targets.

Location	Run Escapement Goal	pNOB Conservation Program	pNOB Safety Net Program	pHOS	PNI
Above TWD	1,094	1.0	0.0	Varies	Varies
Below TWD	406	N/A	N/A	< 0.10	< 0.67
Basin Total	1,500	N/A	N/A	Minimal	Average = 0.67

6.0 Methow Steelhead

Methow steelhead PNI targets are currently in development.

7.0 Okanogan Steelhead

Current program has no PNI goal. CTCR submitted an Okanogan steelhead HGMP to NOAA Fisheries on February 4, 2014. Within the HGMP provisions were included to allow a greater collection of natural-origin broodstock and multiple adult management strategies to address over-escapement of hatchery-origin steelhead to the spawning grounds. The HGMP also identified a near-term (1-4 years) and a long-term PNI objectives of 0.50 and > 0.67, respectively. Once NOAA has completed the consultation and issued a new permit, providing the opportunity to increase the proportion of natural-origin fish in the broodstock and additional adult management strategies, the program will adopt the PNI objectives and this Appendix can be amended accordingly.

8.0 Wells Columbia Mainstem Safety-net Steelhead

The Safety-Net Mainstem Columbia component released below Wells Dam will be managed primarily at the Wells Hatchery volunteer channel. The objective of the adult management of the Safety-Net Mainstem Columbia component is to prevent runs of this component from moving into natural spawning areas. This will be accomplished through in-river harvest and removal of volunteers at the Wells Hatchery outfall. There are no PNI goals for this component.

9.0 Wenatchee Summer Chinook

No PNI goals are established.

10.0 Methow Summer Chinook

No PNI goals are established.

11.0 Okanogan Summer Chinook

Okanogan summer/fall Chinook will be managed to achieve a 5-year rolling average PNI of 0.67 and pHOS of 0.30. Strategies to achieve that PNI target include up to 100% pNOB, aggressive removal of hatchery-origin Chinook in selective fisheries, at the Okanogan weir, and during surplusing at CJH ladder. Reduction in the number of juveniles released in the Okanogan River Basin (integrated program) is also a management option, should adult management actions be unable to control the proportion of hatchery fish on the spawning grounds to achieve that PNI target.

CJH segregated summer/fall Chinook program rears/acclimates/releases smolts into the mainstem Columbia River at CJH. Broodstock are 100% hatchery-origin, as such no PNI target for this production component. Stray rate (i.e. contribution to upper Columbia summer/fall Chinook

populations) is 5% or less. Adult management on returning adults from the segregated program include fisheries, removal at the Okanogan weir, and removal at the CJH ladder.

12.0 Upper Columbia Summer Chinook (Chelan Falls and Wells)

No PNI goals are established. Chelan Falls and Wells FH summer Chinook programs are segregated harvest programs designed to provide opportunity for harvest. Adult returns are not intended to spawn naturally; therefore, there is no escapement goal for natural spawning areas. Adult returns will be managed to meet program objectives. Chelan Falls and Wells Hatchery summer Chinook are available for harvest in the ocean and Columbia River commercial, tribal, and recreational fisheries.

13.0 Priest Rapids Fall Chinook

The Hanford Reach fall Chinook population is intentionally supplemented by Grant PUD at the Priest Rapids Hatchery and the ACOE at the Priest Rapids and Ringold Springs hatcheries. Managers desire to achieve a population level PNI that includes all hatchery programs of ≥0.67. Grant PUD and the HSC do not have control over operation or expansion of the ACOE program and therefore will strive to operate the Priest Rapids Hatchery fall Chinook program in a way that does its fair share of achieving a population level PNI of 0.67.

APPENDIX 4: SPATIAL DISTRIBUTION OF SPAWNERS OR REDDS

Strategies for conservation programs typically intend that hatchery and naturally produced fish spawn together and in similar locations. However, in some cases, strategies may differ from this paradigm. In Table 1, conservation programs that have a spatial distribution management plan that deviates from similar to the natural spawning spatial distributions are presented. Otherwise, conservation programs are intended to have a spawning distribution similar to the natural origin spawning spatial distributions, as described by M&E Objective 5.3.

Table 1. Management targets for the spatial distribution of hatchery-origin redds for conservation programs that deviate from Objective 5.3.

Program	Target	Rational	Source
Carlton Summer Chinook	The observed spawning distribution of hatchery origin Methow summer Chinook from 2005-2010 represents the base-line spawner distribution for evaluating the performance of the hatchery program (i.e., M&E plan check-ins). It is acknowledged that this distribution is lower in the River than the spawning distribution of natural origin summer Chinook salmon.	Based upon an assessment of summer Chinook and ESA-listed spring Chinook abundance and spawner distribution, it was determined that an increase in summer Chinook spawning abundance in the upper most range of natural origin summer Chinook distribution or potentially above the current range may pose an unknown and potentially adverse impact to ESA listed spring Chinook. Due to the concern for spring Chinook, the HSC has endorsed an acclimation site in the Methow Basin that is lower in the basin than may be required to attain exact replication of natural and hatchery origin summer Chinook spawner distribution.	SOA 2011-02 Priest Rapids Coordinating Committee Hatchery Subcommittee Statement of Agreement on Monitoring & Evaluation (M&E) Objective for Spawning Distribution of Hatchery-Origin Summer Chinook
Dryden Summer Chinook	The observed spawning distribution of hatchery origin Wenatchee summer Chinook from 2008-2013 (previous 5 years to the current M&E check-in cycle) represents the base-line spawner distribution for evaluating the performance of the	The primary site endorsed by the HSC for Grant PUD overwinter acclimation of summer Chinook is the Dryden Pond, and is the current acclimation and release site for the existing summer Chinook supplementation program	Adapted from SOA 2011-02 Priest Rapids Coordinating Committee Hatchery Subcommittee Statement of Agreement on Monitoring & Evaluation (M&E) Objective for Spawning Distribution of Hatchery-Origin Summer Chinook

	hatchery program (i.e., M&E plan check-ins).	funded and owned by Chelan PUD. Because current data indicates that spawning distribution of hatchery summer Chinook from the existing program is lower in the Wenatchee River than natural origin spawners, expectations are that acclimation of Grant PUD's summer Chinook at Dryden Pond would continue to return hatchery origin summer Chinook that result in different spawning distributions for hatchery and natural summer Chinook.	

APPENDIX 5: WITHIN HATCHERY REARING TARGETS

Rearing Targets for Upper Columbia River Hatchery Programs. K-factor or fork length targets will be determined based on data from the pending "Five-Year Report."

Table 1. Numbers, fish per pound (fpp), coefficient of variation (CV), and condition factor (K) targets at release of Upper Columbia River Hatchery Programs.

Hatchery	Species	Life Stage	Basin	Release number	FPP	CV	K-factor
Methow	Spring Chinook	Yearling	Methow	193,765[1]	15	<10	TBD
Methow	Spring Chinook	Yearling	Twisp	30,000	15	<10	TBD
Chief Joseph	Spring Chinook	Yearling	Columbia	700,000	15	<10	TBD
Chief Joseph	Spring Chinook	Yearling	Okanogan	200,000	15	<10	TBD

Chief Joseph	Summer Chinook	Yearling	Okanogan	799,998[7]	10	<7	TBD
Dryden	Summer Chinook	Yearling	Wenatchee	500,001	18	9.0	TBD
Priest	Fall Chinook	Subyearling	Columbia	7.3 M[8]	50	<10	TBD
Ringold	Fall Chinook	Subyearling	Columbia	3.5 M	50	<10	TBD

[1] The total release includes the release of 108,249 into the Methow River at the Methow Fish Hatchery, 25,000 into the Methow River at the Goat Wall site, and 60,516 into the Chewuch River at the Chewuch Acclimation Facility.

[2] These fish come from Winthrop National Fish Hatchery (MetComp) eyed eggs.

[3] The total release includes 125,000 conservation fish and 98,670 safety net fish.

[4] The combined Okanogan and Omak steelhead release number is 100,000.

[5] The total release includes 66,771 fish into Nason Creek, 53,170 into the Chiwawa River, 102,359 into the Wenatchee River, and 25,000 into Blackbird Pond.

[6] The Wells subyearling Chinook are not reared to achieve a specific size target. The fish are released on a date to optimize survival and are grown to the largest size possible before release.

[7] The total release is divided equally among the Omak, Riverside, and Similkameen Acclimation Ponds.

[8] The total release consists of 5.6 m fall Chinook for the Grant PUD program and 1.7 M fall Chinook for the Army Corps of Engineers program.

APPENDIX 6: IDENTIFYING AND ANALYZING REFERENCE POPULATIONS

An important goal of supplementation is to increase spawning abundance and natural-origin recruitment of the supplemented population, and not reduce the productivity of the supplemented population. Indeed, a successful supplementation program must increase spawning abundance and natural-origin recruitment to levels above those that would have occurred without supplementation. There are several methods that can be used to test the effects of supplementation programs on these population metrics. One important method is to compare the performance of population metrics (e.g., spawning abundance, natural-origin recruitment, and productivity) in the supplemented population to those in un-supplemented (reference) populations. By comparing supplemented populations to reference populations, one can determine if the supplementation programs benefit, harm, or have no effect on the supplemented populations. These comparisons, however, are only valid if the performance of the reference populations is similar to the performance of the supplemented population prior to the period of supplementation. If the performance of the two populations differs significantly before any supplementation occurs, then any results from comparing the two populations after supplementation will be suspect. It is therefore important to select reference populations that are as similar as possible to the supplemented populations.

One of the goals of the Conceptual Approach to Monitoring and Evaluating the Chelan County PUD Hatchery Programs (Murdoch and Peven 2005) is to use reference populations to analyze the potential effects of hatchery supplementation programs on natural-origin salmon and steelhead spawner abundance and productivity[13]. Murdoch and Peven (2005) identified specific objectives to evaluate the performance of the program. For example, Objective 1 determines if the supplementation programs have increased the number of naturally spawning and naturally produced adults of the target population (supplemented population) relative to a reference population. Objective 7 determines if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity (e.g., number of juveniles per redd) of supplemented streams when compared to reference streams. The relevant questions tested under each objective are as follows:

Objective 1:

- Is the annual change in the number of natural-origin recruits produced from the supplemented populations greater than or equal to the annual change in natural-origin recruits in an un-supplemented population?
- Is the change in natural replacement rates within the supplemented population greater than or equal to the change in natural replacement rates in an un-supplemented population?

Objective 7:

13 Productivity is defined as adult recruits per spawner, where recruits are the number of adults produced from a given brood year (i.e., spawners plus adults harvested).

- Is the change in numbers of juveniles (smolts, parr, or emigrants) per redd in the supplemented population greater than or equal to that in an un-supplemented population?[14]

In this paper, we describe methods used to identify suitable reference streams and statistical techniques that can be used to compare reference populations with supplemented populations. Although we apply the methods described in this paper to Chiwawa spring Chinook salmon (hereafter referred to as Chinook), the methods should also apply to steelhead and other supplemented salmon stocks in the Upper Columbia Basin.

Identification of Reference Populations

Reference populations are an important component of an effectiveness monitoring design because they provide the standard by which treatment conditions are compared (ISRP and ISAB 2005; Murdoch and Peven 2005; Galbreath et al. 2008). Selecting appropriate reference areas and maintaining them over long periods of time is needed to establish the effectiveness of supplementation programs.

We developed a three-step process for identifying suitable reference populations (Figure 1). Each step serves as a filter. That is, potential reference populations are evaluated based on specific criteria under each step. Populations that pass through each step are considered suitable reference populations for a specific supplemented population.

[14] In this paper, we only address adult recruits, not juvenile recruits. This is because we were unable to find suitable reference populations for analysis of juveniles. However, the methods described in this paper would also apply to juveniles.

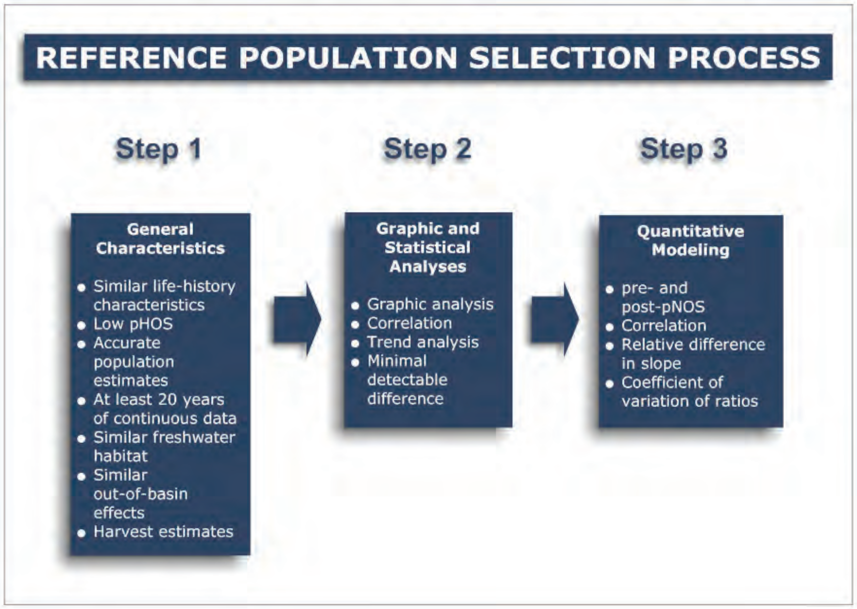

Figure 1. Criteria evaluated during each step in the process of identifying suitable reference populations.

Step 1: General Characteristics

Under step 1, potential reference populations are evaluated based on several general criteria. When compared to the supplemented population, potential reference populations should have:

- Similar life-history characteristics (e.g., run timing, migration characteristics, etc.).
- No or few hatchery fish in the reference area (pHOS < 10%).
- Accurate abundance estimates.
- Long time series of natural-origin abundance and productivity estimates (at least 20 years of continuous data).
- Similar trends in freshwater habitat.
- Similar out-of-basin effects (i.e., similar migration and ocean survivals).
- Harvest estimates for adjusting escapement estimates.

We used these criteria to begin the process of selecting suitable reference populations for the Chiwawa spring Chinook program. We began by identifying stream-type Chinook populations within the Columbia Basin. Galbreath et al. (2008; their Table 1) identified stream-type Chinook populations within the Columbia River Basin that may serve as suitable reference populations for hatchery programs. Supplementing their work with data from the NOAA Fisheries Salmon Population Summary Database, we identified 18 candidate stream-type Chinook populations that may serve as reference populations for the Chiwawa supplementation program (Table 1).

Table 1. Populations of stream-type Chinook salmon and their comparison to Chiwawa spring Chinook.

Population	Similar life-history	No or few hatchery fish	Accurate abundance estimates	Long time series (at least 20 years)	Similar freshwater habitat impairments	Similar out-of-basin effects	Comments
Deschutes River	Yes	Yes	Yes	Yes	No	No	
John Day mainstem	Yes	Yes	Yes	Yes	No	No	
Middle Fk John Day	Yes	Yes	Yes	Yes	No	No	
North Fk John Day	Yes	Yes	Yes	Yes	No	No	
Granite Creek	Yes	Yes	Yes	Yes	No	No	
Wenaha River	Yes	No	Yes	Yes	Yes	No	Hatchery strays (>10%)
Minam River	Yes	No	Yes	Yes	Yes	No	Hatchery strays (>10%)
Slate Creek	Yes	Yes	Yes	No	No	No	
Secesh River	Yes	Yes	Yes	Yes	Yes	No	
Middle Fk Salmon River	Yes	Yes	Yes	No	No	No	Fair productivity est.
Big Creek	Yes	Yes	Yes	Yes	No	No	
Camas Creek	Yes	Yes	Yes	Yes	No	No	Fair productivity est.
Loon Creek	Yes	Yes	Yes	Yes	No	No	Fair productivity est.
Sulphur Creek	Yes	Yes	Yes	Yes	No	No	
Bear Valley Creek	Yes	Yes	Yes	Yes	No	No	
Marsh Creek	Yes	Yes	Yes	Yes	Yes	No	
North Fk Salmon River	Yes	Yes	No	No	Yes	No	
Lemhi River	Yes	Yes	Yes	Yes	No	No	
East Fk Salmon River	Yes	No	Yes	Yes	No	No	Hatchery strays (>10%)
Valley Creek	Yes	No	Yes	Yes	No	No	Hatchery strays (>10%)
Chamberlain Creek	Yes	Yes	Yes	No	Yes	No	
Naches River	Yes	Yes	Yes	Yes	Yes	No	
Little Wenatchee River	Yes	No	Yes	Yes	Yes	Yes	Hatchery strays (>10%)
Entiat River	Yes	No	Yes	Yes	No	No	Hatchery release ending

We then assessed the accuracy and length of the series of abundance estimates. We assumed that abundance estimates generated from expanded redd counts or adjusted weir counts would compare well with estimates in the Chiwawa Basin, which were based on expanded redd counts. In addition, we looked for populations that had an abundance data series that extended from at least 1981 to present. Based on this analysis, we identified 18 populations with abundance estimates that could be compared to those from the Chiwawa Basin (Table 1).

Next, we determined if the potential reference populations came from watersheds with habitat conditions similar to those in the Chiwawa Basin. For this exercise, we searched recovery plans and draft recovery plans to identify tributary factors that limit Chinook abundance, productivity, and survival within the reference populations. We compared these factors with those limiting

Chinook salmon in the Chiwawa Basin. Based on this analysis, we identified eight populations with habitat impairments similar to those in the Chiwawa Basin (Table 1).

Finally, we examined the potential reference populations to see if they experienced out-of-basin effects similar to spring Chinook from the Chiwawa Basin. In this case, we compared the number of mainstem dams that each potential reference population passes during migration. Six of the potential reference populations pass less than six mainstem dams; the other populations pass eight mainstem dams (Table 1). Only the Little Wenatchee population passes seven dams, similar to the Chiwawa population.

In sum, there were no reference populations that matched the Chiwawa spring Chinook population on all the criteria identified above. Differential out-of-basin effects and freshwater habitat conditions prevented most reference populations from matching with Chiwawa spring Chinook. However, some of the potential reference populations were similar to the Chiwawa population on several criteria and warranted further investigation. We selected the following populations for further investigation: Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River.

We included the Little Wenatchee because it is within the Wenatchee River basin and experiences similar out-of-basin effects and has the same climatic and environmental conditions as the Chiwawa. A confounding effect with the Little Wenatchee is that Chiwawa hatchery fish have strayed into the Little Wenatchee. However, straying of Chiwawa hatchery fish should decrease with the change in source water to the Chiwawa acclimation ponds in 2006. We also included the Entiat River because it is an adjacent basin to the Chiwawa and experiences similar climatic and environmental conditions. The spring Chinook hatchery program that has operated in the Entiat since 1975 has been discontinued. Therefore, this population offers a unique opportunity to compare the Chiwawa population to a population in which the hatchery program has been discontinued.

Step 2: Graphic and Statistical Analysis

Graphic Analysis

Although we were unable to find potential reference populations that matched with the Chiwawa population on all criteria considered under Step 1, spawner abundance, natural-origin recruits (NORs), and productivity of some of the potential reference populations may nevertheless track closely with the Chiwawa population. If the time series of abundance, NORs, and productivity of a potential reference population tracks closely with the abundance, NORs, and productivity of the Chiwawa population, the reference population may provide a reasonable reference condition for testing the effects of supplementation on the Chiwawa population.

Under Step 2, we used graphing techniques to examine the relationship of abundance, NORs, and productivity between the Chiwawa population and the five reference populations (Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River). We compiled spawner abundance, NORs, and productivity data from local biologists and the NOAA Fisheries Salmon Population Summary Database. We then compared time series plots of spawner abundance, NORs, and productivity data of potential reference populations with the Chiwawa population (Figures 2, 3, and 4; plots on the left side of figures). The time series only included the period 1981 to 1992, which represented the period before supplementation of the Chiwawa population (pre-treatment period). We also plotted the relationship between the abundance, NORs, and productivity of each

potential reference population to the Chiwawa population (Figures 2, 3, and 4; plots on right side of figures). These plots show whether the reference populations closely tracked the Chiwawa population. As a point of reference, data points that fall along the dashed line would represent a perfect relationship between the two populations (i.e., both populations have identical abundance, NORs, and productivity estimates). While a perfect relationship between two independent populations is unrealistic, a strong linear relationship between the two populations indicates populations with similar trends.

Based on analysis of spawner abundance, the Naches River time series tracked more closely with the abundance of Chiwawa spring Chinook than did the other potential reference populations. The poor relationship with the other potential reference streams was largely because of the relatively high abundance of Chiwawa spring Chinook during the mid-1980s. As with spawner abundance, analyses of NORs indicated a close relationship between the Naches and Chiwawa populations. The other potential reference populations tracked poorly with the Chiwawa. The analyses of productivity indicated close relationships between potential reference populations and the Chiwawa population. The Naches, Sesech, and Little Wenatchee populations tracked the closest with the Chiwawa population.

When analyzing the potential effects of a supplementation program on fish performance, it is common to transform the data to meet various assumptions of statistical analysis. The most common transformation used to adjust abundance, NORs, and productivity data is the natural logarithm (LN or $\log_e$). We therefore transformed the spawner abundance, NORs, and productivity data using LN and re-plotted the relationships between the potential reference populations and the Chiwawa population (Figures 5, 6, and 7). We added 1 to each observation before taking its logarithm to avoid taking the logarithm of 0, which is undefined (note that the LN of 1 is 0).

By transforming spawner abundance, NORs, and productivity data, most of the potential reference populations tracked more closely with the Chiwawa population. The Naches, Entiat, and Little Wenatchee abundance data tracked the closest with the Chiwawa abundance data (Figure 5). For NORs, Marsh Creek and the Little Wenatchee populations tracked the closest with the Chiwawa (Figure 6). For productivity, the Naches, Sesech, and Little Wenatchee tracked the closest with the Chiwawa (Figure 7).

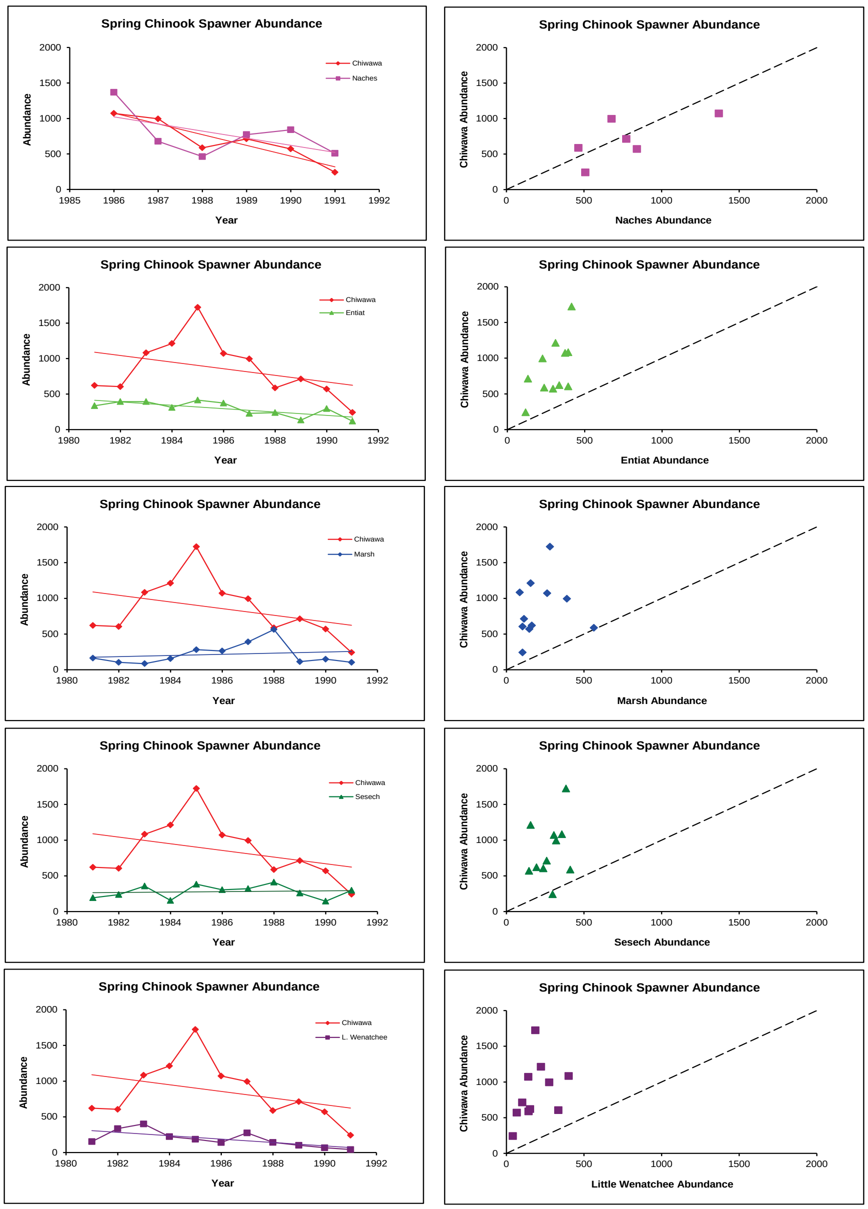

Figure 2. Time series of spawner abundance of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

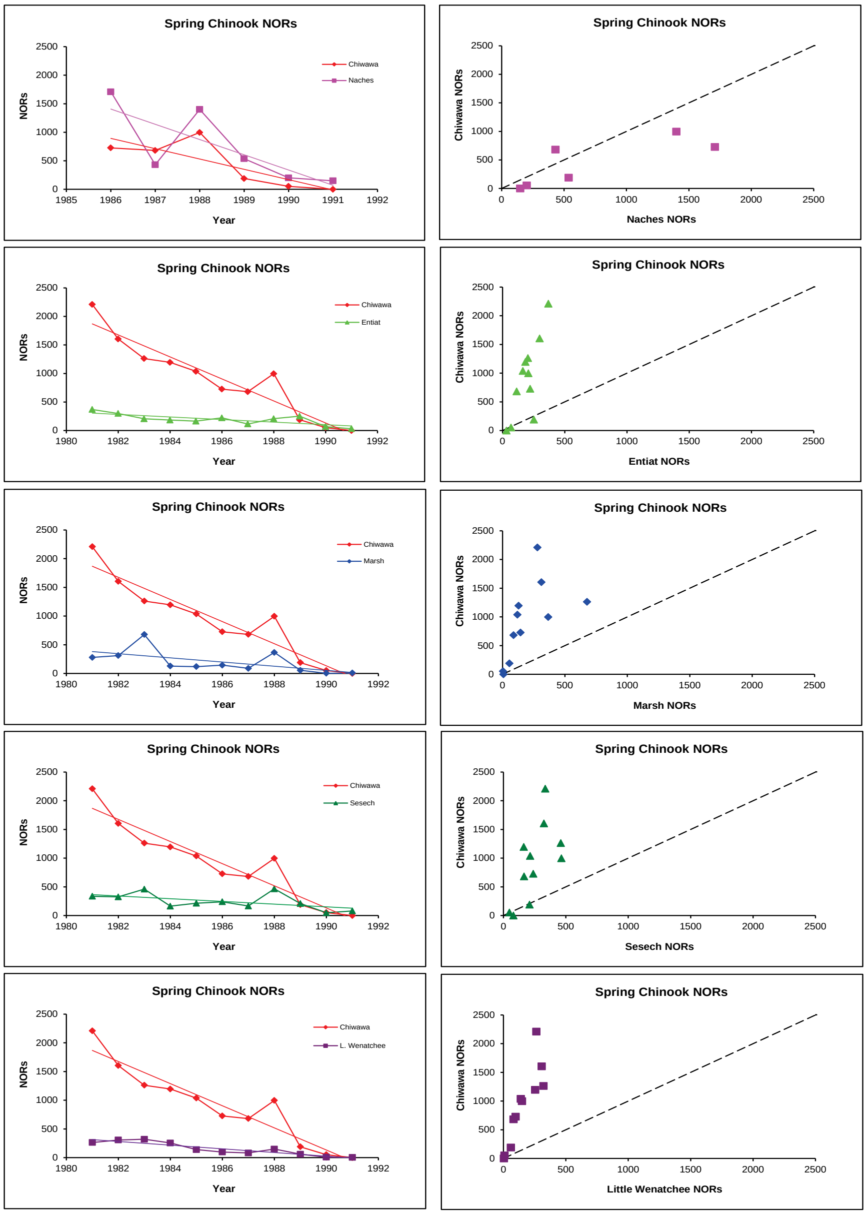

Figure 3. Time series of natural-origin recruits (NORs) of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

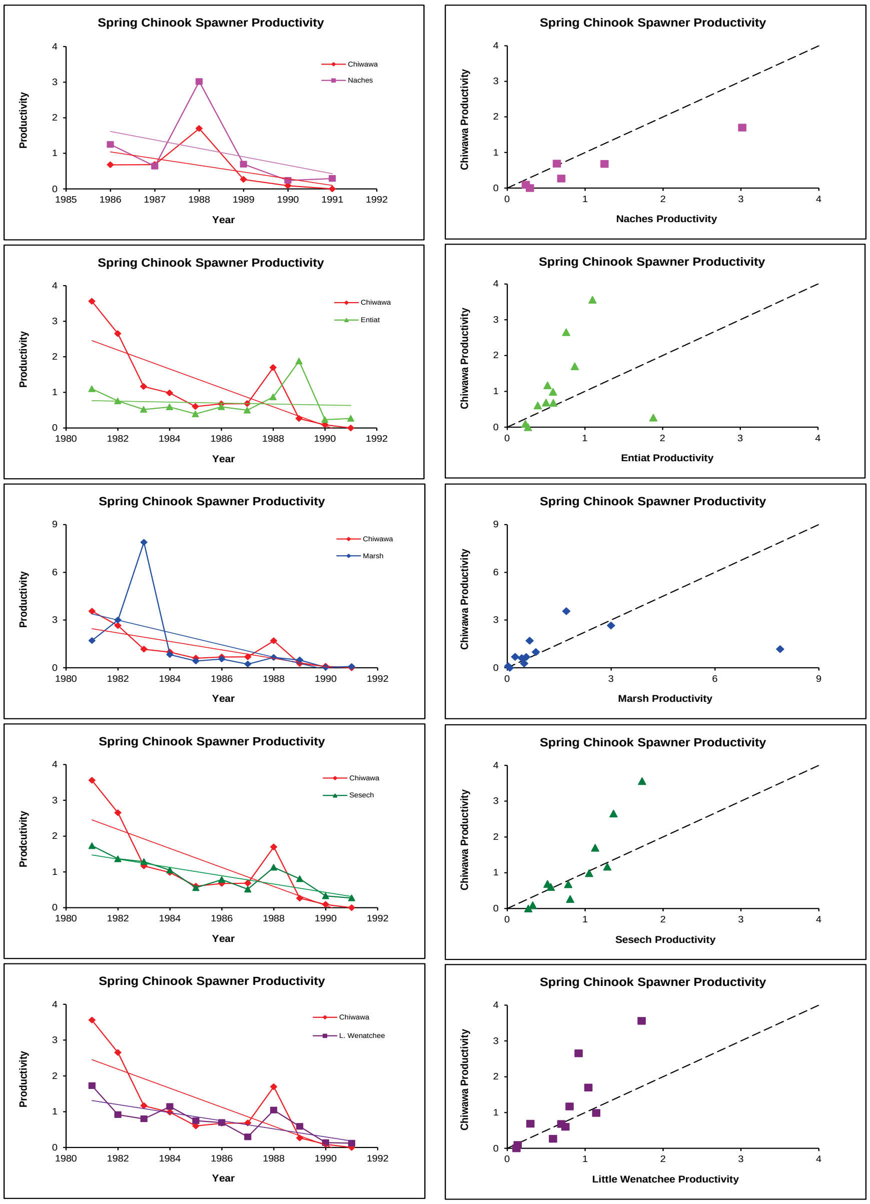

Figure 4. Time series of adult productivity of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

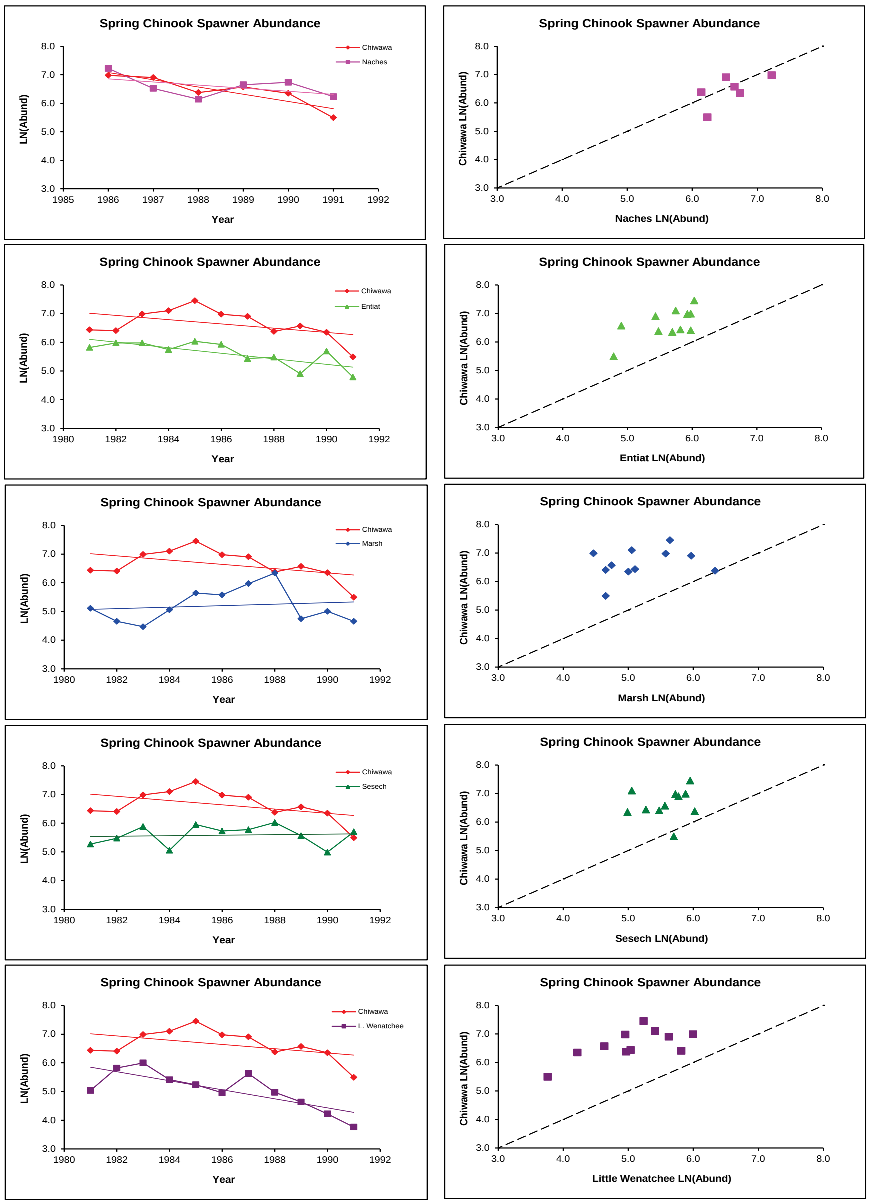

Figure 5. Time series of natural log spawner abundance of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

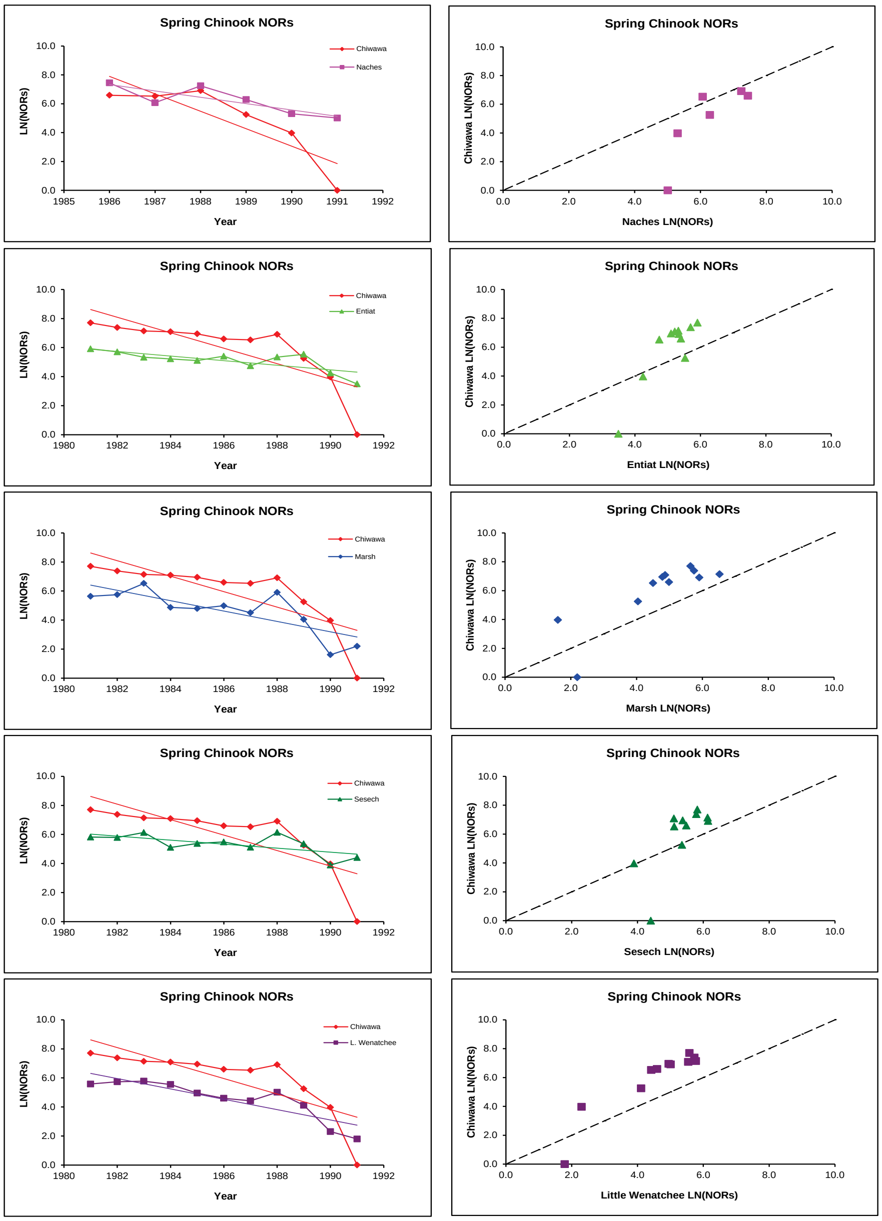

Figure 6. Time series of natural log natural-origin recruits (NORs) of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

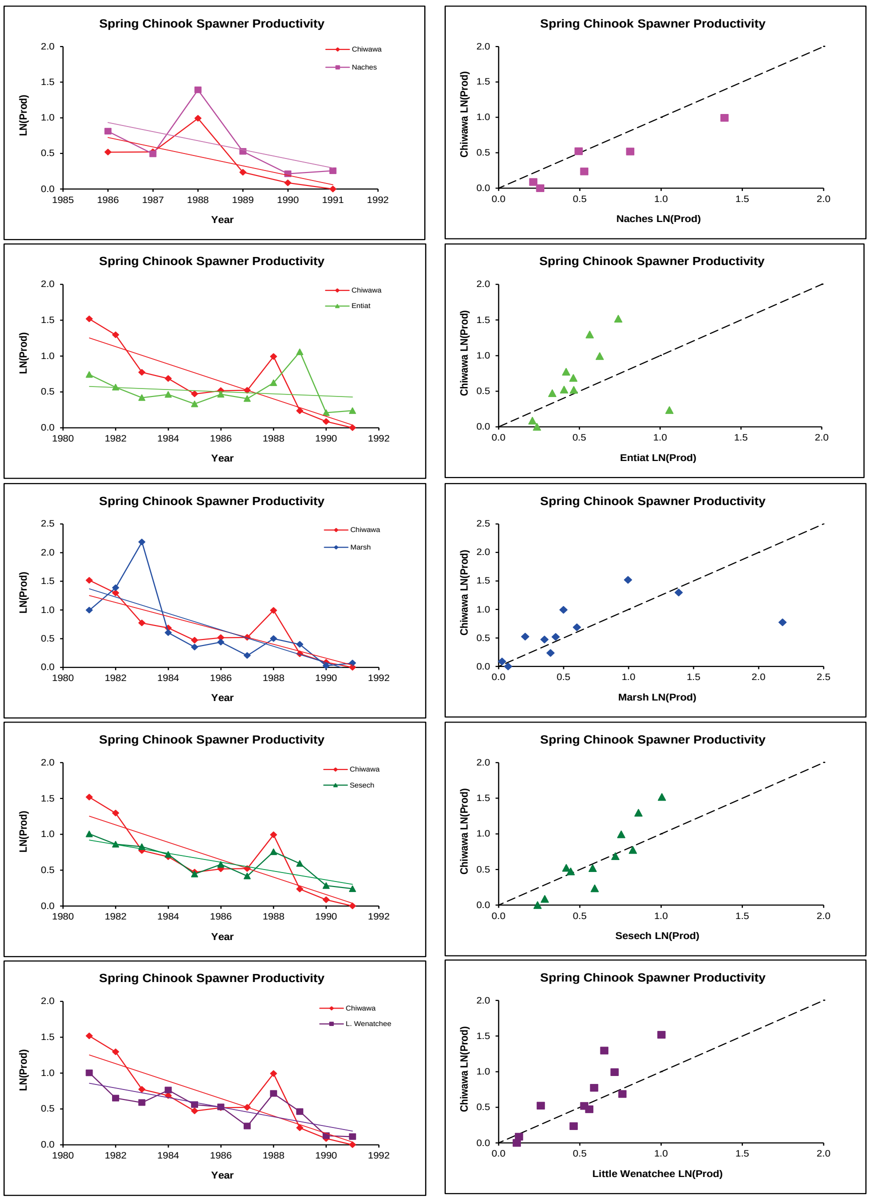

Figure 7. Time series of natural log adult productivity of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

Correlations and Trends

Other methods for evaluating the suitability of potential reference populations under Step 2 include correlation and trend analyses. For correlation analysis, we simply calculated the Pearson correlation coefficient, which is an index of the strength of the association between the potential reference populations and the Chiwawa population. The coefficient ranges from -1 to 1, where a value near 1 or -1 represents that strongest association between the populations. A value of 0 means no association. We used only spawner abundance, NORs, and productivity data during the pre-treatment period (1981-1992). We assumed that populations with coefficients greater than 0.6 represented reasonable reference conditions.

For trend analyses, we used least squares techniques to compute a straight-line trend through the spawner abundance and productivity data for the potential reference populations and the Chiwawa population. Trends were fit to the pre-treatment time series data (1981-1992). We then used t-tests to determine if the slopes of the trends between potential reference populations and the Chiwawa population differed significantly.

It is important to note that time-series trend analyses are susceptible to temporal correlations in the data. Autoregressive integrated moving average (ARIMA) models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). However, these models require a long time series (N > 40) and therefore we could not use them to model the spring Chinook data. As such, we were unable to correct for any temporal correlation that may exist within the time series.

Tests of correlation with spawner abundance data indicated that the Naches River closely correlated with the Chiwawa population (Table 2). There was no difference in abundance trends between the potential reference populations and the Chiwawa population (Table 2; Figure 2). For NORs, all potential reference populations correlated with the Chiwawa population (Table 2). However, trends in NORs of all reference populations, except Naches, differed significantly from the Chiwawa population (Table 2; Figure 3). For productivity, the Naches, Sesech, and Little Wenatchee correlated with the Chiwawa population (Table 2). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 2; Figure 4).

Table 2. Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (*) indicates significance at P < 0.05.

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Spawner Abundance Data				
Naches	0.684*	-0.659	8	0.528
Entiat	0.598*	-0.596	18	0.559
Marsh	0.147	-1.341	18	0.197
Sesech	0.274	-1.265	18	0.222
Little Wenatchee	0.399	-0.591	18	0.562
Natural-Origin Recruits				
Naches	0.803*	0.666	8	0.524
Entiat	0.795*	-7.495	18	0.000

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Marsh	0.605*	-5.786	18	0.000
Sesech	0.648*	-6.874	18	0.000
Little Wenatchee	0.880*	-7.206	18	0.000
Productivity Data				
Naches	0.960*	0.169	8	0.870
Entiat	0.272	-3.057	18	0.007
Marsh	0.320	0.605	18	0.553
Sesech	0.903*	-2.059	18	0.054
Little Wenatchee	0.848*	-2.065	18	0.054

We also ran correlation and trend analyses on natural-log transformed spawner abundance, NORs, and productivity data. These analyses indicated that the Naches, Entiat, and Little Wenatchee abundance data correlated with the Chiwawa population data (Table 3). None of the abundance trends of the potential reference populations differed significantly from the Chiwawa population trend (Table 3; Figure 5). For NORs, all potential reference populations correlated with the Chiwawa population (Table 3). Only trends in NORs of the Entiat and Sesech differed significantly from the Chiwawa population (Table 2; Figure 6). For productivity, the Naches, Marsh, Sesech, and Little Wenatchee correlated with the Chiwawa population data (Table 3). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 3; Figure 7).

Table 3. Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (*) indicates significance at P < 0.05. Analyses were conducted on natural-log transformed abundance and productivity data.

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
LN Spawner Abundance Data				
Naches	0.642*	-1.323	8	0.222
Entiat	0.652*	0.412	18	0.685
Marsh	0.294	-1.324	18	0.202

LN Productivity Data				

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Naches	0.944*	-0.042	8	0.968
Entiat	0.373	-3.043	18	0.007
Marsh	0.610*	0.428	18	0.674
Sesech	0.913*	-2.050	18	0.055
Little Wenatchee	0.862*	-1.811	18	0.087

In summary, based on correlation, trend, and graphic analyses, the Naches, Entiat, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. For NORs, the Naches, Marsh, and Little Wenatchee appear to be reasonable reference populations. For productivity, the Naches, Marsh, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for the Chiwawa population.

Minimal Detectable Differences (MDD)

Given a suite of potential reference populations, it is important to conduct power analyses to determine the minimum differences that can be detected when comparing the reference populations to the supplemented population. As a final exercise under Step 2, we examined potential reference populations for the smallest minimal detectable differences. Before conducting power analyses, several decisions needed to be made, including what statistical procedures will be used to analyze the data, the desired level of statistical power (probability of rejecting a false null hypothesis), the size of the type-I error (the probability of rejecting a true null hypothesis of no difference), and the number of samples (i.e., years) included in the analysis. In this case, the number of samples represents the number of treatment (supplementation) years. The number of pre-treatment years (1981-1992) was based on the number of years of quality data available for Chiwawa spring Chinook and potential reference populations.

We designed the study as a modified BACI (Before-After, Control-Impact) design, which includes replication before and after supplementation in both the treated (T) population and the reference (R) populations. A common approach used to analyze data from BACI designs includes analysis of difference scores (Stewart-Oaten et al. 1992; Smith et al. 1993). Differences are calculated between paired treatment and reference population scores (i.e., T-R). Another approach is to calculate ratios (treatment/reference; T/R) for paired treatment and reference population scores (Skalski and Robson 1992). Finally, differences in annual changes in paired treatment and reference population scores can be calculated (i.e., ΔT-ΔR) (Murdoch and Peven 2005; Hays et al. 2006).[15] These derived difference and ratio scores are then analyzed for a before-after treatment effect with a two-sample t-test, Aspin-Welch modification of the t-test, or a randomization test. For power analyses, we calculated minimal detectable differences assuming the use of an independent two-sample t-test with a type-I error rate of 0.05, power of 0.80 (beta or type-II error rate of 0.20), and sample sizes (treatment years) of 5, 10, 15, 20, 25, and 50 years.

15 The difference of annual difference scores was estimated by first subtracting the population parameter (e.g., spawner abundance) in year 2 from year 1. This continues for all years in the data series for both treatment ($T_{t+1} – T_t$) and reference populations ($R_{t+1} – R_t$). We then calculated differences between paired treatment and reference annual difference scores [($T_{t+1} – T_t$) - ($R_{t+1} – R_t$) = ΔT-ΔR].

The power analysis calculated the minimal detectable difference between mean difference or ratio scores before and during supplementation. We used existing data to calculate variances for the pre-supplementation and supplementation periods. Thus, variances were known and unequal. For both spawner abundance and NORs, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was less than the mean difference during supplementation (one-tail test; Difference < 0). For productivity, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was greater than the mean difference during supplementation (one-tail test; Difference > 0).

Based on spawner abundance data, power analysis indicated that the Sesech-Chiwawa pairing consistently produced the smallest detectable differences (Table 4). However, when the abundance data were transformed using natural logs, the Entiat-Chiwawa pairing produced the smallest detectable difference (Table 5). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 334 to 394 adult spawners; transformed data ranged from 0.479 to 1.010. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

Table 4. Minimal detectable differences between mean difference and ratio scores before and during supplementation. Analyses were conducted on spawner abundance data.

Based on NORs, power analysis indicated that the Entiat-Chiwawa, Marsh-Chiwawa, and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 6). When NORs were transformed using natural logs, the Little Wenatchee-Chiwawa pairing produced the smallest detectable difference (Table 7). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 483 to 640 NORs; transformed data ranged from 0.958 to 2.262. These analyses indicate that the Entiat, Marsh, and Little Wenatchee populations appear to be reasonable reference populations for comparing NORs with Chiwawa data.

Using untransformed productivity data, power analysis indicated that the Little Wenatchee-Chiwawa pairing consistently produced the smallest detectable differences (Table 8). The Marsh-Chiwawa pairings produced the largest detectable differences. When we analyzed natural-log transformed productivity data, the Naches-Chiwawa and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 9). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 0.754 to 1.839; transformed data ranged from 0.277 to 0.477. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing productivity data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

Step 3: Quantitative Method for Ranking Selection Criteria

Not surprisingly, different selection criteria produced different results (Table 10). Determining whether a given population is or is not a suitable reference population based on selection criteria such as graphic analysis can be subjective. In addition, treating each selection criterion as equally important may not be appropriate. For example, using the information in Table 10, is it appropriate to select a reference population that has two or three "Yes" entries, or should only populations with four "Yes" entries be selected as suitable reference populations? This approach does not allow certain selection criteria to carry more weight in the overall selection process. That is, correlation may be more important than graphic analysis in the overall selection process. In order to reduce

subjectivity, we developed a method of scoring and weighting each selection criterion. This method allows a more quantitative process for selecting suitable reference populations.

Table 10. Summary of results from graphic analysis, correlations, trend analysis, and power analysis (minimal detectable differences). "Yes" indicates that the population is a suitable reference population for the Chiwawa population; "No" indicates that it may not be a suitable reference population.

Potential reference populations	Graphic analysis	Correlation	Trends	Minimal detectable differences
Spawner Abundance				
Naches	Yes	Yes	Yes	Yes
Entiat	Yes	Yes	Yes	Yes
Marsh	No	No	Yes	No
Sesech	No	No	Yes	Yes
Little Wenatchee	Yes	Yes	Yes	Yes
Natural-Origin Recruits				
Naches	Yes	Yes	Yes	No
Entiat	No	Yes	No	Yes
Marsh	Yes	Yes	Yes	Yes
Sesech	No	Yes	No	No
Little Wenatchee	Yes	Yes	Yes	Yes
Productivity				
Naches	Yes	Yes	Yes	Yes
Entiat	No	No	No	Yes
Marsh	No	Yes	Yes	No
Sesech	Yes	Yes	Yes	Yes
Little Wenatchee	Yes	Yes	Yes	Yes

We developed scoring methods for each of the following five selection criteria:

(1) The proportion of natural-origin spawners (pNOS) in the reference population for the period before supplementation (pre-pNOS);

(2) pNOS in the reference population for the period following supplementation (post-pNOS);

(3) The correlation between the reference and supplemented populations before supplementation;

(4) The relative difference in slopes between the reference and supplemented populations before supplementation; and

(5) The coefficient of variation (CV) of the ratio of supplemented to reference populations before the period of supplementation.

Each selection criteria was scored from 0 to 1, with 0 being the worst possible score and 1 being the best.

The pre- and post-pNOS values were calculated as the average pNOS values before and after supplementation, respectively. Because pNOS values range from 0-1, we did not need to rescale

these values. When using reference populations to evaluate the effects of supplementation programs, it is important that the reference populations maintain high values of pNOS throughout the life of the monitoring program. Therefore, we heavily weighted the mean pNOS scores. We assigned weights of 30 and 40 to the mean pre- and post-pNOS scores, respectively. The relatively larger weight for the post-supplementation period is to reduce the likelihood of retaining a reference population that becomes influenced by hatchery fish during the supplementation period.

We assessed the association between the reference and supplemented populations during the pre-supplementation period by calculating the Pearson correlation coefficient, which ranges from -1 to 1. To scale the coefficient between 0 and 1, we took the absolute value of the coefficient. Thus, a coefficient of -0.92 would be reported as 0.92. For our analyses, we were not concerned with the direction of the relationship, only the strength of the relationship. The correlation coefficient was given a weight of 12.5.

As noted earlier, we used least squares to fit a linear trend to each of the reference populations and the supplemented population during the pre-supplementation period. Using the slope estimates for each trend line, we calculated the relative difference in slopes as the slope of the supplemented population minus the slope of the reference population, divided by the slope of the reference population. To scale this value between 0 and 1, we used absolute values, and depending on the direction of the slopes, we subtracted the relative difference from 1. The latter was needed to make sure a larger relative difference value indicated a small difference in slopes between the supplemented and reference populations. The relative difference score was given a weight of 7.5.

Finally, as a means to score effect size, we calculated the CV of the ratio of supplemented to reference population parameters (i.e., T/R). The CV was calculated as the standard deviation of the ratios divided by the absolute value of the mean ratios. The CV was subtracted from 1. This scaled the value from 0 to 1 with larger values representing the best condition. The CV was given a weight of 10, which is greater than the weight for trend, but less than the weight for correlation.

The total score for a reference population was calculated by multiplying the estimated value, which ranged from 0 to 1, by its weight. The sum of the five weighted values provided a total score, which ranged from 0 to 100. Based on several simulations, we set the cut-off score at 81. That is, if the total score for a given reference population equaled or exceeded 81, the population was included as a suitable reference population. If the total score fell below 81, the population was not considered a suitable reference. Based on the distribution of all scores possible, a score of 81 or greater represented only 3% of the total distribution. Thus, a cut-off of 81 is quite conservative.

Under Step 3, we used this method to select the final suite of suitable reference populations. Table 11 shows results from scoring each of the reference populations using the quantitative method. Using the cut-off criterion of 81, only the Naches, Marsh, and Sesech populations would be considered suitable reference populations for the Chiwawa supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values).

Table 11. Results from scoring potential reference populations using the selection criteria (pNOS, correlation, trend, and effect size). Populations with scores less than 81 were considered unsuitable as reference populations. Populations with scores equal to or greater than 81 were considered suitable references. These results were based on natural-log transformed data.

Potential reference populations	Population metric		
	Abundance	NORs	Productivity
Naches	85	88	91
Entiat	23	21	16
Marsh	79	91	87
Sesech	84	85	88
Little Wenatchee	51	53	49

An important benefit from scoring the different selection criteria is that the total scores can be used to weight the outcome of differing statistical results. For example, analyses may show that when three suitable reference populations are compared to the supplemented population, two of the reference populations may indicate a significant treatment effect, while the third indicates no effect. Under this scenario it is not clear if the supplementation program has or has not affected the abundance or productivity of the supplemented population. If, however, the two reference populations that produced a significant result had higher total scores than the reference population that did not indicate a significant result, one can place more weight on the results from populations with higher total scores.

Conclusions

The purpose of this exercise was to develop a method for selecting suitable reference populations that could be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity. The selection process included a three-step process (Figure 8). Step 1 identified populations with similar life-history characteristics, few or no hatchery spawners, a long time series of accurate abundance and productivity estimates, and similar freshwater habitat impairments and out-of-basin effects. Populations that met these criteria were then examined for their graphical and statistical relationship with the supplemented population (Step 2). The statistical analysis under Step 2 were converted to a quantitative model (Step 3) that was used to generate a weighted score for pNOS, correlation, trends, and effect sizes for each potential reference population. Reference populations with total scores of 81 or greater were selected as suitable reference populations.

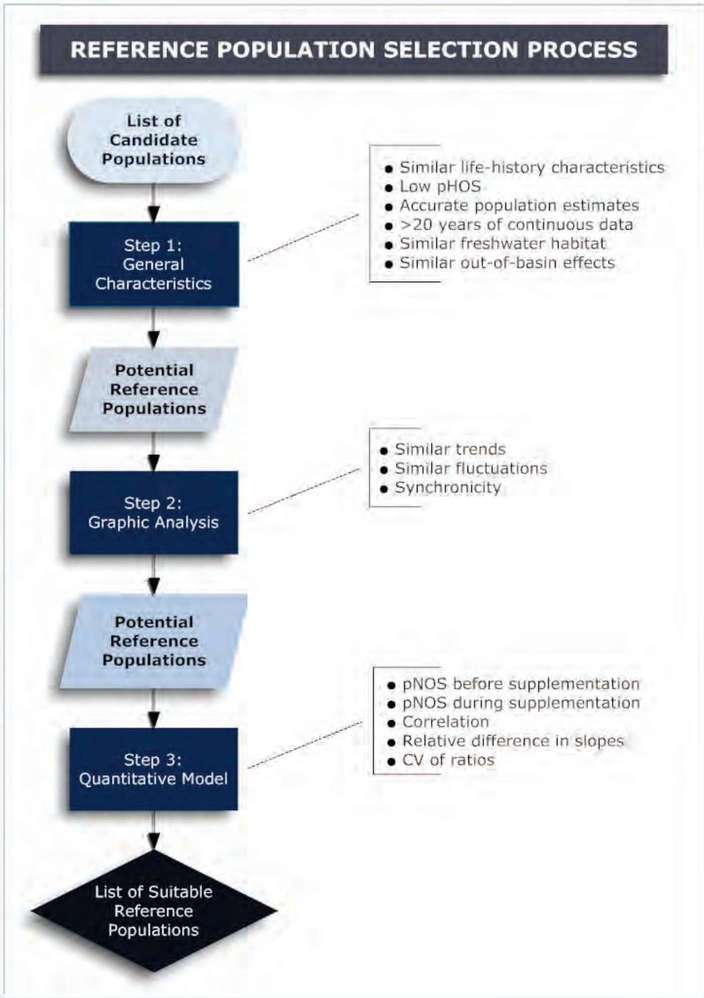

Figure 8. Three-step process for selecting suitable reference populations for supplemented populations.

We used this approach to select suitable reference populations for analyzing the effects of the Chiwawa spring Chinook supplementation program on fish abundance and productivity. The method indicated that the Naches, Marsh, and Sesech populations would serve as suitable reference populations for the Chiwawa spring Chinook supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values). However, because the presence of hatchery spring Chinook within those populations should decrease, they may serve as unique reference populations in which the comparisons change from all populations receiving

hatchery fish to only the Chiwawa population receiving hatchery fish. Therefore, we will continue to include both the Little Wenatchee and Entiat populations in future analyses.

An important assumption in the use of reference populations is that the supplemented and reference populations that tracked each other before supplementation would continue to track each other in the absence of supplementation. Given that the reference populations did not match the Chiwawa population on all criteria examined (Table 1) and some reference populations tracked the Chiwawa population more poorly than others (Figures 2-7; Tables 2-4), there may be some uncertainty as to whether differences observed between the Chiwawa and reference populations during the supplementation period are associated with the hatchery program, "nuisance" factors[16], or a combination of both. In addition, we have no ability to regulate or control activities in reference areas. Any large-scale change (man-made or natural) in reference areas could affect our ability to assess the effectiveness of the supplementation program.

Because we have no ability to maintain reference areas for long periods of time and may not be able to control all activities even within the supplemented populations, we propose the use of a "causal-comparative" approach to strengthen the certainty of our inferences (Pearsons and Temple 2010). The causal-comparative approach relies on correlative data to try and make a case for causal inference.[17] Correlation is used to rule out alternative hypotheses (note that we make our case as much if not more by disproving plausible alternatives as we do by showing that the data are consistent with a hypothesis). For example, large scale land-use activities or natural events can affect stream flows, fine sediment recruitment, and water temperatures. Changes in these factors can affect the freshwater survival and productivity of fish independently of supplementation programs. If changes in habitat, migratory, and ocean conditions do not affect reference and treatment populations similarly, inferences associated with supplementation programs may be confounded. By measuring and tracking these extraneous factors within reference and treatment areas, we can assess the effects of these state variables on population conditions independent of the supplementation programs. This allows us to more effectively assess the influence of supplementation programs on populations.

To that end, we recommend that the following state variables be measured and tracked within the Chiwawa Basin and each of the reference areas: mean annual precipitation, total and riparian forest cover, road density, impervious surface, and alluvium. These variables can be used to describe differences in water temperatures at different life stages (pre-spawning, egg incubation, and summer rearing) and substrate characteristics, including fine sediments and embeddedness (Jorgensen et al. 2009). They can be used to assess possible changes in spawner abundance, NORs, and productivity that are independent of supplementation.

---

[16] A "nuisance" factor is any factor that is outside the control of the experimenter and can affect the response variable (spawner abundance or productivity). In this case, nuisance factors may include differences in freshwater habitat trends and conditions, out-of-basin effects (e.g., migration and ocean survival), and hatchery strays that affect the Chiwawa and reference populations differently.

[17] It is important to point out that correlation does not demonstrate cause-and-effect. It only suggests a relationship between variables. Thus, inferences based on correlation lack the certainty that is associated with a design-based approach.

Analyses with Reference Populations

Once suitable reference populations are selected, methods for analyzing the supplemented and reference populations need to be identified. What follows is a description of different analyses that can be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity using reference populations. Later in this report we describe methods for assessing supplementation effects when reference populations are not available.

We used some of the reference populations selected for the Chiwawa program to illustrate the different methods for evaluating the effects of the supplementation program on spawner abundance, NORs, and productivity. For abundance, we selected the Naches, Entiat, Little Wenatchee, and Sesech populations as suitable references for the Chiwawa population. For NORs, we selected the Naches, Entiat, Marsh, and Little Wenatchee populations as suitable references. For productivity, we selected the Naches, Sesech, Little Wenatchee, and Marsh Creek as suitable references for the Chiwawa. As noted earlier, we included the Little Wenatchee and Entiat populations, even though they did not meet all the criteria for suitable reference populations.

Analysis of Trends

As a first step, we used trend analyses to assess the effects of the Chiwawa supplementation program on spring Chinook spawner abundance, NORs, and productivity. Here, we compared the slopes of the trends between each treatment/reference pair before and during supplementation using t-tests. If the hatchery program is successfully supplementing the natural spring Chinook population, trends in spawner abundance and NORs should deviate significantly (i.e., the slope of the supplemented population should be greater than the slopes of the reference populations during the supplementation period). For productivity, the slope of the supplemented population, relative to the reference population, should increase or remain the same.

Trend analysis indicated that the relationship of slopes of spawner abundance between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 9; Table 12). This was true for both transformed and untransformed abundance data. Before supplementation, spawner abundances trended down in both the Chiwawa and reference populations (Figure 9). During the period of supplementation, abundances in both the Chiwawa and reference populations trended upward. Interestingly, in nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the supplementation period than in the pre-supplementation period (Table 12). This was most evident in the transformed abundance data (Figure 9).

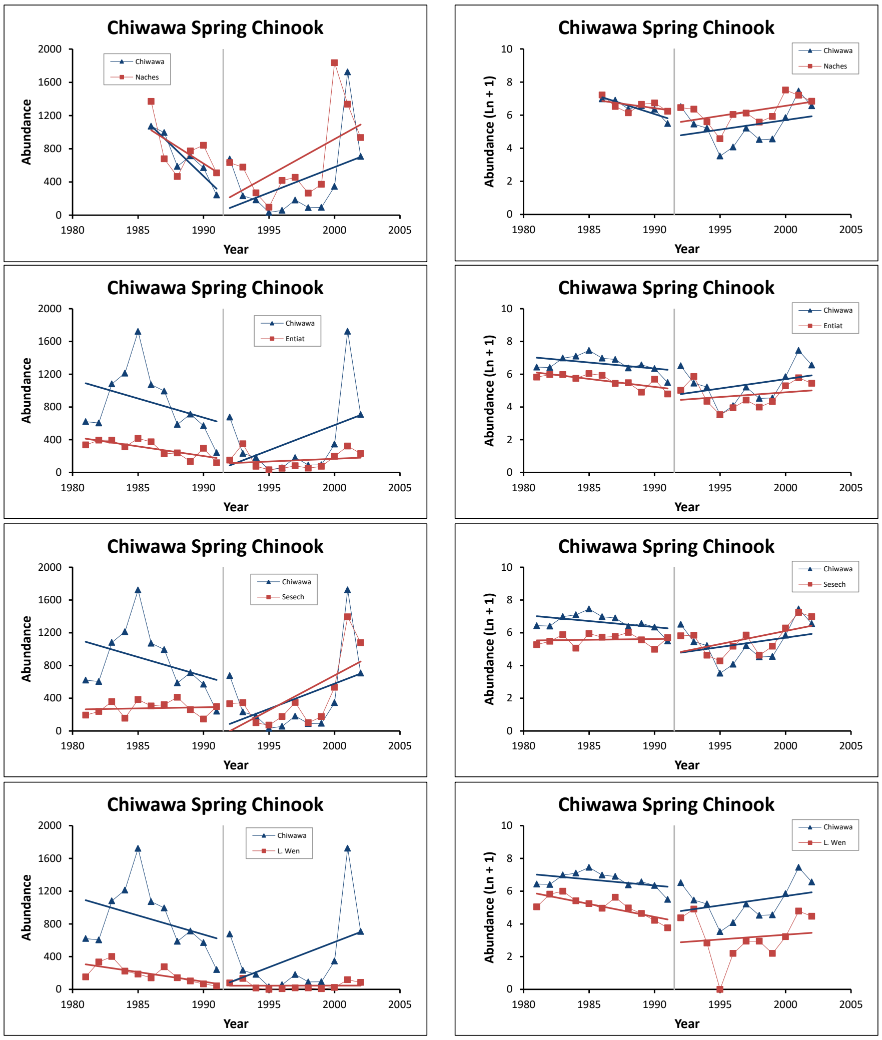

Figure 9. Trends in spring Chinook spawner abundance in the Chiwawa and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed spawner abundance data; those on the right include natural-log transformed data.

Table 12. Trend analysis indicated that the relationship of slopes of NORs between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 10; Table 13). Before supplementation, Chiwawa NORs trended downward more strongly than the reference populations (Figure 10). However, during the supplementation period, both the Chiwawa and reference population NORs trended upward in parallel. In nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the pre-supplementation period than in the supplementation period (Table 13).

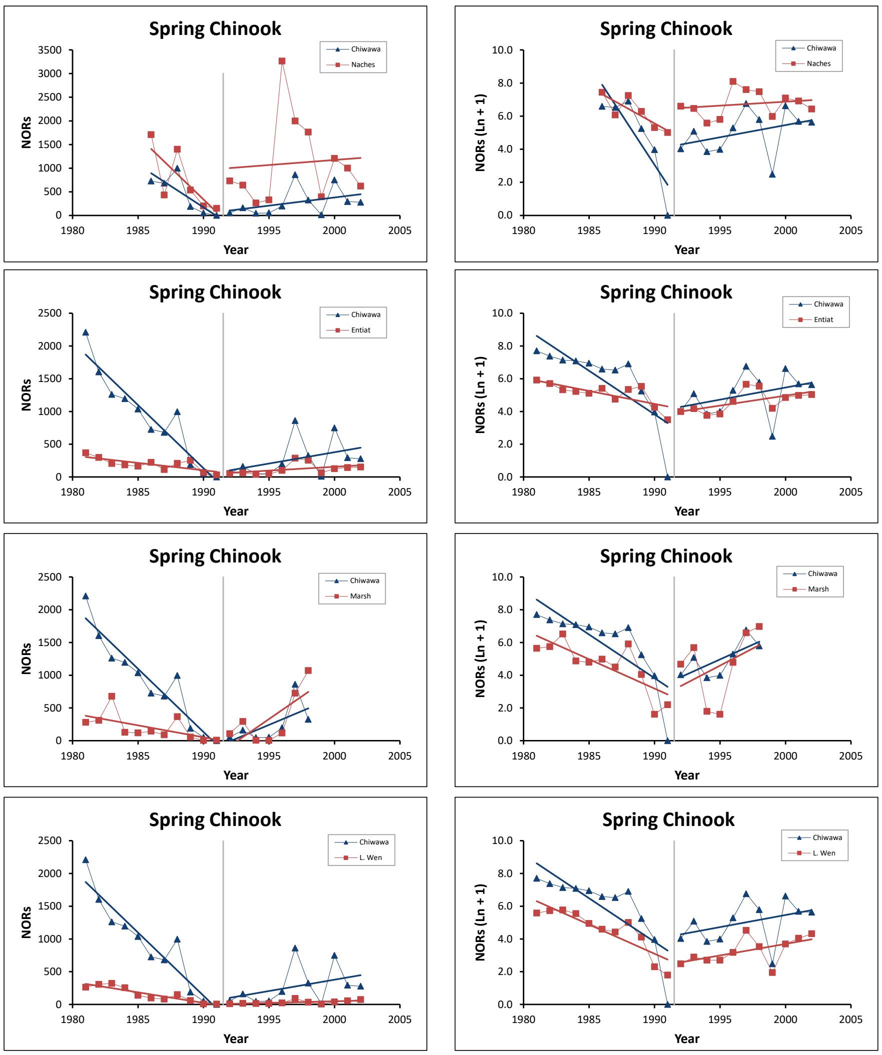

Figure 10. Trends in spring Chinook natural-origin recruits (NORs) in the Chiwawa and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed NORs; those on the right include natural-log transformed data.

Table 13. As with NORs and spawner abundance data, trend analysis indicated that the relationship of slopes of productivity (recruits/spawner) between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 11; Table 14). This was true for both transformed and untransformed productivity data. Before supplementation, productivities trended down in both the Chiwawa and reference populations (Figure 11). During the period of supplementation, productivities fluctuated widely in both the Chiwawa and reference populations. Nevertheless, during the supplementation period, productivities generally increased in both the reference and Chiwawa populations. Unlike with spawner abundance, the Pearson correlation coefficients resulting from analysis of productivity data were generally higher in the pre-supplementation period than during the supplementation period (Table 14).

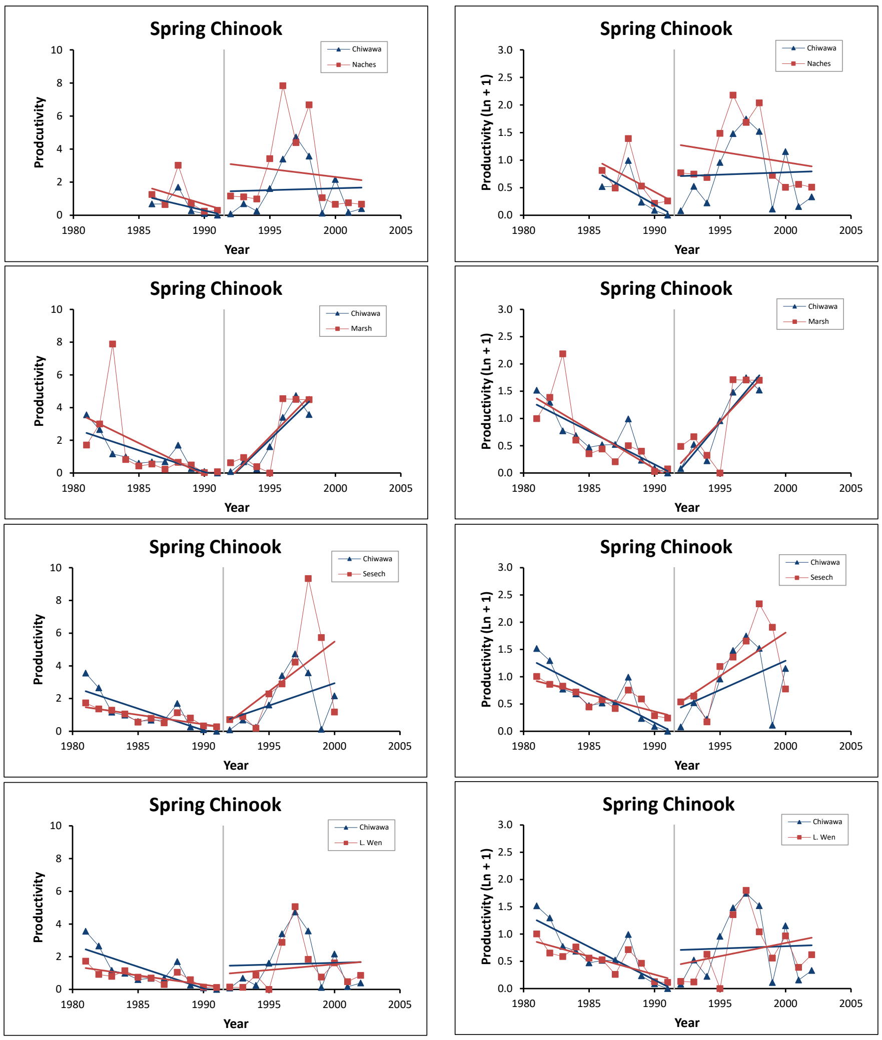

Figure 11. Trends in spring Chinook productivity (recruits/spawner) in the Chiwawa (supplemented) and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed productivity data; those on the right include natural-log transformed data.

Table 14. Little Wenatchee	0.862*	0.751*	-1.811	-0.480	0.087	0.637

Using trend analysis, we found no evidence that the supplementation program has significantly increased the spawner abundance and NORs of spring Chinook in the Chiwawa Basin. Even though we documented an increasing trend in spawner abundance and NORs during the supplementation period, a similar increase in spawner abundance and NORs was observed in the reference populations. In addition, we found no evidence that the supplementation program has increased the productivity of spring Chinook in the Chiwawa Basin. Importantly, the productivity of spring Chinook in the Chiwawa Basin did not trend downward during the supplementation period. Thus, based on trend analysis, it appears that the supplementation program has not increased or decreased the abundance and productivity of spring Chinook in the Chiwawa Basin.

We note that this exercise only tests the slopes of the trend lines. It does not test for differences in elevations of the trend lines. A supplementation program could increase spawner abundance, NORs, and productivity of the target population without changing the slopes of the trend lines. That is, supplementation could cause the elevation of the trend line to be greater during the supplementation period than during the pre-supplementation period. In the next section we evaluate elevation differences by testing mean differences before and after supplementation.

Analysis of Mean Differences, Ratios, and Rates

For assessing mean differences between supplemented and reference populations, we derived three different response variables using transformed and untransformed spawner abundance, NORs, and productivity data. The first included difference scores, which were calculated as the difference between paired treatment and reference data (T-R). The second included ratios, which were calculated as the ratio of paired treatment and reference data (T/R). Finally, we calculated the differences in annual changes in paired treatment and reference population data (ΔT-ΔR; see footnote #2).

If the hatchery program is successfully supplementing the natural spring Chinook population, the mean difference or ratio score of paired spawner abundance data and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean difference or ratio score during the supplementation period should be equal to or higher than the pre-supplementation period. We tested the following statistical hypotheses.

Spawner Abundance and NORs:

Ho: Mean Difference (or Ratio) before supplementation ≥ Mean Difference (or Ratio) during supplementation.

Ha: Mean Difference (or Ratio) before supplementation < Mean Difference (or Ratio) during supplementation (i.e., $\mu_{pre} - \mu_{post} < 0$).

Productivity (Recruits/Spawner):

Ho: Mean Difference (or Ratio) before supplementation ≤ Mean Difference (or Ratio) during supplementation.

Ha: Mean Difference (or Ratio) before supplementation > Mean Difference (or Ratio) during supplementation (i.e., $\mu_{pre} - \mu_{post} > 0$).[18]

For each set of response variables, we tested before/after supplementation effects using a one-tailed Aspin-Welch unequal-variance test. We used the Aspin-Welch unequal-variance test instead of Student's t-test, because in nearly every case, the variances of response variables in the pre-treatment and supplementation periods were unequal.[19] This was true even for natural-log transformed variables. We used the modified Levene equal-variance test to assess the equality of variance. In some cases, the distributions of response variables were not normal (based on the Omnibus Normality test and examination of histograms, normal probability plots, and box plots). Therefore, we also used a randomization test, based on 10,000 Monte Carlo simulations, to assess differences in response variables before and during supplementation. The randomization procedure only allowed the testing of two-tailed hypotheses. Therefore, we generated 95% confidence intervals on the mean difference ($\mu_{pre} - \mu_{post}$) using bootstrapping methods to determine the direction of the difference. We generated 5,000 bootstrap samples to calculate confidence intervals.

All these statistical methods assume that the samples of derived difference or ratio scores from the pre-supplementation and supplementation periods were independent. However, BACI designs, like time-series trend analysis, are repeated-measures designs and therefore are susceptible to temporal correlations in the data. This means that the two samples of difference or ratio scores may not be independent. Under this scenario, ARIMA models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). ARIMA models can be fit individually to the reference and supplemented time series data, or to a derived data series created by taking the ratio or difference of the supplemented/reference data at each time step. ARIMA models, however, require a long time series (N > 40) and therefore we could not use them to model

18 Because of the logic of null hypothesis testing, the rejection of the null hypothesis of no difference in productivity would mean that the supplementation program has reduced the productivity of the target population (here rejection of the null indicates "harm"). Notice that the rejection of the null hypothesis of no difference in spawner abundance means that the supplementation program has improved the spawner abundance in the target population (here rejection of the null indicates "benefit").

19 In cases in which the variances were equal, both the Aspin-Welch test and Student's t-test gave the same result.

the spring Chinook data. Thus, we acknowledge that our analyses may be confounded if the samples are not independent.

Difference Scores (T-R)

Analysis of supplementation effects on spawner abundance using difference scores indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 15; Figure 12). Only the Little Wenatchee-Chiwawa pairing using transformed abundance data indicated a significant increase in spawning abundance following supplementation. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction (i.e., CIs > 0). That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 12).

Table 15. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed spawner abundance data. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

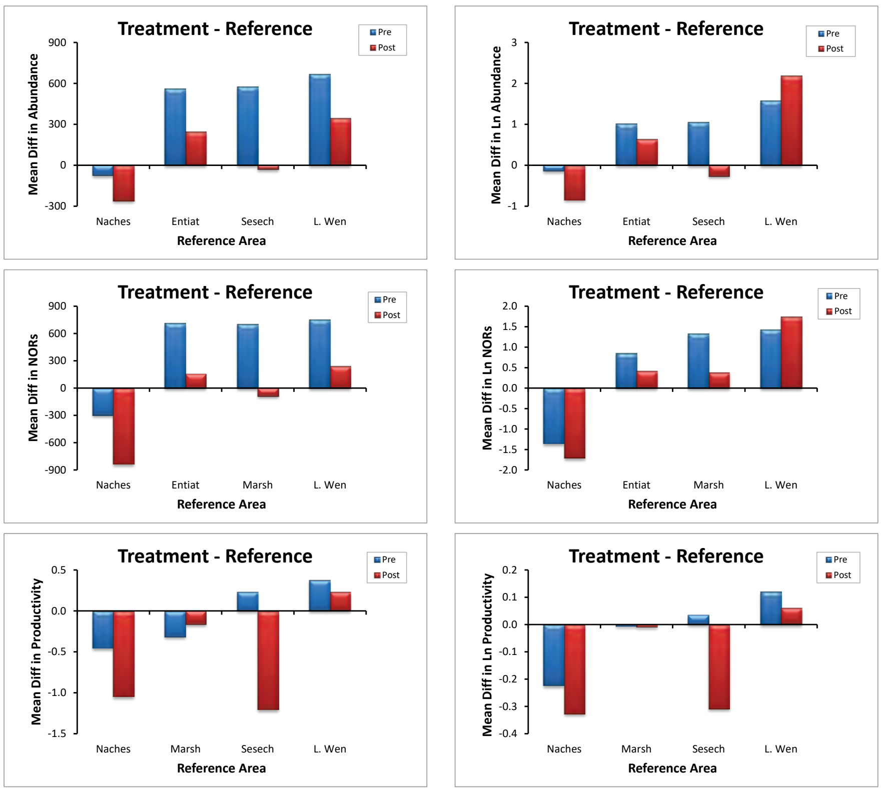

Figure 12. Mean difference (Treatment – Reference) scores of untransformed (figures on the left) and transformed (figures on the right) spawner abundance, natural-origin recruits (NORs), and productivity data before (pre) and after (post) spring Chinook supplementation in the Chiwawa Basin. Positive effects of supplementation on spawner abundance and NORs are indicated when the post-supplementation (red) bars are greater than their corresponding pre-supplementation (blue) bars. Negative effects of supplementation on productivity are indicated when the pre-supplementation (blue) bars are greater than their corresponding post-supplementation (red) bars.

Analysis of supplementation effects on NORs using difference scores indicated that supplementation did not significantly increase NORs in the Chiwawa Basin (Table 16; Figure 12). The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction. That is, compared to the reference populations, NORs decreased in the Chiwawa Basin during the supplementation period (Figure 12).

Table 16. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed natural-origin recruits. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

Analysis of supplementation effects on productivity (adult recruits/spawner) using difference scores indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 17; Figure 12). All tests, regardless of treatment-reference pairs, indicated that productivity did not change significantly during the supplementation period. These tests indicate that supplementation has not negatively affected the productivity of spring Chinook salmon in the Chiwawa Basin.

Table 17. Ratio Scores (T/R)

As with difference scores, analysis of supplementation effects on spawner abundance using ratios indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 18; Figure 13). Only the Little Wenatchee-Chiwawa pairing indicated a significant increase in spawning abundance following supplementation. Analysis with both transformed and untransformed Little Wenatchee-Chiwawa data indicated a significant effect. In contrast, only difference scores derived from transformed data indicated a significant effect. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction. That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 13).

Analysis of supplementation effects on productivity (adult recruits/spawner) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 20; Figure 13). Although the Aspin-Welch test indicated a significant effect when comparing the Chiwawa to the Marsh Creek population, both the randomization test and the bootstrap CI did not indicate a significant effect. These tests indicate that supplementation has probably not negatively affected the productivity of spring Chinook salmon in the Chiwawa Basin.

We believe results from analysis of mean differences of annual change (ΔT-ΔR) in spawning abundance, NORs, and productivity are difficult to interpret and may be insensitive to treatment effects. A simpler analysis, which is also easier to interpret, is the use of trend analysis. Therefore, we recommend that analyses using differences of annual change be replaced with trend analysis.

Corrections for Density Dependence and Carrying Capacity

The analyses described above assume that the density of spawners or recruits does not affect the survival and productivity of fish. However, it is well known that the density of fish can affect the number of recruits as well as the productivity of the population. This occurs through the relationship between density and mortality. Mortality of fish can be generally classified as density independent and density dependent. In general, when densities are low, the mortality is density independent, but as densities increase, the amount of density-dependent mortality increases. Monitoring programs can make use of this information to derive density-corrected estimates of productivity. In this section, we describe two different methods for deriving density-corrected estimates of productivity.

The first method controlled the effects of density on productivity (adult recruits/spawner; R/S) by partitioning observed productivities into density-independent and density-dependent productivity. When abundance is below the minimum number of spawners (S) needed to produce the maximum number of recruits (K_{sp}), the observed productivity is used in statistical tests. However, when the abundance is equal to or above K_{sp}, the modeled value of productivity (R/K_{sp}) is used in statistical tests.

$$\boldsymbol{Adj\ R/S} = \begin{cases} \boldsymbol{R/S,} & \boldsymbol{if\ S < K_{sp}} \\ \boldsymbol{R/K_{sp},} & \boldsymbol{if\ S \geq K_{sp}} \end{cases}$$

The density-independent and density-dependent productivities were then combined in a single test.

The second method was based on one of the goals of supplementation, which is to fill the capacity of the environment with fish. This method corrects for differences in carrying capacities between the supplemented and reference populations. We did this by calculating the percent saturation of NORs. That is, we calculated the fraction of the habitat (τ) that was filled with NORs by dividing the observed NOR by the modeled maximum number of NORs (K_R) that the habitat could support.

$$\boldsymbol{\tau = \frac{NOR_{obs}}{K_R}}$$

Note that 1-τ represents the unused portion of the carrying capacity and is the term that is multiplied by the exponential growth equation to derive the logistic growth equation. We included τ in the statistical analyses.

These two methods require the estimation of carrying capacity (K_R) and the spawning abundance that produces the maximum number of recruits (K_{sp}). We estimated these parameters for both reference populations and the supplemented population using Ricker, Beverton-Holt, and smooth hockey stick stock-recruitment models. We used only spawner abundance as a predictor of subsequent brood recruitment. We made the following assumptions in proceeding with the analysis:

- *Density-dependent mortality*—For some time period before recruitment, the brood instantaneous mortality rate is proportional to the number of parent spawners (Ricker 1954).
- *Lognormal variation*—At any particular spawning stock size, the variation in recruitment is log-normally distributed about its average, and acts multiplicatively (Quinn and Deriso 1999).
- *Measurement error*—Error in spawning stock size estimates (measurement error) is small relative to the range of spawning stock sizes observed (Hilborn and Walters 1992). Variation in realized recruitment at any particular spawning stock size (process error) dominates recruitment measurement error.
- *Stationarity*—The average stock-recruitment relationship is constant over time (Hilborn and Walters 1992). That is, environmental conditions randomly affect survival independent of stock size or time.

In general, the methods we used to fit the models to the data followed those outlined in Hilborn and Walters (1992) and Froese (2008). The Ricker model, which assumes that the number of recruits increases to a maximum and then declines as the number of spawners increases, takes the form:

$$\boldsymbol{E(R) = \alpha S e^{-\beta S}}$$

where E(R) is the expected recruitment, S is spawner abundance, α is the number of recruits per spawner at low spawning levels, and β describes how quickly the recruits per spawner drop as the number of spawners increases. We estimated K_R as:

$$\boldsymbol{K_R = \left(\frac{\alpha}{\beta}\right) e^{-1}}$$

and K_{sp} as:

$$\boldsymbol{K_{sp} = \frac{1}{\beta}}$$

The Beverton-Holt model assumes that the number of recruits increases constantly toward an asymptote as the number of spawners increases. After the asymptote is reached, the number of recruits neither increases nor decreases. The asymptote represents the maximum number of recruits the system can support (i.e., carrying capacity for the system; K_R). The Beverton-Holt curve takes the form:

$$\boldsymbol{E(R) = \frac{(\alpha S)}{(\beta + S)}}$$

where E(R) and S are as above, α is the maximum number of recruits produced (K_R), and β is the number of spawners needed to produce (on average) recruits equal to one-half the maximum number of recruits. Because $K_{sp} = \infty$ in the Beverton-Holt model, we estimated K_{sp} as the number of spawners needed to produce 0.99(K_R).

Like the Beverton-Holt model, the smooth hockey stick model assumes that the number of recruits increases toward an asymptote (carrying capacity; K_R) as the number of spawners increases. After the carrying capacity is reached, the number of recruits neither increases nor decreases. The carrying capacity represents the maximum number of recruits the system can support. This curve

takes the form (Froese 2008):

$$\boldsymbol{E(R) = R_\infty\left(1 - e^{-\left(\frac{\alpha}{R\infty}\right)S}\right)}$$

where E(R) and S are as above, α is the slope at the origin of the spawner-recruitment curve, and R_∞ is the carrying capacity of recruits (note that $R_\infty = K_R$). As with the Beverton-Holt model, we estimated K_{sp} as the number of spawners needed to produce $0.99(K_R)$.

We used non-linear regression to fit the three models to spawner-recruitment data. Before fitting the models, we transformed recruitment data using natural logs. We estimated bias and uncertainty measures (95% CI) for the model parameters using bootstrap procedures, which assumed that the {R, S} sample represented or approximated the population. The number of bootstrap samples was 3,000. We computed and stored the non-linear regression results for each bootstrap sample. We then calculated the bootstrap 95% CI by arranging the 3,000 bootstrap parameter values in sorted order and selected the 2.5 and 97.5 percentiles from the list.

We used Akaike's Information Criterion for small sample size (AIC_c) to determine which model(s) best explained the relationship between spawners and recruitment in the supplemented and reference populations. AIC_c was estimated as:

$$\boldsymbol{AIC_c = -2log\big(£(\theta|data)\big) + 2K + \left(\frac{2K(K+1)}{n-K-1}\right)}$$

where *log(£(θ|data))* is the maximum likelihood estimate, *K* is the number of estimable parameters (structural parameters plus the residual variance parameter), and *n* is the sample size (Burnham and Anderson 2002). We used least-squares methods to estimate *log(£(θ|data))*, which was calculated as $log(\sigma^2)$, where σ^2 = residual sum of squares divided by the sample size ($\sigma^2 = RSS/n$). AIC_c assessed model fit in relation to model complexity (number of parameters). The model with the smallest AIC_c value represented the "best approximating" model within the model set. Remaining models were ranked relative to the best model using AIC_c difference scores (ΔAIC_c), Akaike weights (w_i), and evidence ratios. Models with ΔAIC_c values less than 2 indicated that there is substantial support for these models as being the best-fitting models within the set (Burnham and Anderson 2002). Models with values greater than 2 had less support. Akaike weights are probabilities estimating the strength of the evidence supporting a particular model as being the best model within the model set. Models with small w_i values are less plausible as competing models (Burnham and Anderson 2002). If no single model could be specified as the best model, a "best subset" of competing models was identified using (1) AIC_c differences to indicate the level of empirical support each model had as being the best model, (2) evidence ratios based on Akaike weights to indicate the relative probability that any model is the best model, and (3) coefficients of determination (R^2) assessing the explanatory power of each model.

Stock-Recruitment Analysis

We successfully fit stock-recruitment models to the Chiwawa and reference population data. The span of spawner data for the Chiwawa and reference populations was greater than 14 times the minimum observed spawners, which should provide sufficient contrast for estimation of model parameters. In addition, the span of recruitment data was greater than 12 times the minimum observed recruitment, again providing sufficient contrast for estimation of parameters. The relationship between natural log R/S and spawners indicated that some of the highest productivities occurred at the lower spawner levels and the lowest productivities generally occurred at the highest spawner levels (Figure 15). This is consistent with the assumption of density-dependent mortality.

Although model fits were generally poor, explaining less than 40% of the residual variation in natural-log recruitment data, we were able to estimate average maximum recruitment levels (K_R) and the spawning levels needed to produce maximum recruitment (K_{sp}) (Table 24; Figure 15). For all populations examined, Akaike information criterion was unable to identify a best approximating model (i.e., ΔAIC_c values were less than 2, indicating support for all three models). However, evaluation of 95% CIs and the asymptotic correlation coefficients indicated that the smooth hockey stick model may be the best approximating model for each population. Therefore, we used estimates of K_R and K_{sp} derived from the smooth hockey stick model to correct for density dependence and different carrying capacities in treatment-reference comparisons.

As part of the regression diagnostics, we examined the dependence of the model residuals on time and found a significant ($P < 0.05$), positive, one-year-lag autocorrelation for the Entiat (0.562), Marsh (0.551), Sesech (0.564), and Little Wenatchee (0.629) populations. For the purposes of our work here, we did not attempt to correct for this one-year-lag correlation in the residuals. Future analyses will explore the use of autoregressive models (e.g., AR1; Noakes et al. 1987) to correct for autocorrelation.

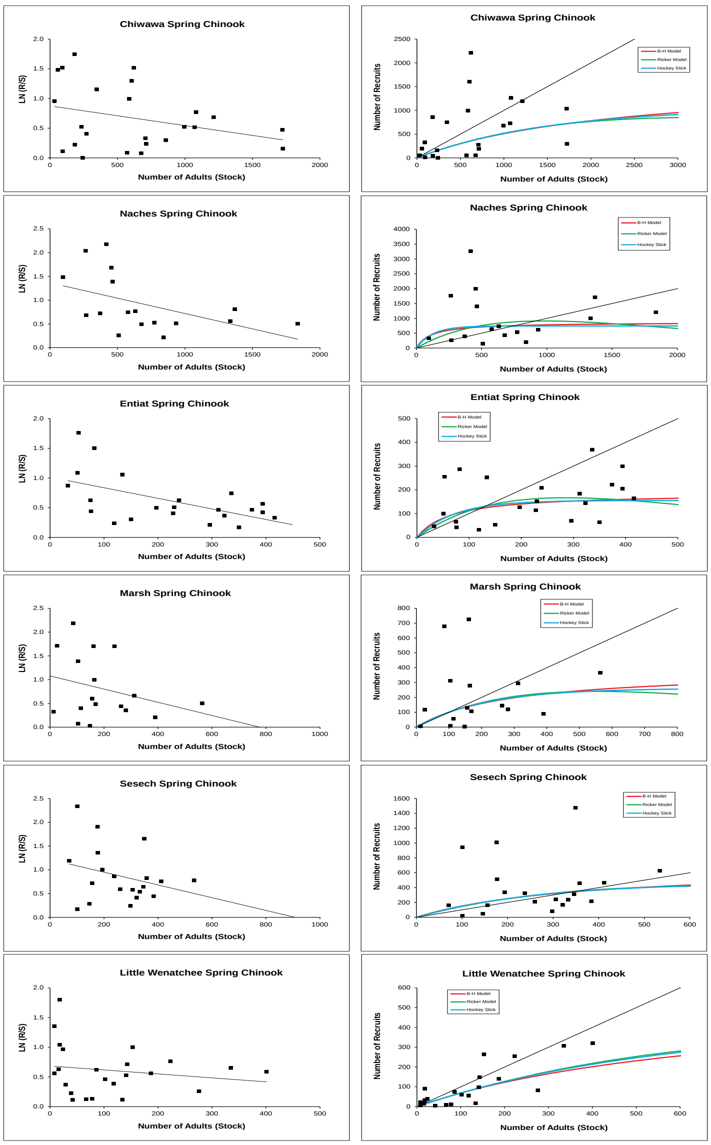

Figure 15. Relationships between natural log recruits/spawner (LN R/S) and spawners (Stock) in the Chiwawa and reference populations (figures on the left) and relationships between numbers of untransformed recruits and spawners in the Chiwawa and reference populations (figures on the right). Figures on the right also show the fit of the Ricker, Beverton-Holt, and the smooth hockey stick models to the data (black straight line represents R=S).

Table 24. Results from fitting Ricker, Beverton-Holt, and smooth hockey stick models to stock-recruitment data from the Chiwawa and reference populations. 95% CI on parameter estimates are based on 3,000 bootstrap trials; Corr coef = asymptotic correlation of the parameter estimates; K_R = maximum natural origin recruits (recruits at carrying capacity); K_{sp} = number of spawners needed to produce K_R; AICc = Akaike's Information Criterion for small sample size; Adj R^2 = coefficient of determination that is adjusted for the number of parameters in the model.

Method 1: Productivity Data Adjusted for Density Dependence

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects based on the smooth hockey stick model) using difference scores indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 25; Figure 16). All tests, regardless of treatment-reference pairs, indicated that productivity did not change significantly during the supplementation period, even though productivity did decrease during the supplementation period (Figure 16). These results are consistent with those based on unadjusted productivity data (Table 17). This is because most abundance estimates were below the level of assumed density dependence.

Table 25. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

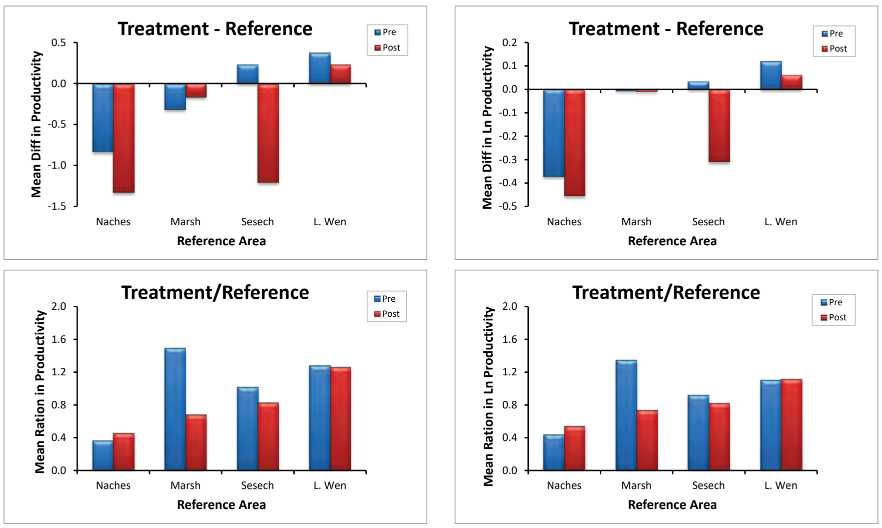

Figure 16. Mean differences (Treatment – Reference; figures on the top) and mean ratios (Treatment/Reference; figures on the bottom) of transformed and untransformed productivity data (adjusted for density dependence) before (pre) and after (post) spring Chinook supplementation in the Chiwawa Basin. Negative effects of supplementation on productivity are indicated when the pre-supplementation (blue) bars are greater than their corresponding post-supplementation (red) bars.

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 26; Figure 16). The Aspin-Welch test and the 95% CIs did indicate a significant effect when comparing the Chiwawa to the Marsh Creek population. These results are consistent with those using unadjusted productivity data (Table 20). Again, this is because most abundance estimates were below the level of assumed density dependence.

Table 26. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean ratios during the supplementation period were less than mean ratios during the pre-supplementation period.

Our analyses assume that there is a spawner abundance (K_{sp}) at which density-independent effects end and density-dependent effects begin. In reality, density-dependent effects occur at low spawning abundance and intensify as spawning abundance increases (evident in the changing slope of the three stock-recruitment curves used in our analyses). We did not account for these increasing density-dependent effects at spawner abundances less than K_{sp}. If we accounted for the increasing effects of density dependence at spawning abundances less than K_{sp}, the analysis with and without productivity adjustments may give different results.

Method 2: Fraction of Carrying Capacity Filled with NORs

We analyzed the effects of supplementation on filling the capacity of the habitat with natural-origin recruits. The smooth hockey stick model derived the carrying capacity (K_R) estimates for the Chiwawa and reference populations. The fraction of the carrying capacity filled with Chinook recruits before and during supplementation for the Chiwawa and reference populations is provided in Table 27. These data indicate that for the Chiwawa population, the mean fraction of the K_R filled with fish decreased significantly from the pre-supplementation period through the supplementation period (Table 27). Likewise, the Entiat and Little Wenatchee populations showed a significant decline in the mean fraction of K_R filled with adult recruits. In contrast, the mean fraction of K_R in the Naches and Marsh Creek populations increased during the same period (Table 27).[20] Interestingly, the fraction of K_R filled with adult recruits for all populations trended downward during the pre-supplementation period (Figure 17). During the supplementation period, however, the fraction of K_R filled with adult recruits trended upward for all populations. These results suggest that agents of mortality outside the Chiwawa and reference populations were reducing recruitment to the populations.

20 Although we do not show the results here, statistical analysis of the mean fraction of carrying capacity filled by adult recruits using natural-log transformed data produced the same result as using untransformed data. This was true for all populations.

Table 27. Fraction of the carrying capacity that was filled with Chinook salmon adult recruits in the Chiwawa and reference populations before (pre) and during (post) supplementation in Chiwawa Basin. The smooth hockey stick model estimated carrying capacity for each population. Statistical results from comparing the pre and post mean scores using the Aspin-Welch unequal-variance test are provided at the bottom of the table.

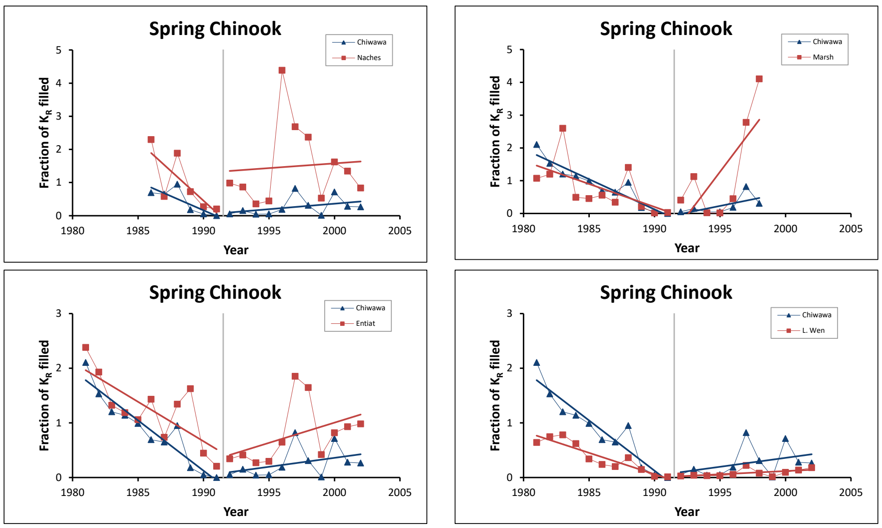

Figure 17. Trends in the fraction of the carrying capacity that was filled with Chinook salmon adult recruits in the Chiwawa and reference populations before (pre) and during (post) supplementation in Chiwawa Basin. The vertical lines in the figures separate the pre- and post-supplementation periods. The smooth hockey stick model estimated carrying capacity for each population.

We then compared the mean difference scores and ratios between the Chiwawa and reference populations before and during supplementation using data representing the fraction of K_R filled with adult recruits. In most of the Chiwawa-reference population comparisons, the absolute value of the mean difference between the fraction of K_R filled with recruits was greater in the supplementation period than during the pre-supplementation period; two of the four pairings were significant (Table 28; Figure 18). Analysis of difference scores using natural-log transformed data indicated that three of the four pairings were significant (Table 28).

Results from analyses using ratios were similar to results using difference scores. Mean ratio scores were generally smaller during the supplementation period than during the pre-supplementation period (Figure 18). This indicated that the mean fraction of K_R filled by adult recruits in most reference populations was greater during the supplementation period than during the pre-supplementation period (i.e., the denominator in the ratio increased between the pre- and post-supplementation periods). In contrast, the fraction of K_R filled by adult recruits in the Chiwawa decreased from the pre- to post-supplementation period (i.e., the numerator in the ratio decreased between the pre- and post-supplementation periods). Thus, unlike the Chiwawa population, the capacity of most reference populations was becoming more saturated during the period when the Chiwawa was being supplemented. Statistical analysis with mean ratios indicated that two of the four pairings were significant (Table 29).

Analyses comparing the Little Wenatchee with the Chiwawa indicate that adult recruits to the Little Wenatchee have been well below its carrying capacity. During the pre-supplementation period, the capacity of the Little Wenatchee was on average 37% saturated with adult recruits. During the supplementation period, the capacity of the Little Wenatchee declined to 8% saturation

with adult recruits (a 22% decline). The Chiwawa, during the pre-supplementation period, was on average 86% saturated. During the supplementation period, percent saturation in the Chiwawa decreased to 26% (a 30% decrease). During the same time periods, the capacity of the Entiat population, which until recently has been supplemented, declined from 124% to 78% saturation (a 63% decline).

Table 28. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on the fraction of the habitat capacity (K_R) that is filled with natural origin recruits. Analyses include both transformed and untransformed data. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

Comparing Stock-Recruitment Curves

As a final set of treatment and reference population comparisons, we compared the stock-recruitment curves of the Chiwawa population (using {R, S} data only from the supplementation period) to the reference populations (using all available {R, S} data). Specifically, we tested whether the regression parameters were equal between the Chiwawa population and the reference populations, and whether the fitted curves coincided between populations. Earlier in this report we described the data, methods, and results of fitting the Ricker, Beverton-Holt, and smooth hockey stick curves to the data. Because AIC_c was unable to identify a best approximating model, here we included all three models in our analyses. We tested the following hypotheses.

Parameter equivalence:

Ho: Stock-recruitment parameters (α and β) of the Chiwawa population = Stock-recruitment parameters of the reference populations.

Ha: Stock-recruitment parameters (α and β) of the Chiwawa population ≠ Stock-recruitment parameters of the reference populations.

Curve equivalence:

Ho: Modeled stock-recruitment curves of the Chiwawa population = Modeled stock-recruitment curves of the reference populations.

Ha: Modeled stock-recruitment curves of the Chiwawa population ≠ Modeled stock-recruitment curves of the reference populations.

We used two-sided randomization tests to test the null hypotheses of equal model parameters and that fitted curves coincided. Because the total number of permutations was in the millions, we used a Monte Carlo approach to randomly select 10,000 permutations. The test statistic for comparing the model parameters was formed by summing the difference between the population parameter estimates for each pair of populations. The test statistic for comparing the whole curve was formed by summing the difference between the estimated predicted values for each pair of populations at 500 equally spaced points along the curve.

Ricker Relationships

Ricker curves differed significantly between the Chiwawa and reference populations (Figure 19; Table 30). Interestingly, however, the parameters in the Ricker model did not differ significantly among most populations (Table 30). Only the β parameter differed significantly between the Chiwawa and Entiat populations.

In the Ricker model, the α parameter represents intrinsic productivity (i.e., recruits per spawner at low spawner densities). In this analysis, there was not enough evidence in the stock-recruitment data to reject the hypothesis of inequality in intrinsic productivity. Thus, this test was unable to demonstrate that supplementation, based on the Ricker curve, affected productivity in the Chiwawa population.

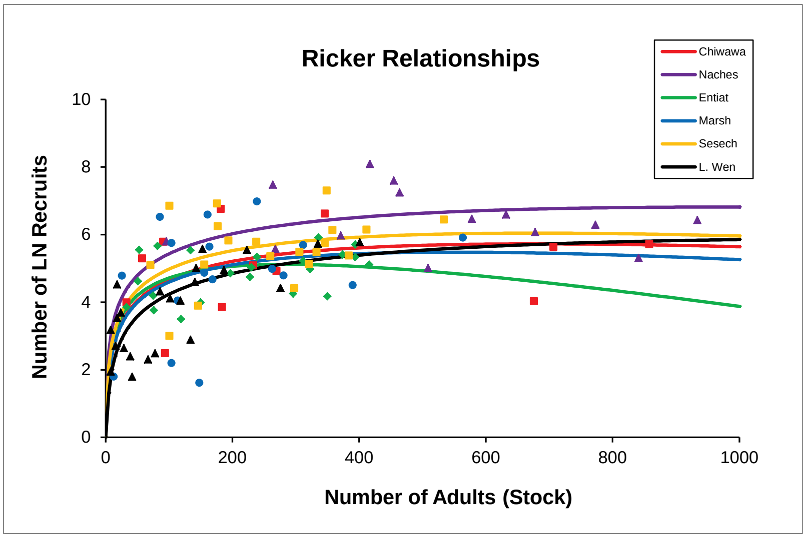

Figure 19. Scatter plot of the number of spawners and natural log adult recruits and fitted Ricker curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

Table 30. Randomization test results comparing the equality of Ricker curves and equality of parameter values (α and β). Randomization tests were based on 10,000 Monte Carlo samples. Equality or curves was based on 500 points along the x-axis (spawner abundance axis).

Curves tested	Curve inequality randomization P-value	Parameter inequality		
		Model Parameter		Randomization P-value
		Chiwawa	Reference

		β = 0.0015	β = 0.0008	0.203

Beverton-Holt Relationships

Beverton-Holt curves differed significantly only between the Chiwawa and Naches populations (Figure 20; Table 31). There was no significant difference in curves between the Chiwawa and the other reference populations. The parameters in the Beverton-Holt model did not differ significantly among any of the populations (Table 31). This was true even for the Chiwawa and Naches populations.

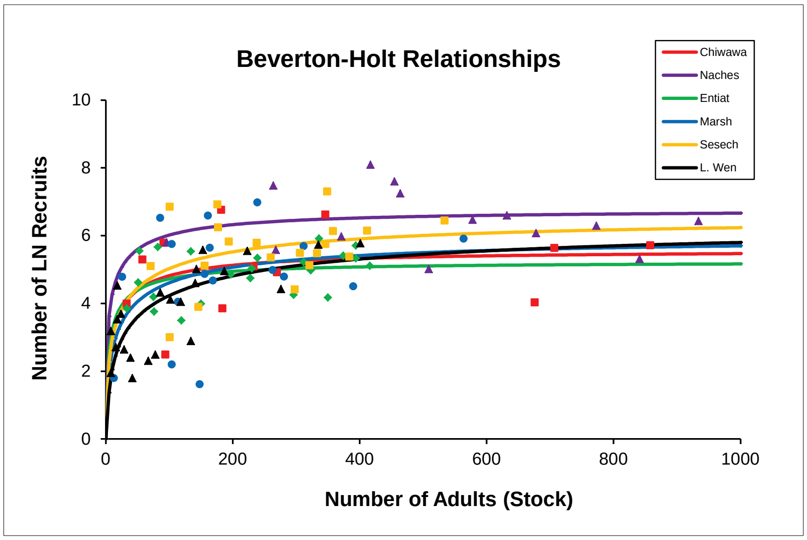

Figure 20. Scatter plot of the number of spawners and natural log adult recruits and fitted Beverton-Holt curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

Table 31. Randomization test results comparing the equality of Beverton-Holt curves and equality of parameter values (α and β). Randomization tests were based on 10,000 Monte Carlo samples. Equality or curves was based on 500 points along the x-axis (spawner abundance axis).

Smooth Hockey Stick Relationships

Smooth hockey stick curves differed significantly between the Chiwawa and Naches populations and the Chiwawa and Sesech populations (Figure 21; Table 32). There was no significant difference in curves between the Chiwawa and the other reference populations. Most of the parameters in the smooth hockey stick model did not differ significantly among the populations (Table 32). However, the productivity parameter β did differ significantly between the Chiwawa and the Naches and the Chiwawa and Little Wenatchee populations. The β parameter for the Naches was significantly greater than the Chiwawa, while the β parameter for the Little Wenatchee was significantly less than the Chiwawa.

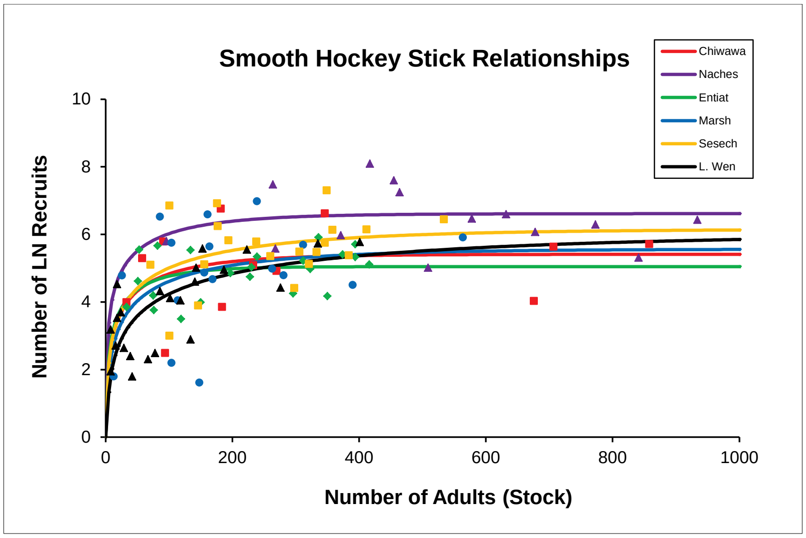

Figure 21. Scatter plot of the number of spawners and natural log adult recruits and fitted smooth hockey stick curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

Table 32. Randomization test results comparing the equality of smooth hockey stick curves and equality of parameter values (α and β). Randomization tests were based on 10,000 Monte Carlo samples. Equality or curves was based on 500 points along the x-axis (spawner abundance axis).

		β = 1.84	β = 0.75	0.000

Comparing different stock-recruitment curves and their parameters did not provide strong evidence that the supplementation program has negatively affected the productivity of the Chiwawa population.

Analysis without Reference Populations

In some cases, suitable reference populations may not exist to compare with supplemented populations. It is therefore important to have alternative analyses to assess supplementation effects. In this section, we describe methods that can be used to assess supplementation effects when suitable reference populations are not available. We discuss before-after comparisons, correlation analysis, and comparisons to standards as alternatives when reference populations are unavailable.

Before-After Comparisons

Before-after analyses compare population metrics (spawner abundance, NORs, and productivity) before supplementation to those during supplementation. In this case, data collected before supplementation represent the reference condition. The assumption is that population trajectories measured during the pre-supplementation period would continue in the absence of supplementation. We compared trends in abundance and productivity, mean abundance and productivity, and stock-recruitment relationships before and after supplementation.

Trend Analysis

Comparing trends before and after supplementation can be used to assess the effects of supplementation. Here, we compared the slopes of trends of spawner abundance, NORs, and productivity before and during supplementation using t-tests. If the hatchery program is successfully supplementing the natural spring Chinook population, the trend for spawner abundance and NORs during supplementation should be greater than the slope during the pre-supplementation period. For productivity, the slope during the supplementation period should increase or remain the same as that during the pre-supplementation period.

Visual examination of trends of Chiwawa data indicates that spawner abundance, NORs, and productivity decreased during the pre-supplementation period, but increased during the supplementation period (Figure 22). Only the changes in NOR trends were significant (Figure 22). This was true for both transformed and untransformed data.

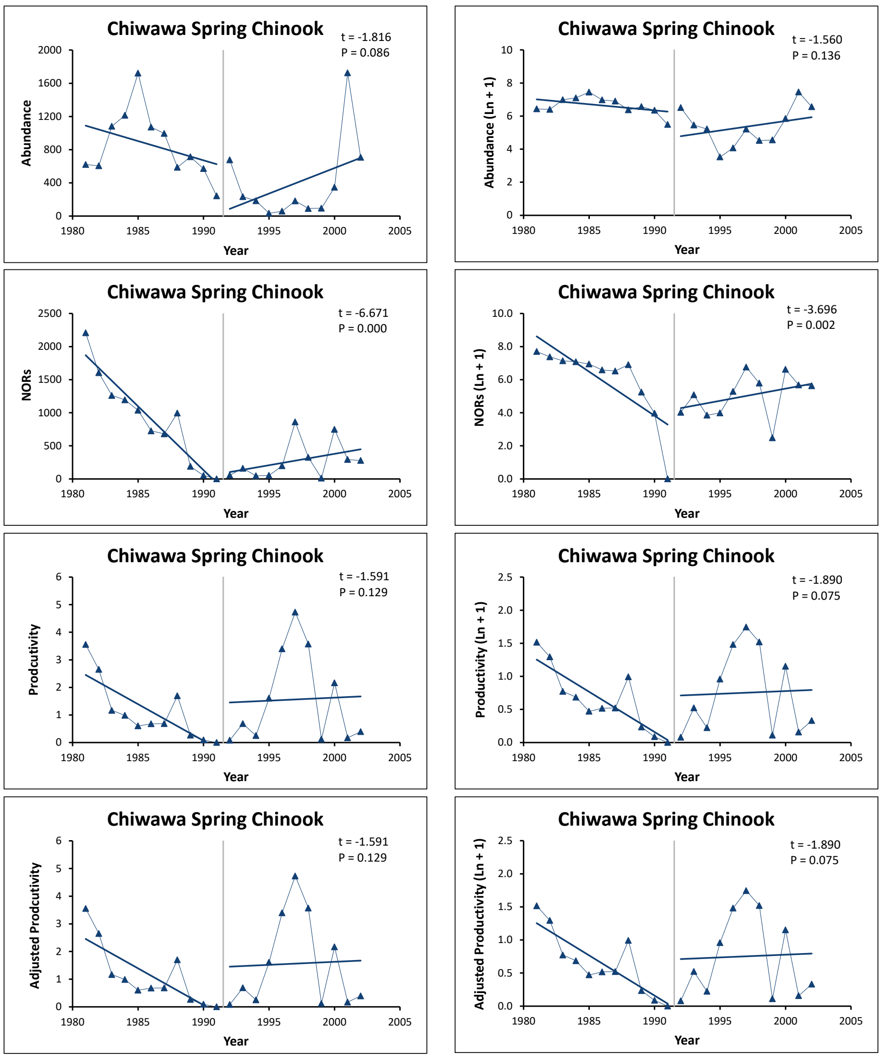

Figure 22. Trends in Chiwawa spring Chinook spawner abundance, natural-origin recruits (NORs), productivity (adults recruits per spawner), and adjusted productivity (adjusted for density dependence) before and during supplementation. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left show untransformed data; figures on the right include natural-log transformed data. Figures include results of t-tests comparing slope of trends before and during supplementation.

Analysis of Mean Scores

We also compared mean spawner abundance, NORs, and productivity data before and after supplementation. If the hatchery program is successfully supplementing the natural spring Chinook population, mean spawner abundance and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean productivity during the supplementation period should be equal to or higher than the pre-supplementation period. We tested the following statistical hypotheses.

Spawner Abundance and NORs:

Ho: Mean spawner abundance and NORs before supplementation ≥ Mean spawner abundance and NORs during supplementation.

Ha: Mean spawner abundance and NORs before supplementation < Mean spawner abundance and NORs during supplementation.

Productivity (Recruits/Spawner):

Ho: Mean productivity before supplementation ≤ Mean productivity during supplementation.

Ha: Mean productivity before supplementation > Mean productivity during supplementation.

We tested before-after supplementation effects using a one-tailed Aspin-Welch unequal-variance test. We also used a randomization test, based on 10,000 Monte Carlo simulations, to assess differences in spawner abundance and productivity before and during supplementation. The randomization procedure only allowed the testing of two-tailed hypotheses. Therefore, we generated 95% confidence intervals on the mean difference (μ_{pre} - μ_{post}) using bootstrapping methods to determine if the significant result from the randomization test was in the right direction. We generated 5,000 bootstrap samples to calculate confidence intervals.

Mean spawner abundance during the supplementation period was significantly less than the pre-supplementation spawner abundance (Table 33). Mean spawner abundance decreased 46% between the pre- and post-supplementation periods. Likewise, mean NORs decreased significantly between the two periods (Table 33). On the other hand, productivity increased slightly, but not significantly, between the pre- and post-supplementation periods (Table 33). This was true for both adjusted and transformed productivity data.

Table 33. Statistical results comparing mean scores of spawner abundance, natural-origin recruits (NORs), and productivity (using both untransformed and natural-log transformed) before and during supplementation of Chiwawa spring Chinook. Randomization tests were based on 10,000 Monte Carlo samples and 95% CI were based on 5,000 bootstrap samples.

Population metric	Mean scores		Test on means			
			Aspin-Welch test		Random test P-value	Bootstrap 95% CI
	Before	During	t-value	P-value		
Abundance	856	393	2.383	0.986	0.028	112 - 843
LN Abundance	6.6	5.4	3.304	0.997	0.004	0.56 – 1.99
NORs	905	275	2.846	0.993	0.009	214 – 1034
LN NORs	6.0	5.0	1.197	0.876	0.250	-0.40 – 2.54
Productivity	1.13	1.56	-0.721	0.759	0.479	-1.55 – 0.73
LN Productivity	0.64	0.75	-0.450	0.671	0.649	-0.55 – 0.35
Adj Productivity	1.12	1.56	-0.721	0.759	0.477	-1.54 – 0.71
LN Adj Productivity	0.64	0.75	-0.450	0.671	0.652	-0.57 – 0.34

Analysis of Stock-Recruitment Curves

The third method compared stock-recruitment curves of the Chiwawa population during supplementation with those generated before supplementation. Specifically, we tested whether the regression parameters were equal between the pre- and post-supplementation periods, and whether the fitted curves coincided between the two time periods. We used the methods described earlier to fit the Ricker, Beverton-Holt, and smooth hockey stick curves to the two data sets. We tested the following hypotheses.

Parameter equivalence:

Ho: Stock-recruitment parameters (α and β) of the pre-supplementation period = Stock-recruitment parameters of the supplementation period.

Ha: Stock-recruitment parameters (α and β) of the pre-supplementation period ≠ Stock-recruitment parameters of the supplementation period.

Curve equivalence:

Ho: Modeled stock-recruitment curves from the pre-supplementation period = Modeled stock-recruitment curves from the pre-supplementation period.

Ha: Modeled stock-recruitment curves from the pre-supplementation period ≠ Modeled stock-recruitment curves from the pre-supplementation period.

We were only able to fit stock-recruitment curves to the post-supplementation data. Non-linear regression was unable to converge on a solution using only pre-supplementation data. Therefore, we were unable to use this method to test supplementation effects on the Chiwawa spring Chinook population. If we could have fit curves to both the pre- and post-supplementation periods, we would have used two-sided randomization tests to evaluate the null hypotheses of equal model parameters and that fitted curves coincided.

Before describing correlation approaches, it is important to note that comparing before-after data can sometimes be misleading. For example, the spawner abundance, NORs, and productivity data presented in Figure 22 suggest that supplementation is increasing the abundance and productivity of spring Chinook in the Chiwawa Basin. However, when we compared these trends to those from reference populations during the same time periods (Figures 9-11), it becomes clear that supplementation was not responsible for increasing the trends in spawner abundance, NORs, and productivity of the Chiwawa population. Thus, whenever possible, it is wise to compare before-after data with a reference population.

Correlation Analyses

A simple way to see if the supplementation program is increasing or decreasing productivity is to assess the association between the proportion of adult spawners that are made up of hatchery adults (pHOS) and productivity (recruits/spawner). If the supplementation program is working as planned, the increase in hatchery fish spawning naturally should increase the productivity of the population. It should not decrease the productivity of the population.

We tested the association between pHOS and adult productivity[21] using Pearson correlation. During the pre-supplementation period, productivity averaged 1.13 recruits/spawner; during the supplementation period, productivity averaged 1.39 recruits/spawner. This increase in productivity did not appear to be strongly correlated to pHOS (Figure 23). Correlation analysis showed that there was no significant association between pHOS and productivity, even though productivity increased with increasing pHOS.

21 Note that the analysis could also include juvenile productivity (e.g., smolts/spawner).

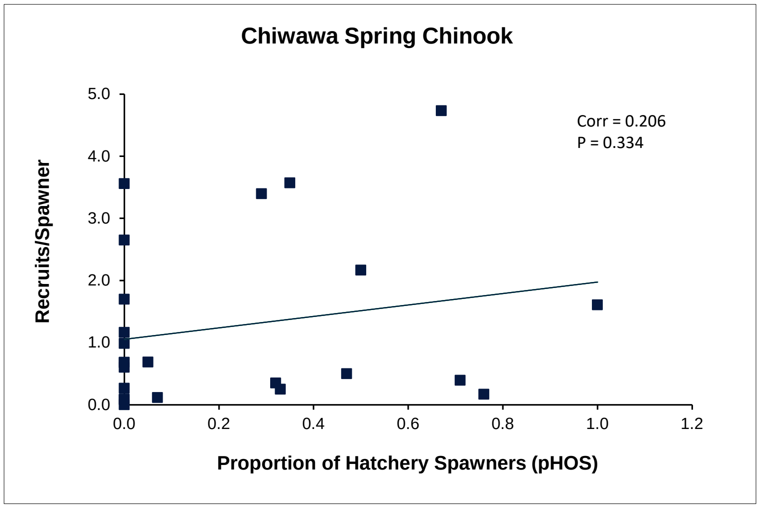

Figure 23. Association between the proportion of spawners that are made up of hatchery adults (pHOS) and the number of natural-origin recruits. The Pearson correlation coefficient (Corr) and its P-value (P) are shown in the figure.

The association between pHOS and productivity can also be assessed by testing the correlation between pHOS and the residuals from stock-recruitment curves fitted to the Chiwawa spawner and natural-origin recruitment data. This approach removes the effects of density dependence on the relationship between pHOS and productivity. A significant negative association provides evidence that hatchery-origin spawners may not be as productive as natural-origin spawners.

The Ricker, Beverton-Holt, and smooth hockey stick models were fit to the Chiwawa stock and recruitment data (including {S, R} data from both the pre- and post-supplementation period, 1981-2004) using methods described earlier. Residuals were calculated by subtracting the predicted recruitment values from the observed (modeled) values. Pearson correlation then tested the association between pHOS and the residuals from each model.

Although there was a negative trend in residuals with increasing pHOS, suggesting that hatchery-origin spawners may not be as productive as natural-origin spawners, the association was not significant (Figure 24). Thus, based on these analyses, there is no strong evidence that the supplementation program has significantly benefited or harmed the natural spring Chinook population.

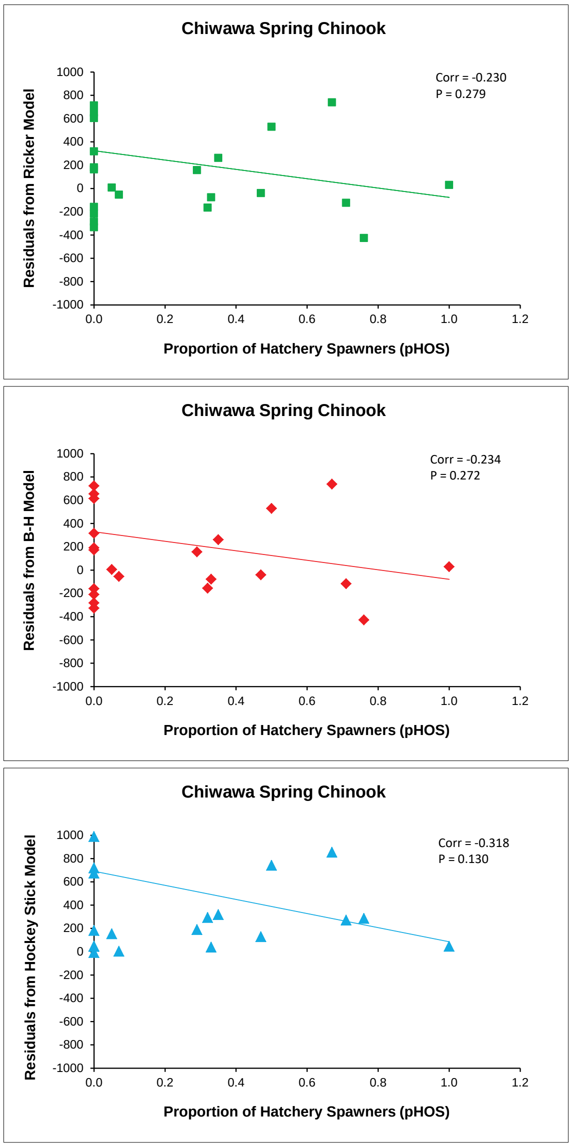

Figure 24. Association between the proportion of spawners that are made up of hatchery adults (pHOS) and the residuals from Ricker, Beverton-Holt (B-H), and smooth hockey stick stock-recruitment models. The Pearson correlation coefficient (Corr) and its P-value (P) are shown in the figures.

Comparison to Standards

In those cases in which suitable reference populations are not available and there are no pre-supplementation data, the investigator is left with comparing population parameters to relevant standards. Standards can include performance of natural-origin fish in similar environments (a type of reference condition), mitigation requirements, quantitative objectives of the program, Biological Assessment and Management Plan (BAMP) values, or other appropriate standards. An example of a statistical hypothesis would be:

Ho: Productivity (Recruits/Spawner) of the supplemented population ≥ standard productivity.

Ha: Productivity (Recruits/Spawner) of the supplemented population < standard productivity.

For these analyses to be useful, the standards must be based on biological reality.

Conclusions and Recommendations

Hatcheries are an important component of fish production within the Upper Columbia Basin. The goal of some of these programs is to supplement natural production in declining populations. The supplementation programs generally use both hatchery and natural (spawned and reared in nature from either wild or hatchery parents) adults for hatchery broodstock. These programs are designed to supplement natural populations by increasing natural reproduction while preventing the establishment of a domesticated hatchery stock. Thus, the programs should increase total spawning escapement and NORs, and not reduce the productivity of the natural population. Measuring the success of these programs is challenging and expensive.

In this paper, we described methods that can be used to determine if supplementation programs are achieving some of their goals. This paper focused on the use of reference populations to determine if the supplementation programs increase total spawning escapement, NORs, and maintain or increase productivities. In some cases, suitable reference populations may not be available (e.g., we found no suitable reference populations for Upper Columbia steelhead and sockeye). In these cases, alternative methods are needed to assess supplementation effects. We also described these alternative methods in this paper.

Identification of Reference Populations

Finding suitable reference populations that match well with supplemented populations is a difficult and time-consuming process. Our three-step selection process included identification of populations with similar life-history characteristics, few or no hatchery spawners, a long time series of accurate abundance and productivity estimates, and similar freshwater habitat impairments and out-of-basin effects. Those populations that met these criteria were then examined for their relationship with the supplemented population (in this case, the Chiwawa spring Chinook population). Several criteria were scored, including pNOS, correlation, trend, and effect size. Reference populations with total weighed scores of 81 or greater were selected as suitable reference populations.

This selection process provided a valuable framework for selecting suitable reference populations for supplemented populations. Interestingly, we found that a given reference population may match well with one parameter of the supplemented population (e.g., spawning escapement), but not for all parameters (e.g., not NORs or productivity). The reason for this may be related to errors

in the estimation of population parameters and/or differential factors limiting population parameters of supplemented and reference populations. Therefore, depending on the parameter analyzed, a different suite of reference populations may be needed.

An important assumption in the use of reference populations is that the supplemented and reference populations that tracked each other before supplementation would continue to track each other in the absence of supplementation. Given that the reference populations did not match the Chiwawa population on all criteria examined, and some reference populations tracked the Chiwawa population more poorly than others, there may be some uncertainty as to whether differences observed between the supplemented and reference populations during the supplementation period are associated with the hatchery program, or other unaccounted factors. For example, any large-scale change (man-made or natural) within the reference or supplemented population could affect our ability to assess the effectiveness of the supplementation program.

To account for some of these uncontrollable factors, we recommend the use of a "causal-comparative" approach to strengthen the certainty of our inferences. This approach relies on correlative data to try and make a case for causal inference. We recommend that the following state variables be measured and tracked within the supplemented and reference populations: mean annual precipitation, total and riparian forest cover, road density, impervious surface, and alluvium. These variables can be used to describe differences in water temperatures at different life stages (pre-spawning, egg incubation, and summer rearing) and substrate characteristics, including fine sediments and embeddedness. These state variables can be used to help explain possible changes in spawner abundance, NORs, and productivity that are independent of supplementation. In addition, the use of multiple reference streams reduces the possibility that man-made changes to a single reference stream will influence the interpretation of the results.

Analyses with Reference Populations

Using reference populations, we evaluated the effects of supplementation on natural-log transformed and untransformed total spawning escapement, NORs, and productivity by comparing trends, analyzing mean differences, ratios, and rates, and comparing stock-recruitment curves and their parameters. For trend analysis, we compared the slopes of the trends between each supplemented/reference pair before and during supplementation. If the hatchery program is successfully supplementing the natural population, trends in spawner abundance and NORs should deviate significantly during the supplementation period (i.e., the slope of the supplemented population should be greater than the slopes of the reference populations during the supplementation period), but not during the pre-supplementation period. For productivity, the slope of the supplemented population, relative to the reference population, should increase or remain the same.

Because trend analysis only tests the slopes of the trend lines, it does not test for differences in elevations of the trend lines, additional analyses were needed to determine if supplementation increased spawner abundance, NORs, and productivity of the target population without changing the slopes of the trend lines. To do this, we derived three different response variables using natural-log transformed and untransformed spawner abundance, NORs, and productivity data. The first derived variable included difference scores, which were calculated as the difference between paired treatment and reference data (T-R). The second included ratios, which were calculated as the ratio of paired treatment and reference data (T/R). Finally, we calculated the differences in annual changes in paired treatment and reference population data (ΔT-ΔR). If the hatchery

program is successfully supplementing the natural population, the mean difference or ratio score of paired spawner abundance data and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean difference or ratio score during the supplementation period should be equal to or higher than the pre-supplementation period.

As a final set of analyses, we compared the stock-recruitment curves of the supplemented population (using stock and recruitment data only from the supplementation period) to the reference populations (using all available stock and recruitment data). Specifically, we tested whether the regression parameters were equal between the supplemented population and the reference populations, and whether the fitted curves coincided between populations. Here, we were most interested in comparing the productivity parameters in the models.

Surprisingly, these different analyses yielded similar results when they were applied to the Chiwawa spring Chinook and reference population data. Trend analysis was unable to detect a significant difference in trends between the supplemented and reference populations during the supplementation period. Even though we measured an increasing trend in spawner abundance, NORs, and productivity in the supplemented population during the supplementation period, these same parameters trended upward in the reference populations. Likewise, we were unable to detect a significant supplementation effect using difference scores, ratios, and differences in annual changes. However, we found the results from analysis of mean differences of annual change difficult to interpret and they may be insensitive to treatment effects. A simpler analysis, which is also easier to interpret, is to use trend analysis. Finally, comparing stock-recruitment curves and their parameters did not provide strong evidence that supplementation has affected the productivity of the natural population.

Based on these results, we do not recommend using difference scores of annual change (ΔT-ΔR), nor do we recommend comparing stock-recruitment curves and their parameters. As noted above, difference scores of annual change are difficult to interpret and may be redundant with trend analysis. Testing stock-recruitment curves and their parameters appears redundant with testing differences in productivity using difference scores or ratios. In addition, the analyses are computer intensive and do not appear to be very sensitive to changes.

There was little difference in results using difference scores and ratios. It appears that ratios may be more sensitive to change than difference scores (e.g., we found significant differences in some comparisons using ratios but not with difference scores), but ratios can be more difficult to interpret than difference scores. Nevertheless, we recommend the use of ratios in future analyses.

Correcting for Density Dependence and Carrying Capacity

The analyses described so far assumed that the density of spawners or recruits did not affect the survival and productivity of fish. However, without controlling for density effects, productivity of the population would continue to decline with increasing abundance. This scenario could occur in supplementation programs that increase the number of spawners, and could result in lower productivities relative to reference populations. In addition, lower productivities may be caused by differential environmental carrying capacities rather than the capacity of the supplemented fish to produce offspring. Therefore, we described two different methods for deriving density-corrected estimates of productivity. The first controlled the effects of density on productivity by partitioning observed productivities into density-independent and density-dependent productivity. These productivities were then combined in a single test. The second method corrected for differences in carrying capacities between the supplemented and reference populations. This was accomplished

by calculating the percent saturation of NORs, which was estimated as the ratio of observed NORs to the maximum number of NORs that the habitat could support.

We fit Ricker, Beverton-Holt, and smooth hockey stick models to stock and recruitment data to estimate the maximum number of NORs (NORs at carrying capacity) and the maximum number of spawners needed to produce maximum NORs. We fit models to the supplemented and reference populations. Using information-theoretic criterion and evaluating the precision of estimated parameters, we found that the smooth hockey stick model provided the best estimates of maximum NORs and spawners. We used these modeled values to estimate density-independent and density-dependent productivities, and saturation of NORs.

Statistical analyses, using difference scores and ratios of adjusted Chiwawa spring Chinook productivity data, found no significant effects of supplementation on the productivity of the supplemented population. Indeed, the results from correcting for density dependence were similar to those without correcting for density dependence. This is in part because the abundance of the supplemented and reference populations has been below their respective carrying capacities in most years. This was clearly demonstrated in the analyses of NORs corrected for carrying capacity. In the supplemented population, the mean fraction of the carrying capacity filled with NORs decreased significantly during the supplementation period. In other words, the carrying capacity was filled with more NORs during the pre-supplementation period than during the supplementation period, which is contrary to the goal of supplementation. By comparison, two of the reference populations showed a similar decrease in saturation, while the other two reference populations actually increased in saturation. Analyzing the saturation scores using BACI-design analyses indicated that two of the four pairings differed significantly. That is, the percent saturation of the supplemented population decreased significantly relative to two reference populations.

Because productivity can be affected by the abundance of spawners and recruits, we recommend that future analyses comparing supplemented and reference populations adjust for density-dependent effects and differential carrying capacities. Although we detected only slight differences between adjusted and unadjusted results, as supplemented stocks recover, it will become more important to adjust productivities to account for density dependence. Importantly, the analyses using percent saturation placed NORs in the context of the carrying capacity of the environment. This will help managers determine if supplementation programs are filling or over-filling the capacity of the habitat with NORs.

As we noted earlier, analyses using productivities adjusted for density dependence assume that there is a spawner abundance at which density-independent effects end and density-dependent effects begin. In reality, density-dependent effects occur at low spawning abundance and intensify as spawning abundance increases. We did not account for these increasing density-dependent effects at lower spawner abundances. This is an area that needs additional attention.

Analyses without Reference Populations

Because of the rigorous criteria we used to select reference populations, it is likely that reference populations may not exist for making comparisons with supplemented populations. For example, we used the criteria described in this paper to identify reference populations for supplemented steelhead and sockeye populations in the Upper Columbia Basin. We were unsuccessful in identifying any suitable reference populations. Therefore, in the absence of suitable reference populations, it is important to have alternative methods for assessing supplementation effects. We described three different types of analyses one can use to assess supplementation effects in the

absence of reference populations. They include before-after comparisons, correlation analysis, and comparisons to standards.

Before-after analyses compare population metrics before supplementation with those during supplementation. In this case, data collected before supplementation represent the reference condition. The assumption is that population trajectories measured during the pre-supplementation period would continue in the absence of supplementation. We compared trends in spawner abundance, NORs, and productivity before and after supplementation. In addition, we compared mean scores in these three parameters before and after supplementation. Finally, we attempted to compare stock-recruitment parameters before and after supplementation. The hypotheses examined were that the spawner abundance and NORs would be greater during the supplementation period, and that productivities would not decline during the supplementation period.

Trend analysis indicated that the all three Chiwawa spring Chinook population parameters trended downward during the pre-supplementation period, but trended upward during supplementation. On the other hand, mean spawner abundance and NORs were lower during the supplementation period than during the pre-supplementation period. Mean productivities increased, but not significantly, during the supplementation period. We were unable to compare pre- and post-supplementation stock-recruitment curves because we were unable to fit stock-recruitment models to the pre-supplementation data.

We used correlation analyses to determine if the proportion of hatchery-origin fish that spawn naturally on the spawning grounds (pHOS) increased productivity. In addition, we used correlation to assess the association between pHOS and the residuals from stock-recruitment relationships. A significant negative association provides evidence that hatchery-origin spawners may not be as productive as natural-origin spawners. The analysis indicated that the productivity of Chiwawa spring Chinook increased with increasing pHOS, but the association was not significant. In contrast, there was a negative association between pHOS and the stock-recruitment residuals, but again the association was not significant. The latter analysis accounts for density-dependent effects.

In concert, the before-after comparisons and correlation analyses do not provide conclusive evidence that the supplementation program has increased spawner abundance and NORs, or that it has significantly reduced the productivity of the supplemented population. Although increasing the number of hatchery fish on the spawning grounds appears to reduce NORs and productivity, mean productivity actually increased during the supplementation period compared to the pre-supplementation period.

It is important to note that relying on only one set of analysis could result in drawing a wrong conclusion. For example, if we had only conducted trend analysis, we may have concluded wrongly that the Chiwawa spring Chinook supplementation program significantly increased spawner abundance, NORs, and productivity in the supplemented population. The analysis of mean scores and correlations indicates that the supplementation program has not increased spawner abundance or NORs in the supplemented population. Therefore, in the absence of suitable reference populations, we recommend that analyses include the evaluation of trends, means scores, and correlations. By conducting more than one set of analyses, one can use weight-of-evidence to assess the effects of supplementation programs.

Under the scenario that there are no reference populations or pre-supplementation data, one is left with comparing population parameters to relevant standards. These standards could come from mitigation requirements, quantitative objectives, or published or unpublished standards. One could also use correlation to evaluate the association between productivity and pHOS, but this requires a wide range in pHOS values to be most effective. A more extreme approach, which probably would not gain much traction with managers, is to shutoff the supplementation program for some time and then evaluate the effects of the program in a before-after design. The Entiat spring Chinook hatchery program provides a unique opportunity to evaluate this type of management decision.

Some Concerns and Limitations

No matter how hard we try to explain different sources of variation in population data, we are limited by the quality of the data. Teasing out the effects of supplementation requires long time series of population data. Because funding levels and methods change over time, the quality (i.e., accuracy and precision) of the data also changes over time. Importantly, the population parameters examined in this paper (spawner abundance, NORs, and productivity) are rarely measured directly in the field. That is, other population metrics, such as numbers of redds, number of fish counted at weirs or dams, scales, tags, etc., are sampled in the field. These metrics are then used to calculate spawner abundance[22], NORs, and productivity, often based on assumptions about fish/redd, pre-spawning loss, marking rates, and sampling rates. This has a tendency to increase the variability in the data independent of supplementation programs. In our studies, we can only control sampling within the supplemented populations, and even that is limited by available funding. We have no control over the sampling within reference populations. Thus, we have to assume that sampling within the reference populations will continue and that sampling effort will remain comparable to that in the supplemented populations.

In our analyses, we included both the Entiat and Little Wenatchee populations as references for the Chiwawa population. In the analyses, we treated them as equivalent to the other reference populations. That is, the statistical procedures used to compare the supplemented population to each reference population were identical. This is appropriate. However, the interpretation of the results must be different when comparing the Entiat and Little Wenatchee to the supplemented population, because they are populations that were influenced by hatchery fish. As noted earlier, the Entiat spring Chinook hatchery program has been discontinued. Therefore, it provides a unique type of reference where the comparison changes from both populations being supplemented to only one population being supplemented. For the Little Wenatchee, nearly all the strays came from the Chiwawa program. Straying should stop or be greatly reduced with the change in water supply to the Chiwawa Rearing Ponds. In sum, one must be careful in how they interpret these test-reference results.

Finally, it is important to point out that for this paper, we conducted 463 statistical tests. Because we set our Type I error rate at 0.05, by random chance alone, we may have incorrectly rejected about 23 null hypotheses. Inasmuch as this work was designed to evaluate different ways to analyze test-reference data, the number of future analyses will be greatly reduced based on the results from this work. However, if the Type I error rate is a concern to managers, researchers can

[22] The smooth hockey stick model, which we used to estimate density-dependent correction factors for productivity and NORs, is sensitive to errors in spawner escapement estimates. Therefore, it is important to use accurate and precise estimates of spawner escapement.

use a lower error rate, such as α = 0.01. Another option is to analyze test-reference data graphically. Although this is subjective, there are no statistical analyses and therefore no concerns with violating assumptions of statistical tests, including temporal correlation. We believe researchers should use the statistical procedures recommended in this report to support graphic analysis.

CHELAN AND GRANT PUD HATCHERY PROGRAMS MONITORING AND EVALUATION PROGRESS REPORT AUGUST 2017

August Sampling

Monitoring and evaluation activities during the month of August included monitoring at PIT-tag arrays, juvenile emigration monitoring, juvenile abundance monitoring, fish tagging, spring Chinook spawning surveys, hatchery rearing and spawning activities, broodstock collection, and stock assessments. Monitoring and evaluation activities followed protocols described in Hillman et al. (2013), *Chelan County PUD Hatchery Monitoring and Evaluation Implementation Plan 2016*, and *Grant County PUD Hatchery Monitoring and Evaluation Implementation Plan for Spring and Summer Chinook in the Wenatchee Basin and Summer Chinook in the Methow Basin 2016*.

Juvenile Emigration Monitoring

During the month of August, WDFW operated a rotary smolt trap near the mouth of the Chiwawa River (Chiwawa Trap). WDFW collected biological information including lengths and weights, degree of smoltification, and life-stage characteristics.

Juvenile Abundance Monitoring

During the month of August, BioAnalysts conducted snorkel surveys in the Chiwawa River basin and in sites on Nason Creek and the Little Wenatchee River (reference sites). They counted numbers of all salmonids in randomly selected sites between 31 July and 25 August. All habitat units in the study areas were measured for water surface area and water volume. Results from this work will be presented in a memo to the HCP Hatchery Committees.

PIT-Tagging Activities

WDFW injected PIT tags into juvenile salmon and steelhead captured at the Chiwawa Trap. The goal of the tagging program is to estimate freshwater juvenile productivity, estimate trapping efficiency, better understand the life-history characteristics of salmon and steelhead/rainbow in the Wenatchee River basin, and to estimate SARs.

Spring Chinook Spawning Surveys

During the month of August, Chelan PUD conducted spawning ground surveys for spring Chinook by floating and/or walking streams within the Wenatchee River basin. Surveys were conducted in the

Chiwawa River (including Rock and Chikamin creeks), Nason Creek, Icicle Creek, Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and the White River (including the Napeequa River and Panther Creek).

Hatchery Rearing and Spawning Activities

WDFW continued to document mortalities, abundance, health, and growth of salmon and steelhead within the hatchery complex. They collected adult summer Chinook and steelhead for the Wenatchee programs, and summer Chinook for the Chelan Falls and Methow programs. They also monitored summer steelhead, summer Chinook, and spring Chinook at Tumwater and Dryden dams as part of stock assessment.

Summary of Information Collected

PIT-Tag Interrogations

Little Wenatchee River PIT-Tag Detection Site—The Little Wenatchee interrogation site operated throughout the month with no interruptions. All antennas are operating at full potential. During August, unique detections included one natural-origin adult spring Chinook, two hatchery-origin adult spring Chinook, three natural-origin juvenile spring Chinook, two hatchery-origin adult sockeye, one unknown-origin adult sockeye, one natural-origin juvenile steelhead, and two bull trout.

White River PIT-Tag Detection Site—The White River interrogation site operated throughout August. WDFW conducted routine maintenance on 29 August to check all system components. They found a malfunction on the downstream row of antennas. Antennas 07-0C remain off until repairs or replacements can be made. Unique detections during August included five natural-origin adult spring Chinook, four hatchery-origin adult spring Chinook, one unknown-origin adult Chinook, one natural-origin adult summer Chinook, one hatchery-origin adult summer Chinook, 24 natural-origin adult sockeye, ten unknown-origin adult sockeye, 19 natural-origin juvenile spring Chinook, one cutthroat trout, three bull trout, and six whitefish.

Juvenile Emigration Monitoring

Chiwawa Trap—The Chiwawa Trap captured 2,027 fish during 31 days of fishing in August (Table 1; Figure 1). Most of the fish captured consisted of spring Chinook (97.2%). Steelhead/rainbow (2.5%) and bull trout (0.3%) made up the remainder of the catch. Based on four trap-efficiency trials, the mean capture efficiency for wild spring Chinook parr was 21.7% (Table 1).

Lower Wenatchee Trap—The Lower Wenatchee Trap was removed at the end of July.

Table 1. Summary of the number of fish trapped, their size (fork length and weight), and trap efficiency for the Chiwawa Trap during 31 days of trapping in August 2017.

Species and life stage	Number of fish collected	Number of fish sampled	Fish Condition		Trap Efficiency			
			Mean length (mm)	Mean weight (g)	Number marked	Number recaptured	Pooled efficiency (%)	Number of trials
Wild Spring Chinook (fry)	4	4	48	1.2

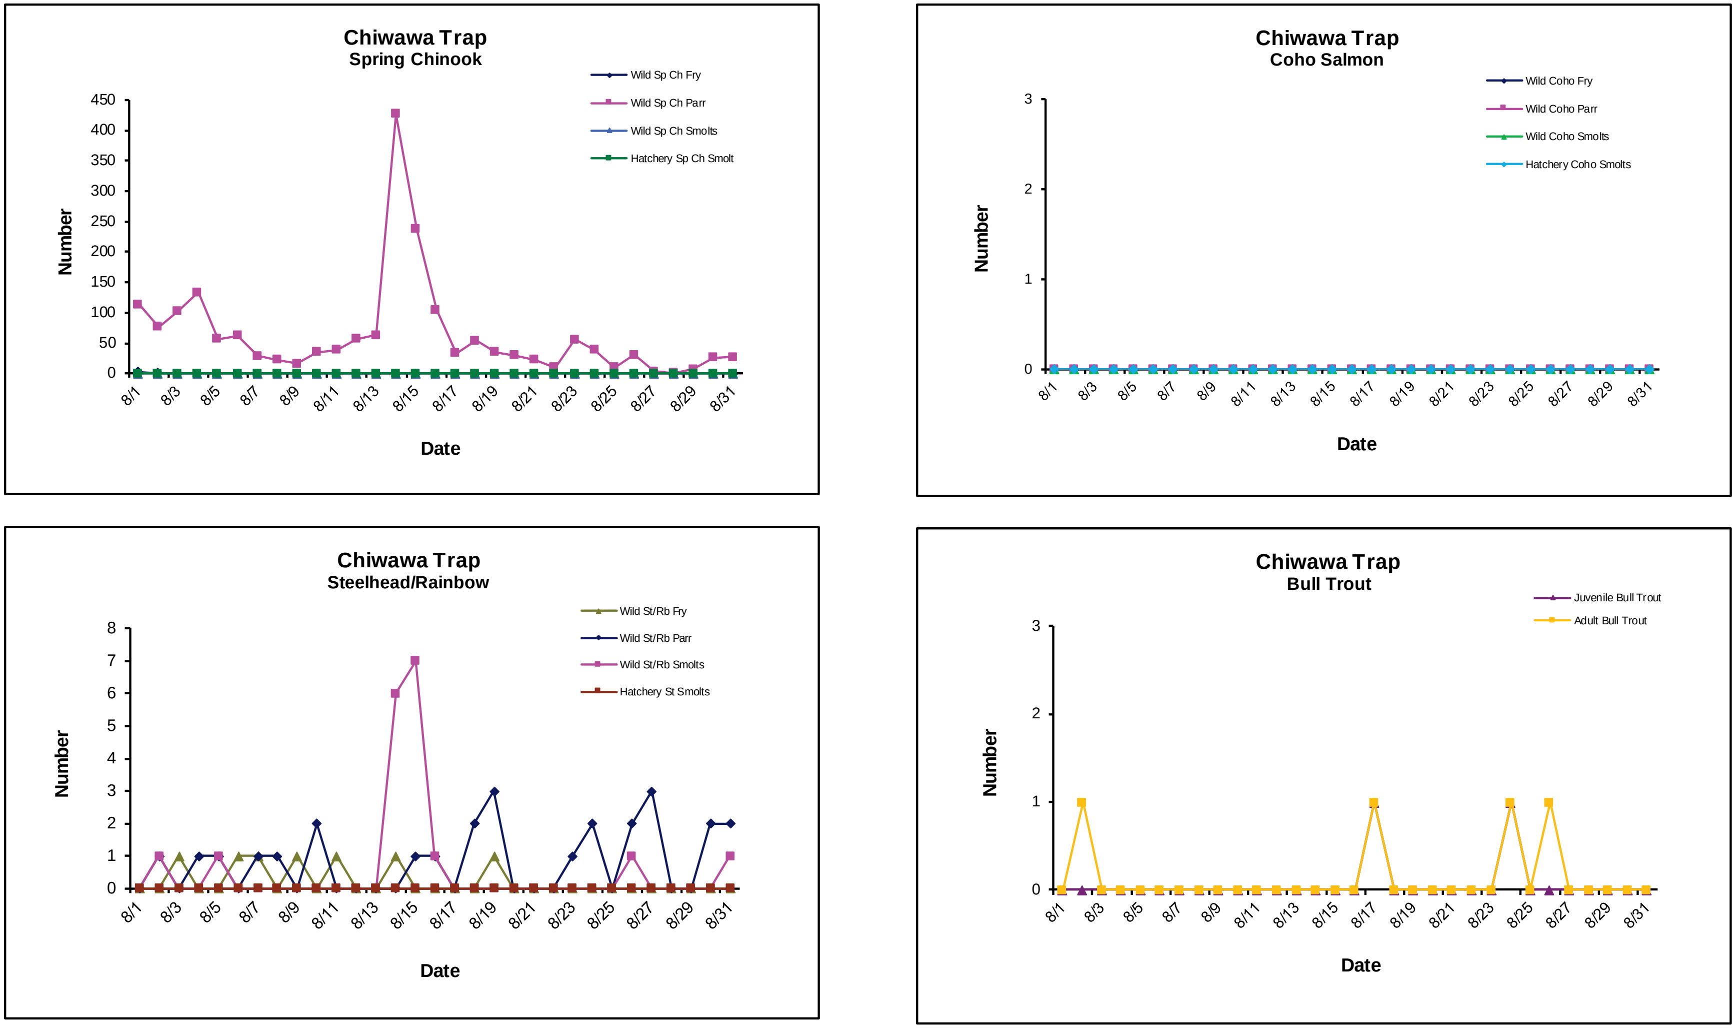

Figure 1. Daily captures of different species and life stages of fish collected in the Chiwawa Trap during August 2017. Note that the scale of the Y-axis differs among graphs.

PIT Tagging Activities

Chiwawa Trap—A total of 1,385 fish were PIT tagged and released at the Chiwawa Trap; 1,350 wild subyearling Chinook, 30 wild steelhead/rainbow, and 5 bull trout (Table 2). Seven wild subyearling Chinook died during trapping. No fish shed their tags during trapping.

Table 2. Summary of the number of fish PIT tagged and released during August 2017.

Sampling Location	Species and Life Stage	Number collected	Number of recaptures	Number tagged	Number died	Shed Tags	Total tagged fish released
Chiwawa Trap	Wild Subyearling Chinook	1,968	120	1,350	7	0	1,350
	Wild Yearling Chinook	0	0	0	0	0	0
	Wild Steelhead/Rainbow	51	1	30	0	0	30
	Hatchery Steelhead/Rainbow	0	0	0	0	0	0
	Wild Coho	0	0	0	0	0	0
	Bull Trout	5	0	5	0	0	5
	Total	**2,024**	**121**	**1,385**	**7**	**0**	**1,385**

The cumulative numbers of fish tagged and released in 2017 are shown in Table 3. In addition, the numbers of fish that died or shed tags are identified in the table. Percent mortality during tagging has been less than 1.5%.

Table 3. Summary of the cumulative number of fish PIT tagged in 2017.

Sampling Location	Species and Life Stage	Number collected	Number of recaptures	Number tagged	Number died	Shed Tags	Total tagged fish released	Percent mortality
Chiwawa Trap	Wild Subyearling Chinook	6,466	222	2,260	16	0	2,260	0.25

Spring Chinook Spawning Surveys

Redd Surveys—Spawning ground surveys for spring Chinook were conducted in the Chiwawa River (including Rock and Chikamin creeks), Nason Creek, Icicle Creek, Upper Wenatchee River, Little Wenatchee River, and the White River (including the Napeequa River and Panther Creek). During the month of August (and the end of July), 191 spring Chinook redds were counted in the Wenatchee River basin. Most of these were observed in the Chiwawa River (127 redds) (Figure 2). Nason Creek had 41 redds (21%), Icicle Creek had 20 redds (10%), the Little Wenatchee had two redds (1%), and the Wenatchee River had one redd. No redds were observed in the White River. Peshastin Creek will be surveyed during the end of the survey period.

Carcass Surveys—A total of 14 spring Chinook carcasses were sampled during spawning surveys in August in the Wenatchee River basin. Most of the carcasses were sampled in Nason Creek (43% or 6 carcasses) and Icicle Creek (36% or 5 carcasses) (Figure 2). Three carcasses were sampled in the Chiwawa River. No carcasses were sampled in the upper Wenatchee, White, or Little Wenatchee rivers in August.

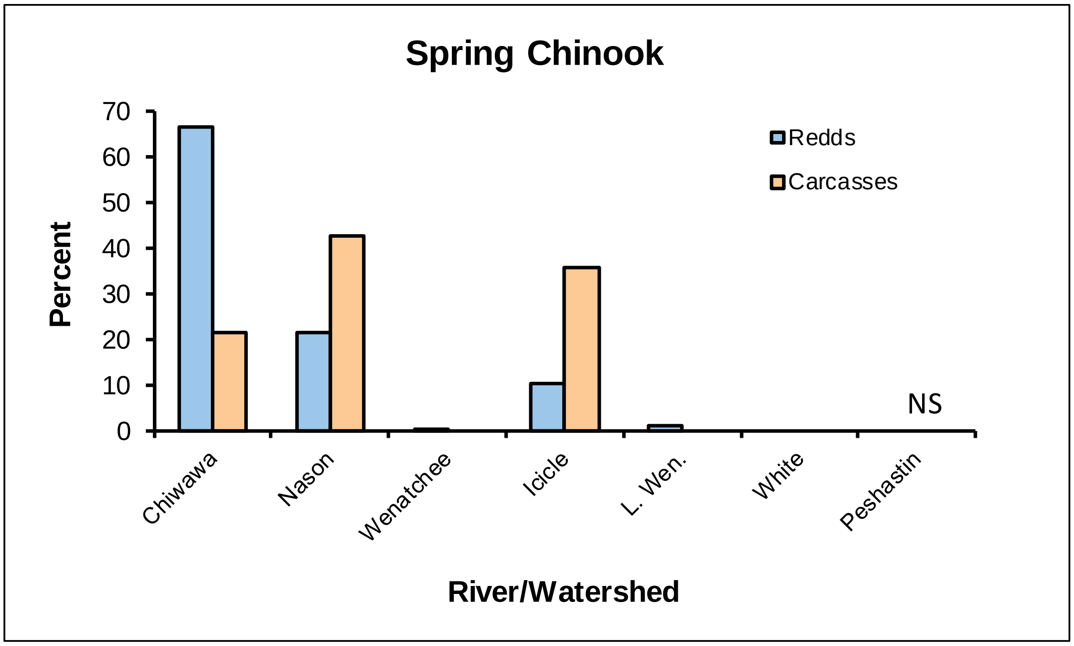

Figure 2. Percent of the total number of spring Chinook redds counted and carcasses sampled in different streams/watersheds within the Wenatchee River basin during August 2017. NS = not sampled.

Hatchery Rearing Activities

2016 Brood Chiwawa Spring Chinook— About 131,176 WxW spring Chinook were present at Eastbank Fish Hatchery at the end of August. A total of 21 fish died during the month. Fish examinations conducted in August indicated no significant health condition. There are no fish health recommendations at this time. Growth information collected during the month is summarized in Table 4.

About 28,317 HxH spring Chinook were present at Eastbank Fish Hatchery at the end of August. A total of 25 fish died during the month. Fish examinations conducted in August indicated no significant health condition. There are no fish health recommendations at this time. Growth information collected during the month is summarized in Table 4.

2016 Brood Nason Spring Chinook—About 158,988 WxW spring Chinook were present at Eastbank Fish Hatchery at the end of August. A total of 65 fish died during the month. Fish examinations conducted in August indicated no significant health condition. There are no fish health recommendations at this time. Growth information collected during the month is summarized in Table 4.

Because of surplus production, 41,263 HxH spring Chinook were released into Banks Lake on 3 August. With a loss of 36 fish during the month, this leaves about 76,135 HxH spring Chinook at Eastbank Fish Hatchery at the end of August.[1] Fish examinations conducted in August indicated no significant health

[1] The production goal for the Nason Spring Chinook program is 125,000 WxW and 98,760 HxH. Because of high fecundity and in-hatchery survival, there was an over production of both WxW and HxH Chinook. To maximize the

condition. There are no fish health recommendations at this time. Growth information collected during the month is summarized in Table 4.

2016 Brood Wenatchee Summer Chinook—About 513,520 summer Chinook were present at Eastbank Fish Hatchery at the end of August. A total of 696 fish died during August. Fish examinations conducted in August indicated no significant health condition. There are no fish health recommendations at this time. Growth information collected during the month is summarized in Table 4.

2016 Brood Methow (Carlton) Summer Chinook—About 215,366 summer Chinook were present at Eastbank Fish Hatchery at the end of August. A total of 425 fish died during August. There was an adjustment of -4,574 after coded-wire tagging. Fish examinations conducted in August indicated no significant health condition. There are no fish health recommendations at this time. Growth information collected during the month is summarized in Table 4.

2016 Brood Chelan Falls Summer Chinook—About 607,465 summer Chinook were present at Eastbank Fish Hatchery at the end of August. A total of 1,160 fish died during August. There was an adjustment of -1,033 after coded-wire tagging. Fish examinations conducted in August indicated no significant health condition. There are no fish health recommendations at this time. Growth information collected during the month is summarized in Table 4.

2017 Brood Wenatchee Summer Steelhead—About 149,561 WxW steelhead were present at the Chelan Fish Hatchery at the end of August. A total of 562 steelhead died during the month. Fish examinations conducted in August indicated no significant health condition. There are no fish health recommendations at this time. Growth information collected during the month is summarized in Table 4.

About 174,174 HxH steelhead were present at Eastbank Fish Hatchery at the end of August. A total of 403 steelhead died during the month. Fish examinations conducted in August indicated no significant health condition. There are no fish health recommendations at this time. Growth information collected during the month is summarized in Table 4.

---

use of wild progeny in the program, the WxW fish were marked up to about 105% of the conservation program goal, and the rest of the WxW were retained and marked as though they were HxH (i.e., ad-clip+cwt). The HxH fish were then marked until about 105% of the safety net program goal was achieved (inclusive of the overage of WxW fish). Any remaining HxH progeny were considered surplus and planted into Banks Lake. Thus, there are 27,462 Chinook from WxW parents that are marked as if they are HxH (ad-clip+cwt).

Table 4. Growth data collected from 2016 and 2017 brood salmon and steelhead in August 2017; SD = standard deviation; CV = coefficient of variation.

Hatchery Broodstock Collection and Spawning

2017 Brood Chiwawa Spring Chinook—WDFW began trapping Chiwawa spring Chinook at Tumwater Dam on 5 June and at the Chiwawa Weir on 11 August. Trapping concluded on 2 August. WDFW began spawning Chiwawa spring Chinook on 31 July. A total of 18 females have been spawned resulting in an egg take of 83,106 eggs (56,225 natural-origin eggs and 68,881 hatchery-origin eggs). No adult Chinook have died.

2017 Brood Nason Creek Spring Chinook—WDFW began trapping Nason Creek spring Chinook at Tumwater Dam on 5 June and concluded on 21 July. They began spawning spring Chinook on 31 July. A total of 22 females have been spawned resulting in an egg take of 100,427 eggs (62,901 natural-origin eggs and 37,526 hatchery-origin eggs). Two adult Chinook have died.

2017 Brood Wenatchee Summer Chinook—WDFW began trapping Wenatchee summer Chinook at Dryden Dam on 27 June and they also collected summer Chinook at Tumwater Dam on 18 and 19 August. Trapping concluded on 17 August. A total of 257 natural-origin summer Chinook (128 females and 129 males) were collected and transferred to Eastbank Hatchery. This equates to an estimated egg take of 581,171 eggs. Five adult Chinook have died.

2017 Brood Chelan Falls Summer Chinook—WDFW began trapping Chelan Falls summer Chinook at the Chelan Falls Canal Trap on 21 July. Trapping concluded on 21 August. A total of 327 hatchery-origin summer Chinook (154 females and 173 males) were collected and transferred to Eastbank Hatchery. In addition, eight hatchery-origin summer Chinook were collected at the Entiat National Fish Hatchery on 30 August. In sum, this equates to an estimated egg take of 663,736 eggs. Nine adult Chinook have died.

2018 Brood Wenatchee Summer Steelhead—WDFW began trapping Wenatchee summer steelhead at Dryden and Tumwater dams on 3 July. A total of 14 hatchery-origin steelhead (8 females and 6 males) and 20 natural-origin steelhead (11 females and 9 males) have been collected and transferred to Eastbank Hatchery. This equates to an estimated egg take of 55,481 eggs from natural-origin fish and 36,878 eggs from hatchery-origin fish. No adult steelhead have died.

Trapping Operations at Dams

Tumwater Dam—WDFW began trapping at Tumwater Dam on 4 April. Beginning on 13 July, trapping operations at Tumwater Dam were limited to five days a week (total of 40 hours per week) and the ladder was opened during nights and weekends to minimize delays in sockeye salmon passage. During the month of August, 16 adult spring Chinook were counted at the dam. Of these, eight hatchery-origin jacks were surplused according to adult management protocols. In addition, a total of 88 steelhead were sampled at the dam in August. Of these, 66 steelhead (17 natural-origin, 12 hatchery-origin, and 37 unknown-origin fish) were released upstream and 22 steelhead were collected for broodstock. Lastly, 598 summer Chinook and 1,529 sockeye were observed at the dam.

Dryden Dam—WDFW began trapping at Dryden Dam on 27 June. During August, catch consisted of 325 summer Chinook, 13 spring Chinook, 99 sockeye salmon, and 29 steelhead. Most summer Chinook and steelhead were sampled, PIT tagged, and either retained for broodstock or released back to the river.

Wells Dam—WDFW began trapping summer Chinook at Wells Dam (West Ladder) on 3 July. During August, 25 natural-origin summer Chinook (12 females and 13 males) were collected for broodstock and 115 fish (31 natural-origin and 84 hatchery-origin Chinook) were sampled and released. Most of the fish released were PIT-tagged.

Stock Assessment

Wenatchee Summer Steelhead—WDFW sampled 88 summer steelhead at Tumwater Dam during August; 18 hatchery, 33 wild, and 37 unknown-origin steelhead (Table 5). Six wild and 16 hatchery steelhead were retained for broodstock; the remainder were measured and released back to the river.

In addition, WDFW sampled 29 steelhead at Dryden Dam during August; 11 hatchery and 18 wild steelhead (Table 6). Seven hatchery steelhead were retained for broodstock. The others were measured and released back to the river.

Table 5. Numbers of adult Wenatchee summer steelhead sampled at Tumwater Dam in August 2017 for broodstock collection and stock assessment.

Summer Chinook—WDFW sampled 598 summer Chinook at Tumwater Dam in August; 11 hatchery and 587 wild summer Chinook (Table 7). All were sampled and released back to the river. In addition, WDFW sampled 197 summer Chinook (77 hatchery and 120 wild Chinook) at Dryden Dam during August (Table 8). A total of 30 wild summer Chinook were retained for broodstock. The remainder were sampled and released back to the river. WDFW also sampled 309 summer Chinook (303 hatchery and 6 wild Chinook) at the Chelan Falls Canal (Table 9). Of these, 214 hatchery fish were retained for broodstock. Finally, WDFW sampled 119 summer Chinook at Wells Dam (72 hatchery and 47 wild fish) (Table 10). Of these, 21 wild fish were retained for broodstock. The remaining fish were sampled and released back to the river.

Spring Chinook—WDFW sampled six spring Chinook (5 hatchery and 1 wild Chinook) at the Chiwawa Weir in August (Table 11). The wild Chinook was retained for broodstock. The remaining fish were sampled and released back to the river. In addition, WDFW collected 16 spring Chinook at Tumwater Dam during August (Table 12). Of these, eight were surplused (hatchery jacks) and the remaining spring Chinook (3 hatchery, 4 wild, and 1 unknown-origin Chinook) were sampled and released back to the river.

ANCHOR QEA

Memorandum

To:	Wells, Rocky Reach, and Rock Island HCP Hatchery Committees	Date: November 16, 2017
From:	Tracy Hillman, HCP Hatchery Committees Chairman	
cc:	Sarah Montgomery, Anchor QEA, LLC	
Re:	**Final Minutes of the October 18, 2017 HCP Hatchery Committees Meeting**	

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Hatchery Committees meeting was held at the Grant PUD office in Wenatchee, Washington, on Wednesday, October 18, 2017, from 9:00 a.m. to 12:15 p.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A). *(Note: this item is ongoing.)*
- Mike Tonseth will coordinate with Todd Seamons (WDFW) to produce an outline or recommended approach for genetic monitoring (Item I-A). *(Note: this item is ongoing.)*
- Kirk Truscott will discuss internally and coordinate with Keely Murdoch on potential edits to Chelan PUD's Draft Statement of Agreement (SOA) Regarding District's Coho Obligation (Item I-A). *(Note: this item is ongoing.)*
- Sarah Montgomery and Mike Tonseth will coordinate to revise and finalize the September 20, 2017 Hatchery Committees meeting minutes (Item I-A). *(Note: Tonseth provided revisions and Montgomery distributed the final version on October 19, 2017.)*
- Sarah Montgomery will distribute Barry Berejikian's (Northwest Fisheries Science Center [NWFSC]) presentation, "Potential to improve the conservation benefits of steelhead hatcheries," to the Hatchery Committees (Item II-C). *(Note: Montgomery distributed the presentation on October 19, 2017.)*
- Bill Gale, Matt Cooper, Charlie Snow (WDFW), Tom Kahler, and Greg Mackey will develop management alternatives for the Twisp River and Winthrop National Fish Hatchery (NFH) steelhead programs (Item II-C).
- Sarah Montgomery will notify the Hatchery Committees that the Draft Monitoring and Evaluation Plan for PUD Hatchery Programs (2017 Update) will be a decision item at the Hatchery Committees November 15, 2017 meeting (Item III-C). *(Note: Montgomery notified the*

Hatchery Committees on October 19, 2017, and this item is also described below in "Review Items".)

- Tracy Hillman will distribute the draft timelines for Wenatchee and Methow spring Chinook salmon programs for Hatchery Committees review (Item III-D). *(Note: Hillman sent the timelines to Montgomery, who forwarded them to the Hatchery Committees on October 18, 2017.)*

Decision Summary

- There were no decisions approved during today's meeting.

Agreements

- There were no agreements discussed during today's meeting.

Review Items

- Sarah Montgomery sent an email to the Rocky Reach and Rock Island Hatchery Committees on August 15, 2017, notifying them that the Chelan PUD Draft SOA Regarding District's Coho Obligation is available for a 30-day review, with comments due to Catherine Willard by September 14, 2017. Chelan PUD indicated they will request approval of the SOA at the Hatchery Committees September 20, 2017 meeting. *(Note: this item will be discussed at the November 15, 2017 Hatchery Committees meeting.)*
- Sarah Montgomery sent an email to the Hatchery Committees on October 16, 2017, notifying them that the draft plan, *Implementation of Comprehensive Monitoring and Evaluation of Wells Hatchery Complex Programs in 2018*, is available for review with edits and comments due to Greg Mackey by December 1, 2017.
- Sarah Montgomery sent an email to the Hatchery Committees on October 19, 2017, notifying them that the Draft M&E Plan for PUD Hatchery Programs (2017 Update) is available for review and will be a decision item at the November 15, 2017 Hatchery Committees meeting.

Finalized Documents

- Sarah Montgomery sent an email to the Hatchery Committees on September 15, 2017, notifying them the Chelan PUD and Grant PUD 2016 Final M&E Annual Report and Appendices are now available for download from the Hatchery Committees Extranet site.
- Sarah Montgomery sent an email to the Hatchery Committees on October 24, 2017, notifying them the Chelan PUD 2018 Hatchery Monitoring and Evaluation Implementation Plan

(approved on August 18, 2017) is available for download from the Hatchery Committees Extranet site.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the September 20, 2017 Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the Hatchery Committees and asked for any additions or changes to the agenda. None were requested.

The Hatchery Committees representatives reviewed the revised draft September 20, 2017 meeting minutes. Sarah Montgomery said there are a few outstanding comments, and representatives revised the meeting minutes. Hatchery Committees representatives present conditionally approved the draft September 20, 2017 meeting minutes, pending further clarification from Mike Tonseth. (Note: Tonseth revised the minutes, and Montgomery distributed the final approved version on October 19, 2017.)

Action items from the Hatchery Committees meeting on September 20, 2017, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meeting on September 20, 2017)*:

- *Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A).*
  This item is ongoing.
- *Mike Tonseth will coordinate with Todd Seamons (WDFW) to produce an outline or recommended approach for genetic monitoring (Item I-A*).
  This item is ongoing.
- *Tracy Hillman will distribute the Upper Columbia Salmon Recovery Board's (UCSRB) discussion draft Hatchery Report to the Hatchery Committees when he receives it (Item I-A).*
  Hillman sent the report to Montgomery, who distributed it to the Hatchery Committees on October 13, 2017.
- *Tracy Hillman will invite Greer Maier (UCSRB) to an upcoming Hatchery Committees meeting to discuss the Hatchery Report (Item I-A).*
  Maier plans to attend the November 15, 2017 Hatchery Committees meeting.
- *Kirk Truscott will discuss internally and coordinate with Keely Murdoch on potential edits to Chelan PUD's Draft Statement of Agreement Regarding the District's Coho Obligation (Item II-A).*

Keely Murdoch said Yakama Nation (YN) and Colville Confederated Tribes (CCT) have met, and Truscott will be discussing this further internally. Mike Tonseth asked when the current agreement expires. Catherine Willard said the agreement expires in October 2017, but a signed agreement is likely not needed until production occurs in 2018.

- *Tom Kahler will send Douglas PUD's Transition Plan Outline to Sarah Montgomery for distribution to the Hatchery Committees (Item III-A).*
  Montgomery distributed the outline following the meeting on September 20, 2017.
- *Douglas PUD will provide their Transition Plan to the Hatchery Committees for review (Item III-A).*
  Tom Kahler sent the plan to Sarah Montgomery, which she forwarded to the Hatchery Committees on October 16, 2017.
- *Hatchery Committees representatives will review the revised Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs and discuss it during the October 18, 2017 Hatchery Committees meeting (Item IV-D).*
  Sarah Montgomery distributed the latest version of the plan on October 10, 2017, and this item will be discussed today.
- *Tracy Hillman will invite Barry Berejikian (Northwest Fisheries Science Center) to the October 18, 2017 Hatchery Committees meeting to discuss steelhead in the Twisp River (Item V-A).*
  Berejikian is present today for this discussion.

II. Douglas PUD

A. Draft 2018 M&E Implementation Plan (Greg Mackey)

Greg Mackey said the draft plan, *Implementation of Comprehensive Monitoring and Evaluation of Wells Hatchery Complex Programs in 2018*, is available for Hatchery Committees review. Mackey shared the plan (Attachment B), which Sarah Montgomery distributed to the Hatchery Committees on October 16, 2017. Mackey said Douglas PUD requests comments by December 1, 2017, to finalize the contract for M&E by January 1, 2018. He said the plan is nearly identical to the previous year, with the following exceptions:

- The Okanogan Safety-Net and Omak Creek Conservation programs are now reported on by Grant PUD (contracted to BioAnalysts) and therefore will not be reported by Douglas PUD to prevent reporting the same results in two reports.
- Language was changed in various sections to improve clarity.

Greg Mackey said the plan includes pilot studies, such as the Twisp River juvenile population estimate study. He said continued implementation of the pilot studies will be determined based on analysis of the approach and results, which Douglas PUD will be working on this winter.

B. Wells Transition Plan (Tom Kahler)

Greg Mackey shared the document, *Draft Transition Plan for Wells and Methow Fish Hatcheries* (Attachment C), which Sarah Montgomery distributed to the Hatchery Committees on September 16, 2017. He said since the last Hatchery Committees meeting, Douglas PUD has been working with WDFW to develop the plan and has also drafted an internal version of the plan with contractual information, internal strategy, and other details. He said Douglas PUD expects more edits from WDFW, but in the meantime wanted to distribute a version to the Committee for review. Tom Kahler said he was hoping the group could discuss WDFW's edits today, but Douglas PUD has not received them yet. He said Douglas PUD and WDFW are working together and coordinating via point people for the transition.

Mackey said the Transition Plan is available for review and requested comments as soon as possible. He said Douglas PUD has hired managers for the Methow Fish Hatchery and Wells Fish Hatchery, and has interviewed candidates for the remaining jobs with offers being made soon. Bill Gale asked if Douglas PUD will hire a Doctor of Veterinary Medicine, and Mackey said Douglas PUD hopes to, but has not confirmed anyone for that position yet.

Tracy Hillman asked if the transition is still planned to occur within a 90-day period. Mackey said yes, but if some tasks require a longer transition time an extension of time for such tasks may be negotiated with WDFW as needed. He said extensions will occur on a case-by-case basis, but there is no plan to employ a blanket extension for the transition. Kahler said so far Douglas PUD expects the transition to be completed in 90 days, by the end of the contract on November 28, 2017.

Gale said he has two comments regarding the Transition Plan. He said at U.S. Fish and Wildlife Service (USFWS) fish hatcheries, maintenance staff are identified separately from fish culture staff, and hatchery maintenance expectations are detailed for both groups. Gale suggested that Douglas PUD include information about maintenance responsibilities for the staff that will be maintaining the hatcheries so no maintenance tasks are left undone. Mackey said a landscaping company and cleaning staff will perform some of the maintenance duties in addition to hatchery staff, and more information can be included in the plan based on hatchery staff job descriptions.

Gale said the plan also includes some discussion about coordination with USFWS regarding adult management. He suggested that coordination between Methow Fish Hatchery and Winthrop NFH be clearly identified, especially regarding spring Chinook salmon and steelhead broodstocking. Mackey said this information can be added under the hatchery supervisor's job description. Mike Tonseth said those details should also be included in the Broodstock Collection Protocols. Gale added he did not see the Broodstock Collection Protocols mentioned in the Transition Plan. Kahler said the Broodstock Collection Protocols are listed in the Transition Plan. Tonseth said the plan should identify how coordination between the hatcheries is laid out and agreed-to. Gale said the Transition Plan is not intended to be a hatchery operations plan. Rather, it is a guiding document for the transition. Gale said for that reason, the plan should at least include a discussion on coordination and how it will be developed. Mackey thanked Gale for his suggestions and encouraged representatives present to review and provide any comments on the plan as soon as possible.

C. Steelhead Presentation and Discussion of Twisp Steelhead Program (Berejikian/Kahler)

Tracy Hillman welcomed Barry Berejikian and said Berejikian has prepared a presentation about his work on steelhead in Hood Canal and a discussion about the Twisp steelhead program will follow the presentation. Berejikian shared the presentation, "Potential to improve the conservation benefits of steelhead hatcheries" (Attachment D), and said the Hood Canal steelhead project has many willing partners such as non-profits and state, tribal and federal governmental entities including the USFWS and NWFSC. He said he has also worked on a project at Winthrop NFH, and those data will be discussed along with the Twisp program. A summary of the presentation and questions and comments are included in the following sections.

Introduction (slides 1-4)

Berejikian said the presentation will include approaches for egg collection, and rearing and release for small steelhead programs similar to the Twisp program. Effects on abundance and genetic diversity, and alternative rearing strategies to improve smolt performance and reduce domestication selection will also be discussed. Lastly, Berejikian said he will talk about developing practical and flexible rearing strategies for conservation and supplementation programs.

To increase diversity, the Hood Canal steelhead project uses hydraulic sampling to extract eggs from redds, thus natural-origin adults are not handled. This project includes captive rearing and release of age-2 (S2) smolts, and the project monitors effects on abundance and genetic diversity of the natural population.

Hydraulic redd sampling (slides 5-8)

Hydraulic extraction of eggs from redds is an alternative to artificial spawning in hatcheries. It includes identifying redds, marking them, triangulating the redds so they can be found again, then using a hydraulic water pump, cage, and seine to work the redd and collect eggs. Collection goals change as spawning progresses, and this type of sampling allows for sampling the downstream part of a redd and leaving an upstream section undisturbed.

Hydraulic redd sampling produces high proportions of viable eggs (0.93), fish that survive to ponding (0.94), and productive redds (0.76). Berejikian said producing eyed embryos is not a limiting factor. Hydraulic sampling in this study also produced greater genetic diversity among offspring produced than what would be estimated by artificial spawning.

In the Hamma Hamma River, redds were hydraulically sampled and fish were reared and released at age-2. Genetic results of the study show that steelhead mating patterns are complex, females produce on average 1-2 redds, and males service multiple redds.

Keely Murdoch asked if Berejikian has studied the impacts to the remaining eggs in a redd after hydraulic sampling has removed some of the eggs. Berejikian said he does not think there are effects to remaining embryos after hydraulic sampling occurs because a spawning channel study at Manchester Research Station with Chinook salmon measured the egg-to-fry survival of remaining eggs to be about 70%. Greg Mackey asked how many egg pockets on average do steelhead create in one redd. Berejikian said between 6 and 8 on average. Bill Gale asked if female steelhead spawn with different males when they construct a second redd. Berejikian said males can be territorial and follow females to different redds, but it varies and ends up being a combination of the same and different males.

Berejikian said hydraulic sampling works better in rain-driven systems than snow-driven systems (like the Methow basin) due to water-level changes during spring. Todd Pearsons asked about the Chinook salmon spawning channel study—are there significant differences in redd construction that would be affected differently by hydraulic pumping? Berejikian said redd construction for the two species is similar, and Chinook salmon dig deeper redds and cover their redds more entirely.

<u>Hood Canal project, smolting and rearing (slides 9-24)</u>

The Hood Canal steelhead project includes three facilities, which produced varied numbers of smolts and adults for release. Variation between hatcheries was one potential cause of difference in smolt quality. Murdoch asked if the adult release groups were fully grown steelhead, or if they resembled rainbow trout. Berejikian said those fish were about 520 millimeters long, which is smaller than a natural steelhead, but male maturation was not generally observed until age-3. Berejikian said some of the fish were kept in freshwater, and the Skokomish group of fish was transitioned to seawater before being raised to maturity. Size data are not available yet, but the project will look at the effects of early growth history, and differences in water type on growth, maturation, survival, and reproductive success to inform hatchery planning discussions. Pearsons asked what the project did with females that matured at age 3. Berejikian said those females were stripped of eggs and held to age-4 to live-spawn.

The Hamma Hamma and Duckabush groups raised at Lilliwaup Hatchery had downstream and early marine survival rates on par with wild fish, while the Skokomish fish raised at McKernan Hatchery had lower survival rates. Density and vessel shape at the hatchery were likely major contributors to the variation in downstream and early marine survival rates.

Numbers of redds in supplemented rivers (slide 14) increased once supplementation began in 2011. Pearsons asked if redd counts include adult outplants. Berejikian said yes. In the Hamma Hamma River, for example, redd counts increased during supplementation from 2002 to 2009. Genetic diversity improved during and after supplementation in the Hamma Hamma River. Allelic richness did not change, heterozygosity increased slightly, and effective population size increased. Berejikian surmised that the addition of more anadromous steelhead spawners may have attracted more natural spawners. Berejikian summarized that conservation programs can increase natural spawning in the short-term and in the generation after supplementation.

Berejikian said fitness loss in steelhead can be genetically or epigenetically heritable and discussed the potential causes for fitness loss.

Berejikian summarized the effects of rearing steelhead to age-2 smolt. Smolting is a threshold trait in steelhead, and hatchery and wild fish vary in their approximate age of smoltification.

<u>Winthrop NFH (slides 25-29)</u>

Berejikian is also working with Winthrop NFH to study how size and age affect migratory performance of steelhead. He said S2 fish travel faster no matter their size. Body size at release explained most of the differences in downstream survival between S1 and S2 smolts. Volitional releases resulted in faster out-migration rates than forced releases, and volitionally released migrants were larger and had higher survival than forced release migrants.

<u>Heritability and body size (slides 30-36)</u>

Berejikian said one study at Manchester Research Station focused on whether heritable size-selective mortality can be avoided, and the study looked at growth rate and body size at smoltification. S1 fish in this study (with smaller fork lengths) had higher seawater mortality than S2 fish (larger fork lengths). There is more heritability in body size with S1 fish than S2 fish, and heritability has a greater affect while fish are younger. Body size and mass varies among families, and mean family body size is correlated with survival.

Pros and cons of S2 programs (slides 37-49)

Berejikian said one negative effect of S2 programs is greater precocious maturation in males than in S1 smolts. He said not all hatcheries should implement S2 programs, but more flexible strategies can be designed for S2 programs. For example, a size sorting experiment shows that growth rate is determined early in life, and early growth rate influences size at smolting. By sorting steelhead in the fall and splitting fish into two groups, an S1 and S2 group can be produced from the same broodstock. He said this is a more proactive approach than trying to grow an S1 or S2 group, and reacting when fish grow too big or too small. Berejikian said programs can take advantage of the current size of fish and propensity to feed in order to sort fish by size and produce higher quality smolts.

Questions and comments

Mackey said one way to make fish self-sort is to place a rack with bar spacing in the raceways, and only small fish can move to the other side of the rack. He said this allows stocking small fish as parr; however, there are some handling issues with this approach.

Gale asked when Berejikian will have more data on juveniles transferred from Winthrop NFH that are segregated. Berejikian said he will have more information in spring 2018, and he will know how the S1s performed. After that, data on S2s will also be available.

Catherine Willard asked why the study sorts juvenile fish at 8 weeks. Berejikian said with previous sorting efforts, research shows size variation at that stage carries through the rearing process. He said the Hood Canal program had success sorting first in October, and again in March for the S2 program. He said sorting twice might be challenging for a large production hatchery.

Pearsons asked if these study results correspond to relative reproductive success (RRS) results. Berejikian said there is no direct comparison between those types of studies. Pearsons asked if there are results from the Hood Canal studies that support RRS studies. Barry responded that it is difficult to compare studies, but since the program started, the effective size of the wild population has increased almost linearly in Hood River (he referred to Table 3 in Christie et al. 2012). He commented that they (Christie et al.) concluded that there was a large Ryman-Laikre effect, but he thinks the data show the opposite effect. Results need to be evaluated in context with abundance and productivity information.

The Twisp Steelhead Program

Tom Kahler said this discussion will inform the future of the Twisp program, and said the Hatchery Committees should carefully consider a wide range of alternatives. He said Berejikian is knowledgeable about issues affecting the Twisp program, and Kahler asked him to attend today to provide input on the future of the program. Mackey summarized the steelhead programs in the Methow basin and said Douglas PUD operates the Twisp program, which uses wild-by-wild brood collected in the Twisp River. He said fish from this program are released in the Twisp River as S1s, and the Winthrop NFH program releases S2s. He said the Hatchery Committees have been discussing the potential to combine the programs, and need to collectively decide how to rear and release the 248,000 conservation fish available. Gale added that the discussion is about steelhead conservation programs in the Methow basin, not just the Twisp River, and some decisions about the programs will need to be made soon.

Gale said Winthrop NFH has one group of steelhead that could be released in the Twisp River in spring 2018, and a consensus needs to be reached about how, when, and where to release these fish. He said the Hatchery Committees also need to discuss whether and how to composite the programs before broodstock is collected. He said longer-term decisions include how to mix age-at-release groups throughout the basin, and whether to transition to a phase where different release strategies are used.

Kahler said an additional item of concern is that not many families are represented in the Twisp steelhead program, so what is the best way to increase genetic diversity without mining wild stock? Mike Tonseth said the relative reproductive success study in the Twisp River indicated that there may be a Ryman-Laikre effect occurring in this population. Tonseth asked if negative genetic effects are occurring, what is the best way to improve the situation? Tonseth said the Twisp Weir only provides access to about half of the steelhead population in the Twisp River due to its location, limiting genetic diversity in broodstock collected at that location. He said an additional piece to consider is that the relatedness of individuals being collected at the Weir is unknown, and understanding the relatedness may also guide discussions moving forward.

Kahler asked if YN has tried partially live-spawning steelhead. Murdoch said no, but the Columbia River Inter-tribal Fish Commission staff may have information about that from their kelt reconditioning programs. Berejikian said he is not aware of any programs using partial live-spawning, but it was discussed as an option for the Tucannon River. Murdoch said in order to partially live-spawn fish, post-release survival and success would have to be studied. She said after being partially spawned and released, female fish would have to select a site and partner before continuing to spawn. Gale asked if partially spawning male fish would help genetic diversity. Murdoch said she does not think that would increase diversity. Tonseth said it would be similar to using reconditioned kelt. Murdoch agreed and said reconditioned kelt spawn in a subsequent year outside of the hatchery, which increases lifetime fecundity, but does not provide more diversity to the hatchery program.

Gale said there are many possible options for the future of the Twisp and Winthrop NFH programs, and the first decisions should focus on whether to composite broodstock. If the programs are not going to be composited, options are more limited. This first decision will set the stage for future decisions. Murdoch said combining programs should be considered as an option so that there are more overall options available to discuss. She said keeping the Twisp program separate may not be a viable option because there are signs of a Ryman-Laikre effect occurring, which is a concern for the future of natural fish. She said the genetic issues occurring in the Twisp River are exacerbated because it is a subset of the population. She said because it is not a unique spawning aggregate, combining the programs is not necessarily a "composite" approach because they are not genetically distinct. She said implementing hydraulic redd sampling to improve diversity would be difficult in the Twisp River because of spawn timing. Eggs are in the gravel by June, which is also peak runoff for the system, and high water and flow levels would likely prevent access to redds for sampling. She said another concern with using hydraulic sampling for the Twisp program is that it is a mitigation program, not a research program. She said removing eyed eggs from natural-origin fish that are in the wild may not even meet the mitigation requirement. She said with in-gravel mortality, and an eye-up rate likely lower than in hatcheries, it would require much effort for maybe not enough eggs. She said there is also likely less impact on the population overall by collecting adults rather than eggs to meet the mitigation number. She said she favors combining broodstock for the Twisp and Winthrop programs, and releasing fish in the Twisp River and other areas could be part of a comprehensive reworking of steelhead supplementation in the Methow basin.

Tonseth said the hydraulic approach likely will not work in the Methow basin because it is a snow-fed system. Even if it were attempted though, he said there is uncertainty about additional take associated with hydraulically removing eggs from redds, and it may be difficult to permit. He said assessing the permitting feasibility as well as the physical feasibility of different options should be considered as discussions move forward. Gale said one positive aspect of sampling directly from redds is that it allows natural mate choice and redd site selection. He said using spawning channels may be a substitute to redd sampling in the natural environment, and has been successful at Winthrop NFH. He said if, as a group, the Hatchery Committees think that natural mate selection and sorting are important program components, using spawning channels could be a viable way to achieve those priorities. Mackey asked if using spawning channels is a feasible way to achieve the production levels needed for the Twisp program. Gale said more broodstock would probably be needed, and Tonseth said it would require collecting nearly 100% of the eggs produced in the channels.

Gale said he is not opposed to combining the programs, and said he is not too alarmed by the Ryman-Laikre effects occurring in the Twisp River. He said if the Twisp program were kept separate from the Winthrop NFH program, one option would be to take adults from the 48,000 fish Twisp program to Methow Fish Hatchery to spawn, and then remove a percentage of the fish that are smallest and use them in a 2-year program at Methow Fish Hatchery. The other fish would then be sent to Wells Fish Hatchery for release into the Twisp River. Gale said a 2-year program at Methow Fish Hatchery would add an additional brood year each year to the basin.

Tonseth said assessing the relatedness of adults being collected for broodstock in the Twisp River would still be helpful to determine how many families are represented. Murdoch said the Weir might pick up a small proportion of the families in the river. Tonseth said even by adding diversity with factorial mating at the hatchery, there might not be enough diversity to increase the effective population size. Tonseth said hook-and-line broodstock collection might be one way to increase genetic diversity. Mackey said the genetic [relatedness] distance between fish could be used to determine a mating scheme for fish. Gale said another option for increasing diversity is releasing 1- and 2-year old fish in the Twisp River for a few years, then changing the release location and rotating a mixed-smolt-age release group of fish throughout the basin.

Mackey said there are some additional factors to consider when assessing whether to combine broodstock. He said there may be no genetic difference detected between the Twisp River and other areas, but there could be a difference that was not detected. He said there may be selective pressures effecting local adaptation in the Twisp River that, by combining programs, would be precluded. Murdoch said at a larger scale, keeping the Methow population separate from the Okanogan population provides opportunity for local adaptation. Mackey said genetic diversity is not necessarily a step-wise process; if diversity can be increased immediately with local adaptation, it should not be precluded. He said separate spawning aggregates are identified as part of recovery for steelhead. Tonseth said the recovery criteria look at the distinct population segment (DPS) level, and do not identify individual spawning aggregates. He said current actions should focus on DPS-level diversity criteria. Murdoch said local adaptation is important, but in this case, there may be greater concerns for diversity at a higher level. Mackey said a small population with closely related individuals that are more fit for that envorinment could quickly amplify genetic adaptation to the local environment, and local adaptation should be considered as alternatives are developed. He said a do-no-harm approach could include managing the Methow basin as one population, so if severe bottlenecking is occurring in the Twisp River, it could be mitigated by the rest of the population. He said assessing the Twisp River in isolation is not entirely appropriate for determining whether a Ryman-Laikre effect is occurring. He said if there is genetic divergance in the Twisp River it should not be precluded from continuing; homogenizing the population could even be a greater threat to recovery than a perceived Ryman-Laikre effect. Tonseth said he does not necessarily advocate homogenizing the populations. Mackey said he advocates diversification.

Gale said one option is to combine broodstocks and have mixed-age release groups spread into different areas over time. He said that way, after the release into the Twisp River is stopped, for example, the natural population can adapt locally. He said a basin-wide perspective should include a 20-year plan that all parties agree to.

Hillman said that within-population structure and diversity is a requirement for recovery within the Upper Columbia Recovery Plan. He said this is assessed at the population scale, and the Plan requires steelhead spawning within certain spawning areas or tributaries. He asked if the National Marine Fisheries Service (NMFS) has in the past weighed in on whether spawning aggregates can be combined. Murdoch said NMFS previously indicated that this would be okay, and included language for that possibility in the draft Methow steelhead BiOp.

Hillman asked for volunteers to start drafting management alternatives for steelhead in the Methow basin, so it will be easier to discuss this with NMFS and to inform Broodstock Collection Protocols. USFWS and Douglas PUD representatives volunteered to continue this discussion and develop alternatives. Gale said he, Matt Cooper, Charlie Snow, Kahler, and Mackey will develop management alternatives for the Twisp River and Winthrop NFH steelhead programs.

Berejikian said coming up with a list of alternatives is a good plan. Regarding the uncertainty about a Ryman-Laikre effect occurring with Twisp River steelhead, he asked what the trend is, and suggested fully understanding the effects and variables then checking with Craig Busack (NMFS) about intended approaches to address the issues. He said there is an opportunity to consider multiple combined approaches. He said, for example, spawning channels have been mentioned. He said in his own study, the number of fry acquired from one channel (35,000 to 40,000 fry) was nearly equal to the fecundity of the female fish put into the channel, in one out of two channels used in the study. Tonseth suggested testing the spawning channel approach using hatchery fish before putting wild broodstock in it. He also asked what the genetic effects would be if one male fertilizes multiple redds in the spawning channel. Berejikian said he has data he could share with the group on the numbers of males and females placed into the channels in his study, their individual relative reproductive success, and effective population size. Tonseth said those data could help determine if using spawning channels would improve genetic diversity. Berejikian summarized that there are many tradeoffs to consider when thinking about the future of steelhead programs in the Methow basin.

Tonseth asked if a one-year smolt can be produced from a spawning channel. Berejikian said yes, and also suggested working with the WDFW regional office to coordinate on fish health issues. Pearsons asked if there were any fish health issues with using spawning channels in Berejikian's studies. Berejikian said no, because in the Hood Canal study, adults are not handled. The study takes eyed eggs from the natural environment and puts them into a quarantine system. Mackey said in his previous work in the northeast United States, he collected parr by electrofishing natural spawning areas. He said electrofishing has been used in the Twisp River to collect age-0 fish (parr) in September. He said collecting fry could help improve genetic diversity. Tonseth said electrofishing for fry would hopefully result in a mix of families, and Mackey said it can be performed throughout the whole river in contrast to using the Twisp Weir, which only collects a subset of the population. Mackey noted that it would be difficult or impossible to collect an entire program this way. Berejikian said one program in Oregon was collecting juvenile steelhead, and they had skewed sex ratios, disease issues in the hatchery, and eventually switched to an egg collection approach due to successful egg collection in other programs. Representatives present thanked Berejikian for his presentation and input.

III.Joint HCP-HC/PRCC HSC

A. NMFS Consultation Update (Emi Kondo)

Emi Kondo provided an update on consultation for the unlisted programs in the upper Columbia River. She said she requested an initiation of consultation from Chelan PUD, Grant PUD, and WDFW, which would serve as their official request to NMFS to begin consultation. Bill Gale asked if the parties sent a letter initiating consultation when they submitted Hatchery and Genetic Management Plans (HGMPs). Kondo said HGMPs were submitted in 2010, and recalculation for No Net Impact occurred since then, so it is appropriate for the PUDs to submit initiation requests for current programs. She said Chelan PUD and Grant PUD should submit requests, but Douglas PUD should not, as their program has not changed since the HGMPs were submitted. Deanne Pavlik-Kunkle (Grant PUD) said Grant PUD is drafting their request. Kondo said the next step after NMFS receives requests is to respond with a letter of sufficiency. Regarding the Biological Opinion (BiOp) for the unlisted programs, Kondo said the draft will be finished soon and will go to internal review, then comanager review.

B. USFWS Bull Trout Consultation Update (Matt Cooper)

Matt Cooper said Karl Halupka provided him an update on USFWS bull trout consultations, which he summarized as follows:

- Halupka is working to get the BiOp for the batch of Wenatchee subbasin programs signed this week.
- USFWS is continuing regular coordination with NMFS (Emi Kondo and Charlene Hurst) and Mike Tonseth on the Methow steelhead consultation, the consultation for the batch of hatchery programs for unlisted Chinook salmon stocks in the Columbia River, and reinitiation

of Mitchell Act consultation for the Ringold fall Chinook salmon program with the U.S. Army Corps of Engineers. NMFS may initiate consultation on the upper Columbia batch next week.

- USFWS completed expedited consultation on Nason Creek Acclimation Facility intake maintenance and are discussing consultation options for covering future intake maintenance with NMFS and Grant PUD.

Todd Pearsons asked if the signed BiOp for the batch of Wenatchee subbasin programs will be distributed to all Hatchery Committees and PRCC HSC parties. Tonseth said National Oceanic and Atmospheric Administration (NOAA) is the action agency and is consulting with USFWS, so the signed BiOp will be directly transmitted to NOAA and the applicants will likely also be notified. Tonseth said he heard that comments are still being incorporated into the BiOp, and may not be signed this week.

C. M&E Plan for PUD Hatchery Programs 2017 Update (Hillman)

Tracy Hillman said he revised the M&E Plan for PUD Hatchery Programs to reflect changes discussed during the September 20, 2017 Hatchery Committees meeting and distributed it (Attachment E). Hillman reviewed the new information in Section 7.2 (Non-target Taxa of Concern), and Section 8 (Adaptive Management).

He said he also added Appendix 1, Estimation of Carrying Capacity, which Andrew Murdoch (WDFW) is reviewing. Hillman defined two types of carrying capacity as follows:

- Population equilibrium capacity—the maximum number or biomass of a species that can occur based on density dependent mechanisms that reduce population growth rates as population size increases
- Habitat capacity—the maximum number or biomass of a species that habitat can support

He said the appendix includes an example of how carrying capacity is estimated for spring Chinook salmon in the Chiwawa River watershed and the entire Wenatchee River basin. He described methods for assessing density dependence in juvenile spring Chinook salmon and described the importance of having large contrast in spawner abundances in identifying the presence of density dependence and estimating carrying capacity. Keely Murdoch asked if there is a way to discuss the geospatial component to capacity related to the graphs in Appendix 1. She said spring Chinook salmon in the Chiwawa River watershed are a hatchery-driven population, and in years with big escapement, the proportion of hatchery origin spawners is very high. She added that the reproductive success study shows unequal spawner distributions, and a reduction in productivity (parr production) is related to distribution. Hillman agreed and indicated that calculation of habitat capacity, which is based on fish-habitat data and not just fish data, which are used to estimate population equilibrium capacity, should not be affected by hatchery production within the watershed. He said he calculated both habitat and population equilibrium capacities and compared those results in the appendix. Hillman then described the different models used to calculate carrying capacity and their associated assumptions. He said capacity estimates can be standardized by dividing the estimates by watershed area, intrinsic potential, or other watershed-scale metrics. This allows comparisons among different basins or watersheds.

Hillman said for spring Chinook salmon in the Chiwawa River, models produced a range of estimates for parr and smolt capacities. He said the smolt capacity estimates are about half of the parr capacity estimates, and these estimates can be extrapolated to the entire Wenatchee River basin using intrinsic potential. He then compared extrapolated capacity estimates based on intrinsic potential to actual capacity estimates based on data collected at the lower Wenatchee smolt trap. The actual and extrapolated estimates did not differ greatly.

Hillman also reviewed the calculation of habitat capacity using a fish-habitat model (Quantile Regression Forest Model) and using quantile regression to estimate the 90% reference interval for the stock-recruitment functions. He then compared results from all the different models. Todd Pearsons asked why there is a difference in number of spawners needed to reach parr habitat capacity between the Chiwawa River and Wenatchee River. Hillman said the Chiwawa River has higher quality habitat, so one unit of intrinsic potential in the Chiwawa produces more fish than say a unit of intrinsic potential in another area within the Wenatchee.

Hillman suggested that the Hatchery Committees review the recommendations included in Appendix 1. He said one item not included in the appendix is if abundance and productivity data should be normalized using population equilibrium capacity estimates or habitat capacity estimates. Catherine Willard suggested providing the estimate with associated levels of error. Hillman said appendices in annual reports provide error bars for stock-recruitment data, and the Chiwawa River data have less error in their estimates than other areas. Hillman said another item that will need to be decided is how to calculate carrying capacity for summer Chinook salmon.

Pearsons said in order for this document to be useful to the Independent Scientific Advisory Board (ISAB), the Hatchery Committees and PRCC HSC should try to approve it in November 2017. He said the ISAB hopes to finish their assessment by December 2017, but may continue into 2018. Hillman asked representatives present if approving this document in November would be reasonable, and they agreed. Sarah Montgomery said she will distribute the draft again as a decision item for the November 15, 2017 Hatchery Committees meeting.

D. Timeline of Changes in Spring Chinook Salmon Programs (Tracy Hillman)

Tracy Hillman said he drafted timelines for the Wenatchee and Methow spring Chinook salmon programs to determine interruptions for statistical analysis. Hillman shared a document, *Draft Hatchery Program Timelines* (Attachment F), and representatives present reviewed the timelines.

Hillman said he reviewed reports, permitting documents, and other items and picked events or changes he thought might interrupt the time series in a statistically important way. He requested that the Hatchery Committees review the timelines and suggest additions. Catherine Willard said these timelines might also be useful to the ISAB, and suggested adding adult management to the timeline. Keely Murdoch asked if the timelines should just have hatchery program information, or should also include other effects to populations. Hillman said as a minimum, the timelines should include anything that would potentially affect statistical analyses. Todd Pearsons agreed and suggested making a timeline with all suggested events as the first step. Mike Tonseth said the Hatchery Committees should compile one set of timelines with all suggested events, then a subset of timelines including just the major events to be used for statistical analysis. Pearsons suggested checking the timeline included in the UCSRB's Draft Hatchery Report for comparison. Hillman said he did this and found some discrepancies between his version and the draft report. In one example, Matt Cooper explained the difference is due to stating the brood year a hatchery program began, as opposed to the release year. Hillman summarized that the Hatchery Committees will review the timelines, and provide comments and suggestions to him via email. He said he will distribute the draft timelines for review.

IV. HCP Administration

A. Next Meetings

The next Hatchery Committees meetings are on November 15, 2017 (Grant PUD), December 20, 2017 (TBD), and January 17, 2018 (Grant PUD).

EXHIBIT A

SCOPE OF WORK

IMPLEMENTATION OF COMPREHENSIVE MONITORING AND EVALUATION OF WELLS HATCHERY COMPLEX PROGRAMS IN 2018

Greg Mackey - Douglas County PUD

Todd Pearsons - Grant County PUD

Catherine Willard - Chelan County PUD

Charlie Snow

Alf Haukenes

Methow Research Team

Hatchery/Wild Interactions Unit, Science Division

Washington Department of Fish and Wildlife

20268 Hwy 20, Suite 7

Twisp, WA 98856

September 2017

Introduction

The contractor for the M&E Implementation Plan will conduct the field work, data collection, and data management. Reporting will be a collaborative effort between the contractor, Douglas PUD, Grant PUD, and Chelan PUD.

The Douglas County PUD and Grant County PUD Monitoring and Evaluation Plans (M&E Plan; Wells HCP Hatchery Committee 2007) described eight objectives specific to the hatchery programs funded by Douglas County PUD, Grant County PUD, and Chelan County PUD, and two regional objectives that were related to artificial propagation in general. These objectives were designed to address key questions regarding the use of supplementation as mitigation for unavoidable mortality associated with the operation of the Wells Hydroelectric Project (Douglas PUD), the Priest Rapids Hydroelectric Project (Grant PUD), and Rock Island and Rocky Reach hydroelectric projects (Chelan PUD). In 2013, these M&E Plans were reviewed and updated (Hillman et al. 2013) to reflect shifting management paradigms and to incorporate data collection and analysis from the first five years of hatchery program monitoring (Murdoch et al. 2012) conducted under the original M&E Plans. The updated M&E Plan (hereafter referred to as the M&E Plan) contains ten objectives specific to hatchery programs funded by PUDs and two regional objectives. One regional objective has been completed and the other is not planned to be addressed. The primary focus of this plan is assessment of the first ten objectives outlined in the M&E Plan.

Successful implementation of the M&E Plan requires relationships between the PUDs, M&E contractor, and other entities conducting similar field work in the Upper Columbia River Basin. Certain objectives require the collection of data from both target populations and non-target populations, such as reference populations. This proposal does not include field activities conducted by other entities to collect data for reference non-target populations required to implement the M&E Plan.

Addressing all the objectives within the M&E Plan requires multiple years of data collection. This is year five under the 2013 update of the M&E Plan and year thirteen of the plan under the HCP. Objectives 5, 7, 8, and 10 are designed to be addressed after one year or five years (Table 1), and may require only periodic monitoring. Statistical analyses will be conducted consistent with the M&E Plan, revisions thereof, or the 5-year M&E report (Murdoch et al. 2012) as applicable. A revised schedule and definition of M&E reports was recently approved by the hatchery committees. This approved schedule formalizes and supercedes previous schedules. The Implementation Plan is formatted such that species, programs, and the associated M&E Objectives are presented in separate sections that are subdivided into modules to clearly define actions under the M&E Plan and allow flexibility in administering budgets.

Table 1. A potential long-term implementation schedule of objectives outlined in the PUD M&E Plan. The HCP HCs/PRCC HSC may change the M&E plan, its objectives, and implementation in future years. Monitoring and evaluation of hatchery programs in years prior to the 6-9 year period have been completed and are included here for reference only. The work conducted within this proposal would be implementation year thirteen.

Objective	Year of implementation									
	1-4	5	6-9	10	11-14	15	16-19	20	21-24	25
1	X	X	X	X	X	X	X	X	X	X
2	X	X	X	X	X	X	X	X	X	X
3	X	X	X	X	X	X	X	X	X	X
4	X	X	X	X	X	X	X	X	X	X
5	X	X		X		X		X		X
6	X	X	X	X	X	X	X	X	X	X
7	X				X				X	
8	X				X				X	
9	X	X	X	X	X	X	X	X	X	X
10	X	X		X		X		X		X

This plan encompasses one year of work to implement the updated Monitoring and Evaluation Plan for PUD Hatchery Programs operated at the Wells Hatchery and Methow Hatchery, as described in the work plan, below.

2017 M&E Work Plan by Species, Programs, and Activities

Summer Steelhead

Module 1: In-Hatchery Metrics – Steelhead

Required to meet:

Objective 3: Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.

Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

Objective 9: Determine if hatchery fish were released at the programmed size and number.

Biological data for origin, sex, age, size, fecundity, and survival of broodstock will be recorded for all steelhead hatchery programs: Twisp Conservation, Methow Safety-Net, and Columbia Safety-Net. (The Okanogan Safety-Net, Omak Creek Conservation programs are now reported on separately by Grant PUD.) Number of fish, stage-specific survivals, size, coefficient of variation, condition factor, and fish health issues will be recorded. An annual review of size, number and supporting statistics of fish from each program will be compared to those values defined in the M&E Plan Appendix 6, or adjusted values agreed to by the Wells HCP Hatchery Committee. Values within acceptable precision (i.e., +/-10% of HCP defined values) will constitute achievement of program objectives. Failure to achieve release targets will trigger evaluation to determine probable causation and recommendations, when necessary, for improving performance.

Hatchery personnel will assess fecundity of spawned females when fertilized eggs are at the eyed stage, and will provide data to evaluation staff. To assess overall egg mass, we will collect total egg weight samples just after removal from lethally-spawned females, and will record the weight of female fish after egg removal.

Module 2: Steelhead Adult Stock Assessment

Required to meet:

Objective 1: Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.

Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.

Objective 3: Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.

Objective 4: Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.

Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.

Objective 7: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.

Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

The Twisp Weir will be operated for steelhead adult stock assessment between March 1, 2018 (approximate as environmental conditions allow) and June 30, 2018. Activities implemented at the Twisp Weir will include sampling all adult steelhead captured (origin, length, sex, genetic tissue sample, record any marks or tags, Floy tag fish to be released according to color scheme [Table 2]); PIT tagging and releasing adult steelhead (abdomen or pelvic girdle); retain (as necessary) natural origin Twisp returns for broodstock; handle any non-target species captured according to operational protocols and permit conditions; and, perform adult management of hatchery origin returns to achieve a 1:1 hatchery:natural origin ratio of spawners and the removal of non-Twisp hatchery origin adults upstream of the Twisp Weir. Fish sacrificed for adult management may be sampled for fecundity to augment the sample size for hatchery-origin fish. Rainbow trout and cutthroat trout captured at the Twisp Weir will also be sampled and tagged similarly to steelhead.

Table 2. Floy tag colors for adult Twisp steelhead released upstream of the Twisp Weir in 2018.

Sex	Origin	Tag color
Female	Natural	Blue
Female	Hatchery	Red
Male	Natural	Pink
Male	Hatchery	Chartreuse

Floy tag colors will be alternated every other year between hatchery and wild fish to control for any potential color effects on reproductive success.

Wells Dam fish counts will provide data on escapement upstream of Wells Dam. Stock assessment will be used to estimate the composition of the escapement. Wells Dam stock assessment will be performed concurrent with broodstock collection activities at Wells Dam and Wells Hatchery from July 2018 – November 2018. Activities will include sampling all adult steelhead captured (origin, length, sex, genetic tissue sample (broodstock only), record any marks or tags, PIT tags may be applied to released fish [pelvic girdle]), retain hatchery-origin returns for Columbia Safety-Net, Methow Safety-Net, and Okanogan broodstock, handle any non-target species captured according to operational protocols and permit conditions. Management (removal) of excess hatchery origin adult steelhead may also occur at the Wells Hatchery volunteer channel and the Methow Hatchery outfall channel between March and May, 2018.

HRR will be estimated and values that fall below the expected values or the corresponding estimate of NRR (Appendix 2 of the M&E Plan) will be evaluated to determine whether in-hatchery or out-of-hatchery factors contributed to the reduced survival. Smolt to adult returns (SAR) will be estimated for each program and for the natural origin Twisp population. The proportion of hatchery origin spawners (pHOS) and proportion of natural influence (PNI) will be estimated for the Twisp steelhead program and population. Data for pHOS and PNI (for broodstock within Douglas PUD program facilities) will be collected for other parts of the basin. Numbers and proportions of hatchery origin returns removed for adult management for the Twisp, Methow and Columbia programs will be estimated and reported consistent with terms and conditions (Appendix 3 of the M&E Plan) in the pending Wells Complex Summer Steelhead HGMP ESA permit.

Module 3: Report Steelhead Contribution to Harvest

Required to meet:

Objective 10: Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.

In years when the expected returns of hatchery adults exceed the level required to meet program goals of Wells Complex steelhead programs, surplus fish may be available for harvest. The contribution to harvest will be reported for programs that are consistent with harvest. Conservation fishery data derived from creel census (funded and conducted by WDFW) are reported to NMFS annually, and harvest data reported outside the scope of this plan (PTAGIS, etc.) will be summarized.

Module 4: Steelhead Spawning Distribution and Timing

Required to meet:

Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.

Spawner surveys will be conducted at least weekly in the Twisp River using standard spawning ground survey methodology and data analysis as described in Snow et al. (2012). Locations of redds will be recorded using GPS; fish location and origin (identified by Floy tags) will also be recorded. Data collected will provide the number of redds, and timing and spatial distribution of spawning by fish origin. Any carcasses encountered will be sampled for sex, origin, age, egg retention, PIT tag, and other relevant biological data. Spawn timing comparisons of hatchery and natural origin steelhead will be conducted using data from Twisp River reaches T4-T10. The capture efficiency of the Twisp Weir will be estimated by comparing observations of Floy tagged and un-tagged fish in sections upstream of the weir.

Additionally, temporary in-stream PIT tag antenna arrays may be placed in selected tributaries in the Twisp drainage to assist with evaluation of spawning spatial distribution and timing. In conjunction with returning steelhead adults tagged as juveniles and adult steelhead tagging at the Twisp Weir and the Wells and Priest Rapids dams, these arrays are expected to provide a reliable, cost-effective means of corroborating current survey methodologies with observed steelhead use, and detect spawning (if any) in locations where spawning is presumed to not occur, or where surveys are difficult to conduct. Permanent PIT tag arrays located in the Chewuch River, the

Methow River near Winthrop, Washington, and in lower Methow tributaries (i.e., Beaver, Gold, and Libby creeks) will be used to estimate overall steelhead spawner abundance, origin of spawners, and pHOS, for the Chewuch River, and the upper and lower Methow River subbasins. Index redd surveys will be used in the lower Methow reaches in conjunction with PIT tag detection. DCPUD will explore AUC modeling methods to estimate the number of spawners in the lower Methow.

Module 5: Estimation of Steelhead Stray Rates

Required to meet:

Objective 6: Determine if the stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.

Stray rates of Twisp conservation, Methow Safety-Net, and Columbia Safety-Net steelhead will be estimated by PIT tag detections at in-stream PIT tag detection stations in the Methow Basin and in watersheds outside the Methow Basin (via PTAGIS), and positive identification of recovered or captured steelhead at traps (Twisp Weir, Methow Hatchery, Winthrop NFH, Omak Weir), during spawner surveys, or through creel census.

Collecting stray rate information for steelhead poses a challenge because carcasses are not available for examination. Adult PIT tag monitoring provides the most accurate assessment of stray rates, both within and among populations.

Module 6: Steelhead Juvenile Population Assessment

Required to meet:

Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.

The population abundance of juvenile steelhead will be estimated in the rivers supplemented by Douglas PUD's steelhead hatchery programs. Sampling locations and methods may utilize a combination of the following methods: screw traps, mark-recapture population estimates, electrofishing removal population estimates, snorkel surveys, and PIT tag based survival modeling.

Approach 1: The efficacy of this approach is currently being analyzed and continued implementation of this approach will be determined based on this assessment. Under this approach, rotary screw smolt traps are used in the Twisp and Methow rivers, and trapping locations and methods will remain as described in Snow et al. (2012). Biological data (species, length, origin, scale samples, genetic samples [Twisp River only]) will be collected from fish collected each day. Scale samples will be taken from random samples of steelhead juveniles to estimate the age structure of the emigrants. The Twisp trap will be fished from early March through late November, and the Methow Trap will be fished from late February through late November, as conditions allow at both trapping locations. Steelhead greater than 65 mm will be PIT tagged. Trap efficiency trials will be conducted at various flows as the number of available fish for trials allows. Population estimates will be calculated by expanding the number of fish caught on a daily basis by the estimated trap efficiency on that day as estimated using a flow-efficiency model.

Approach 2: The efficacy of this approach is currently being analyzed and continued implementation of this approach will be determined based on this assessment. Under this approach, juvenile population estimates are derived through in-stream PIT tagging coupled with survival modeling in the Twisp River, Methow and/or Chewuch rivers. Sampling may be limited to testing the methodology. Steelhead will be captured by electrofishing at sites chosen using General Random Tessellation Sampling (GRTS) or other random sample method. The standing crop of juveniles will be estimated by both multiple-pass removal estimates or mark-recapture estimates coupled with single-pass electrofishing extrapolated to the amount of habitat in the stream. Captured fish will be PIT tagged. Survival of the fish will be estimated through emigration using a multi-state survival model (J. Skalski and R. Buchanan, personal communication). The number of emigrants will be estimated using this PIT tag based survival model. This approach will be implemented for the fourth time in the fall of 2017. The results of the pilot studies in 2014-2017 will be used to improve the assessment. As informative results from the initial implementation become available, this approach may be modified to better meet M&E objectives.

Module 7: Steelhead Population Genetic Monitoring

Required to meet:

Objective 7: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.

Hypotheses related to genetic diversity, population structure, and effective population size were addressed in the 2008-2010 work plans and will not be addressed in 2018. However, to provide the ability to conduct future analysis, we will collect and archive representative tissue samples (opercle-punch or fin clip) from all steelhead broodstocks, and from natural origin steelhead collected on the spawning grounds and at the Twisp River Weir. Samples will have associated data recorded (fish origin, age, date, location, sex, and biological characteristics).

Table 3. Cross reference of steelhead M&E implementation modules and M&E objectives.

	Objective	Modules	Data
1	Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.	2, 4	• Adult returns • Sex and Origin of Adults • Number of Spawners
2	Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.	2, 4, 6	• Adult Returns • Sex and Origin of Adults • Number of Spawners • Juvenile Population Estimates
3	Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.	1, 2, 4	• Broodstock Data • Adult returns • Sex and Origin of Adults • Number of Spawners
4	Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.	2, 4	• Adult returns • Sex and Origin of Adults • Number of Spawners
5	Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.	2, 4	• Run timing • Spawn timing • Spatial Distribution of Spawning • Adult returns • Sex and Origin of Adults • Number of Spawners
6	Determine if the stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.	4, 5	• Sex and Origin of Adults • Number of Spawners • Spatial Distribution of Spawning
7	Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.	1, 2, 4, 7	• Sample Broodstock • Sample Adult Returns • Sample Spawners • Sample Juveniles • Various Population Genetic Analyses
8	Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.	1, 2	• In-Hatchery Metrics • Adult Phenotype Metrics
9	Determine if hatchery fish were released at the programmed size and number.	1	• In-Hatchery Metrics
10	Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.	3	• Various Harvest Data (PTAGIS, RMIS, Agency Reports, etc.)

Spring Chinook

Module 8: Spring Chinook In-Hatchery Metrics

Required to meet:

Objective 3: Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.

Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

Objective 9: Determine if hatchery fish were released at the programmed size and number.

Biological data for origin, sex, age, size, fecundity, and survival of broodstock will be recorded for the Twisp and Methow Conservation hatchery programs. Number of fish, stage-specific survivals, size, coefficient of variation, condition factor, and fish health issues will be recorded. An annual review of size, number and supporting statistics of fish from each program will be compared to those values defined in the M&E Plan Appendix 6, or adjusted values agreed to by the Wells and Rocky Reach HCP Hatchery Committees and PRCC HSC. Values within acceptable precision (i.e., +/- 10% of HCP defined values) will constitute achievement of program objectives. Failure to achieve release targets will trigger evaluation to determine probable causation and recommendations, when necessary, for improving performance.

Hatchery personnel will assess fecundity of spawned females when fertilized eggs are at the eyed stage, and will provide data to evaluation staff. To assess overall egg mass, we will collect total egg weight samples just after removal from lethally-spawned females, and will record the weight of female fish after egg removal.

Module 9: Spring Chinook Adult Stock Assessment

Required to meet:

Objective 1: Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.

Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.

Objective 3: Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.

Objective 4: Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.

Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.

Objective 7: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.

Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

The Twisp Weir and Methow Hatchery volunteer trap(s) will be operated for spring Chinook broodstock collection primarily between July 1, 2018 and August 30, 2018 (Twisp Weir is operated under the auspices of steelhead collection and sampling through June 30, but spring Chinook will be collected opportunistically prior to July 1). Wells Dam fish ladders will be operated between about 1 May and 30 June for spring Chinook broodstock collection and overall population stock assessment. Activities will include sampling all adult spring Chinook captured (origin, length, sex, genetic tissue sample, record any marks or tags, retain natural origin Twisp returns for broodstock, handle any non-target species captured according to operational protocols and permit conditions, and PIT tags may be applied to the pelvic girdle of released fish).

Carcass recoveries and coded wire tag data will be the primary means of stock assessment (see the spawner survey section for more information). Samples and data for run composition, age, origin, size, spawn timing, egg retention, and population genetic analyses will be collected. HRR will be estimated and values that fall below the expected values or the corresponding estimate of NRR (Appendix 2 of the M&E Plan) will be evaluated to determine whether in-hatchery or out-of-hatchery factors contributed to the reduced survival. SAR will be estimated for each program and for the natural origin fish of the Twisp River and Methow Basin. SAR for the Chewuch River natural origin fish will be estimated if appropriate PIT tag groups are available.

The pHOS and PNI will be estimated for the Twisp and MetComp programs and populations. Numbers and proportions of hatchery origin returns removed for adult management for the Twisp and Methow programs will be estimated and reported consistent with terms and conditions (Appendix 3 of the M&E Plan) in the Methow Hatchery Spring Chinook ESA permit.

Module 10: Spring Chinook Contribution to Harvest

Required to meet:

Objective 10: Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.

In years when the expected returns of hatchery adults exceed the level required to meet program goals for the Methow Hatchery spring Chinook programs, surplus fish may be available for harvest. The contribution to harvest will be reported based on numbers of fish released for programs that are consistent with harvest. Conservation fishery data derived from creel census (funded and conducted by WDFW) will be reported to NMFS annually, and harvest data reported outside the scope of this plan (PTAGIS, RMIS, etc.) will be summarized.

Module 11: Spring Chinook Spawner Surveys

Required to meet:

Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.

Spawner surveys will be conducted at least weekly in all spawning reaches of the rivers supplemented by the Methow Hatchery (Table 4) using standard spawning ground survey methodology and data analysis as described in Snow et al. (2012), and may incorporate surveyor efficiency models to estimate precision. Locations of redds will be recorded using GPS. Data collected will provide the number of redds, and timing and spatial distribution of spawning by origin. Carcasses encountered will be sampled for location of recovery, sex, origin, age, egg retention, CWT, PIT tag, and other relevant biological data.

Table 4. Spring Chinook spawning ground surveys and methods.

River	Spawning ground methodology	Spawner composition	Age composition
Methow	Total ground	Carcasses	Wells Dam
Chewuch	Total ground	Carcasses	Wells Dam
Twisp	Total ground	Carcasses	Wells Dam

Module 12: Estimation of Spring Chinook Stray Rates

Required to meet:

Objective 6: Determine if the stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.

Stray rates of Twisp, Chewuch, and Methow conservation programs will be estimated by CWT recoveries within and outside of the Methow Basin. The Regional Mark Information System (RMIS) database will provide all necessary CWT information needed to estimate stray rates for each brood year for within- and outside-basin stray rates based on spawning escapement estimates. Brood year stray rates for Chinook will require multiple-year CWT recoveries (i.e., all age classes) from broodstock and carcass recoveries on the spawning grounds to account for all cohort age classes. The estimated number of strays for the entire brood year will be calculated by dividing the number of strays by the total number of hatchery fish that returned. Stray rates within, and between independent populations will be calculated in a similar manner as brood year stray rates, except on an annual basis and based on the estimated spawning escapements of the receiving populations.

Module 13: Juvenile Spring Chinook Population Assessment

Required to meet:

Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.

The population abundance of juvenile spring Chinook will be estimated in the rivers supplemented by the PUDs' spring Chinook hatchery programs. Sampling locations and methods may utilize a combination of the following methods: screw traps, mark-recapture population estimates, electrofishing removal population estimates, snorkel surveys, and PIT tag based survival modeling.

Approach 1: The efficacy of this approach is currently being analyzed and continued implementation of this approach will be determined based on this assessment. Under this approach, rotary screw smolt traps are used in the Twisp and Methow rivers, and trapping locations and methods will remain as described in Snow et al. (2012). Biological data (species, length, origin, scale samples, genetic samples) will be collected from fish trapped each day. The Twisp trap will be fished from early March through late November, and the Methow Trap will be fished from late February through late November, as conditions allow at both trapping locations. Spring Chinook greater than 65 mm will be PIT tagged. Trap efficiency trials will be conducted at various flows as the number of available fish for trials allows. Population estimates will be calculated by expanding the number of fish caught on a daily basis by the estimated trap efficiency on that day as estimated using a flow-efficiency model. A similar methodology will be employed with the Twisp PIT tag antenna array to estimate over-winter emigration provided that adequate numbers of spring Chinook parr are PIT tagged under Approach 2.

Approach 2: The efficacy of this approach is currently being analyzed and continued implementation of this approach will be determined based on the assessment. Under this approach, juvenile population estimates are derived through in-stream PIT tagging coupled with survival modeling in the Twisp River, Methow and/or Chewuch rivers. Spring Chinook will be captured by electrofishing at sites chosen using General Random Tessellation Sampling (GRTS) or other random sample method. The standing crop of juveniles will be estimated by multiple-pass removal estimates or mark-recapture estimates coupled with single-pass electrofishing extrapolated to the amount of habitat in the stream. Captured fish will be PIT tagged. Survival of the fish will be estimated through emigration using a multi-state survival model (J. Skalski and R. Buchanan, personal communication). The number of emigrants will be estimated using this PIT tag based survival model. This approach was implemented for the fourth time in the fall of 2017. The results of the pilot studies in 2014-2017 will be used to assess whether to continue the field sampling for this work in 2018. As informative results from the initial implementation become available, this approach may be modified to better meet M&E objectives.

Module 14: Spring Chinook Population Genetic Monitoring

Required to meet:

Objective 7: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.

Hypotheses related to genetic diversity, population structure, and effective population size were addressed in the 2008-2010 work plans and will not be addressed in 2018. However, to provide the ability to conduct future analysis, we will collect and archive tissue samples (opercle-punch or fin clip) from all spring Chinook broodstock, and from natural origin spring Chinook collected on spawning grounds and at the Twisp River Weir. Samples will have associated data recorded (fish origin, age, date, location, sex, and biological characteristics).

Table 5. Cross reference of spring Chinook M&E implementation modules and M&E objectives.

	Objective	Modules	Data
1	Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.	9, 11	• Adult returns • Sex and Origin of Adults • Number of Spawners
2	Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.	9, 11, 13	• Adult Returns • Sex and Origin of Adults • Number of Spawners • Juvenile Population Estimates
3	Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.	8, 9, 11	• Broodstock Data • Adult returns • Sex and Origin of Adults • Number of Spawners
4	Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.	9, 11	• Adult returns • Sex and Origin of Adults • Number of Spawners
5	Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.	9, 11	• Run timing • Spawn timing • Spatial Distribution of Spawning • Adult returns • Sex and Origin of Adults • Number of Spawners
6	Determine if the stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.	11, 12	• Sex and Origin of Adults • Number of Spawners • Spatial Distribution of Spawning
7	Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.	8, 9, 11, 14	• Sample Broodstock • Sample Adult Returns • Sample Spawners • Sample Juveniles • Various Population Genetic Analyses
8	Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.	8, 9	• In-Hatchery Metrics • Adult Phenotype Metrics
9	Determine if hatchery fish were released at the programmed size and number.	8	• In-Hatchery Metrics
10	Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.	10	• Various Harvest Data (PTAGIS, RMIS, Agency Reports, etc.)

Summer Chinook

Module 15: Summer Chinook In-Hatchery Metrics

Required to meet:

Objective 3: Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the target hatchery survival rate.

Objective 9: Determine if hatchery fish were released at the programmed size and number.

Biological data for origin, sex, age, size, fecundity, and survival of broodstock will be recorded for the Wells yearling and subyearling hatchery programs. Number of fish, stage-specific survivals, size, coefficient of variation, condition factor, and fish health issues will be recorded. An annual review of size, number and supporting statistics of fish from each program will be compared to those values defined in Appendix 6, or adjusted values agreed to by the Wells HCP Hatchery Committee. Values within acceptable precision (i.e., +/-10% of HCP defined values) will constitute achievement of program objectives. Failure to achieve release targets will trigger evaluation to determine probable causation and recommendations, when necessary for improving performance.

Module 16: Summer Chinook Adult Stock Assessment

Objective 3: Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.

Stock assessment will be performed on broodstock collected at Wells Hatchery. Activities will include sampling all adult summer Chinook broodstock for origin, length, sex, genetic tissue sample (for CRITFC PBT), record any marks or tags, handle any non-target species captured according to operational protocols and permit conditions. Coded wire tag data will be the primary means of stock assessment. Samples and data for run composition, age, origin, size, spawn timing, egg retention, and population genetic analyses will be collected. HRR will be estimated and values that fall below the expected value (Appendix 2 of the M&E Plan) will be evaluated to determine whether in-hatchery or out-of-hatchery factors contributed to the reduced survival. SAR will be estimated for each program.

Module 17: Summer Chinook Contribution to Harvest

Required to meet:

Objective 10: Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.

In years when the expected returns of hatchery adults exceed the level required to meet program goals, surplus fish may be available for harvest. The contribution to harvest will be reported based on numbers of fish released for programs that are consistent with harvest and harvest data funded, collected, and reported outside the scope of this plan (PTAGIS, RMIS, etc.).

Module 18: Estimation of Summer Chinook Stray Rates

Required to meet:

Objective 6: Determine if the stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.

Stray rates of Wells yearling and subyearling summer Chinook will be estimated through CWT recoveries reported in RMIS. The RMIS database will provide all necessary CWT information to estimate stray rates for each brood year for within- and outside-basin stray rates based on spawning escapement estimates. Brood year stray rates for Chinook will require multiple-year CWT recoveries (i.e., all age classes) from broodstock and carcass recoveries on the spawning grounds to account for all cohort age classes. The estimated number of strays for the entire brood year will be calculated by dividing the number of strays by the total number of hatchery fish that returned. Stray rates in independent populations will be calculated in a similar manner as brood year stray rates, except on an annual, run-year basis and based on the estimated spawning escapement.

Module 19: Summer Chinook Population Genetic Monitoring

Required to meet:

Objective 7: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.

Hypotheses related to genetic diversity, population structure, and effective population size were addressed in the 2008-2010 work plans and will not be addressed in 2018. However, to provide the ability to conduct future analysis, we will collect and archive tissue samples (opercle-punch or fin clip) from summer Chinook broodstock. Samples will have associated data recorded (fish origin, age, date, location, sex, and biological characteristics).

Table 6. Cross reference of summer Chinook M&E implementation modules and M&E objectives.

	Objective	Modules	Data
1	Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.	NA	NA
2	Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.	NA	NA
3	Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.	15, 16	• Broodstock Data • Adult returns • Sex and Origin of Adults
4	Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.	NA	NA
5	Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.	NA	NA
6	Determine if the stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.	18	• Sex and Origin of Adults • Number of Spawners • Spatial Distribution of Spawning
7	Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.	19	• Sample Broodstock • Sample Adult Returns • Sample Spawners • Sample Juveniles • Various Population Genetic Analyses
8	Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.	NA	NA
9	Determine if hatchery fish were released at the programmed size and number.	15	• In-Hatchery Metrics
10	Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.	17	• Various Harvest Data (PTAGIS, RMIS, Agency Reports, etc.)

DELIVERABLES

Annual Reports: Reporting will follow the schedule in Table 7.

Table 7. Monitoring and Evaluation Annual Report Review Dates.

Date	Reporting Phase
June 1	WDFW Internal Review
July 15	Draft submitted to PUDs for 30 day review
August 15	PUDs comments to WDFW
September 15	Draft to HC for 30 day review
October 15	HC comments to PUDs and WDFW
November 1	Final Report submitted to NMFS and HC

The annual report will summarize all field activities conducted during the contract period (January 1 – December 31). The report will be in a scientific format, organized so that the HCP HCs and the PRCC HSC members can clearly and concisely evaluate M&E Plan results. Data tables and figures will be cumulative such that all comparable data from previous years is included and that the most recent report supersedes all previous reports. Monitoring indicators and the data used in calculations will be presented for each hypothesis evaluated.

Monthly Reports: Monthly reports will be provided to keep Douglas PUD, Grant PUD, Chelan PUD, as well as the HCP HCs and PRCC HSC members and co-managers informed on all hatchery and evaluation related activities. Unless otherwise requested by the PUDs, the role of monthly reports will remain the same. Upon request, additional information can be included in the monthly reports.

COORDINATION

Douglas PUD's M&E contractor will be required to closely coordinate and collaborate with hatchery staff at the Wells and Methow hatcheries. Hatchery staff conduct many of the in-hatchery routine sampling and data collected by hatchery staff must be provided to evaluation staff to ensure the data are included the M&E Plan reports. However, special meetings with the hatchery staff are typically conducted prior to significant events (i.e., broodstock collection, spawning, release of juveniles) to ensure proper methodologies are used and critical data are collected. Evaluation staff will be present at all significant events to collect data needed for evaluation purposes. Coordination between evaluation staff, hatchery staff, and the ESA Permit compliance officer is required to ensure that conditions of ESA Section 10 permits are not violated. All ESA reporting related to the hatchery programs is the responsibility of the ESA compliance officer.

Exhibit B

Budget

Methow Basin Natural Evaluation Budget: 1 January 2017 to 31 December 2017 NOT UPDATED YET		
Salaries		
Research Scientist 2 (2 months at 5,804/ month)		11,608
Fish Biologist 4 (12 months at 5,804/month)		69,648
Fish Biologist 3 (12 months at 5,657/month)		67,884
Fish Biologist 2 (12 months at $4,208/month)		50,496
Perm Sci Tech 2 (21.5 months at $3,287/month)		70,671
Temp Sci Techs (66.5 months at $3,287/month)		218,586
Office Assistant Senior (1 month at $2,768/month)		2,768
	Subtotal	**491,660**
Benefits		
OASI and Medicare (7.65% of salaries; 2016 = same)		37,612
Retirement (11.18% of salaries; 2016 = same)		54,968
Labor and Industries ($171/month x 27 months; 2016 = $161/mo)		21,717
Health Insurance rep ($894.00/month x 60.5 months; 2016 = 840/mo)		54,087
Health Insurance non-rep ($894.00/month x 66.5 months; 2016 = 840/mo)		59,451
	Subtotal	**227,835**
	Total Salaries and Benefits	**719,495**
Goods and Services		
Office supplies (paper, notebooks, tally meters, etc.)		1,000
Utilities (phone; 3 @ $220 month, electricity [smolt trap])		2,640
Copier rental ($140.00/month for 12 months)		1,680
Snow plowing at office		1,000
Sampling supplies (knives, bags, scale, vests, etc.,)		800
Cellular phones		200
Waders and hip boots		2,800
Portable toilet		520
MS-222/Alcohol		1,000
Gas and maintenance (34,000 miles @ $0.35/mile)		11,900
Vehicle lease (7 vehicles, $1,914/month)		22,968
Rope and fasteners (crosbys, nuts and bolts)		500
Crane rental		1,200
Equipment maintenance and repair, projected to include:		10,000
Smolt trap safety upgrades = 3,500		
PIT antenna maintenance = 5,000		
DNA SAMPLING		
BY 14 Sub Chinook from Methow smolt trap (100@$43/sample)		4,300
	Total Goods and Services	**62,508**

1.0 ORGANIZATIONAL CHART

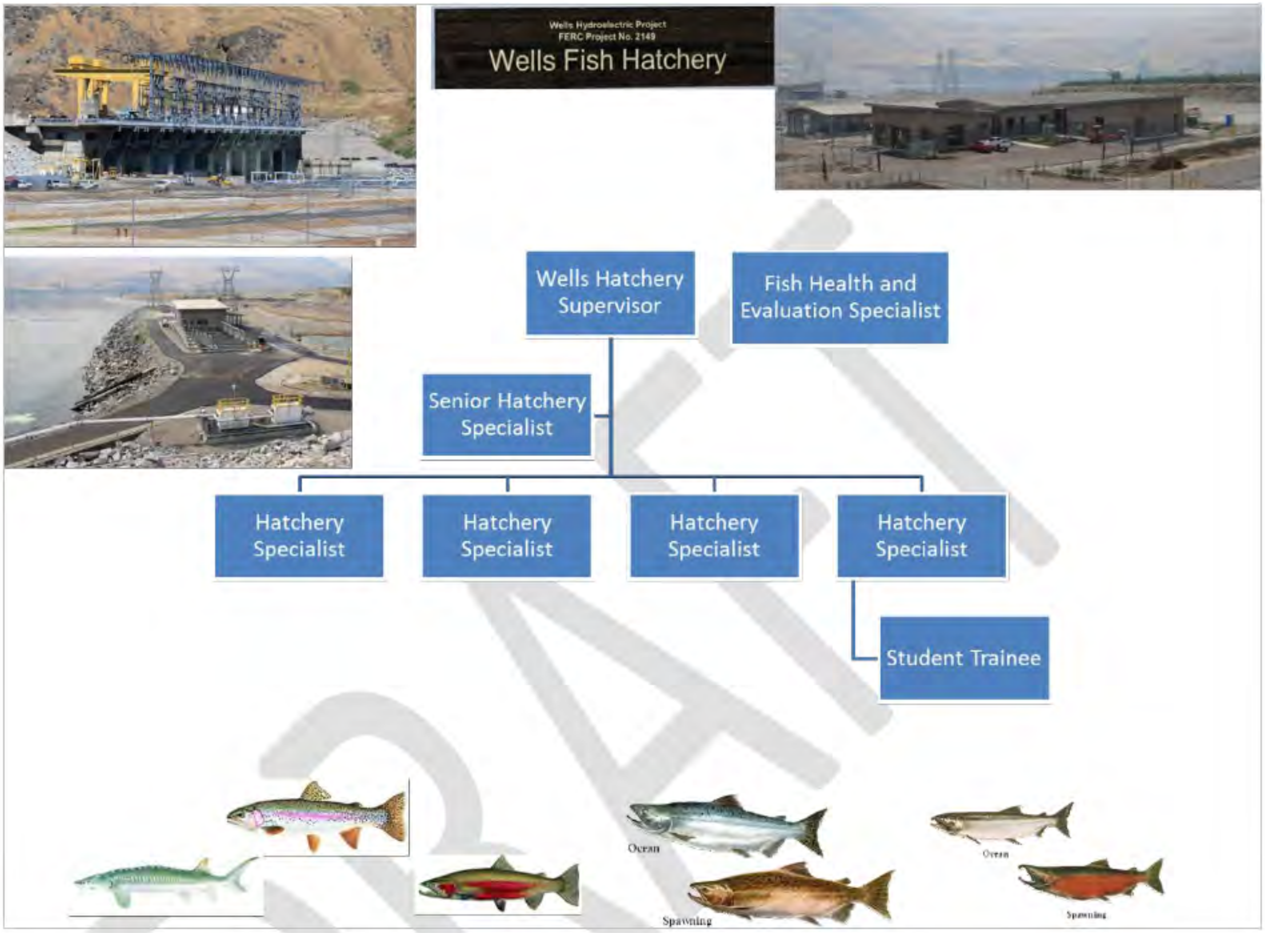

Figure 1. Wells Fish Hatchery Organizational Chart

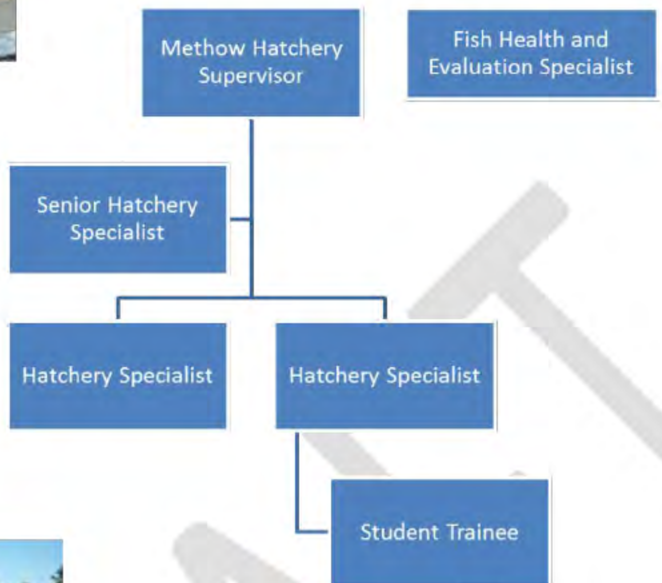

Figure 2. **Methow Fish Hatchery Organizational Chart**

2.0 PERSONNEL AND STAFFING

2.1 Timing and Strategy for Hiring Personnel

The Public Utility District No. 1 of Douglas County (District) has identified the need to hire and train 11 full time hatchery workers: 2 Hatchery Supervisors, 2 Senior Hatchery Specialists, 6 Hatchery Specialists, a Fish Health and Evaluation Specialist, and up to three additional seasonal/temporary workers, on an as needed basis.

The Hatchery Supervisor positions were posted on September 1, 2017. The other eight hatchery worker (Hatchery Senior Specialists and Hatchery Specialists) job notices were posted on September 7, 2017. The Fish Health and Evaluation Specialist position was posted on September 18, 2017. Interviews began on September 15, 2017 and will continue through October 18, 2017, or as needed. Positions will be filled as qualified candidates are identified and will remain open until filled.

We accomplished our goal of having the Hatchery Supervisor positions filled first and all other positions filled as shortly thereafter as possible, so that the new supervisors were included in the interview/hiring process for the Senior Hatchery Specialist and Hatchery Specialist positions.

Brandon Kilmer has formally accepted the Methow Hatchery Supervisor position. Brandon started September 29th. Pat Phillips has accepted the Wells Hatchery Supervisor position and started October 2nd. David Dinsmore has accepted the Methow Senior Hatchery Specialist positions and will start November 1st. The District has interviewed for the Wells Senior Hatchery Specialist position, and we hope to fill this position by November 1st. The Fish Health Specialist position will be filled by November 15, 2017.

All of the remaining positions will be filled by November 15th so that at least two weeks of training and transition can occur prior to the end of the contractual transition period (November 28th).

2.2 Job Descriptions

The job descriptions were posted on the PUD website (Douglaspud.org). Postings were removed when interviews began and there were sufficient numbers of qualified applicants. See http://www.douglaspud.org/your-pud/job-listings

As of October 2nd all jobs have closed with the notable exception of the Fish Health and Evaluation Specialist. Applications received to date included ten applications for the Methow Supervisor, 12 for the Wells Supervisor, 21 for the Methow Senior Specialist, 28 for the Wells Senior Specialist, 30 for the Methow Hatchery Specialists and 49 for the Wells Hatchery Specialist positions.

2.3 Duties

The duties listed below provide a general outline of the responsibilities for the hatchery operations across all levels of staffing, and will include permitting, planning, development of operational protocols, implementation of hatchery actions under the protocols, maintenance and operations, data collection and management and reporting.

- Trapping, fish sorting, and workup. Fish will be trapped for broodstock, Monitoring and Evaluation (M&E) sampling, and gene flow management according to protocols developed under the Wells Habitat Conservation Plan (HCP) and Endangered Species Act (ESA) processes. Coordination and collaboration with staff from the M&E program and other parties as appropriate.
- Spawning steelhead and salmon – egg and milt take, tracking matings, biological sampling, fertilizations, laying down eggs in incubation stacks, husbandry of incubating eggs and all life stages thereafter (see item below). Coordination and collaboration with staff from the M&E program.
- Fish culture from egg through release point for: steelhead, spring Chinook, summer Chinook, coho salmon, white sturgeon, rainbow trout, various other trout, kokanee and other species if and when such programs are fully authorized and developed.
- Operation of the Twisp Weir and Twisp Acclimation Pond. Coordination and collaboration with staff from the M&E program.
- Coordination and ongoing contractual relationship support with the Twisp Valley Irrigation Company and the Chewuch Canal Company.
- Coordination with USFWS on maintenance of Foghorn Ditch.
- Operation and maintenance of Foghorn fishway and intake.
- Proper and safe operation of all equipment at the hatcheries.
- Data entry, auditing, data storage, reporting. Coordination and collaboration with staff from the M&E program to assist data transfer, analyses, and reporting.
- Driving various vehicles, including CDL rated trucks (Class B).
- Attend District and departmental meetings.
- Employ strong communication skills with other District staff, contractors, sharing partners, etc.
- Maintenance of equipment and facilities.
- Maintenance of the grounds (snow plowing, irrigation system operation, tending to plants, grass areas, landscaping).
- Maintenance of buildings.
- Maintenance of vehicles.
- Operation of the hatcheries through the Supervisory Control and Data Acquisition (SCADA) systems and optimization of the systems via SCADA.
- Operation and maintenance of groundwater wells. Department of Ecology (Ecology) data collection.
- Operation and maintenance of surface water supply sources. Ecology data collection.
- Obtaining and maintaining permits (NPDES, HPA, Fish Transfer, etc.).

- Reports – support for writing reports, ESA reporting, NPDES reporting, and various other reporting responsibilities, data requests, etc. Coordination and collaboration with District staff and staff from the M&E program.
- Work collaboratively with M&E staff and District personnel to ensure optimal and efficient assessment of the hatchery programs.
- Attend professional trainings and conferences as appropriate.
- Staff shall strive to meet the District's mitigation and sharing partner's mitigation with the highest level of professionalism and quality as possible.
- Work with, hire, and manage District contractors to achieve District's goals and meet all District responsibilities.
- Participate in fishway drawdowns (Fish Rodeo) and other activities related to fish passage, and fishway maintenance and operations.
- Perform all required environmental and safety inspections, sampling, and reporting, and training as required by permits, state and federal rules and regulations, and District policies.
- Work with regulators – compliance with state and federal rules, laws, permit conditions, etc., related to the District's hatchery programs and M&E programs.
- Develop work plans, budgets, budget requests, purchase requests related to the hatchery programs and facilities.
- Perform project/contract management and oversite at the hatchery facilities.
- Surplusing fish – provide operational support and facility oversite when surplusing fish. Coordinate with Washington Department of Fish and Wildlife (WDFW), and tribes and other entities that may receive fish. It is WDFW's purview and responsibility to determine the disposition of surplus fish. The District will support this effort in our facilities.
- Adult management (gene flow management). Provide operational support when conducting adult management. Follow adult management plans established by the HCP committees under the appropriate ESA permits. Coordinate with federal, WDFW, and co-manager authorities to ensure proper execution of the adult management plans. It is WDFW's purview and responsibility to determine the disposition of surplus fish. The District will support this effort in our facilities.
- ESA reporting. Coordination and collaboration with District staff, staff from the M&E program, and federal agencies to ensure timely and proper reporting under ESA.
- Coordinating with other agencies and tribes as related to their use of District facilities and collaborative programs that may involve other entities.

2.3.1 Worker Training

Training will be provided and mandated as appropriate for each position. All employees will be trained on all District policies, safety policies, and human resource-specific training regarding workplace conduct.

Training video development is underway for the new Wells Hatchery. The District is creating in-depth training videos for all of the systems, processes and operations activities at the Wells Hatchery. These videos feature factory representatives and technicians, construction supervisors, and District staff explaining and demonstrating how all features of the new facility work, maintenance of the features, and how these features integrate to form a cohesive fish-rearing infrastructure. The videos will be completed by October 15th and until final are available in draft format for review and training.

Trainings may include, but not be limited to:

- Sexual harassment training
- Workplace safety
- Formalin training
- Respirator training
- Confined space training
- District workplace policies
- District purchasing procedures
- District bid document procedures
- CDL Class B with tanker and air brake endorsements
- Fork lift operator
- Tractor operation
- Snow plow operation
- Operation of Wells Hatchery training videos (see discussion, above) and in person training
- Operation of Methow Hatchery (in person training)
- Biosecurity protocols
- Professional development – as required and appropriate
- Endangered Species Act – ESA permit conditions compliance
- Trapping protocols (operations)
- Broodstock protocols
- Habitat and Conservation Plan – understanding the HCP
- Aquatic Settlement Agreement (ASA) – understanding the ASA
- Off-License Settlement Agreement (OLSA) –understanding the OLSA
- Hatchery Sharing Agreements – understanding the hatchery sharing agreements
- Acting on the behalf of the District and proper implementation of its mitigation programs
- Survival studies – planning and execution of District survival studies
- Washington State Boat Operator Training
- Pesticide application
- Computers and phones – District policies and technical use of devices
- Network security (cyber security)
- Cell phone policies
- Vehicle use policies
- North American Electric Reliability Corporation (NERC) and Federal Energy Regulatory Commission (FERC) requirements and awareness
- Wells Hatchery training – training videos and in-person trainings
- SCADA systems training and support
- District FERC License reporting tasks and requirements
- Dam safety training and awareness

- Dam security, emergency action plan at dam
- Develop and train: hatchery emergency action plans for the fish
- Develop and train: hatchery emergency action plans for human safety

2.3.2 Orientation

- Human Resource Paperwork
  - Survivor benefits, deferred compensation, W-2 payroll deductions
- Vehicles
  - Mileage sheet
  - Keys and maintenance logs and schedules
  - Gas cards
- Cellular phone reimbursement and telephone extensions
  - Administrative bulletin on cell phone use

- Network access
  - Username, passwords, RSA credentials
  - Purchase requests, purchase orders, work orders, NISC, ESS
  - Training for timesheet
  - Per diem books, petty cash
  - Remote access
  - Notebook computer assignments
- Wells Hatchery training – training videos and in-person trainings (see above)
- Methow Hatchery training (see above)
- SCADA systems training and support

2.3.3 Certifications

Each employee will receive proper training in order to receive certification and/or licensing for any duties or responsibilities needed for their particular position.

- CDL Class B license with air brake and tanker endorsements
- Respirator
- Confined space
- DVM – prescriptions
- Fork lift
- Pesticide applicator
- CPR & First Aid
- Washington State Boat Operator License
- Others as needed

2.3.4 PUD Strategic Plan and Administrative Bulletin

Mission Statement: To provide the best possible utility services at the lowest possible cost consistent with sound business principles.

Value Statements:

- Douglas PUD makes policy decisions in open public meetings with consideration of community needs, public input, and the best interests of the District
- Douglas PUD is fiscally responsible
- Douglas PUD is environmentally responsible
- Douglas PUD is service oriented and responsible to its public owners
- Douglas PUD values its employees
- Douglas PUD employees take ownership in the services they provide and the assets for which they are responsible
- Douglas PUD provides a safe workplace and promotes a safe community
- Douglas PUD pursues regional issues through, and is committed to, the success of its industry associations

Planning Statements:

- Douglas PUD follows an Integrated Resource Plan for electric supply focused on meeting resource needs with owned assets or long-term contracts
- Douglas PUD prefers renewable resources in new power-supply decisions
- Douglas PUD is committed to local and bulk electric system security and reliability
- Douglas PUD promotes information-age technology development
- Douglas PUD monitors growth potential to plan system changes proactively

2.3.5 Compensation

In addition to salary grades that exceed the State's hatchery salary grades, all of the PUD's hatchery employees will benefit from the PUD's benefit package including the full medical, dental, vision, deferred compensation, VEBA, short- and long-term disability, worker compensation and life insurance benefits.

All of the hatchery workers will be expected to cover standby time at some time during the year due to planned and unplanned absences by designated standby employees. Hatchery housing is a requirement of employment for those employees designated as being essential for the function of the facilities. Employees in District hatchery housing will be required to cover their own utility expenses with the notable exception of phone and power (Wells Hatchery) and phone (Methow Hatchery). Compensation levels for each position are designed to reflect the job duties that have been assigned to each employee.

3.0 CULTURE/TONE OF WORK PLACE

The District's workplace culture will be held to the highest standards that include, but are not necessarily limited to, the following attributes:

- Professionalism
- Integrity
- Honesty

- Goal-oriented
- Respect for others
- Report problems to supervisors
- Supervisors must act on observed or reported information regarding possible workplace violations
- Motivated workforce
- Creative problem solving
- All employees contribute to improving the District's programs and workplace
- Positive attitude
- Collaborative – teamwork approach and environment
- Excellent communication
- Support and acceptance of those who report mistakes or problems
- Compliance with rules and regulations

4.0 FISH ACCOUNTING PRE AND POST TRANSITION

Work with WDFW to provide current numbers of fish on station and records pertaining to the fish on station (mortalities, transfers, releases, egg take, etc.).

Set up fish accounting system for Wells Hatchery. The District will develop a data management system for the hatcheries that captures the types of data entered into WDFW FishBooks to the extent the similar data can be reported to co-managers and in reports. The District's Information Services Department (IS) will assist the Natural Resources Department (NR) in developing this new more user-friendly fish accounting and tracking database. Greg Mackey (NR) will take the lead in the database development in coordination with Charlie Snow and hatchery staff:

- Obtain samples of FishBooks data structure.
- Create draft data structure for the District's database development.
- Set up Excel or Access database for interim data management while the full database is developed (if needed).
- IS and NR will work together to develop a SQL database (SQL Server).
- IS and NR will work together to develop a front end for the database (MS Access).
- Hatchery staff and M&E Program staff will be involved in the development of the database so it meets their needs.
- Train staff and implement the database.
- The database should be available to all NR staff (hatchery and East Wenatchee staff).
- Establish permission levels for the staff (read only, data entry, data steward, and administrator).

Establish HCP Hatchery Committee-approved formal methods of accounting for fish at various life stages. Work with WDFW M&E Program staff to ensure sampling methods are transparent and consistent with past methodologies. Seek improvement to methodologies where needed.

5.0 PERMITS – ESA, CWA, NPDES, FISH TRANSFER PERMITS, HPA

The new hatchery managers, working with established NR staff, will be responsible for obtaining and complying with the applicable hatchery permits. However, in the transition window, existing NR staff must take the lead role in obtaining any necessary permits that are not already in the District's possession or name.

As of September 25, 2017 the District is not aware of any additional permits necessary for the operation of the hatcheries other than those identified below. The list below is prioritized in terms of which permits are needed first.

5.1 ESA Permits

There are six ESA permits that provide the District with ESA direct and/or incidental take coverage in association with the operation of the Methow and Wells hatcheries. Permit No. 1391 authorizes incidental take associated with operation of the Wells Project in accordance with the Wells HPC, including the HCP hatchery programs. Additionally, there are separate permits for the respective hatchery programs: two permits for the Methow spring Chinook program, one permit for the Wells, Methow, Twisp, Okanogan and Omak steelhead programs, one permit for the summer Chinook program at Wells Hatchery, and one bull trout hatchery operation permit.

5.1.1 Spring Chinook (Grant/Douglas PUDs)

Under Permit No. 18925, the District is a Permit Holder authorized to take ESA-listed species in the course of operating and monitoring the spring Chinook hatchery program at Methow Hatchery. WDFW remains responsible for the disposition of fish deemed surplus to recovery needs. The District plans to continue to have WDFW perform M&E covered by this permit (with the District's assistance, as currently occurs). District hatchery employees will work with WDFW M&E staff to identify clearly defined roles and responsibilities for recording M&E data for the in-hatchery evaluation activities.

5.1.2 Spring Chinook (Chelan PUD)

Under Permit No. 20533, the District, as an agent, is authorized to take ESA-listed species in the course of operating and monitoring the spring Chinook program Methow Hatchery. WDFW remains responsible for the disposition of fish deemed surplus to recovery needs. The District plans to continue to have WDFW perform M&E covered by this permit (with the District's assistance, as currently occurs). District hatchery employees will work with WDFW M&E staff to identify clearly defined roles and responsibilities for recording M&E data for the in-hatchery evaluation activities.

5.1.3 Steelhead (Douglas PUD Programs)

Under Permit No. 1395, the District is a Permit Holder authorized to take ESA-listed species in the course of operating and monitoring the summer steelhead hatchery program at Wells Hatchery. Additionally, per the Wells HPC, the District is in an active consultation for a new permit with NOAA to replace Permit No. 1395. The District plans to continue to have WDFW perform the M&E actions covered by this permit (with the District's assistance, as currently occurs). WDFW remains responsible for the disposition of fish deemed surplus to recovery needs, including fisheries. District hatchery employees will work with WDFW M&E staff to identify clearly defined roles and responsibilities for recording M&E data for the in-hatchery evaluation activities.

The District filed a Hatchery Genetic Management Plan with the National Marine Fisheries Service in 2011 requesting coverage for these programs to replace Permit No. 1395, per the Wells HCP. The District anticipates receiving a new permit in mid-2018 for the steelhead programs.

5.1.4 Steelhead (Grant PUD Programs)

Under Permit No. 1395, the District is a Permit Holder for Grant PUD's steelhead programs at Wells Hatchery (see above). District hatchery employees will work with WDFW M&E staff and Colville Confederated Tribes (CCT) staff to identify clearly defined roles and responsibilities for recording M&E data for the in-hatchery evaluation activities. The District does not conduct any actions under this program that results in incidental take outside the hatchery facility. The CCT conduct broodstock collection and release juveniles into the Okanogan River and tributaries. All of these actions occur under the jurisdiction of the CCT Tribal Resource Management Plan. The CCT are expected to continue conducting the off-station M&E tasks identified in this permit.

5.1.5 Summer Chinook (Douglas/Grant/Chelan PUDs)

Under Permit No. 1347, the District is a Permit Holder authorized to take ESA-listed species in the course of operating and monitoring the summer/fall Chinook hatchery program at Wells Hatchery. WDFW remains responsible for the disposition of fish deemed surplus to recovery needs, including fisheries. The District plans to continue to have WDFW perform M&E actions covered by this permit (with the District's assistance, as currently occurs). District hatchery employees will need to work with WDFW M&E staff to identify clearly defined roles and responsibilities for recording M&E data for the in-hatchery evaluation activities.

The District filed a Hatchery Genetic Management Plan with the National Marine Fisheries Service in 2013 requesting coverage for these programs to replace Permit No. 1347, per the Wells HCP. The District anticipates receiving a new permit in mid- to late-2018.

Douglas PUD's Okanogan spring and summer Chinook mitigation obligations and Methow summer Chinook obligations are met through a cooperative rearing agreement between BPA, CCT, and Douglas PUD. These fish are produced at the Chief Joseph Hatchery, and the CCT and BPA have ESA coverage for their authorized action at this facility.

5.1.6 Coho Salmon (Douglas PUD)

Douglas PUD's Coho salmon mitigation obligations are scheduled to start with brood year 2018 in the Methow Basin in close association with the actions being carried out by the Yakama Nation. Yakama Nation staff will be responsible for capturing brood stock. Douglas PUD will be responsible for producing juveniles at Wells Hatchery for release to the Twisp River drainage from the Twisp Acclimation Pond. The Yakama Nation has ESA coverage for their authorized actions at both the Wells and Methow hatcheries and associated acclimation facilities, including brood collection and juvenile releases.

5.1.7 Bull Tout (Douglas 2012)

The District's bull trout permit (2012) provides incidental take coverage for all of the District's current hydro and hatchery programs including brood collection and release of fish reared at the Wells and Methow hatcheries.

5.2 NPDES Permits

Several steps have been identified to complete hatchery compliance with National Pollutant Discharge Elimination System (NPDES) permitting. Steps include submitting to the Washington Department of Ecology (Ecology) an Upland Fin-Fish Hatching and Rearing General Permit Coverage Modification Due to Change in Facility Status (Transfer Application) for both Methow and Wells Fish Hatcheries. The Washington Department of Fish and Wildlife Service (WDFW) will need to complete their section of the transfer application and return it to the District. Transfer Applications were signed by the District's General Manager and mailed to WDFW September 14, 2017 via certified mail.

As of September 28, 2017, an account has been set up with Secure Access Washington, which will be the electronic reporting mechanism once the District takes over NPDES sampling and reporting. The District submitted to Ecology an Electronic Signature Agreement Form (ESAF) along with the Transfer Application. In addition, the District's General Manager will need to sign a letter that gives qualified District employees signing authority within the Secure Access Washington reporting platform (Signing Authority Letter). Each District employee that is granted signing authority for NPDES reporting will need to complete an ESAF document that lists both hatchery permit numbers on it (WAG 135000 and WAG 135009). The Transfer Application, ESAF request form(s), and Signing Authority Letter will be submitted to Ecology's Central Regional Office immediately following WDFW returning the signed Transfer Applications.

Additional steps will include updating the Site Specific Plans, the Solid Waste Management Plans, and the Pollution Prevention Plans, for each hatchery with new hatchery drawings and locations of sampling, designating staff, etc. This may also include developing a Standard Operating Procedures document for where and how samples are taken from each facility. New hatchery supervisors at Methow and Wells hatcheries will work closely with existing District NR staff to complete these updated plans. Revised plans will be submitted to Ecology's Central Regional Office.

The District will also seek quotes from qualified vendors to analyze various monthly and non-routine samples such as total suspended solids. Other samples will be taken onsite at hatcheries using qualified equipment (e.g. pH meter). Cascade Analytical of Wenatchee has been identified as a qualified laboratory for analyzing these samples. They are currently performing similar work for the CCT's Chief Joseph Hatchery.

Ecology's Central Regional Office and the District have tentatively scheduled a site inspection for the spring of 2018.

Ecology and the District have also discussed requirements to seek fish food with low PCBs from vendors and PCB monitoring that is currently ongoing in Spokane, which may influence PCB reduction at all hatcheries in Washington State that discharge waters into the Columbia River.

Annual Chemical Use Reporting, Quarterly Reporting, and Permit Expiration/Update deadlines, biennial inspections will be added to the District's FERC and Water Quality Reporting Compliance Database. The District's Compliance Officer will add these compliance criteria and ensure that hatchery supervisors and other key District staff are sent reminders via email in order to maintain routine compliance deadlines. Although these steps are not required for NPDES permitting they are consistent with the District's existing internal compliance monitoring and allow the District to meet compliance criteria in advance of deadlines per District standards.

5.3 Hydraulic Permit Application

The Twisp Weir traps have been installed and removed each year under the WDFW state-wide HPA. The District shall seek its own HPA for installation of the Twisp Weir traps (and any seasonal adjustments to the existing Methow outfall trap), although WDFW M&E staff annually assist in installing and operating the traps at the weir, and the WDFW HPA may still be used for such installation. HPA permitting will likely also be required for work that may be conducted in the future on the Methow Hatchery outfall trap and channel, and possibly other District-owned or funded facilities such as the Twisp Pond and Foghorn fishway and intake. Certain other activities, such as planting in-stream egg incubators or installing scour monitors may require an HPA, but may also be covered via state-wide HPA when performed by or in coordination with the M&E staff.

The District has determined that it will seek and receive their own HPA for the installation of the Twisp and Methow traps, and certain other activities as described above. These permits will not be needed until March 2018 but the permit application will be filed to ensure that proper authorization is received in ample time to install the Twisp traps. Application for the HPA permits was initiated prior to September 20, 2017.

5.4 Fish Transfer and Stocking Permits

On a case by case basis, the District Hatchery Supervisors will request fish transfer and fish stocking permits from WDFW. WDFW will need to sign each transfer or stocking request for each group of juvenile and adult fish transferred between hatcheries, and to acclimation or release sites. All of the District's fish movements between facilities and acclimation ponds and release sites are known many months in advance and are either associated with the implementation of the HCP, Aquatic Settlement Agreement, or Off-License Settlement Agreement, or agreements held by District hatchery sharing partners.

The District will explore receiving an annual fish transfer permit from WDFW to reduce the tedious permit request/receipt work load on both District hatchery personnel and WDFW.

6.0 MONITORING AND EVALUATION PLAN

The District's M&E Plan will continue to function as it has for the past ten years. WDFW will perform the activities identified in the HCP Hatchery Committee-approved Monitoring and Evaluation Plan in cooperation with District personnel. This includes the conduct of the in-hatchery M&E as well as the field M&E. The District's Fish Health Specialist will coordinate and collaborate with WDFW M&E staff to conduct sampling and manage data. Production of reports and analyses will continue to be completed in collaboration between WDFW M&E and District staff.

Regarding the in-hatchery M&E work, there are times when the hatchery staff collect data that are used by the M&E program in the WDFW M&E reports and conversely, the hatchery needs data collected by the M&E staff. The District will continue to collect and provide that information as required by the M&E plan. The District will also engage with the M&E staff to ensure the proper flow of information to the hatchery staff. The WDFW M&E staff, led by Charlie Snow, will engage in the implementation of the Transition Plan. District and WDFW M&E staff will coordinate the assignment of data collection and reporting roles.

District hatchery employees will work with WDFW M&E staff to identify clearly defined roles and responsibilities for recording and exchanging M&E data for the in-hatchery evaluation activities. The Fish Health and Evaluation Specialist will be responsible for ensuring that the M&E plans are properly implemented at all of the District's hatchery facilities.

6.1 Marking, Tagging, and CWT and Scale Reading

Marking and tagging will conform to the requirements established in ESA permits and through the HCP committees and ASA committee. The co-managers, through the HCP process and under the ASA, will determine marking plans. The status quo marking plan will be followed until a new marking plan can be approved by the HCP Hatchery Committee.

At this time, the next coded wire tagging (CWT) and fin clip marking would not occur until spring or summer 2018. This provides some time to establish necessary arrangements for CWT and fin clipping. Currently WDFW performs all of the District's marking, tagging, and CWT- and scale-reading functions. Continuation of this arrangement is pending discussions with WDFW.

PIT tagging in the hatcheries is currently performed by Biomark (under contract with the District).

7.0 PATHOLOGY

The District is seeking to hire a doctor of veterinary medicine (DVM) licensed in Washington State for the Fish Health and Evaluation Specialist position. This position will be responsible for all fish health matters at the hatcheries and will conform to or exceed standard-of-care levels for fish culture facilities. The Fish Health and Evaluation Specialist will be an integral part of the hatchery team and will be involved in all aspects of fish rearing and handling that relate to fish health and will ensure a seamless coordination of activities between hatchery rearing and M&E staff. The Fish Health and Evaluation Specialist will also be responsible for conducting research at the two facilities to identify and test new ways to treat diseased fish and to contain active outbreaks of disease in the facility. Areas of emphasis include finding alternatives to antibiotics and formalin.

When the District hires the DVM, the new employee will be responsible for purchasing all of the laboratory equipment and supplies necessary to ensure that proper screenings and sampling can take place in a timely manner. Microscopes, chemicals, a new work station in the research room at Wells Hatchery and in the administration offices will need to be provided to the new Fish Health and Evaluation Specialist. The District's DVM will obtain the services of necessary specialized laboratories, either via contract or on a case-by-case basis.

If a suitable candidate cannot be hired for the Fish Health and Evaluation Specialist, the District will pursue contracting for fish-health services.

8.0 OUTREACH PLAN – AGENCIES, TRIBES, PUDS

Call the HCP Coordinating and Hatchery committee members to inform them of the District's decision to take over operation of the hatcheries and discuss transition-planning scenarios and concepts (completed during week of August 28, 2017). Provide the HCP Hatchery Committee with a list of transition issues (completed on September 20, 2017). Provide the HCP Hatchery Committee with a copy of the Public Transition Plan (scheduled for the first week of October).

The District has and will continue to provide updates to HCP committees, tribes and agencies, as needed, and during scheduled HCP and ASA meetings (and others as needed). The District will pursue potential collaboration or partnerships that may be advantageous to the District and collaborators for improving the hatchery programs.

9.0 TRAPPING

Fish trapping will conform to all ESA permit condition and protocols or conditions established by the HCP committees, including the Broodstock Protocol. Staff will be trained to use trapping facilities and on the trapping rules, as noted above. Trapping will be coordinated with staff from the M&E program and will be a collaboration of District staff and WDFW M&E staff as needed to optimize the trapping operations. Trapping will also be coordinated and supervised during the YN coho and CRITFIC sockeye trapping. The same supervision will be required for any other non-District trapping request and operation. Real-time reporting of trapping results, as needed, will be conveyed through the M&E staff, or directly through District staff.

Staff will be trained as to the Broodstock Protocols, and ESA permit conditions and HCP committees trapping requirements. The training will be coordinated with staff from the M&E program to ensure that all personnel are working from a common basis of knowledge.

M&E and District crews will be involved in setting up and operating trapping, including coordination of fish assessments and target numbers. The extent and focus of this coordinating will depend on the specifics of the trapping.

10.0 ADULT MANAGEMENT AND SURPLUSING

WDFW is currently and will continue to be responsible for the disposition of fish captured for adult management and surplusing. The PUD will be responsible for trapping at District hatchery facilities and providing to WDFW those fish determined surplus to recovery needs. District hatchery staff will work collaboratively with WDFW, as the responsible party, but also with USFWS, Colville Tribes, Yakama Nation and the Spokane Tribes (and others as appropriate) to ensure that surplus hatchery fish are made available to authorized personnel within these organizations. The District's Hatchery Supervisor and Safety Officer will ensure strict adherence to worker safety and humane surplusing during all adult management activities. Indemnification and facility use agreements will be required for all tribal entities that are invited by WDFW to participate in surplusing activities at the District's hatchery facilities.

The District is currently funding a long-term Relative Reproductive Success Study on Methow Basin steelhead where hatchery-origin steelhead have been removed at the Twisp Weir to attain a certain ratio of hatchery to wild fish upstream of the weir. The need to conduct this adult management for the study ended in 2017, but adult management is expected to continue with a defined target (yet to be established via the HCP Hatchery Committee) for the proportion of hatchery fish to allow upstream. WDFW (via the M&E program) is currently the District contractor for these actions.

11.0 GENETICS

The operation and monitoring of the District's hatchery programs include the following genetic services:

Spring Chinook broodstock stock assignment – Will be budgeted under the M&E contract.

Broodstock and run sampling for population genetic analysis (steelhead, spring Chinook, summer Chinook) – sample collection performed through the M&E contract; past analyses were performed through stand-alone contracts (for analyses performed periodically).

Juvenile Chinook assignment – covered under the M&E contract.

Twisp Steelhead Reproductive Success – performed through a stand-alone contract with WDFW.

For genetic services not performed under the M&E contract the District will review options among labs capable of performing the specified work.

12.0 FISH HUSBANDRY

Fish husbandry will follow current best-management practices for biosecurity, spawning, holding adult and juvenile fish, incubation, treatment of fish for disease or pathogens, fish health, appropriate feeding regimes, rearing densities and flow indices, water quality, humane treatment of the animals, predator control, and any other actions or factors that influence the quality and quantity of the fish produced at District facilities.

The hatchery supervisors will be responsible for developing the fish-husbandry protocols and keeping them current. The hatchery staff will be expected to maintain best practices and remain educated on advances in fish culture, and implement advances as they are appropriate and advantageous to the program(s) at the District's facilities. Experimental fish-culture approaches must be proposed to and approved by the appropriate governing committee(s) if those approaches may alter conformance to the specific rearing targets in the various agreements and management plans for the District's and its sharing partners' programs.

The following resources will be used as guiding documents for fish health and culture practices:

Co-managers (Washington Department of Fish and Wildlife and Western Washington Treaty Indian Tribes). 1998. Co-managers of Washington fish health policy. Washington Dept. Fish and Wildlife, 600 Capitol Way N, Olympia, WA. 98501-1091.

IHOT (Integrated Hatchery Operations Team). 1995. Policies and procedures for Columbia Basin anadromous salmonid hatcheries. Annual Report 1994. Bonneville Power Administration, Portland, OR. Project Number 92-043.

Pacific Northwest Fish Health Protection Committee (PNFHPC). 1989. Model comprehensive fish health protection program. 19 pp.

Piper, R.G., I.B. McElwain, L.E. Orme, J.P. McCraren, L.G. Fowler, and J.R. Leonard. 1982. Fish Hatchery Management. United States Department of the Interior. Fish and Wildlife Service. Washington D. C. 517 p.

Washington Department of Fish and Wildlife (WDFW). 1996. Fish health manual. Fish Health Division, Hatcheries Program. Washington Dept. Fish and Wildlife, 600 Capitol Way N, Olympia, WA. 98501-1091.

12.1 Fish Culture Practices – Expertise and Training

All of the District's hatchery workers will be required to have extensive hatchery or aquaculture experience including professional, technical, and/or on-the-job training experience before coming to work for Douglas PUD. This includes the Supervisors, Senior Hatchery Specialists and Hatchery Specialists. Fish-culture practices and procedures will follow guidance provided by the HCP Hatchery Committee, experience of District staff, and other respected resources such as Piper et al., etc. Staff will be encouraged to review current literature, attend continuing education, conferences, and training events to advance their knowledge of fish-culture practices.

Vocational hatchery culture training or higher levels of education are highly desirable in these programs. Work experience coupled with demonstrated ability to culture fish with excellence will also be highly desirable.

12.2 Fish Feed Contract

Fish feed currently used at District facilities includes products from three major vendors: EWOS, Rangen, and BioOregon. Bio-Oregon is the largest single provider for fish feed for the Wells and Methow hatcheries. The District is initiating contractual purchase agreements with feed vendors informed by an inventory of existing feed and new estimates of monthly feed deliveries. Delivery and storage at both facilities will be coordinated with new District hatchery personnel.

Selected feed will remain consistent with that feed that has been used for the current cohorts on station. However, the Hatchery Supervisors may revise the feed choice at any time, as has been their practice. Feed deliveries will be set up to ensure sufficient feed is on station at each hatchery for all programs.

13.0 EQUIPMENT INVENTORY

The District will work with existing WDFW staff to perform inventories of equipment and supplies, determine which items should have a District number and label and record, develop an inventory list, and develop a list of necessary purchases prior to November 28th.

The District will train hatchery supervisors and senior hatchery specialists on the new PUD purchasing system. The hatcheries make a tremendous number of purchases each year, some of which are very time sensitive requiring specialized procurement procedures that ensure rapid deliveries of products.

13.1 Transfer Titles - Vehicles

The District will work with existing WDFW staff to request transfer of vehicle titles or certificates of ownership back to the District as per the contract. An inventory of all vehicles or items for which WDFW may hold title or certificate of ownership is required in order to request all titles and certificates of ownership. Titles or certificates of ownership include vehicles, ATVs, fish pumps, and tractors. The District's Purchasing Department will assist with titles to vehicles and other items that may have title or certificates of ownership.

The District would prefer to receive title to all of the hatchery vehicles by October 31st so that new PUD hatchery employees can use existing vehicles for hatchery duties. The District's vehicle insurance policy covers all of the District contractors, allowing all of the new and existing hatchery workers (WDFW or PUD employees) to perform station-service duties during the transition window.

If necessary, the District has several surplus and excess vehicles that can be used for a short-term (30 days) basis to move equipment and material around the hatchery site.

Table 1. Inventory of vehicles associated with the Wells Hatchery.

14.0 INSURANCE

Insurance for the existing WDFW hatchery vehicles will be converted to District coverage once title to the vehicles has been transferred back to Douglas PUD per the contract. Similarly, once the title to the hatchery housing at Wells Hatchery has been transferred back to the District, then appropriate insurance will be established to protect the District's investment.

All of the new buildings, pumps and associated hatchery equipment at Wells Hatchery will need to be moved off of the builder liability policy and to the District's comprehensive insurance policy as soon as the owner begins to occupy and operate the new buildings. The square footage of these buildings has been provided to the District's insurance agent.

15.0 JANITORIAL AND GROUNDS KEEPING

The District will obtain a janitorial and/or landscaping contract for the Wells Hatchery and possibly the Methow Hatchery. In the short-term, janitorial services will be covered via a purchase authorization. Long-term janitorial services for Wells Hatchery will be bid along with services for the boat launches and Vista Overlook Park.

Landscaping will be covered under the District's existing contract until December 2017. The scope of work for this contract already covers all of the East Wenatchee headquarters building and all of the landscape surrounding Wells Dam and Hatchery. In the short-term no modifications to the contract are necessary to cover the new hatchery grounds per the existing weed-control plan.

A new bid document for landscaping services will be issued by the end of 2017 toward coverage for a new term starting in January 2018.

16.0 DIESEL FUEL AND SERVICE

The District will establish a contract to purchase diesel fuel for the Methow Hatchery backup generator. The District will also establish a contract for maintenance and repair of the Methow Hatchery backup generator. The Hatchery Supervisor will take the lead on these items.

17.0 TRASH

The District will establish a contract to have trash picked up at the Wells Hatchery and Methow Hatchery. The Hatchery Supervisors will establish a plan to handle trash and recycling at their respective facilities. The Hatchery Supervisors will take the lead on this item.

18.0 SAFETY

Workplace safety is a core mission of Douglas PUD. The District's Safety Officer will prepare a Workplace Safety Training and Procedures Manual for each facility. These documents will be ready for implementation prior to December 1, 2017. New safety grating, railing, and signage currently being installed at Wells Hatchery should be completed by October 31st. Formalin eye-wash and showers are scheduled for installation by November 15th.

19.0 HOUSING

The District will determine which employees/positions shall occupy the on-station hatchery houses and be responsible for stand-by duties associated with the hatcheries.

The District will also need to establish a rental agreement that can be signed as part of the employment package. The rental agreement must include the rules of conduct for tenants, the assignment of costs for utilities, and the reason that on-station housing exists (emergency and stand-by support). The agreement must also address damage to District houses and damage repair/repayment procedures, the need for the employer to undertake quarterly inspections, the expectation that each home will be properly maintained and that behavior at the houses will be safe, ethical, and legal. The agreement must also address the responsibility for repairs and maintenance of each house.

Two of the homes at Wells are currently vacant and will both be cleaned, new interiors fitted, where applicable, and an owner occupancy release provided. Both homes were inspected on September 18, 2017. The southern home needs new paint, carpet, and siding. The northern home needs touchup paint on the interior and a simple carpet cleaning. The third home at Wells Hatchery will need to be vacated prior to inspection.

Neither of the houses at Methow Hatchery have been inspected yet, as the tenants still occupy the houses. Repairs to the houses will be performed prior to occupancy by new employees, dependent on the condition of the house and timing of occupancy. If houses must be occupied prior to repair, then a plan will be developed on a case-by-case basis to address the needed repairs.

19.1 Utilities

All new hatchery employees living in District housing will be responsible for paying their own utility bills including garbage, internet, satellite or cable TV, or other services that they desire. The only utility that the PUD will provide is phone service so that employees can be notified of hatchery emergencies and outages. Electric utilities may also be offered at the Wells hatchery houses depending upon the cost and difficulty in unbundling the houses from the current single owner electric meter that serves all three houses.

The District is in the process of installing DCCN fiber optics to the houses at the Wells Hatchery and will be assuming the CenturyLink phone accounts associated with the Methow Hatchery. WDFW has already been provided the transfer paperwork for this account-transition request.

19.2 Titles for Houses

The District's current contract with WDFW mandates the transfer of the hatchery houses at Wells Hatchery back into District ownership upon termination of the Contract. The Methow Hatchery houses remain under District ownership.

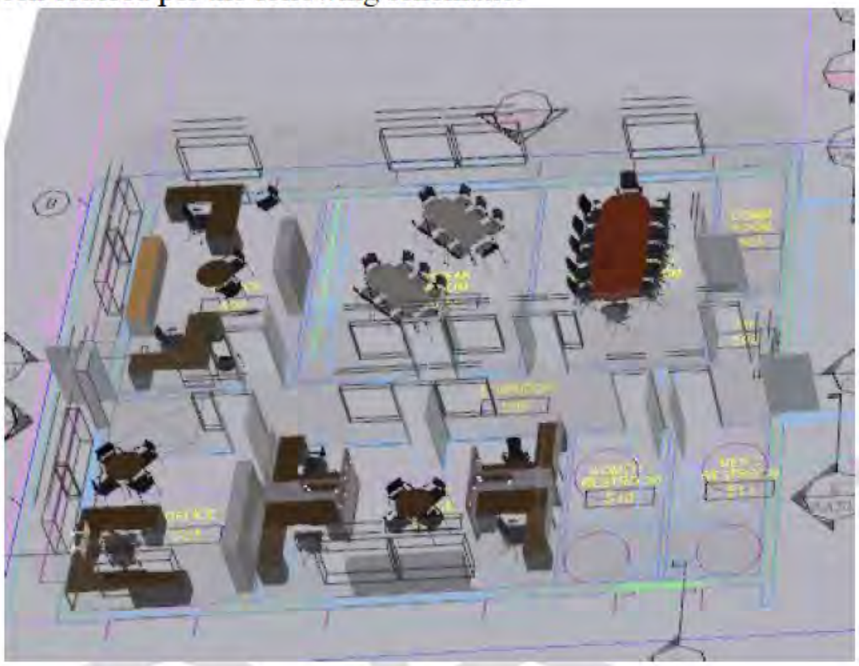
19.3 Land Titles

The District's current contract with WDFW mandates the transfer of the land under the hatchery houses at Wells Hatchery back into District ownership upon termination of the Contract. The land at the Methow Hatchery remains within District ownership.

20.0 COMPUTERS, PHONES AND COMMUNICATION EQUIPMENT

20.1 Office Furniture

Furniture has been ordered per the following schematic.



20.2 Wells Hatchery Network Connectivity

Wells hatchery will connect directly to the business network, SCADA network, phone network, and wireless network through District-owned fiber connections. Business network connectivity will be provided in the office locations (work stations) and the adult handling building through physical connections. Wireless network connectivity will be in the office areas provided by an access point that is controlled through the EW wireless management solution. Phone network connectivity will be provided in the office locations (workstations), conference room, and other areas on an as-needed basis.

Cellular connectivity will be provided by installing 2 FemToCell devices in the office area wired into the Wireless network. Verizon and AT&T will be the two cellular companies supported. A cellular booster will be installed to cover as much of the facility as possible.

The Wells Hatchery houses will get fiber connectivity provided by DCCN. The connectivity will be used to provide District owned FemToCell for work purposes and/or an IP phone supplied through the Wells phone switch. The connectivity also allows the staff residing within to obtain an internet connection through an ISP for personal purposes.

20.3 Wells Hatchery Phones

Current WDFW phone lines provided by CenturyLink will be transferred into Douglas PUD's name. Technicians will explore the possibility of using the hatchery incoming lines as additional incoming lines to the Wells Dam phone switch to increase overall capacity and provide IP Phones to the hatchery.

The Wells Hatchery houses will initially be supplied phone lines from CenturyLink, but after fiber is installed to the houses, exploration of IP Phones provided from the Wells phone switch will be explored.

20.4 Wells Hatchery PCs and Printers

The District will provide hardware in the following locations (Figure 4):

- Office West (1 desktop)
- Office East (2 desktops)
- Staff Office (1 desktop, 2 MS surface with docking station)
- Break Room (1 multi-function printer, legal only)
- Meeting Room (1 desktop, 1 large screen monitor, 1 external connection module for monitor)

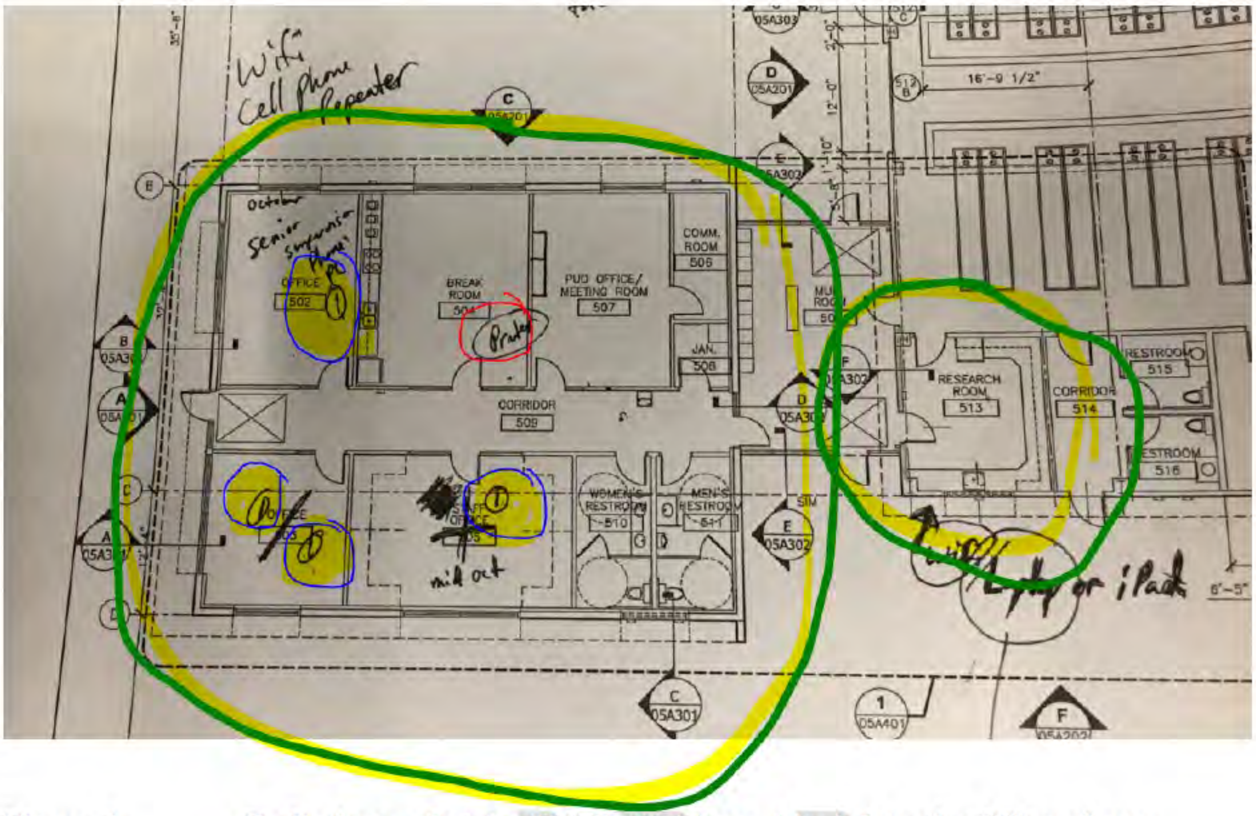


Figure 4. **Preliminary sketch of Wells Hatchery Administrative Wing of new Hatchery Building depicting layout of computer and printer infrastructure.**

20.5 Methow Hatchery Network Connectivity

Methow hatchery does not have District-owned fiber connectivity. CenturyLink provides a wireless internet connection currently that will need to be transferred into the District's name. The District is exploring the possibility of having CenturyLink run fiber lines to the facility to provide more bandwidth, but the likelihood and costs are unknown. Thus, we are proceeding with the only current connectivity option, which is the wireless connection already in place. The District will install a small firewall/router. Two point-to-point VPN's will be configured between the Methow Hatchery firewall to the East Wenatchee HQ firewalls. One VPN will be for Business network traffic, the other for Wireless network traffic.

Wireless network connectivity will be in the office area provided by an access point that is controlled through the EW wireless management solution.

This facility has cellular network coverage.

The Methow Hatchery houses can obtain internet access for personal purposes through local providers if they wish. If the District works with CenturyLink to run fiber to the facility, the option should be explored to also run it to the houses.

20.6 Methow Hatchery Phones

Current WDFW phone lines provided by CenturyLink will be transferred into Douglas PUD's name. Currently there are two lines used for voice and one for fax purposes. They are using an answering machine for messages. There isn't a good option to extend our internal phone system at this time to the facility. We will need to continue using the CenturyLink provided phone lines. When the District considers a new phone system, there may be opportunities presented that may change this.

The Methow Hatchery houses will be supplied phone lines from CenturyLink. Currently the lines are held in the occupant's names, but will be transferred to the District.

20.7 Methow Hatchery PCs and Printers

The District will provide hardware in the following locations:

- Supervisor Office (1 desktop, 1 multi-function printer, legal only)
- Staff Office (1 desktop, 1 MS surface with docking station)

20.8 Twisp Weir and Pond

Current WDFW phone lines provided by CenturyLink will be transferred into Douglas PUD's name. The Twisp Weir has two phone lines. One is used for the alarm system and the other is the landline for voice.

20.9 Chewuch Pond

Current WDFW phone lines provided by CenturyLink will be transferred into Douglas PUD's name. The Chewuch Weir has one phone line used for the alarm system. There is Verizon cellular coverage in the area (quality of coverage is not known at this point) that has been utilized by staff in the past.

20.10 Software Technology

Employees will need all standard District software (MS Office, timesheets, Purchasing (iVue), SharePoint, etc.). All hatchery employees need to be proficient on computers, which may require training.

Custom databases will be required to track fish production and other hatchery and M&E needs. The District will develop the necessary systems (see above). Initial system will be an Access Forms front end to a SQL Server database back end.

Planning includes future enabling of systems for use throughout the facilities, not just in the offices where there is a business network connection. This will most likely be handled through providing a publicly accessible interface to the system and utilize cellular enabled iPads to access the publicly available interface. The interface would require authentication to use. Since cellular access is being installed at Wells, and Methow already has it, this connection option is desired.

21.0 EMERGENCY PROCEDURES

The District will provide training for emergency procedures that already exist (such as emergency action plan for Wells Dam). Additional emergency procedures will be developed as needed, falling into two broad categories; 1) human health and safety, and 2) fish health.

1. Human health and safety emergency procedures will be governed by the District's Safety Specialist. HDR has been directed to produce a technical plan for Wells Hatchery for water-supply emergencies, and this plan will form part of the emergency plan for Wells Hatchery. Dam safety at Wells Hatchery will be paramount in such plans.

2. Fish health emergency plans will be developed by the Hatchery Supervisors in collaboration with NR staff. Training for these plans will be provided at the earliest practicable time for hatchery staff. HDR has been directed to produce a technical plan for Wells Hatchery for water supply emergencies related to fish rearing. This plan will form the core of the fish health emergency plan for Wells Hatchery. Dam safety at Wells Hatchery will be paramount in such plans.

22.0 AS-BUILT DRAWINGS

Development of as-built drawings is underway for Wells Hatchery and these drawings will be available within six months of the District's acceptance of the completion of Wells Hatchery by Lydig Construction.

As-built drawings for Methow Hatchery already exist and are available within the District.

23.0 HAZARDOUS MATERIALS HANDLING AND ACCOUNTING

The District will develop lists of all MSDS and chemicals on site, beginning with the collection of MSDS that WDFW maintained. The District will inventory all chemicals (formalin, cleaning agents, pesticides, MS222, etc.). All chemicals will be stored properly.

The District's Safety Specialist will develop procedures for hazardous material handling and accounting that conform to District, L&I, OSHA, EPA, and any other regulatory rules that may apply. Development of these procedures, and associated training and certification (as needed) must be accomplished in a timely manner.

The formalin storage rooms at the Adult Handling Building and the Incubation Building will need to be stocked with formalin within days of the hatchery turning over to District operation. This hazardous material will need to be purchased, stored and inventoried periodically throughout the year. Formalin is being used currently on adult Chinook and steelhead..

24.0 SECURITY BADGES

The District will identify security-badge privileges for staff levels. The Wells Dam staff will be notified that badges will be needed, and they will assign security badges to hatchery staff on training and orientation day, or as soon thereafter as practicable.

The District will install several Hirsch pads at the Wells Hatchery, including a pad at the new west entrance gate, administration building, and adult handling building. Security badges will be required to enter all of these sites.

25.0 KEYS

The District will identify key privileges for staff levels. The Wells Dam staff will be notified that keys will be needed, and they will assign keys to all hatchery personnel on training and orientation day.

Keys and access codes to both the gas and diesel pumps, hatchery, adult handling building, potable water building, surface water intake, west and east ladder traps are required.

26.0 CHEWUCH POND

The District will provide training and orientation for the Chewuch Pond to the Methow Hatchery staff, and as needed, to Wells Hatchery staff. The District will develop operational protocols, led by the Methow Hatchery Supervisor.

27.0 TWISP POND

The District will provide training and orientation for the Twisp Pond to the Methow Hatchery staff, and as needed, to Wells Hatchery staff. The District will develop operational protocols, led by the Methow Hatchery Supervisor.

28.0 TWISP WEIR

The District will provide training and orientation for the Twisp Weir to the Methow Hatchery staff, and as needed, to Wells Hatchery staff. The District will review and update operational protocols, led by the Methow Hatchery Supervisor. The District will receive an HPA from

WDFW prior to any work to install the traps at this location. The first opportunity to install the trap at the weir will occur in late February 2018.

29.0 GRANT AND CHELAN INTERLOCAL COOPERATIVE AGREEMENTS

The District will provide new hatchery employees with necessary training regarding the District's interlocal cooperative agreements with Grant and Chelan PUDs for fish production at Wells and Methow hatcheries, as applicable.

30.0 OFF-LICENSE SETTLEMENT – TROUT PRODUCTION

The Off-License Settlement Agreement between the PUD and WDFW requires the District to produce 20,000 pounds of trout equivalents for planting into the lakes of Okanogan, Douglas and Chelan counties impacted by the operation of the Wells Project. Douglas PUD staff will continue to work with WDFW's regional fish biologists to identify the species and life stages of fish to be provided to WDFW to satisfy this requirement.

Potential to improve the conservation benefits of steelhead hatcheries

Abstract

Hatchery programs that are designed to aid recovery of natural populations of anadromous salmonids, including steelhead *Oncorhynchus mykiss*, require locally derived, natural-origin broodstock. In such programs, achieving smoltification size thresholds may require extending hatchery rearing beyond age 1. We compared out-migration survival and travel rates of 142,990 PIT-tagged steelhead smolts released at age 1 (S1 rearing strategy) or age 2 (S2 rearing strategy) over five release years at Winthrop National Fish Hatchery (WNFH, Okanogan County, Washington). An S2 rearing cycle produced larger smolts with more uniform size distributions, resulting in higher survival during the first portion of their out-migration than for S1 smolts in three of the five release years. The S2 smolts migrated more rapidly to the ocean than S1 smolts in all years except 2011 and arrived in the Columbia River estuary 5.4 d earlier on average than the S1 smolts. The S1 steelhead that did not leave during the volitional release were subsequently forced from the hatchery to measure their survival. Nonvolitional S1 migrants were smaller and had survival rates that were 2.3–66.3 times lower than those of S1 steelhead that left WNFH on their own. The same was true for S2 steelhead, but the magnitude of the survival difference between volitional migrants and fish forced from the raceways was less variable and ranged from 2.5- to 4.6-fold. We conclude that S2 rearing can be a successful strategy for producing smolts from local natural-origin broodstock, with out-migration survival and travel times that are equivalent to or better than those of S1 smolts produced from nonlocal broodstock.

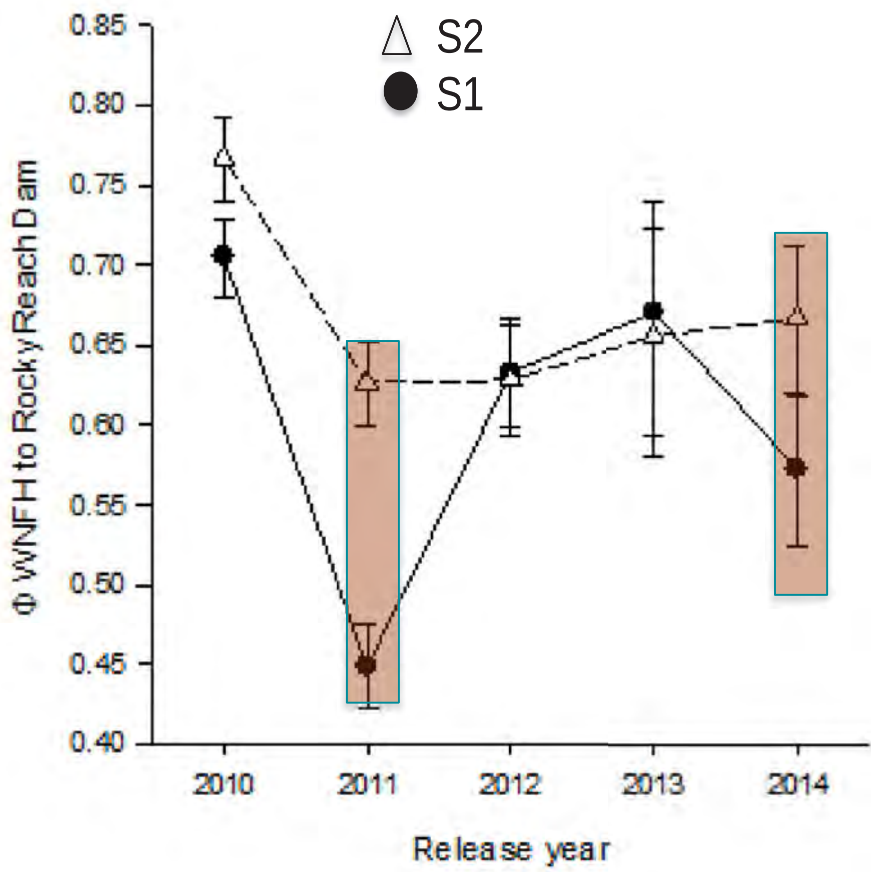
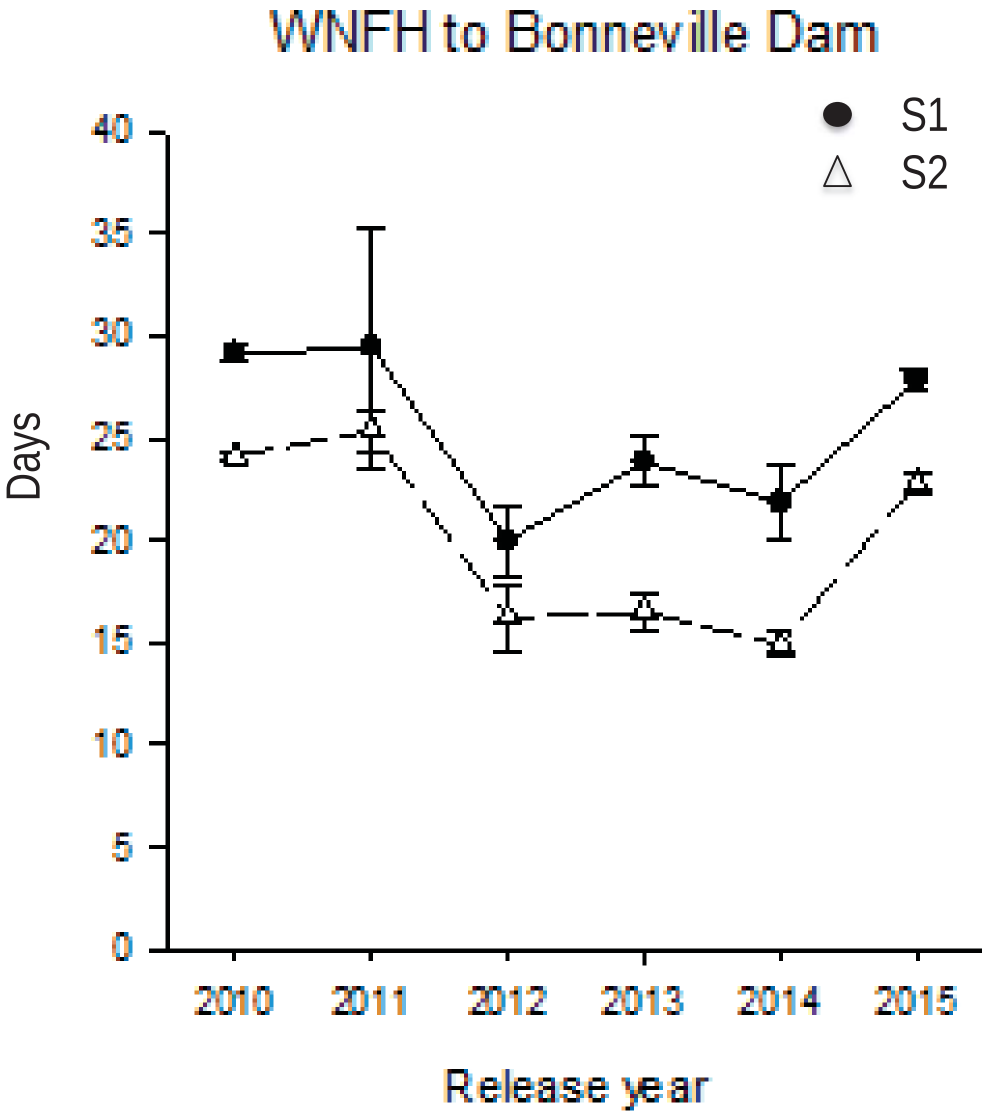
Size affects downstream migration

Release year	Rearing type	Fork Length	Mass (g)
2011	S1	158.3 (35.1)	48.2 (30.0)
	S2	186.6 (25.7)	72.3 (29.2)
2012	S1	172.2 (28.4)	60.6 (25.4)
	S2	185.5 (21.7)	70.0 (22.8)
2013	S1	195.1 (21.6)	82.6 (26.0)
	S2	193.7 (22.0)	83.6 (25.9)
2014	S1	177.2 (23.4)	62.8 (22.3)
	S2	190.6 (18.6)	76.0 (20.5)



Outmigration travel rate



Tatara et al. 2017. N. Am. J. Fish. Manage.

Winthrop NFH S1 v S2 summary

1. Survival of S2 steelhead to RRJ was either higher than or not significantly different from survival of S1 steelhead.

2. Body size at release explained most of the differences in survival to RRJ both within and between the S1 and S2 rearing groups.

3. S2 steelhead migrated more rapidly than S1 steelhead.

4. The rate of out-migration was faster in years of volitional release than in years of forced release.

5. Volitional migrants from both treatments were larger and had higher survival than steelhead that were forced from the hatchery after the volitional release period ended.

Tatara et al. 2017. N. Am. J. Fish. Manage.

Can heritable size-selective mortality be avoided?

- Experimental design
  - 28 individual families
  - S1 and S2 rearing regimes (n = 4 tanks/treatment)
  - Pedigree analysis to assign offspring to families
  - Responses
    - Growth rate and body size at smoltification
    - Seawater challenge
    - Heritability

Summary

- Body size at the time of release from hatcheries influences
  - Downstream migration
  - Survival in seawater challenge

- In S1 rearing regime
  - Size-selective mortality
  - Response to selection is possible

- In S2 rearing regime
  - No size-selective mortality
  - No possible response to selection (low heritability)

- Practical changes to hatchery practices show promise for reducing domestication selection

Are there negative effects associated with S2 steelhead programs?

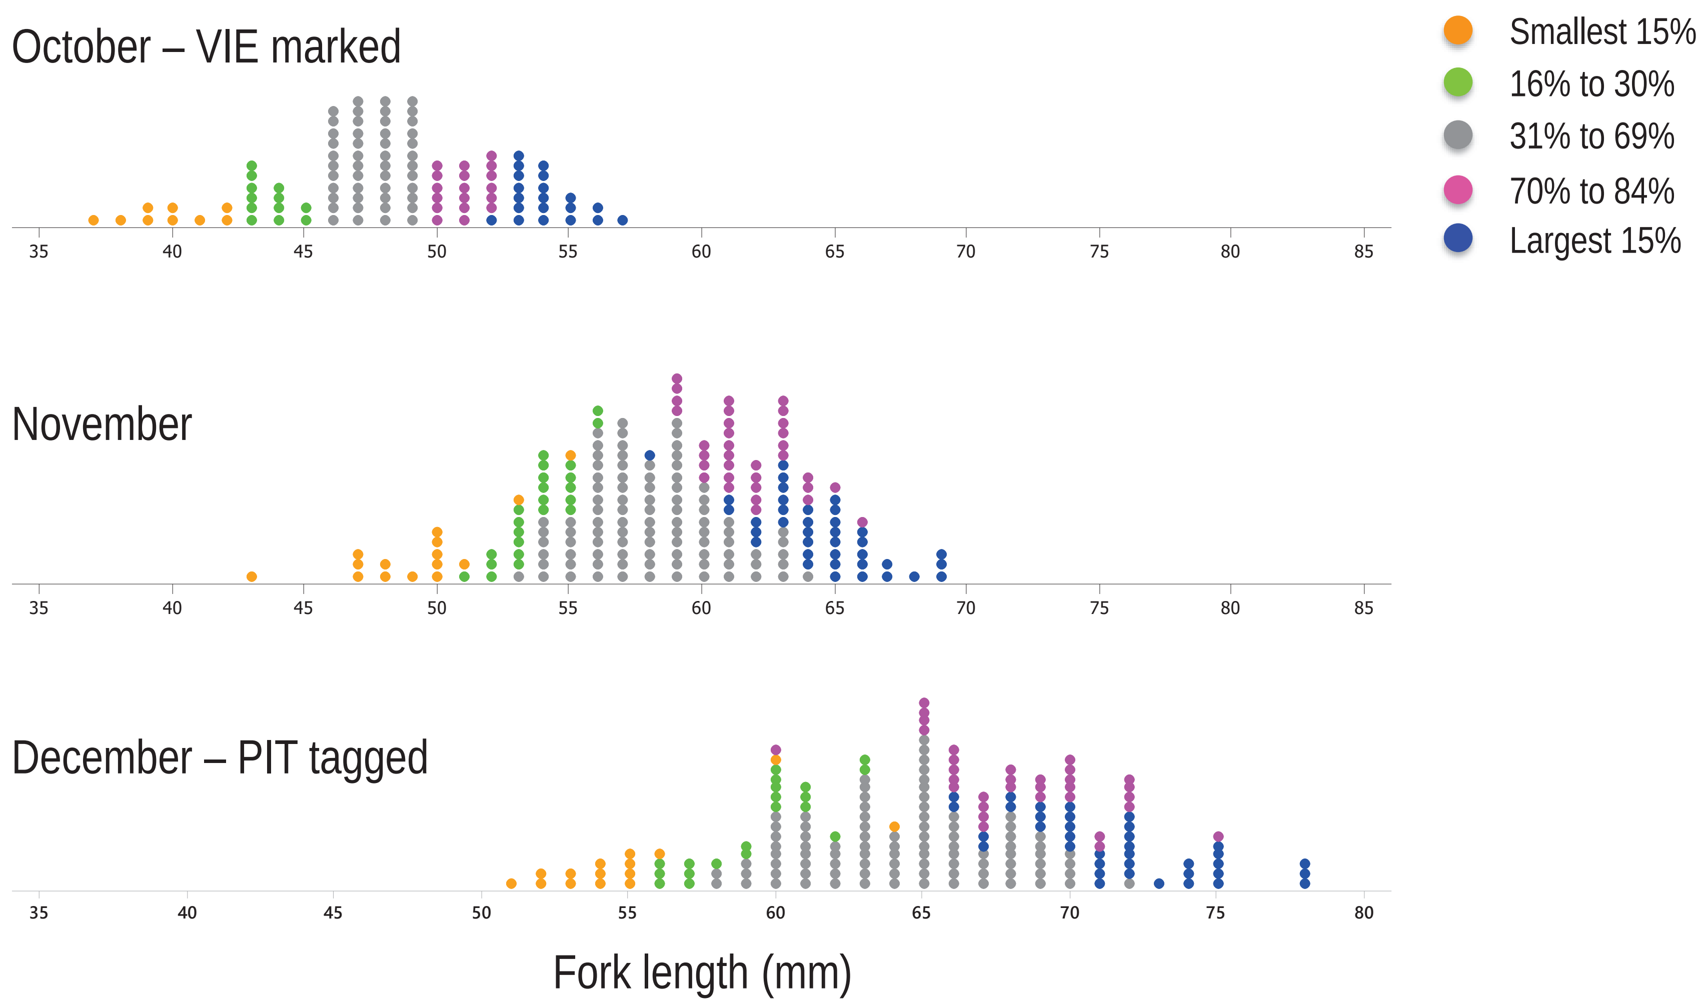
Not all hatcheries can/should implement S2 smolt programs.

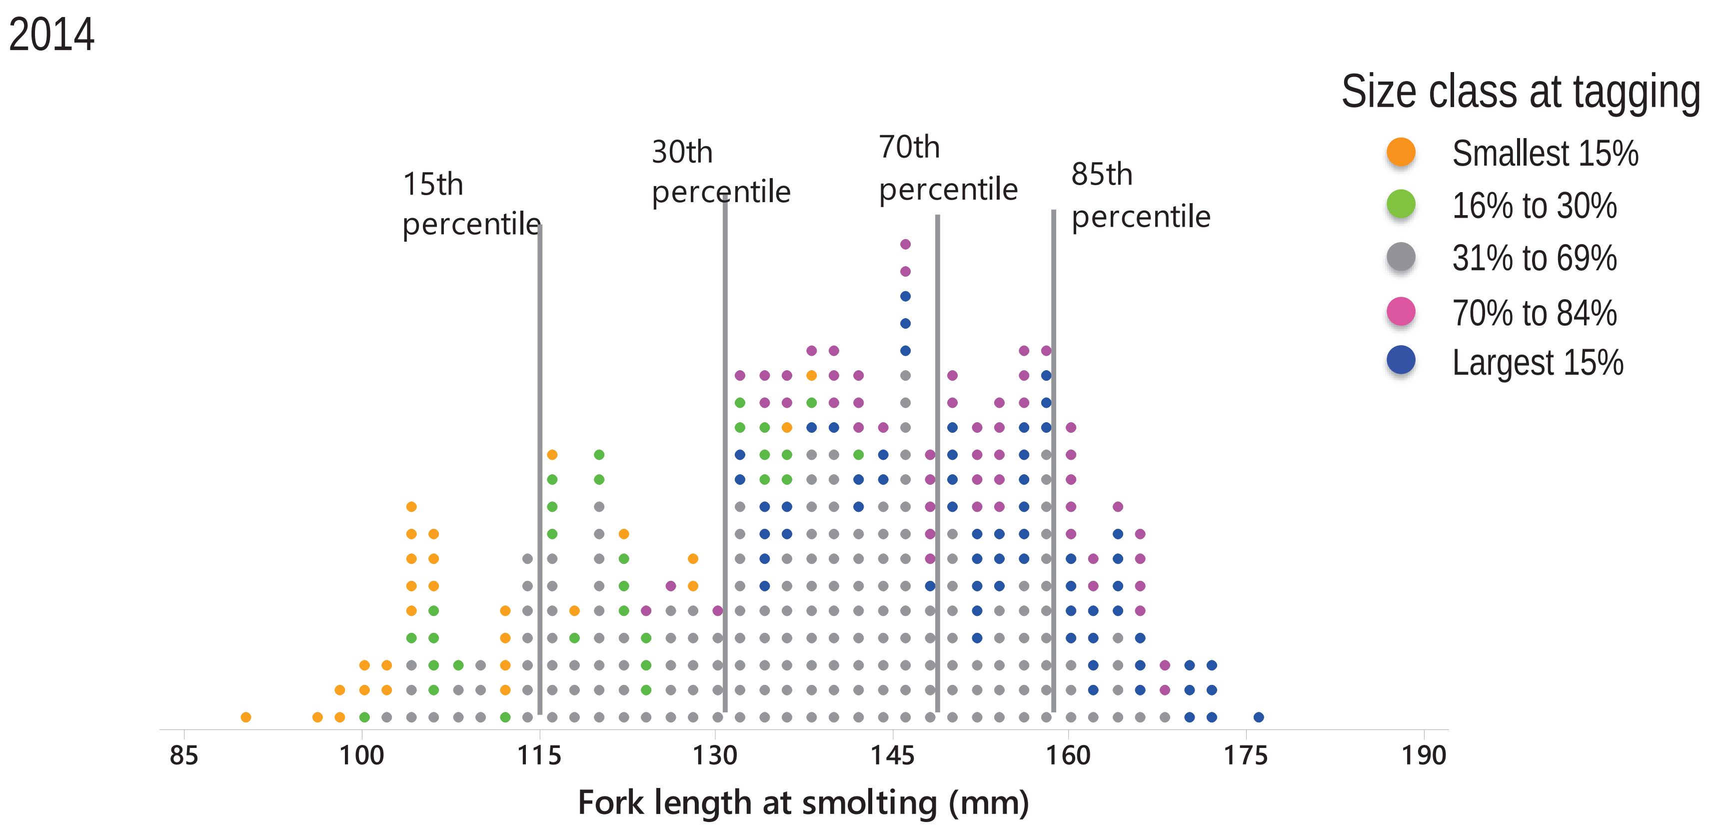
Can we design more flexible strategies?

Early growth rate influence on size at smolting



NOAA FISHERIES

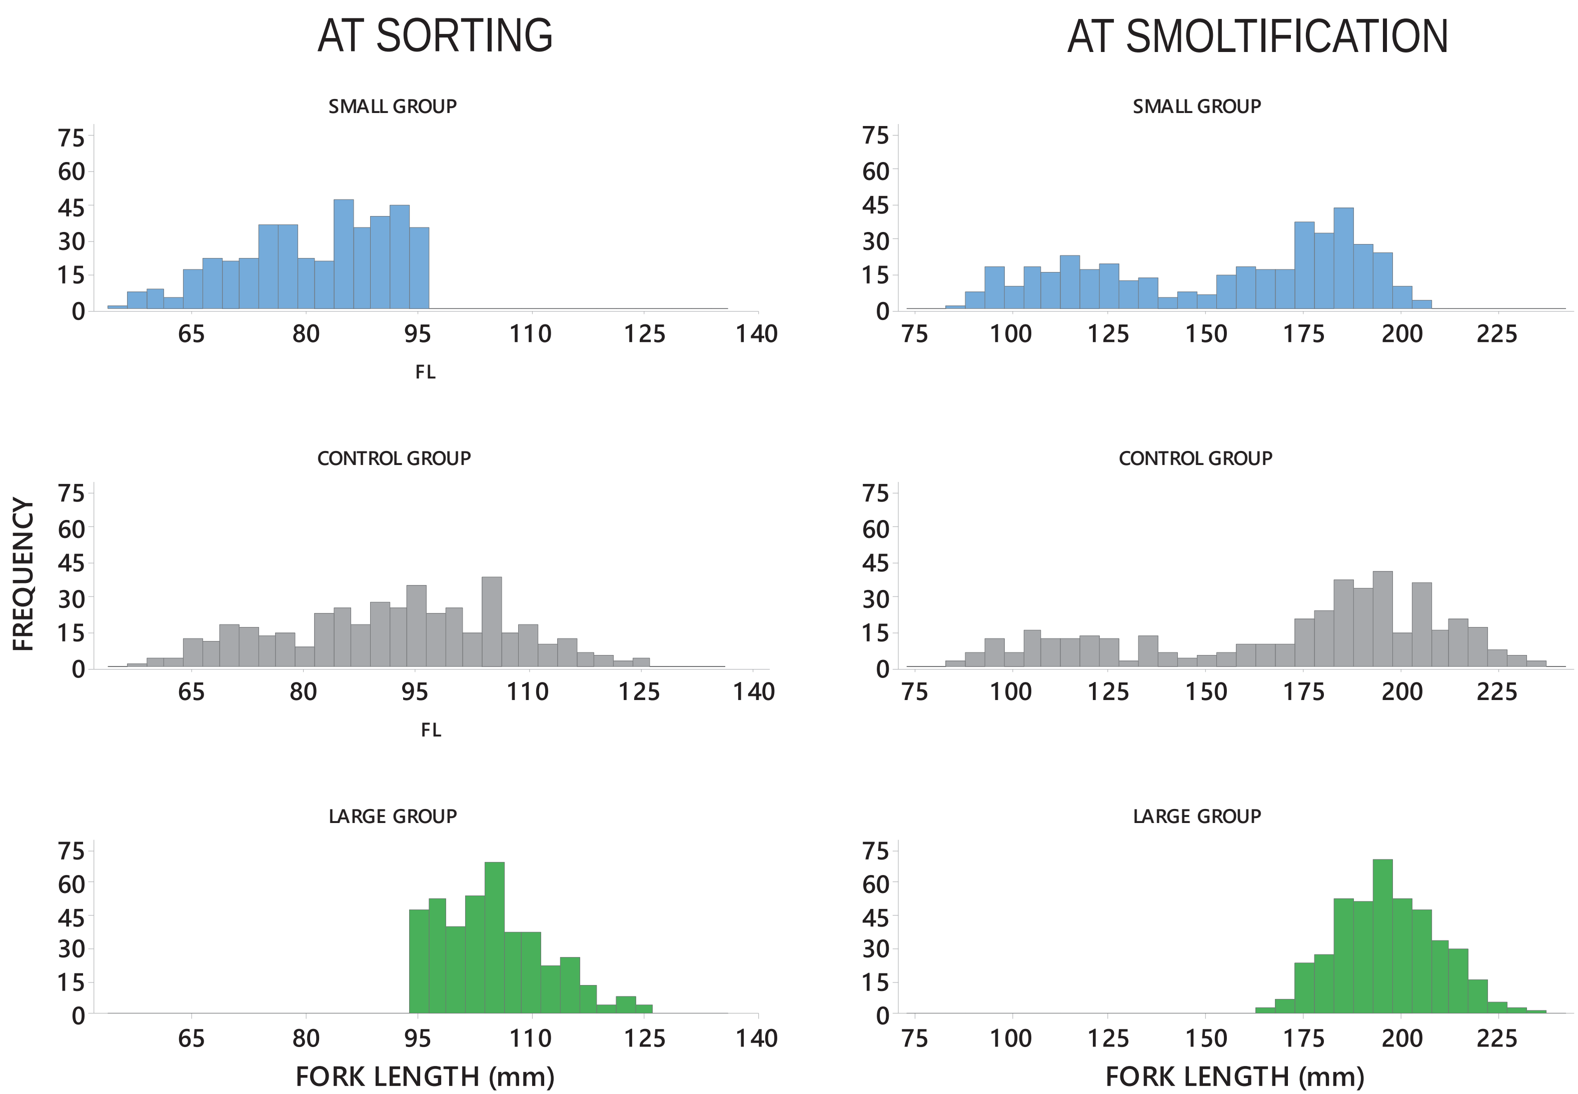
Early growth rate influence on size at smolting



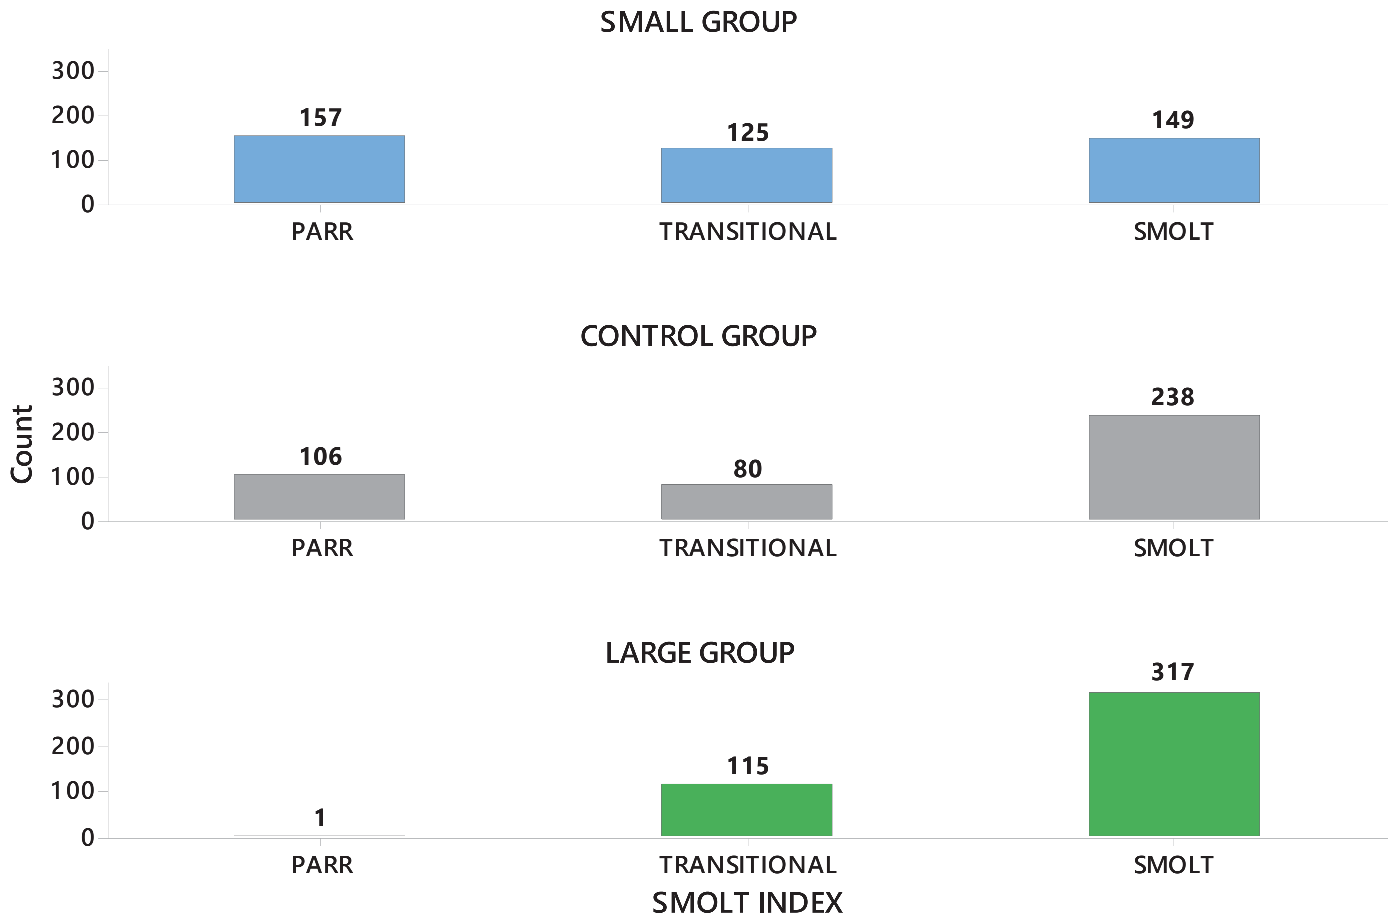
Effects of size-based competition on size variation?

- Mechanism
  - Interference competition may supress the growth of smaller fish and increase size variation
- Size sorting experiment
  - Three treatments (n = 3 tanks per treatment)
    - Small – Below median fork length at tagging
    - Large – Above median fork length at tagging
    - Control – Not sorted by size

Size sorting improve growth of small fish?



Effect of size sorting improve smoltification rate?



Optimizing smolt production with NOR broodstock

- Three treatments established 8 weeks post-ponding:
  - Control: unsorted + high ration
  - S1: largest 67% of fish ≥ 61mm + high ration
  - S2: smallest 33% of fish ≤60 mm + modulate growth

- Three replicate tanks per treatment

- Target smolt size = 90 g

SECTION 1: INTRODUCTION

This document is an update of the monitoring and evaluation (M&E) plan of the salmon and steelhead hatchery programs funded by Douglas, Chelan, and Grant County Public Utility Districts (PUDs). Programmatic changes, evaluation of data collection methods, and M&E results from the past several years, along with shifting management paradigms affect M&E needs, all of which have occurred under advancing fish culture and monitoring techniques. As required by the programs, this document is a result of a five-year review intended to expand on and coalesce previous M&E documents (BAMP 1998; Cates et al. 2005; Murdoch and Peven 2005; Hays et al. 2006; Pearsons and Langshaw 2009a, 2009b; Hillman et al. 2013) with inclusion of new information.

Fishery management agencies developed the following general goal statements for hatchery programs, which were adopted by the HCPs Hatchery Committees and PRCC Hatchery Sub-Committee (hereafter, Hatchery Committees):

1. Support the recovery of ESA-listed species by increasing the abundance of the natural adult population, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity.
2. Increase the abundance of the natural adult population of unlisted plan species, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity. In addition, provide harvest opportunities in years when spawning escapement is sufficient to support harvest.
3. Provide salmon for harvest and increase harvest opportunities, while segregating returning adults from natural tributary spawning populations.

Following the development of Hatchery and Genetic Management Plans (HGMPs), artificial supplementation programs are now characterized into three categories. The first type, integrated conservation programs, are intended to support or restore natural populations. These programs focus on increasing the natural production of targeted fish populations. A fundamental assumption of this strategy is that hatchery fish returning to the spawning grounds are reproductively similar to naturally produced fish. The second type, safety-net programs, are extensions of conservation programs, but are intended to function as reserve capacity for conservation programs in years of low returns. The safety-net provides a demographic and genetic reserve for the natural population. That is, in years of abundant returns they function like segregated programs, and in low return years they can be managed as conservation programs. Lastly harvest augmentation programs are intended to increase harvest opportunities while limiting interactions with wild-origin counterparts.

Monitoring is needed to determine if the hatchery programs are meeting the intended management objectives of conservation, safety-net, or harvest augmentation programs. Objectives for hatchery programs are generally grouped into three categories of performance indicators:

1. In-Hatchery: Is the program meeting the hatchery production objectives?
2. In-Nature: How do fish from the program perform after release?
    a. Conservation Program:

- How does the program affect target population abundance and productivity?
- How does the program affect target population long-term fitness?

b. Safety-Net Program:

- How does the program affect target population long-term fitness?

c. Harvest Augmentation Program:

- Does the program provide harvest opportunities?

3. Risk Assessment: Does the program pose risks to other populations?

Objectives in this plan have been organized in a hierarchy where productivity indicators are the primary metrics used to assess if conservation and safety-net program goals have been met; harvest rates and effects on non-targeted populations are used for harvest programs. In cases where productivity indicators are not available or results are equivocal, monitoring indicators may be used to help evaluate the performance of the program. Evaluations of monitoring indicators may not provide sufficiently powerful conclusions on which to base management actions, although they may provide insight as to why a productivity indicator did or did not meet the program goal. Therefore, the relationship between hatchery programs and indicators can be viewed in a chain-of-causation: management actions within the hatchery programs affect the status of monitoring indicators, which in turn influence productivity indicators (Figure 1).

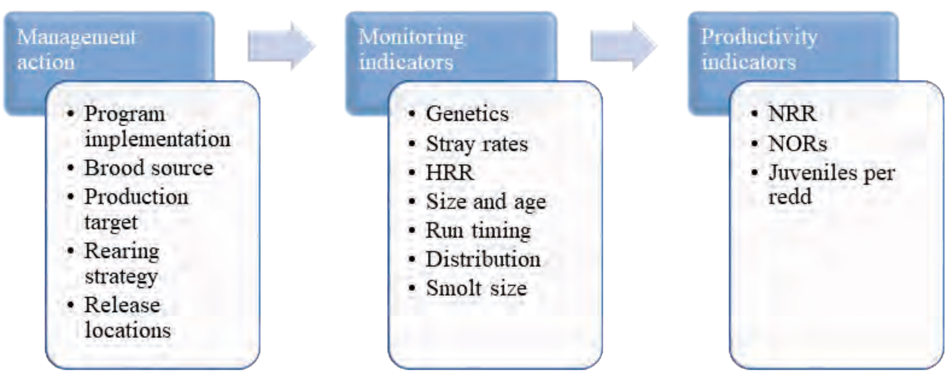

Figure 1. Relationship of indicators to the assessment of supplementation programs. Management actions affect monitoring indicators, which influence productivity indicators. Monitoring indicators may be used to hypothesize the magnitude of influence on productivity.

The primary goal of a conservation program is to contribute to the rebuilding and recovery of naturally reproducing populations within their native habitat. In this plan, natural replacement rates (NRR), recruitment of naturally-produced fish (NOR), and juvenile productivity (juveniles per redd) are important indicators for assessing the success of supplementation. These indicators are difficult to measure precisely and are quite variable in space and time. Therefore, monitoring indicators can be evaluated to help assess if productivity was related to the hatchery programs or other factors (Table 1).

Table 1. Program objectives, indicators, and goals for conservation hatchery programs including productivity and monitoring indicators (also applies to safety-net programs when used to support a conservation program).

				Program goals		
	Objective	**Indicator**	**Target**	**Rebuild natural populations**	**Maintain genetic diversity**	**Opportunity for harvest**
Productivity indicators	Determine if the program has increased the number of naturally spawning adults	Abundance of natural spawners	Increase	✓		✓
		Adult productivity (NRR)	No decrease	✓		
	Determine if the proportion of hatchery fish affects freshwater productivity	Residuals vs. pHOS	No relationship	✓		
		Juveniles per redd vs. pHOS	No relationship	✓		
Monitoring indicators	Determine if run timing and distribution meets objectives	Migration timing	No difference	✓	✓	
		Spawn timing[1]	No difference	✓	✓	
		Redd distribution[2]	No difference	✓	✓	
	Determine if program has affected genetic diversity and population structure	Allele frequency (hatchery vs. wild)	No difference		✓	
		Genetic distance between populations	No difference		✓	
		Effective population size	Increase		✓	
		Age and size at maturity	No difference		✓	
	Determine if hatchery survival meets expectations	HRR	HRR > NRR	✓		
		HRR	HRR ≥ Goal[3]	✓		
	Determine if recipient stray rate of hatchery fish is acceptable	Out of basin	≤ 5%	✓	✓	
		Within basin	≤ 10%	✓	✓	
	Determine if hatchery fish were released at program targets	Size and number	= Target[4]	✓		
	Provide harvest opportunities when appropriate	Harvest	Escapement goals			✓

[1] Hatchery and natural-origin fish should spawn at the same time across the range of elevations within the spawning distribution of each stock.

[2] Hatchery and natural-origin fish should spawn in the same locations. Exceptions are the Carlton and Dryden Summer Chinook programs (see Appendix 4).

[3] HRR targets are identified in Appendix 2.

[4] Number and size targets are identified in Table 3 and Appendix 5.

A flow of information following sequential, logical steps will be employed to evaluate supplementation programs, consistent with the indicators described in Table 1. For example, a hatchery program, at a minimum, must be able to produce more adults per spawner than would occur in the natural environment. Should the program fail this test, hatchery operations should be evaluated to determine if improvements can correct the problem. If a program successfully replaces the required number of adults, it is then evaluated against a reference population or condition, if available, to determine if it has increased the overall number of naturally spawning fish (including both hatchery- and natural-origin adults), increased the number of natural-origin spawners, and to test if productivity of the natural population has changed. When these goals are met, the program is considered successful. When these goals are not met, monitoring indicators may infer why the program is not achieving its goals

If suitable reference populations are not available, other comparisons can be used to help evaluate treatment responses. Evaluation of programs may pursue the following approaches:

- Comparison to reference population(s) that do not contain pre-treatment data.
- Before treatment and after treatment comparisons.
- Comparison to standard(s).
- Comparison to other suitable reference conditions.

Methodologies for selecting reference streams, analyzing data from treatment and reference stream comparisons, and other comparisons are presented in Hillman et al. (2012) (see Appendix 6).

The primary goals of a safety-net program are to provide demographic and genetic reserves for a population that is supplemented by a conservation program (Table 2). Harvest and adult management may be used to control escapement of spawners when appropriate. Monitoring focuses on estimating the number of fish that escape to spawn naturally and stray rates and in-hatchery performance evaluation.

Table 2. Program objectives, indicators, and goals for segregated harvest augmentation hatchery programs including monitoring indicators.

	Objective	Indicator	Target	Program goals: Rebuild natural populations	Program goals: Maintain genetic diversity	Program goals: Opportunity for harvest
Monitoring indicators	Determine if hatchery survival meets expectations	HRR	HRR > NRR			✓
		HRR	HRR ≥ Goal[1]			✓
	Determine if stray rate of hatchery fish is acceptable	Out of basin	≤ 5%		✓	
		Within basin	≤ 10%		✓	
	Determine if hatchery fish were released at program targets	Size and number	= Target[2]			✓
	Provide harvest opportunities when appropriate	Harvest	When greater than escapement goals			✓

[1] HRR targets are identified in Appendix 2.

[2] Number and size targets are identified in Table 3 and Appendix 5.

The primary goal of a harvest augmentation program is to increase harvest opportunities, while segregating adults from natural spawning populations. In this plan, harvest opportunity, survival rates, and stray rates are important indicators for assessing the success of harvest augmentation. These indicators are more readily quantified compared to productivity indicators (Table 2). A flow of information will be employed to evaluate harvest augmentation programs. Since harvest augmentation programs are typically segregated, monitoring indicators will be used to determine the success of a program.

Both monitoring and productivity indicators will be used to evaluate the success of hatchery programs. In the event that the statistical power of tests that involve productivity indicators is insufficient to inform sound management decisions, some of the monitoring indicators may be used to guide management. Figure 2 show the categories of indicators associated with each component of monitoring.

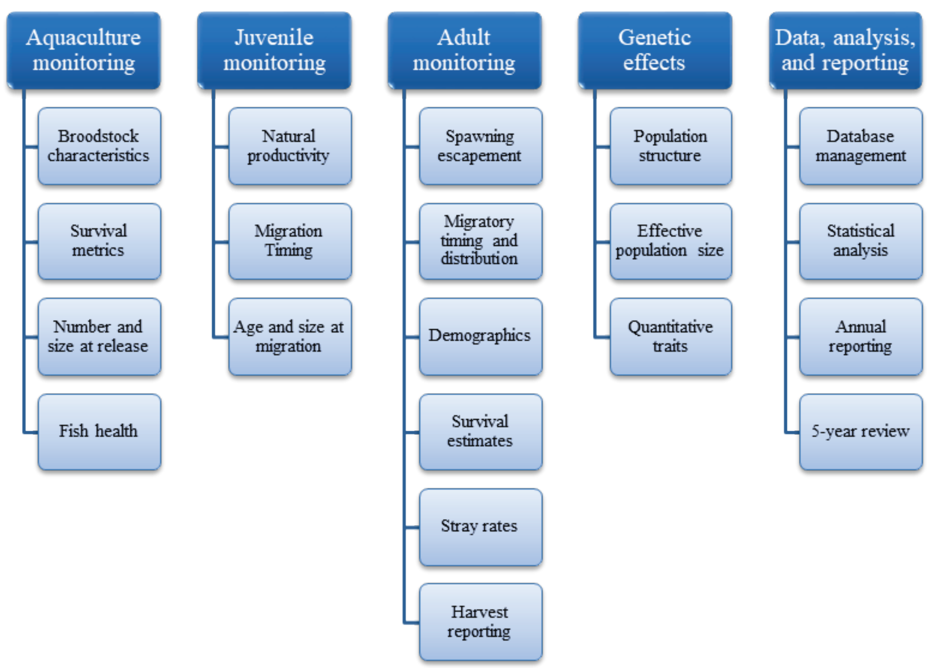

Figure 2. Overview of Monitoring and Evaluation Plan Categories and Components (not including regional objectives).

The overarching goals of conservation, safety-net, and harvest augmentation programs, as described above, are shown in detail in Figure 3. The flow chart (Figure 3) shows the relationship of overarching program goals, the strategies used to meet the goals, the monitoring and evaluation objectives used to evaluate the strategies and determine if goals are being met, and the adaptive

management cycle associated with the programs (see Tables 1 and 2 for the indicators under each objective). The logic depicted in this flow chart shall be used to assess M&E results and apply those results to management decisions. Table 3 presents the current hatchery programs releasing fish in the Upper Columbia Basin.

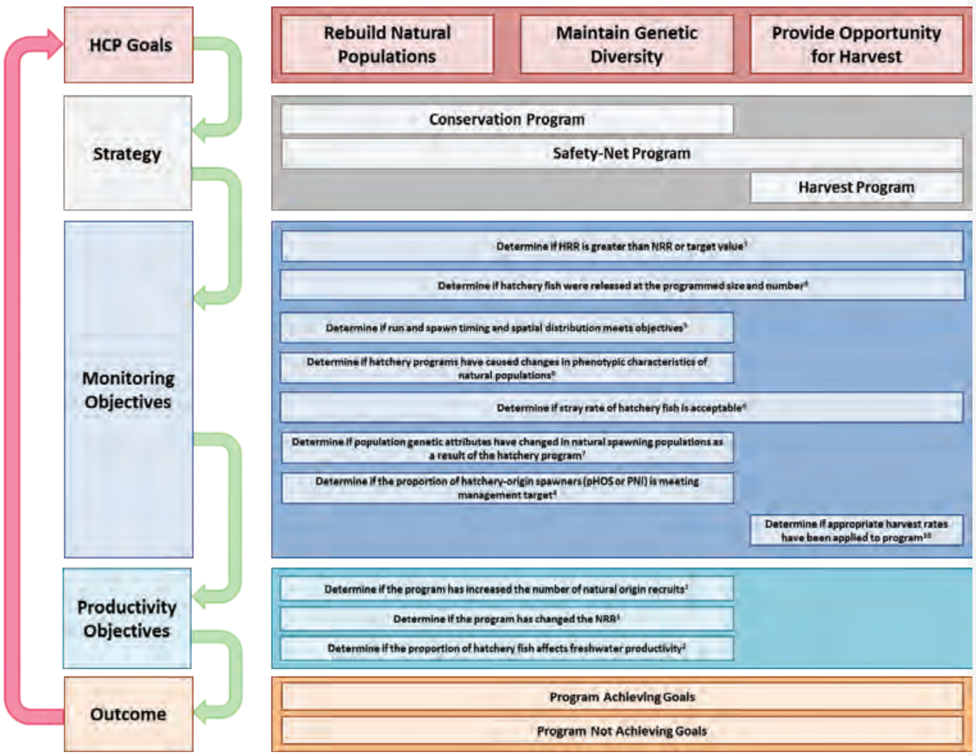

Figure 3. Adaptive management flow chart depicting HCP goals, associated strategies to meet the goals, the monitoring and evaluation objectives (indicated in superscript), and the adaptive management feedback cycle. The strategies, objectives, and outcomes are aligned vertically under the corresponding goals.

Table 3. Hatchery programs in the mid-Columbia River Basin, 2012. Funding entities included Douglas PUD (D), Chelan PUD (C), Grant PUD (G), Bonneville Power Administration (B), Bureau of Reclamation (O), and Army Corps of Engineers (A) and are listed in order of contribution. Total artificial production targets in the mid-Columbia River exceeds 20 million juveniles annually.

[1] Species listed under the Endangered Species Act.
[2] Segregated program.
[3] Sub-yearling production.
[4] Fry production.
[5] Program covered by this M&E Plan.
[6] Program also partially covered by CCT M&E Plan.
[7] Program affects PUD-funded programs covered by this plan.
[8] Planned to increase to 1,000,000.
[9] Part of the Mitchell Act suite of mitigation programs under the FCRPS BiOp.

SECTION 2: ADULT PRODUCTIVITY

2.1 Natural Replacement Rates of Supplemented Populations[1]

Objective 1: Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.

At the core of a conservation program is the objective of increasing the number of spawning adults (i.e., the combined number of naturally produced and hatchery fish) in order to affect a subsequent increase in the number of returning naturally produced fish or natural-origin recruits (NOR). In order for the natural population to remain stable or to increase, the Natural Replacement Rate (NRR), or the ratio of NORs to the parent spawning population, must be at a level where parents are being replaced by their offspring as spawners in the next generation. It is possible to affect an increase in natural-origin spawners through supplementation with a stable or decreasing NRR. However, if the NRR is below replacement (NRR<1.0), termination of the supplementation program will result in a declining natural population should that state of NRR persist. The proportion of the hatchery-origin spawners (pHOS) that will increase natural production without creating adverse effects to the genetic diversity or reproductive success rate of the natural population is unknown, and may be dependent on how individual hatchery programs are operated, as well as available spawning and rearing habitat. Some programs restrict pHOS to reduce the risk to the natural population with the intent of optimizing productivity, concomitantly reducing the overall number of spawners. All other objectives of the M&E Plan either directly support this objective or seek to minimize negative effects of the conservation programs on non-target stocks of concern.

Differences in carrying capacities of supplemented and non-supplemented streams can confound the analysis of the effects of supplementation on total number of spawners returning to the streams. For example, if the supplemented population is at carrying capacity and the non-supplemented population is not, the total number of spawners returning to the non-supplemented population may show an increasing trend over time, while the supplemented population would show no increasing trend. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on total spawners, density corrections should be included in the analyses. Hypotheses that may require density corrections are noted under each monitoring question. Appendix 1 describes methods for estimating carrying capacities.

Monitoring Questions:

Q1.1.1 Has the supplementation program changed the adult productivity (NRRs) of the supplemented populations?[2]

Target Species/Populations:

[1] Supplementation programs may include a safety-net component.

[2] Because adult productivity is affected by the abundance of the population (i.e., productivity decreases with increasing abundance), the goal of supplementation is to increase or maintain productivity, but not decrease it.

- Q1.1.1 applies to all conservation and safety-net stocks.

Statistical Hypotheses 1.1.1[3]:

- $Ho_{1.1.1.1}$: Slope in NRRs before supplementation ≤ slope in NRRs after supplementation.
- $Ho_{1.1.1.2}$: Differences in slopes in NRRs between supplemented and reference populations before supplementation ≤ differences in slopes in NRRs between supplemented and reference populations after supplementation.
- $Ho_{1.1.1.3}$: Mean NRRs before supplementation ≤ mean NRRs after supplementation.
- $Ho_{1.1.1.4}$: Mean ratio scores in NRRs before supplementation ≤ Mean ratio scores in NRRs during supplementation.
- $Ho_{1.1.1.5}$: Mean ratio scores in NRRs (adjusted for density dependence) before supplementation ≤ Mean ratio scores in NRRs (adjusted for density dependence) during supplementation. [This hypothesis adjusts NRRs for density-dependent effects (see Hillman et al. 2012 for details; Appendix 6).]
- $Ho_{1.1.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds
- Number of naturally produced fish harvested

Derived Variables:

- Number of naturally produced recruits by brood year for both naturally produced parents and hatchery parents (≥age-3).
- NRRs (calculated as NORs/spawner).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NRRs (requires reference population[s]).
- Includes calculation of ratios NORs (requires reference population).
- Appendix 1: Spawning escapement and carrying capacity information (as applicable)

Spatial/Temporal Scale:

- Calculated annually based on brood year.
- Time series.

Possible Statistical Analysis:

---

3 Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 6) for details.

- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 6). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NRRs.
- On a five-year period, correlate productivity with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

2.2 Natural-Origin Recruits of Supplemented Populations

Monitoring Questions:

Q1.2.1: Has the supplementation program changed the abundance of NORs within the supplemented population?

Target Species/Populations:

- Q1.2.1 applies to all supplemented or safety net stocks.

Statistical Hypotheses 1.2.1[4]:

- $Ho_{1.2.1.1}$: Slope in NORs[5] before supplementation ≥ slope in NORs after supplementation.
- $Ho_{1.2.1.2}$: Differences in slopes in NORs between supplemented and reference populations before supplementation ≥ differences in slopes in NORs between supplemented and reference populations after supplementation.
- $Ho_{1.2.1.3}$: Mean NORs before supplementation ≥ mean NORs after supplementation.
- $Ho_{1.2.1.4}$: Mean ratio scores in NORs before supplementation ≥ Mean ratio scores in NORs during supplementation.
- $Ho_{1.2.1.5}$: Mean ratio scores in NORs/Maximum Recruitment before supplementation ≥ Mean ratio scores in NORs/Maximum Recruitment during supplementation. [This hypothesis adjusts NORs for the capacity of the habitat; it tests the fraction of the habitat saturated with NORs (see Hillman et al. 2012 for details).]
- $Ho_{1.2.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and NORs; rho = 0. [If there is a significant negative association between

4 Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 7) for details.

5 "Slope in NORS" refers to abundance of NORs across time (years).

pHOS and NORs, then hatchery fish may be reducing the reproductive success of the wild population.]

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish taken for broodstock.
- Number of hatchery and naturally produced fish taken in harvest (if recruitment is to the Columbia).

Derived Variables:

- NORs (number of naturally produced recruits (total recruits) by brood year for both naturally produced parents and hatchery parents [≥age-3]).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NORs (requires reference population[s]).
- Estimates of carrying capacity (see Appendix 1).

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NORs.
- On a five-year period, correlate NORs with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

SECTION 3: JUVENILE PRODUCTIVITY

3.1 Freshwater Juvenile Productivity

Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.

Out-of-basin effects (e.g., smolt passage through the hydro system, harvest, and ocean productivity, etc.) influence the survival of smolts after they migrate from the tributaries. These effects introduce substantial variability into the adult-to-adult survival rates (NRRs and HRRs) and may mask in-basin effects (e.g., habitat quality, density-dependent mortality, and differential reproductive success of hatchery and naturally produced fish). Therefore, an estimate of freshwater productivity may help inform the performance of hatchery and natural-origin spawners.

The objective of estimating freshwater productivity in the Upper Columbia ESU/DPS is to estimate the survival from egg to a critical juvenile life stage(s) of target stocks. Smolt or juvenile production models generated from the information obtained through these programs will provide a level of predictability with greater sensitivity to in-basin effects than spawner-recruitment models that consider all effects.

Differences in the current carrying capacities of supplemented and non-supplemented streams can confound the effects of supplementation on numbers of juveniles per redd. For example, if the supplemented population is at or above carrying capacity and the non-supplemented population is not, numbers of juveniles per redd in the non-supplemented population may be significantly greater than the number of juveniles per redd in the supplemented population. In addition, pHOS may be correlated with overall spawner abundance. In these cases, it is difficult or impossible to separate density-dependent effects from the influence of pHOS on freshwater productivity. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on juveniles per redd, the capacity of the habitats must be included in the analyses. The Supplementary Hypotheses presented below are designed to address the confounding effects of different densities on the analyses.

Monitoring Questions:

Q2.1.1: Has the supplementation program changed the number of juveniles (smolts, parr, and/or emigrants) per redd within the supplemented population?

Q2.2.1: Does the number of juveniles per redd decrease as the proportion of hatchery spawners increases?[6]

Target Species/Populations:

- Both Q2.1.1 and Q2.2.1 apply to all conservation stocks.

Statistical Hypotheses for 2.1.1[7]:

[6] Information is needed to estimate the effects of density dependence on these questions. Consider spatial distribution of redds.

[7] Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. (2012) for details.

- $Ho_{2.1.1.1}$: Slope in juveniles/redd before supplementation ≤ slope in juveniles/redd after supplementation.
- $Ho_{2.1.1.2}$: Differences in slopes in juveniles/redd between supplemented and reference populations before supplementation ≤ differences in slopes in juveniles/redd between supplemented and reference populations after supplementation.
- $Ho_{2.1.1.3}$: Mean juveniles/redd before supplementation ≤ mean juveniles/redd after supplementation.
- $Ho_{2.1.1.4}$: Mean ratio scores in juveniles/redd before supplementation ≤ Mean ratio scores in juveniles/redd during supplementation.
- $Ho_{2.1.1.5}$: Mean ratio scores in juveniles/redd (adjusted for density dependence) before supplementation ≤ Mean ratio scores in juveniles/redd (adjusted for density dependence) during supplementation. [This hypothesis adjusts juveniles/redd for density-dependent effects (see Hillman et al. 2012 for details; Appendix 6).]
- $Ho_{2.1.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

Statistical Hypotheses for 2.2.1:

- $Ho_{2.2.1.1}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]
- $Ho_{2.2.1.2}$: The slope between proportion of hatchery spawners and juveniles/redd is ≥ 0.

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Numbers of redds.
- Number of juveniles (smolts, parr [where appropriate], and emigrants).

Derived Variables:

- Number of juveniles per spawner.
- Number of juveniles per redd.
- Carrying capacity (see Appendix 1).

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- These analyses shall be performed every five-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 6). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and juveniles/redd.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

SECTION 4: NATURAL ENVIRONMENT MONITORING INDICATORS

4.1 Hatchery Replacement Rates (HRRs)

Objective 3: **Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.**

The survival advantage from the hatchery (i.e., egg-to-smolt) must be sufficient to produce a greater number of returning adults than if broodstock were left to spawn naturally. If a hatchery program cannot produce a greater number of adults than naturally spawning fish, then the program should be modified or discontinued. Production levels were initially developed using historical run sizes and smolt-to-adult survival rates (BAMP 1998). Using the stock specific NRR and agreed upon target values (see Appendix 2), comparisons to actual survival rates will be made to ensure the expected level of survival has been achieved.

Monitoring Questions:

Q3.2.1: Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the adult-to-adult survival rate (NRR) of naturally produced fish?

Q3.2.2: Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the Target Value identified in Appendix 2[8]?

Target Species/Populations:

- Q3.2.1 applies to all conservation stocks.
- Q3.2.2 applies to all stocks.

Statistical Hypothesis 3.2.1:

- $Ho_{3.2.1.1}$: $HRR_{\text{Year } x} \geq NRR_{\text{Year } x}$

Statistical Hypothesis 3.2.2:

- $Ho_{3.2.2.1}$: HRR ≥ Target Value identified in Appendix 2

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish harvested.
- Number of hatchery and naturally produced fish collected for broodstock.
- Number of broodstock used by brood year (hatchery and naturally produced fish).

Derived Variables:

- Number of hatchery and naturally produced adults by brood year (≥age-3).

[8] Target values may be adjusted by the hatchery committees.

- HRR (number of returning adults per brood year/broodstock)
- NRR (from Objective 1)
- Appendix 2: HRR targets identified in Appendix 2

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- For Q3.2.1 use graphic analysis and paired-sample quantile tests to compare HRR to NRR
- For Q3.2.2 use graphic analysis and one-sample quantile tests to compare HRR to the target value.
- On a five-year period, correlate HRRs with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.2 Proportion of Hatchery-Origin Spawners (pHOS or PNI)

Objective 4: Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.

Certain hatchery programs have pHOS or PNI targets, while other do not. HGMPs and permits inform the selection of targets, which are identified in Appendix 3.

Monitoring Questions:

Q4.1.1: Is the estimated proportion of hatchery-origin spawners (pHOS) less than or equal to the management target, and/or, is the estimated Percent Natural Influence (PNI) greater than or equal to the management target identified in Appendix 3?

Target Species/Populations:

- Q4.1.1 applies to all conservation and safety-net stocks that have a defined pHOS or PNI target or sliding scale (see Appendix 3).

Statistical Hypothesis 4.1.1:

- $Ho_{4.1.1.1}$: pHOS > target value or $PNI_{\text{Supplemented population}}$ < target value identified in Appendix 3

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds

Derived Variables:

- pHOS or PNI
- Appendix 3: PNI and pHOS targets and sliding scales identified in Appendix 3

Spatial/Temporal Scale:

- Calculate annually.
- Analyzed as time series.

Possible Statistical Analysis:

- Use graphic analysis and summary statistics to compare pHOS or PNI to the target value in Appendix 3.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

4.3 Run Timing, Spawn Timing, and Spawning Distribution

Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.

Strategies for conservation programs typically intend that hatchery and natural-origin fish spawn together and in similar locations. However, in some cases, strategies may differ from this paradigm (e.g., summer Chinook salmon in the Wenatchee and Methow rivers; see Appendix 4). Phenotypic plasticity or selection resulting from the hatchery environment (i.e., domestication) may affect run (migration) timing, spawn timing, and spawning distribution. If conservation programs do not adequately represent the genetic diversity of the natural population, and if phenotypic traits in supplementation fish related to fitness deviate from the naturally produced spawning population, the goals of supplementation may not be achieved. Hatchery adults that migrate and/or spawn at different times or are spatially segregated from natural-origin fish may be subject to reduced fitness. Hatchery adults that spawn at different times or locations than natural-origin fish would be reproductively isolated from the natural population. The extent of such isolation, ranging from no isolation to substantial isolation, may be exploited for management purposes in some cases.

Migration Timing

Monitoring Questions:

Q5.1.1: Is the migration timing of hatchery and natural-origin fish from the same age class similar?

Target Species/Populations:

- Q5.1.1 applies to all conservation stocks.

Statistical Hypotheses 5.1.1:

- $Ho_{5.1.1.1}$: Migration timing $_{\text{Hatchery Age X}}$ = Migration timing $_{\text{Naturally produced Age X}}$

- $Ho_{5.1.1.2}$: The cumulative frequency of migration timing of hatchery-origin fish = the cumulative frequency of migration timing of natural-origin fish.
- $Ho_{5.1.1.3}$: The 10^{th} percentile, 50^{th} percentile (mode), 90^{th} percentile, and mean migration timing of hatchery-origin fish = the 10^{th} percentile, 50^{th} percentile (median), 90^{th} percentile, and mean migration timing of natural-origin fish.

Measured Variables:

- Ages of hatchery and natural-origin fish sampled via PIT tags or stock assessment monitoring.
- Time (Julian date) of arrival at mainstem projects and within tributaries (e.g., traps, PIT arrays) with the intent to identify biologically significant differences.

Derived Variables:

- Mean Julian date for a given age class.

Spatial/Temporal Scale:

- Calculate annually based on return year and age class.
- Time series.

Possible Statistical Analysis:

- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Spawn Timing

Monitoring Questions:

Q5.2.1: Is the timing of spawning similar for conservation hatchery and natural-origin fish?

Target Species/Populations:

- Q5.2.1: Applies to all semelparous species and populations supplemented by conservation programs. Steelhead can only be assessed for natural spawning in situations where hatchery and natural-origin fish can be appropriately marked and detected.

Statistical Hypotheses 5.2.1:

- $Ho_{5.2.1.1}$: The cumulative frequency of spawn timing of hatchery-origin fish = the cumulative frequency of spawn timing of natural-origin fish.
- $Ho_{5.2.1.2}$: The 10^{th} percentile, 50^{th} percentile (mode), 90^{th} percentile, and mean spawn timing of hatchery-origin fish = the 10^{th} percentile, 50^{th} percentile (mode), 90^{th} percentile, and mean spawn timing of natural-origin fish.

- $Ho_{5.2.1.3}$: The relationship between elevation and spawn timing of hatchery-origin fish = the relationship between elevation and spawn timing of natural-origin fish.

Measured Variables:

- Time (Julian date) and elevation (m) of hatchery and natural-origin salmon carcasses or marked steelhead detected on spawning grounds within defined reaches.
- Time (Julian date) of ripeness of hatchery and natural-origin steelhead captured for broodstock.

Derived Variables:

- Mean Julian date.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.
- Use graphic analyses, ANCOVA, and/or regression analysis to assess relationships between elevation and spawn timing.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Spatial Distribution of Redds

Monitoring Questions:

Q5.3.1: Is the distribution of redds similar for conservation hatchery and natural-origin fish?

Q5.3.2: Is the distribution of redds similar to defined management targets (see Appendix 4)?

Target Species/Populations:

- Q5.3.1 applies to all conservation program stocks.
- Q5.3.2 applies only to conservation program stocks with specific spawning distribution targets (Carlton and Dryden summer Chinook programs; Appendix 4).

Statistical Hypothesis 5.3.1:

- $Ho_{5.3.1.1}$: The distribution of hatchery-origin redds (hatchery females) = the distribution of natural-origin redds (natural-origin females).

Statistical Hypothesis 5.3.2:

- $Ho_{5.3.2.1}$: The distribution of hatchery-origin redds (hatchery females) = the target distribution identified in Appendix 4.

Measured Variables:

- Location (GPS coordinate) of female salmon carcasses observed on spawning grounds. The distribution of hatchery and naturally produced steelhead redds may be evaluated if marking or tagging efforts provide reasonable results.

Derived Variables:

- Location of female salmon carcass at the historic reach scale and at the 0.1 km scale.
- Calculate percent overlap in distribution across available spawning habitat or historical reaches.
- Appendix 4: Management targets for spatial distribution of spawners or redds (as applicable).

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates' Chi-square analysis for both Q5.3.1 and Q5.3.2.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.4 Stray Rates

<u>Objective 6</u>: Determine if the recipient stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.

Maintaining locally adapted traits among independent fish populations requires that returning hatchery fish have a high rate of site fidelity to the target population or stream. Hatchery practices (e.g., imprinting on water sources at key life history stages, release methodology, release location, age at return, broodstock used, spawner density, spawning habitat quality and access, and environmental conditions) are the main variables thought to affect stray rates. Regardless of the magnitude of homing of adult returns, if adult hatchery fish do not contribute to the natural population, the program will not meet the basic condition of a supplementation program.

Independent populations are populations that are genetically differentiated from other populations. In some cases, genetic differentiation may be assumed based on phenotypic traits or geographic isolation when molecular genetics analyses are not available. When populations are not independent, straying among them does not pose a risk of genetic homogenization. In addition, stray rates of hatchery-origin fish cannot be expected to be lower than for natural-origin fish. When estimates of stray rates for natural-origin fish are available and if they exceed the 5% among population stray rate or 10% within population stray rate thresholds identified in this plan, analysis

and interpretation of stray rates must take into account the concept that hatchery programs may be held to unattainable standards based on the natural stray rate. Current criteria established by the ICBTRT (2005) and the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) indicate that fish that do stray to other non-target populations should not comprise greater than 5% of the non-target spawning population. Likewise, fish that stray into non-target spawning areas within an independent population should not comprise greater than 10% of the non-target spawning aggregate (see Tables 6.1 and 6.2).

This plan identifies three stray rate metrics; brood-year stray rate, among population return-year stray rate, and within population return-year stray rate. The return-year stray rates have specific targets that are from the ICBTRT (2005) and Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007), and are linked to extinction risk. That is, hatchery strays from other populations cannot make up more than 5% of the spawning escapement within a non-target, recipient population. In addition, hatchery strays from other spawning aggregations within a population (e.g., Chiwawa spring Chinook) cannot make up more than 10% of the spawning escapement within a non-target, recipient spawning aggregate (e.g., White River). Brood-year stray rate, on the other hand, is not discussed in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) or ICBTRT (2005) and therefore has no specific target. Nevertheless, it is important to track brood-year stray rates to determine if hatchery operations affect the homing and straying of specific brood years. These data support the return-year stray metrics and are used to inform possible changes in genetic variation among stocks.

Brood-Year Stray Rates

Monitoring Questions:

Q6.1.1: What is the brood-year stray rate of hatchery fish?

Target Species/Populations:

- Q6.1.1 applies to all hatchery stocks.

Statistical Hypothesis 6.1.1:

- $Ho_{6.1.1.1}$: None.

Measured Variables:

- Number of hatchery carcasses found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.
- Number of hatchery fish collected for broodstock.
- Number of hatchery fish taken in fishery.
- Locations of live and dead strays (used to tease out overshoot).

Derived Variables:

- Total number of hatchery carcasses and take in fishery estimated from expansion analysis.
- Percent of the total brood return that strays.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphical analysis to track brood-year stray rates over time.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Among-Population Return-Year Stray Rates

Monitoring Questions:

Q6.2.1: Do hatchery strays make up less than 5% of the spawning escapement within their non-target independent populations?

Target Species/Populations:

- Q6.2.1 applies to all hatchery stocks.

Statistical Hypothesis 6.2.1:

- $Ho_{6.2.1.1}$: Stray hatchery fish make up ≥ 5% of the spawning escapement (based on run year) within other independent populations [9]

Measured Variables:

- Number of hatchery carcasses (PIT-tagged steelhead) found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

Derived Variables:

- Total number of hatchery salmon carcasses (PIT-tagged steelhead, spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target population that is made up of hatchery strays.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

[9] This stray rate is suggested based on a literature review and recommendations by the ICBTRT (2005) and is identified in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007). It can be re-evaluated as more information on naturally-produced Upper Columbia salmonids becomes available. This will be evaluated on a species and program specific basis and decisions made by the HCP HC and PRCC HSC. It is important to understand the actual spawner composition of the population to determine the potential effect of straying.

- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (5%) stray rate.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Within-Population Return-Year Stray Rates

Monitoring Questions:

Q6.3.1: Do hatchery strays make up less than 10% of the spawning aggregate within non-target spawning areas within the target population?

Target Species/Populations:

- Q6.3.1 applies to all hatchery stocks.

Statistical Hypothesis 6.3.1:

- $Ho_{6.3.1}$: Stray hatchery fish make up ≥ 10% of spawning escapement (based on run year) within non-target spawning areas within the target population

Measured Variables:

- Number of hatchery carcasses (possibly PIT-tagged steelhead) found in non-target and target spawning aggregates or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

Derived Variables:

- Total number of hatchery salmon carcasses (possibly PIT-tagged steelhead or spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target spawning aggregate that is made up of hatchery strays.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (10%) stray rate.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.5 Population Genetics

<u>Objective 7</u>: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.

The genetic component of the M&E Plan specifically addresses the potential for changes in genetic diversity in natural populations as a result of a hatchery program(s). The long-term fitness of populations is assumed to be related to maintaining the genetic diversity of natural populations. However, hatchery programs select a subset of individuals from the population to pass on genetic material to the next generation. This is often a relatively small number of individuals that produce a large number of offspring, and can result in changes in allele frequencies and reductions of effective population size. Therefore, it is important to monitor the genetic status of the natural populations to determine if there are signs of changes in genetic distance among populations, changes in allele frequencies, and to estimate effective population size. Assessing the genetic effects of the hatchery program does not require annual sampling, but does require regular sampling at generational scales. Meeting stray-rate targets (hypotheses tested under Objective 5) should reduce significant changes in population genetics. Stray rates may inform population genetic analyses. Testing statistical hypotheses associated with genetic components (Hypotheses 3.1, 3.2, and 3.3) should be conducted every ten years or two generations.

Allele Frequency

Monitoring Questions:

Q7.1.1: Is the allele frequency of hatchery fish similar to the allele frequency of naturally produced and donor (broodstock) fish?

Target Species/Populations:

- Q7.1.1 applies to all conservation stocks.

Statiscial Hypotheses 7.1.1:

- $Ho_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ = Allele frequency $_{\text{Naturally produced}}$ = Allele frequency $_{\text{Donor pop.}}$
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ ≠ Allele frequency $_{\text{Naturally produced}}$ = Allele frequency $_{\text{Donor pop.}}$ or
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ = Allele frequency $_{\text{Naturally produced}}$ ≠ Allele frequency $_{\text{Donor pop.}}$ or
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ ≠ Allele frequency $_{\text{Naturally produced}}$ ≠ Allele frequency $_{\text{Donor pop.}}$

Measured Variables:

- SNP genotypes

Derived Variables:

- Allele frequency

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples within drainages.

Possible Statistical Analysis:

- Population differentiation tests, analysis of molecular variance (AMOVA), and relative genetic distances.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Genetic Distance Between Populations

Monitoring Questions:

Q7.2.1: Does the genetic distance among subpopulations within a supplemented population remain the same over time?

Target Species/Populations:

- Q7.2.1 applies to all conservation and safety-net stocks.

Statistical Hypothesis 7.2.1:

- $Ho_{7.2.1.1}$: Genetic distance between subpopulations $_{\text{Year x}}$ = Genetic distance between subpopulations $_{\text{Year y}}$

Measured Variables:

- SNP genotypes

Derived Variables:

- Allele frequencies

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples among spawning aggregates.

Possible Statistical Analysis:

- Population differentiation tests, AMOVA, and relative genetic distances.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Effective Spawning Population

Monitoring Questions:

Q7.3.1: Is the ratio of effective population size (N_e) to spawning population size (N) constant over time?

Target Species/Populations:

- Q7.3.1 applies to all supplemented stocks.

Statistical Hypothesis 3.3:

- $Ho_{7.3.1.1}$: $(N_e/N)_{t0} = (N_e/N)_{t1}$ for each population

Measured Variables:

- SNP genotypes

Derived Variables:

- Allele frequencies

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.

Possible Statistical Analysis:

- Population differentiation tests, relative genetic distances, statistics to calculate effective population size (e.g., harmonic means).

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.6 Phenotypic Traits

Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

Fitness, or the ability of individuals to survive and pass on their genes to the next generation in a given environment, includes genetic, physiological, and behavioral components.[10] Maintaining the long-term fitness of supplemented populations requires a comprehensive evaluation of genetic and phenotypic characteristics. Evaluation of some phenotypic traits (i.e., run timing, spawn timing, spawning location, and stray rates) is addressed under Objective 5. Objective 8 assess the potential effects of domestication, including size at maturity, age at maturity, sex ratio, and fecundity. Age and size at maturity shall be assessed for both fish arriving in the Columbia system, and those recovered on the spawning grounds. Size (or age) selective mortality during migration through the Columbia system, such as through fisheries, could alter the age and size of fish on the spawning grounds.

[10] These metrics are difficult to measure, and phenotypic expression of these traits may be all we can measure and evaluate.

Age at Maturity

Monitoring Questions:

Q8.1.1: Is the age at maturity of hatchery and natural-origin fish similar at the time they enter the Columbia River and when they spawn?

Target Species/Populations:

- Q8.1.1 applies to all conservation program stocks.

Statistical Hypotheses 8.1.1:

- $Ho_{8.1.1.1}$: Age at Maturity $_{\text{Hatchery produced spawners Gender X}}$ = Age at Maturity $_{\text{Naturally produced spawners Gender X}}$
- $Ho_{8.1.1.2}$: Age at Maturity $_{\text{All hatchery produced adults Gender X}}$ = Age at Maturity $_{\text{All naturally produced adults Gender X}}$

Measured Variables:

- Total and salt (ocean) age of hatchery and natural-origin salmon carcasses collected on spawning grounds.
- Total and salt age of broodstock.
- Total and salt age of fish at stock assessment locations (e.g., Dryden, Tumwater, Wells, Priest Rapids).
- Whenever possible, age at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).
- Assess age of fish, including harvested fish.

Derived Variables:

- Total age and saltwater age
- Age of fish entering the Columbia River.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates' Chi-square.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Size at Maturity

Monitoring Questions:

Q8.2.1: Is the size (length) at maturity of a given age and sex of hatchery fish similar to the size at maturity of a given age and sex of natural-origin fish?

Target Species/Populations:

- Q8.2.1 applies to all conservation and safety-net stocks.

Statistical Hypothesis 8.2.1:

- $Ho_{8.2.1.1}$: Size (length) at Maturity $_{\text{Hatchery Age X and Gender Y}}$ = Size (length) at Maturity $_{\text{Naturally produced Age X and Gender Y}}$
- $Ho_{8.2.1.2}$: Size (length) at Maturity $_{\text{All hatchery adults Gender X}}$ = Size (length) at Maturity $_{\text{All naturally produced adults Gender X}}$

Measured Variables:

- Size (length), age, and gender of hatchery and natural-origin salmon carcasses collected on spawning grounds.
- Size (length), age, and gender of broodstock.
- Size (length), age, and gender of fish at stock assessment locations (e.g., Priest Rapids, Dryden, Tumwater, Wells, Twisp Weir).
- Whenever possible, size at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).

Derived Variables:

- Total age and saltwater age

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and three-way ANOVA by origin, gender, and age

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Fecundity at Size[11]

Monitoring Questions:

Q8.3.1: Is the fecundity vs. size relationship of hatchery and natural-origin fish similar?

[11] May not apply to all programs.

Q8.3.2: Is the gonadal mass vs. size relationship of hatchery and natural-origin fish similar?

Target Species/Populations:

- Both Q8.3.1 and Q8.3.2 apply to all conservation stocks using both natural- and hatchery-origin broodstock.

Statistical Hypothesis 8.3.1:

- $Ho_{8.3.1.1}$: Slope of Fecundity vs. Size $_{\text{Hatchery}}$ = Slope of Fecundity vs. Size $_{\text{Naturally produced}}$

Statistical Hypothesis 8.3.2:

- $Ho_{8.3.2.1}$: Gonadal Mass vs. Size $_{\text{Hatchery}}$ = Gonadal Mass vs. Size $_{\text{Naturally produced}}$

Measured Variables:

- Length, weight, and age (covariate) of hatchery and natural-origin broodstock after eggs have been removed.
- Number and weight of eggs

Derived Variables:

- Total age and saltwater age.
- Mean weight per egg.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis, regression, t-test, and ANCOVA.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Sex Ratio

Monitoring Questions:

Q8.4.1: Is the sex ratio of hatchery and natural-origin fish similar?

Target Species/Populations:

- Q8.4.1 applies to all conservation stocks.

Statistical Hypothesis 8.4.1:

- $Ho_{8.4.1.1}$: Sex Ratio $_{\text{Hatchery}}$ = Sex Ratio $_{\text{Naturally produced}}$

Measured Variables:

- Age and sex of hatchery and natural-origin salmon carcasses collected on spawning grounds or sampled at dams or weirs.
- Whenever possible sex ratio will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling or ultrasound on live fish).

Derived Variables:

- Ratio of sexes based on brood year returns

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates'Chi-square.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 5: HATCHERY ENVIRONMENT MONITORING INDICATORS

5.1 Release Targets

<u>Objective 9</u>: Determine if hatchery fish were released at the programmed size and number.

The HCP outlines the number and size of fish that are to be released to meet NNI and inundation compensation levels. The size of the fish at release may be altered according to an adaptive management process in the Hatchery Committee(s), and the number of fish can be altered by survival study results and adjustment of hatchery production for population dynamics. Size of fish at release can affect survival, sex ratios, age at return, stray rate, and fecundity. In addition, the variation in size at release may affect performance of the fish.

The coefficient of variation (CV) will be evaluated to ascertain if program performance is related to variation in size at release. Note also that variation in a population is a natural condition and striving to control this variation could result in directional or stabilizing artificial selection that could have unforeseen long-term consequences. Attaining uniform or multi-modal growth in a hatchery environment may not be adaptive for fitness in the wild. Therefore, pursuit of a CV target should be seen as an informative exercise, but is not in itself indicative of success or failure of a hatchery program. Furthermore, growth regimes may prove to be important in affecting adult returns and age structure. Although many factors can influence both the size and number of fish released, past hatchery cultural experience with these stocks should assist in meeting program production levels. Appendix 5 presents the target size at release and CVs for the programs. These targets shall be assessed annually to ensure they are optimized to inform management decisions.

Size at Release of Hatchery Fish

Monitoring Questions:

Q9.1.1: Is the size (fish per pound; fpp) of hatchery fish released equal to the program goal identified in Appendix 5?

Target Species/Populations:

- Q9.1.1 applies to all hatchery stocks.

Statistical Hypothesis 9.1.1:

- $Ho_{9.1.1.1}$: Hatchery fish $_{\text{fpp at release}}$ = Programmed $_{\text{fpp at release}}$ (see Appendix 5)

Measured Variables:

- Fork length and weights of random samples of hatchery juveniles at release.

Derived Variables:

- Mean length (FL), mean weight, and fish per pound
- Appendix 5: Rearing targets

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated fpp of hatchery fish at time of release with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Coefficient of Variation (CV) of Hatchery Fish Released

Monitoring Questions:

Q9.2.1: Is the CV of hatchery fish released equal to the program target identified in Appendix 5?

Target Species/Populations:

- Q9.2.1 applies to all hatchery stocks.

Statistical Hypothesis 9.2.1:

- $Ho_{9.2.1.1}$: Hatchery fish $CV_{\text{at release}}$ = Programmed CV in Appendix 5

Measured Variables:

- Length and weights of random samples of hatchery smolts.

Derived Variables:

- Coefficient of Variation: $cv = (1 + 1/4n) \times (s/x)$ (where s = standard deviation, x = estimated mean, n = sample size)
- Appendix 5: Rearing targets

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated CV of size of hatchery fish released with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Condition Factor (K) of Hatchery Fish Released

Monitoring Questions:

Q9.3.1: Is the K of hatchery fish released equal to the program target identified in Appendix 5?

Target Species/Populations:

- Q9.3.1 applies to all hatchery stocks.

Statistical Hypothesis 9.3.1:

- $Ho_{9.3.1.1}$: Hatchery fish $K_{\text{at release}}$ = Programmed K identified in Appendix 5

Measured Variables:

- Monthly individual lengths and weights of random samples of hatchery juveniles.

Derived Variables:

- Condition Factor: $K = W/L^3 \times 10^5$

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated K of released hatchery fish with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Number of Hatchery Fish Released

Monitoring Questions:

Q9.4.1: Is the number of hatchery fish released equal to the program goal identified in Appendix 5?

Target Species/Populations:

- Q9.4.1 applies to all hatchery stocks.

Statistical Hypothesis 9.4.1:

- $Ho_{9.4.1.1}$: Hatchery Fish Number = Programmed Number identified in Appendix 5

Measured Variables:

- Numbers of smolts released from the hatchery.

Derived Variables:

- Appendix 5: Rearing targets

Spatial/Temporal Scale:

- Calculate annually.

- Time series.

Possible Statistical Analysis:

- Use graphic analysis and one-sample quantile tests to compare the estimated number of hatchery fish released with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 6: HARVEST MONITORING INDICATORS

6.1 Harvest Rates

Objective 10: Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.

Harvest will be applied to different types of programs in an effort to achieve the management objectives of those programs. Programs designed to augment harvest should routinely contribute to harvest at a rate that greatly reduces the incidence of straying to natural spawning grounds, but also allows the program to be sustained. Safety-net programs may be harvested as part of an adult management strategy to minimize excessive escapement of hatchery-origin fish to spawning grounds. Similarly, conservation programs may undergo harvest to manage returning adults, but the emphasis for these programs should be to achieve escapement goals. In all cases, harvest effort should not have the unintended consequence of removing excessive numbers of conservation or natural-origin fish. In years when the expected returns of hatchery adults are above the level required to meet program goals (i.e., supplementation of spawning populations and/or brood stock requirements), surplus fish may be available for harvest. The M&E Plan specifically addresses harvest and harvest opportunities upstream of Priest Rapids Dam. Harvest or removal of surplus hatchery fish from the spawning grounds may assist in reducing potential adverse ecological and genetic impacts to natural populations (e.g., loss of genetic variation within and between populations, loss of fitness, reduced effective population size, and density-dependent effects).

Monitoring Questions:

Q10.1.1: Conservation Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of conservation hatchery fish but low enough to sustain the hatchery program?

Q10.1.2: Safety-Net Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of safety-net hatchery fish but low enough to sustain the hatchery program?

Q10.1.3: Is the harvest on hatchery fish produced from harvest-augmentation programs high enough to manage natural spawning but low enough to sustain the hatchery program?

Q10.1.4: Is the escapement of fish from conservation and safety-net programs in excess of broodstock and natural production[12] needs to provide opportunities for terminal harvest?

Target Species/Populations:

- Q10.1.1 applies to conservation programs.
- Q10.1.2 applies to safety-net programs.

[12] The current best estimates of carrying capacity (maximum recruits) will be used, as available.

- Q10.1.3 applies harvest augmentation programs.
- Q10.1.4 applies to conservation and safety-net programs.

Statistical Hypothesis 10.1.1:

- $Ho_{10.1.1.1}$: Harvest rate ≤ Maximum level to meet program goals

Statistical Hypothesis 10.1.2:

- $Ho_{10.1.2.1}$: Harvest rate ≤ Maximum level to meet program goals

Statistical Hypothesis 10.1.3:

- $Ho_{10.1.3.1}$: Escapement ≤ Maximum level to meet supplementation goals

Statistical Hypothesis 10.1.4:

- $Ho_{10.1.4.1}$: Harvest rate ≤ Maximum level to meet program goals

Measured Variables:

- Numbers of hatchery fish taken in harvest.
- Numbers of natural-origin fish taken in harvest.

Derived Variables:

- Total harvest by fishery estimated from expansion analysis.

Spatial/Temporal Scale:

- Calculated annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and one-sample quantile tests to compare the estimated harvest of hatchery fish with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 7: REGIONAL OBJECTIVES

Hatchery programs have the potential to increase diseases that typically occur at low levels in the natural environment (Objective 9). In addition, hatchery fish can reduce the abundance, size, or distribution of non-target taxa through ecological interactions (Objective 10). In this section, we address incidence of disease and non-target taxa of concern.

7.1 Incidence of Disease

Objective 11: Determine if the incidence of disease has increased in the natural and hatchery populations.

The hatchery environment has the potential to amplify diseases that are typically found at low levels in the natural environment. Amplification could occur within the hatchery population (i.e., vertical and horizontal transmission) or indirectly from the hatchery effluent or commingling between infected and non-infected fish (i.e., horizontal transmission). Potential impacts to natural populations have not been extensively studied, but should be considered for programs in which the hatchery fish are expected to commingle with natural fish. This is particularly important for supplementation type programs. Specifically, the causative agent of bacterial kidney disease (BKD), *Renibacterium salmoninarum* (Rs), could be monitored at selected acclimation ponds, both in the water and fish, in which the risk and potential for transmission from the hatchery is highest. Although it is technologically possible to measure the amount of Rs in water or Rs DNA in smolts and adults non-lethally sampled, the biological meaning of these data are uncertain. Currently, the only metric available for M & E purposes is measuring the antigen level from kidney/spleen samples (i.e., ELISA, PCR). When available, non-lethal sampling may replace or be used in concert with lethal sampling.

Implementation of this objective will be conducted in a coordinated approach within the hatchery and natural environment. BKD management within the hatchery population (e.g., broodstock or juveniles) has the potential to reduce the prevalence of disease through various actions (e.g., culling or reduced rearing densities). BKD management must also take into account and support other relevant objectives of the M & E program (e.g., Hatchery Return Rate [HRR], number of smolts released). Hence, the goal of BKD management is to decrease the prevalence of disease and maintain hatchery production objectives (i.e., number and HRR).

As previously discussed, disease transmission from hatchery to naturally produced fish may occur at various life stages and locations. Of these, horizontal transmission from hatchery effluent, vertical transmission on the spawning grounds, and horizontal transmission in the migration corridor have been identified as disease interactions that could be examined under this objective, although others may also be relevant. Experimental designs addressing this objective may require technology not yet available, although in some instances samples may be collected, but not analyzed until a link can be established between bacteria levels in samples and disease prevalence.

Developing a complete set of questions and hypotheses statements for this objective may not be practical at this time, because there is currently no BKD Management Plan. However, while developing experimental designs for this objective, it may be feasible to incorporate both hatchery and natural environment monitoring under a single study design. Integration of the different

aspects of the objective would likely result in a more robust approach into understanding the effectiveness of disease management strategies.

Proposed Tasks:

T1: Assemble fish health data for fish used as brood (e.g., ELISA results).

T2: Conduct data exploration exercise to identify potential relationships between pathogen profiles and likely causative variables (e.g., rearing conditions and management actions).

T3: Develop hypotheses for potential testing to meet objective.

7.2 Non-Target Taxa of Concern (NTTOC)

Objective 12: Determine if the release of hatchery fish affects non-target taxa of concern (NTTOC) within acceptable limits.

Commented [TH1]: The text below is new.

Hatchery programs have the potential to affect non-target taxa through various types of interactions (e.g., competition and predation). These interactions can reduce the distribution, size, and abundance of non-target species. The non-target taxa of concern (NTTOC) ecological risk assessment was developed as a regional objective that would addressed ecological interactions on non-target taxa.

In 2008, the Wells HCP, Rocky Reach HCP, Rock Island HCP Hatchery Committees, and the Priest Rapids Hatchery Sub-Committee agreed to an approach to evaluate the potential effects of hatchery programs on NTTOC. The committees originally planned to convene a panel of experts to conduct a preliminary evaluation of the potential effects of Plan supplemented species on NTTOC. At the 15 October 2008 Hatchery Committees meeting, the members agreed to convene an expert panel to conduct a preliminary evaluation of potential effects of supplemented Plan Species on non-target taxa using an approach similar to that used in the Yakima Basin (Pearsons and Hopley 1999; Ham and Pearsons, 2001). The Committees agreed to convene the panel in spring or early summer 2009, and focus this initial effort on HCP Plan Species and the two non-Plan Species, westslope cutthroat trout and lamprey. The Committees identified species interactions, containment objectives for non-target species, and fisheries professionals who possessed the expertise to contribute as panel members. However, this expert panel was never assembled. Instead, the Committees directed the Hatchery Evaluation Technical Team (HETT) to pursue assessment of the hatchery programs potential effects on NTTOC.

The HETT evaluated methods to conduct a risk assessment on NTTOC, and proposed using a combined modeling and a Delphi panel approach, whereby the modeling results would be compared and correlated with the Delphi panel results. The HETT identified the PCD Risk 1 model (Busack et al., 2005; Pearsons and Busack, 2012) to conduct the modeling evaluation. The PCD Risk 1 model is a data intensive, individual-based stochastic model. The HETT determined that the assembled data to be used as inputs for the PCD Risk 1 model would also serve to provide expert panelists the necessary data for them to conduct risk assessments. Hence, the HETT embarked on an extensive effort to gather, organize, and extract the required data from existing datasets, literature, and biologists familiar with the programs and/or particular NTTOC. Ultimately the input data were assembled in a relational database that allowed the data to be output in user-friendly formats for modeling or Delphi panel use. The database also served to hold the modeling results, which could be extracted and summarized as needed.

A report titled *Ecological Risk Assessment of Upper-Columbia Hatchery Programs on Non-Target Taxa of Concern* was drafted in 2013 and finalized in 2014, which included the modeling results to date. The results in the report represent a very extensive effort to model the risk of all the upper Columbia hatchery programs for the identified NTTOC for which data and model runs were available. Should new information become available, the Committees agreed to assess the suitability of the data as it relates to conducting future NTTOC evaluations as a regional objective.

Attachment E

SECTION 8: ADAPTIVE MANAGEMENT

Commented [TH2]: The text below is new.

One of the challenges of evaluating PUD hatchery programs is that hatchery programs are modified resulting in hatchery treatments that are uneven throughout the duration of the hatchery program. Modifications occur as a result of recalculating hatchery release numbers every 10 years and also through adaptive management. To solve this evaluation challenge, we propose to conduct two scales of analysis. First, the entire duration of the program will be analyzed using the entire data set. This evaluation will analyze whether the overall adaptively managed program achieved objectives. Second, where appropriate, analyses will be compared across periods or programs to determine if major program changes have resulted in hypothesized changes to key response variables. We acknowledged that partitioning data into shorter periods will likely result in reduced statistical power so only the biggest changes will be evaluated. In the future, the hatchery committees will develop a table or figure that identifies major program changes in fish culture or M&E.

In the past, hatchery programs have been evaluated at the hatchery program scale (e.g., Nason Creek, Carlton summer Chinook). In some cases, it may be worthwhile to evaluate supplementation programs at different spatial scales. For example, the Nason Creek spring Chinook salmon program can be evaluated at the scale of Nason Creek, the combined effects of spring Chinook hatchery programs in the Wenatchee basin at the Wenatchee basin scale, and then all of the spring Chinook programs in the upper Columbia at the upper Columbia basin scale.

Comparisons of supplemented populations (treatments) to in-basin reference populations are the best way to evaluate whether treatments have caused changes to variables such as natural-origin recruits or productivity. Many suitable out-of-basin references are available (see Appendix 6), but these references do not control for unique factors that may be happening in the upper Columbia or areas outside the upper Columbia. For example, large fires that occur in the Upper Columbia may not occur at similar times in areas outside of this area. Candidate in-basin reference populations are not ideal for spring Chinook salmon because they are small and are above a lake (e.g., Little Wenatchee River) or they have had a long history of hatchery stocking (e.g., Entiat River). Every population of upper Columbia summer and fall Chinook is supplemented so in-basin references are not currently available. Without a suitable number of in-basin reference populations that are similar in size and distribution to treated populations, it will be difficult to unambiguously assess hatchery effects on certain variables. Although not ideal, the only way to increase in-basin reference comparisons is to strategically reduce the number of places where hatchery fish are released such as was done for the Entiat River.

Previous stocking history will lessen the value of reference populations; however, they can still be of value. For instance, the Committees can still test whether NORs are increased under supplementation compared to periods when other populations are not supplemented (i.e., a reverse BACI analysis).

SECTION 10: GLOSSARY

Adult-to-Adult survival (Ratio)	The number of parent broodstock relative to the number of returning adults.
Age at maturity	The age of fish at the time of spawning (hatchery or naturally).
Augmentation	A hatchery strategy where fish are released for the sole purpose of providing harvest opportunities.
Broodstock	Adult salmon and steelhead collected for hatchery fish egg harvest and fertilization.
Donor population	The source population for supplementation programs before hatchery fish spawned naturally.
Effective population size (Ne)	The number of reproducing individuals in an ideal population (i.e., Ne = N) that would lose genetic variation due to genetic drift or inbreeding at the same rate as the number of reproducing adults in the real population under consideration (Hallerman 2003).
ESA	Endangered Species Act passed in 1973. The ESA-listed species refers to fish species added to the ESA list of endangered or threatened species and are covered by the ESA.
Expected value	The number of smolts or adults derived from survival rates agreed to in the Biological Assessment and Management Plan (BAMP 1998).
Extraction rate	The proportion of the spawning population collected for broodstock.
Genetic diversity	All the genetic variation within a species of interest, including both within and between population components.
Genetic stock structure	A type of assortative mating, in which the gene pool of a species is composed of a group of subpopulations, or stocks, that mate panmictically within themselves.
Genetic variation	All the variation due to different alleles and genes in an individual, population, or species.
HCP	Habitat Conservation Plan is a plan that enables an individual or organization to obtain a Section 10 Permit which outlines what will be done to “minimize and mitigate” the impact of the permitted take on a listed species.

HCP-HC	Habitat Conservation Plan Hatchery Committee is the committee that directs actions under the hatchery program section of the HCP's for Chelan and Douglas PUDs.
HRR	Hatchery Replacement Rate is the ratio of the number of returning hatchery adults relative to the number of adults taken as broodstock, both hatchery and naturally produced fish (i.e., adult-to-adult replacement rate).
Long-term fitness	Long-term fitness is the ability of a population to self-perpetuate over successive generation.
Naturally produced	Progeny of fish that spawned in the natural environment, regardless of the origin of the parents.
Mean Ratio	The ratio between a treatment and control population, with the mean taken across a time period, such as years. Used in analysis in Before-After-Control-Impact studies.
Ne	Effective population size.
Non-target taxa of concern (NTTOC)	Species, stocks, or components of a stock with high value (e.g., stewardship or utilization) that may suffer negative effects because of a hatchery program.
NRR	Natural replacement rate is the ratio of the number of returning naturally produced adults relative to the number of adults that naturally spawned, both hatchery and naturally produced.
NTTOC	Non-target taxa of concern.
pHOS	Proportion of Hatchery Origin Spawners.
PNI	Proportionate Natural Influence.
pNOB	Proportion of Natural Origin Broodstock.
PRCC HSC	Priest Rapids Coordinating Committee Hatchery Subcommittee.
Productivity	The capacity in which juvenile fish or adults can be produced.
Reference population	A population in which no directed artificial propagation is currently directed, although may have occurred in the past. Reference populations are used to monitor the natural variability in survival rates and out of basin impacts on survival.
Smolt-to-adult survival rate (SAR)	Smolt-to-adult survival rate is a measure of the number of adults that return from a given smolt population.
Segregated	A type of hatchery program in which returning adults are spatially or temporally isolated from other populations.

Size at maturity	The length or weight of a fish at a point in time during the year in which spawning will occur.
Smolts per redd	The total number of smolts produced from a stream divided by the total number of redds from which they were produced.
SNP or single-nucleotide polymorphism	A single-nucleotide polymorphism is a variation in a single nucleotide that occurs at a specific position in the genome, where each variation is present to some appreciable degree within a population.
Spawning Escapement	The number of adult fish that survive to spawn.
Stray rate	The rate at which fish spawn outside of natal rivers or the stream in which they were released.
Supplementation	A hatchery strategy where the main purpose is to increase the relative abundance of natural spawning fish without reducing the long-term fitness of the population.
Target population	A specific population in which management actions are directed (e.g., artificial propagation, harvest, or conservation).

Attachment E

APPENDIX 1: ESTIMATION OF CARRYING CAPACITY

Commented [TH3]: This section is new.

In the ecological literature, carrying capacity is often defined as the maximum population size that can be supported indefinitely by the environment (Cain et al. 2014). Said another way, carrying capacity is the maximum number or biomass of a species that a given habitat can support. This maximal environment load is often referred to as “habitat capacity” and is identified with the letter “C.” In contrast, the carrying capacity parameter “K” in population models (e.g., logistic equation, Beverton-Holt model, hockey stick model, and the Ricker model) defines a maximum equilibrium population size. Maximum equilibrium population size is generated from density dependent mechanisms that reduce population growth rates as population size increases (negative density dependence). This is referred to as compensation. Population size fluctuates about the maximum equilibrium size because of variability in vital rates that are unrelated to density (density independent factors) and measurement error. Maximum equilibrium population size is often referred to as “population capacity.” The two capacities (habitat capacity and population capacity) are related but not identical and therefore should not be confused. Habitat capacity will usually be greater than population capacity.

Estimation of carrying capacity is important because hatchery managers use it to inform supplementation programs, harvest managers use it to set appropriate harvest and escapement levels, modelers use it in life-cycle models to predict the effects of different recovery scenarios, and restoration practitioners use it to guide restoration actions. The purpose of this paper is to describe methods that can be used to estimate carrying capacity for stocks within the Upper Columbia River basin. We apply these methods to Wenatchee and Chiwawa River spring Chinook salmon.[13] Data used in this exercise are shown in Tables 1 and 2 and come from Hillman et al. (2017). We begin by identifying simple methods used to detect density dependence. We then describe the use of population models to estimate population capacity. We also discuss the use of habitat models and quantile regression to estimate habitat capacity. We end by comparing results of different methods and offering recommendations for estimating carrying capacity.

Table 1. Numbers of redds, adult spawners (estimated from redd surveys), eggs (estimated as the number of redds times average brood-year fecundity), summer parr (estimated using snorkel surveys), and yearling smolts (estimates using a rotary screw trap) by brood year for spring Chinook salmon in the Chiwawa River watershed. Smolts represent the number of yearling Chinook produced entirely within the Chiwawa River watershed. Date are from Hillman et al. (2017). NS = not sampled.

Brood year	Numbers of Chiwawa spring Chinook				
	Redds	Spawners	Eggs	Parr	Smolts
1991	104	242	478,400	45,483	42525
1992	302	676	1,570,098	79,113	39723
1993	106	233	556,394	55,056	8662
1994	82	184	485,686	55,241	16472
1995	13	33	66,248	5,815	3830

[13] Technically, Wenatchee River spring Chinook are one population. Chiwawa River spring Chinook are a subgroup of the Wenatchee spring Chinook population.

* From 2000-2010 the smolt trap operated near the Town of Monitor; from 2013 to present the trap operated near the Town of Cashmere.

Evidence of Density Dependence

To calculate population capacity, the size of the population or stock must be influenced to a large degree by density-dependent factors. That is, population growth is affected by mechanisms whose effectiveness increases as population size increases. As population density increases, factors such as competition, predation, and disease (and parasites) cause birth rates to decrease, death rates to increase, and dispersal to increase. When densities decrease, the opposite occurs; birth rates increase and death and emigration rates decrease. In general, when the density of the population becomes high enough, density-dependent factors decrease population size because food or space are in short supply (Chapman 1966). In the ecological literature, this is referred to as “population regulation.”

A simple way to determine if density-dependent factors regulate population size is to plot population growth rate (or appropriate surrogate) against population size. If population regulation is occurring, the relationship between population size and population growth rate decreases exponentially (decreases linearly if data are log-transformed). Surrogates for population growth rate include survival rates, natality (birth rates), productivity, recruits, individual growth rates, and movement. Figure 1 shows the relationship between productivity (parr/spawner and smolts/spawner) and spawning escapement for Wenatchee River and Chiwawa River spring Chinook. One could use redd counts as a surrogate for spawning abundance. Because most female spring Chinook construct only one redd (Murdoch et al. 2009), redd counts reflect the number of female spawners in the population. In this report, we use number of spawners (spawning escapement) because most management decisions are based on spawning escapement.

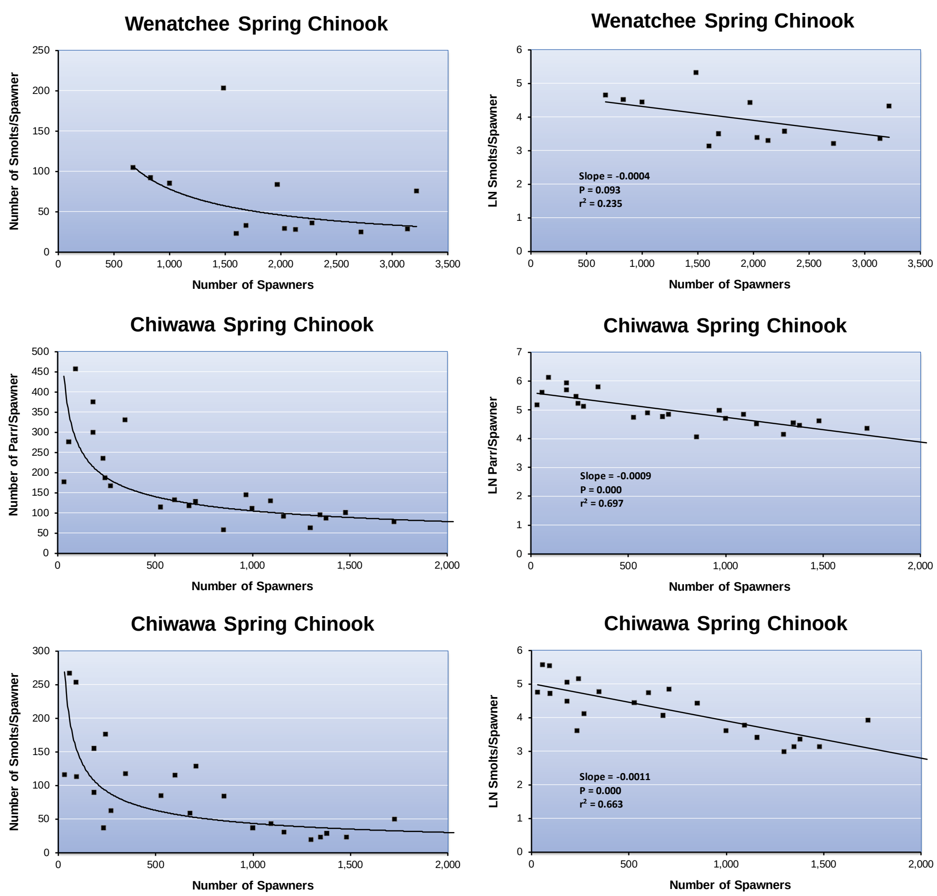

Figure 1. Relationship between spawner abundance and smolts/spawner for Wenatchee spring Chinook (top figures), spawner abundance and parr/spawner for Chiwawa spring Chinook (middle figures), and spawner abundance and smolts/spawner for Chiwawa spring Chinook (bottom figures). Figures on the right show natural log transformed productivity data.

The negative relationship between spawner abundance and juvenile productivity indicates the presence of density dependence in Chiwawa spring Chinook. Although there is a hint of density dependence in the Wenatchee River productivity data, the relationship was not significant statistically. This in part may be related to changes in sampling over the 13-year period. The negative relationship was significant for both summer parr and yearling smolts in the Chiwawa River watershed. We caution, however, that there may be a bias in the simple regression analysis presented in the figures. That is, the dependent (productivity) and independent (abundance) variables are not independent and this can produce a negative bias in regression estimates of slope. Nevertheless, the decline in juvenile productivity with increasing spawner abundance indicates the

presence of density dependence. Given the presence of density dependence, we should be able to estimate population capacity.

Estimating Carrying Capacity

Several different methods can be used to estimate population capacity. For example, time series analyses, including the logistic or Gompertz functions, or stock-recruitment models can be used to estimate population capacity. Common stock-recruitment models include Ricker, Beverton-Holt, and smooth hockey stick models. These models incorporate environmental variability and can be used to estimate the size of the spawning population needed to produce the maximum number of recruits. Habitat capacity, on the other hand, can be estimated using fish-habitat models. In general, these models estimate habitat capacity as the product of habitat area and fish/habitat relationships. These range from simple models such as percent habitat saturation models to more complex models including habitat suitability, quantile regression forest models, dynamic food-web models, and bioenergetic or net rate of energy intake models. In this report, we explore the use of stock-recruitment models to estimate population capacity. We apply quantile regression to stock-recruitment models to estimate habitat capacity and compare those results to a habitat model, the quantile regression forest model.

Population Capacity

To estimate population capacity, we evaluated the fit of three different stock-recruitment models to Chiwawa and Wenatchee River spring Chinook data: Ricker, Beverton-Holt, and smooth hockey stick models. In using these models, we assume:

- *Density-dependent mortality*—For some time period before recruitment, the brood instantaneous mortality rate is proportional to the number of parent spawners (Ricker 1954).
- *Lognormal variation*—At any particular spawning stock size, the variation in recruitment is log-normally distributed about its average, and acts multiplicatively (Quinn and Deriso 1999).
- *Measurement error*—Error in spawning stock size estimates (measurement error) is small relative to the range of spawning stock sizes observed (Hilborn and Walters 1992). Variation in realized recruitment at any particular spawning stock size (process error) dominates recruitment measurement error.
- *Stationarity*—The average stock-recruitment relationship is constant over time (Hilborn and Walters 1992). That is, environmental conditions randomly affect survival independent of stock size or time.

In general, the methods we used to fit the models to the data followed those outlined in Hilborn and Walters (1992) and Froese (2008). The Ricker model, which assumes that the number of recruits increases to a maximum and then declines as the number of spawners increases, takes the form:

$$\boldsymbol{E(R) = \alpha S e^{-\beta S}}$$

where E(R) is the expected recruitment, S is spawner abundance, α is the number of recruits per spawner at low spawning levels, and β describes how quickly the recruits per spawner drop as the number of spawners increases. We estimated population capacity (K) as:

$$\boldsymbol{K = \left(\frac{\alpha}{\beta}\right) e^{-1}}$$

and the number of spawners (SP) needed to produce the maximum number of recruits as:

$$SP = \frac{\mathbf{1}}{\boldsymbol{\beta}}$$

The Beverton-Holt model assumes that the number of recruits increases constantly toward an asymptote as the number of spawners increases. After the asymptote is reached, the number of recruits neither increases nor decreases. The asymptote represents the maximum number of recruits the system can support (i.e., population capacity for the system; K). The Beverton-Holt curve takes the form:

$$\boldsymbol{E(R) = \frac{(\alpha S)}{(\beta + S)}}$$

where E(R) and S are as above, α is the maximum number of recruits produced (i.e., α = K), and β is the number of spawners needed to produce (on average) recruits equal to one-half the maximum number of recruits. The number of spawners needed to produce the maximum number of recruits is ∞ in the Beverton-Holt model.

Like the Beverton-Holt model, the smooth hockey stick model assumes that the number of recruits increases toward an asymptote (population capacity; K) as the number of spawners increases. After the carrying capacity is reached, the number of recruits neither increases nor decreases. The carrying capacity represents the maximum equilibrium number of recruits the system can support. This curve takes the form (Froese 2008):

$$\boldsymbol{E(R) = R_{\infty}\left(1 - e^{-\left(\frac{\alpha}{R\infty}\right)S}\right)}$$

where E(R) and S are as above, α is the slope at the origin of the spawner-recruitment curve, and R_{∞} is the carrying capacity of recruits (i.e., $R_{\infty} = K$). There is no direct estimate of SP in the smooth hockey stick model. Therefore, we estimated SP as the number of spawners needed to produce 0.95(K).

We used non-linear regression to fit the three models to spawner-recruitment data. Before fitting the models, we transformed recruitment data using natural logs. We estimated bias and uncertainty measures (95% CI) for the model parameters using bootstrap procedures, which assumed that the {R, S} sample represented or approximated the population. The number of bootstrap samples was 3,000. We computed and stored the non-linear regression results for each bootstrap sample. We then calculated the bootstrap 95% CI by arranging the 3,000 bootstrap parameter values in sorted order and selected the 2.5 and 97.5 percentiles from the list.

We used Akaike's Information Criterion for small sample size (AIC_c) to determine which model(s) best explained the relationship between spawners and recruitment in the supplemented and reference populations. AIC_c was estimated as:

$$\boldsymbol{AIC_c = -2log\big(\pounds(\theta|data)\big) + 2K + \left(\frac{2K(K+1)}{n-K-1}\right)}$$

where *log(£(θ|data))* is the maximum likelihood estimate, *K* is the number of estimable parameters (structural parameters plus the residual variance parameter), and *n* is the sample size (Burnham and Anderson 2002). We used least-squares methods to estimate *log(£(θ|data))*, which was calculated as $log(\sigma^2)$, where σ^2 = residual sum of squares divided by the sample size ($\sigma^2 = RSS/n$). AIC_c assessed model fit in relation to model complexity (number of parameters). The model with the smallest AIC_c value represented the "best approximating" model within the model set. Remaining models were ranked relative to the best model using AIC_c difference scores (ΔAIC_c), Akaike weights (w_i), and evidence ratios. Models with ΔAIC_c values less than 2 indicated that there is substantial support for these models as being the best-fitting models within the set (Burnham and Anderson 2002). Models with values greater than 2 had less support. Akaike weights are probabilities estimating the strength of the evidence supporting a particular model as being the best model within the model set. Models with small w_i values are less plausible as competing models (Burnham and Anderson 2002). If no single model could be specified as the best model, a "best subset" of competing models was identified using (1) AIC_c differences to indicate the level of empirical support each model had as being the best model, (2) evidence ratios based on Akaike weights to indicate the relative probability that any model is the best model, and (3) coefficients of determination (R^2) assessing the explanatory power of each model.

<u>Chiwawa River Spring Chinook Parr</u>

We successfully fit the three stock-recruitment curves to the Chiwawa spring Chinook parr data (Figure 2).

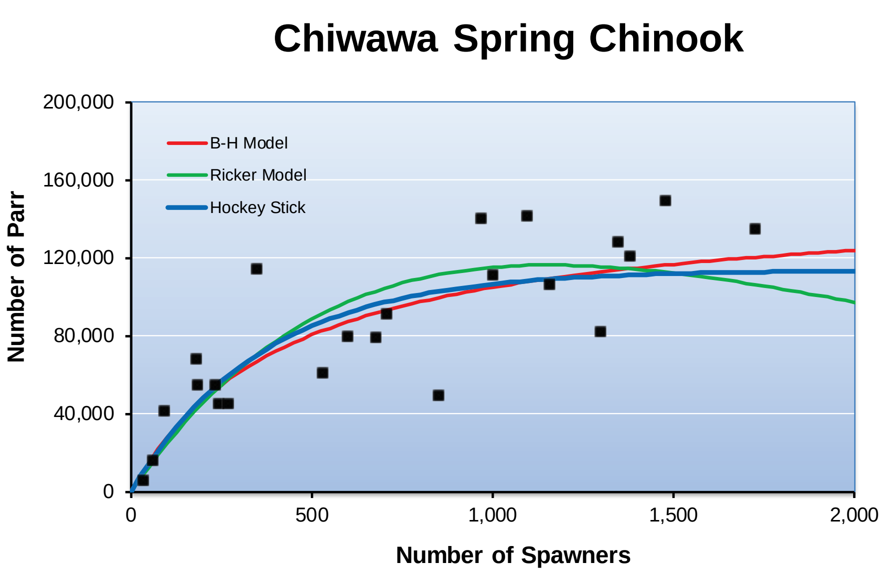

Figure 2. Relationship between numbers of spring Chinook parr and numbers of spawners in the Chiwawa River watershed, 1992-2016 (no sampling occurred in 2000). Figure shows the fit of the Beverton-Holt, Ricker, and smooth hockey stick models to the data.

For summer parr, the use of AIC_c indicated that the Beverton-Holt model best approximated the information in the productivity data. The estimated structural parameters for this model were:

$$Parr = \frac{(150{,}902 \times Spawners)}{(438 + Spawners)}$$

where the bootstrap estimated standard errors for the two parameters were 21,142 and 145, respectively. The adjusted $R^2 = 0.812$.

The second-best model was the smooth hockey stick model, which was 0.245 AIC_c units from the best model. The estimated parameters for this model were:

$$LN(Parr) = 11.6 + LN\left(1 - e^{-\left(\frac{312.9}{113{,}801}\right)Spawners}\right)$$

where the bootstrap estimated standard errors of the two parameters were 0.097 and 57.578, respectively, and the $R^2 = 0.810$.

The AIC_c difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for both the Beverton-Holt and smooth hockey stick models. There was less support for the Ricker model, which was > 2 AIC_c units from the best models. This was further supported by the fact that, relative to the best models, the Ricker model had an evidence ratio greater than 3.

Depending on the stock-recruitment model used, population capacity ranged from 113,801 to 150,902 parr (Table 3). The Beverton-Holt model estimated the highest capacity, while the smooth hockey stick model estimated the lowest. The number of spawners needed to produce the population capacity of parr ranged from 1,089 to 1,163 (Table 3).

Table 3. Estimates of Beverton-Holt, smooth hockey stick, and Ricker model parameters, parr capacity (K), parr productivity (parr per spawner), and the number of spawners needed to produce the maximum number of parr for Chiwawa River spring Chinook.

Model	Parameter		Population capacity (K)	Intrinsic productivity	Spawners
	A	B			
Beverton-Holt	150,902.145	437.655	150,902	345	∞
Smooth Hockey Stick	11.642	312.913	113,801	313	1,089
Ricker	272.696	0.0009	116,650	273	1,163

It is important to note that the population capacity estimates are based on the number of parr counted in the Chiwawa River watershed during August. There are spring Chinook fry and parr that move out of the Chiwawa River watershed during spring and early summer (Hillman et al. 2017). It is unknown if these fish leave because of density-dependent pressures, they are flushed out during high flows, it is a life-history characteristic, or a combination of these. Regardless of the mechanism or reason, some of these fish may survive and rear in the Wenatchee or Columbia rivers. These emigrants are not included in the capacity estimates shown in Table 3.

The capacity estimates for spring Chinook parr apply only to the Chiwawa River watershed, a watershed within the Wenatchee River basin. Estimating parr capacity for the entire Wenatchee River basin using stock-recruitment models is difficult because there is no long-term time series of parr data for the entire basin. However, we can extrapolate parr capacity estimates from the

Chiwawa River watershed to the entire Wenatchee River basin using intrinsic potential (IP). Multiplying the parr capacity per intrinsic potential within the Chiwawa River watershed by the total intrinsic potential within the Wenatchee River basin yields an estimate of parr capacity for the Wenatchee River basin (Table 4). The Interior Columbia Basin Technical Recovery Team estimated IP based on wetted width, valley width (confinement), and gradient (see Cooney and Holzer 2006). They used sedimentation and temperature to refine IP for each 200-m long reach. We used the total stream area (km^2) weighted by intrinsic potential and temperature limited to extrapolate parr capacity to the entire Wenatchee River basin.

Table 4. Estimates of Wenatchee River basin parr capacity based on intrinsic potential (IP). The amount of IP within the Chiwawa River watershed is 0.481 km^2; the total amount of IP within the Wenatchee River basin is 1.798 km^2.

Model	Chiwawa parr capacity	Chiwawa parr/IP	Wenatchee parr capacity
Beverton-Holt	150,902	313,726	564,079
Smooth Hockey Stick	113,801	236,593	425,395
Ricker	116,650	242,516	436,043

Using this simple method, we estimate the Wenatchee River basin supports about 425,395-564,079 parr depending on which model is used. An important assumption of this simple method is that each unit of IP supports the same number of parr. This is clearly not true given that the quality of habitat within each unit of IP can vary greatly. That is, one unit of IP may contain more habitat structure (e.g., wood and cover) than another unit of IP. Importantly, the ratio of parr to IP comes from the Chiwawa River watershed, which contains some of the highest quality habitat within the Wenatchee River basin. Therefore, the estimated total parr capacity for the entire Wenatchee River basin is likely biased high. If habitat conditions throughout the Wenatchee River basin are enhanced to conditions similar to those in the Chiwawa River watershed, we may expect parr abundance to approach those estimated with this simple method.

Chiwawa River Spring Chinook Smolts

We successfully fit the three stock-recruitment curves to the Chiwawa spring Chinook smolt data (Figure 3).

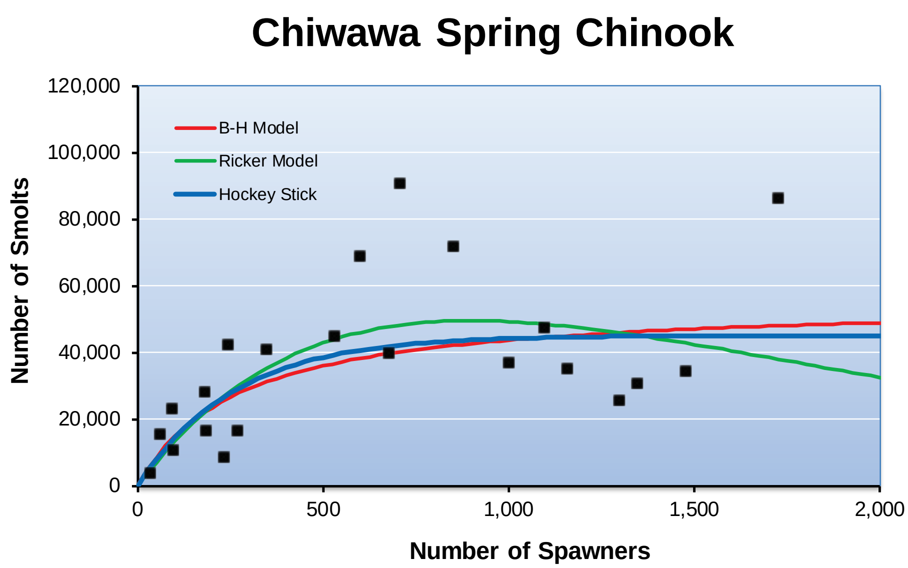

Figure 3. Relationship between numbers of spring Chinook smolts and numbers of spawners in the Chiwawa River watershed, 1992-2015. Figure shows the fit of the Beverton-Holt, Ricker, and smooth hockey stick models to the data.

For yearling smolts produced entirely within the Chiwawa River watershed, the use of AIC_c indicated that the smooth hockey stick model best approximated the information in the productivity data. The estimated structural parameters for this model were:

$$LN(Smolts) = 10.7 + LN\left(1 - e^{-\left(\frac{174.1}{45,161}\right)Spawners}\right)$$

where the bootstrap estimated standard errors for the two parameters were 0.13 and 41.29, respectively. The adjusted $R^2 = 0.569$.

The second-best model was the Ricker model, which was 0.234 AIC_c units from the best model. The estimated parameters for this model were:

$$Smolts = 149.45 \times Spawners(\mathrm{e}^{-0.00111 \times Spawners})$$

where the bootstrap estimated standard errors of the two parameters were 26.23 and 0.00018, respectively, and the $R^2 = 0.573$.

The third-best model was the Beverton-Holt model, which was 0.725 AIC_c units from the best model. The estimated parameters for this model were:

$$Smolts = \frac{(55,702 \times Spawners)}{(273 + Spawners)}$$

where the bootstrap estimated standard errors of the two parameters were 10,421.9 and 123.0, respectively, and the $R^2 = 0.560$.

The AIC_c difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for all three models. Relative to the best model, the other two models had evidence ratios less than 1.5.

Depending on the stock-recruitment model used, population capacity ranged from 45,161 to 55,702 smolts (Table 5). The Beverton-Holt model estimated the highest capacity, while the smooth hockey stick model estimated the lowest. The number of spawners needed to produce the population capacity of smolts ranged from 777 to 901 (Table 5).

Table 5. Estimates of Beverton-Holt, smooth hockey stick, and Ricker model parameters, smolt capacity (K), smolt productivity (smolts per spawner), and the number of spawners needed to produce the maximum number of smolts for Chiwawa River spring Chinook.

Model	Parameter		Population capacity (K)	Intrinsic productivity	Spawners
	A	B			
Smooth hockey stick	10.718	174.077	45,161	174	777
Ricker	149.452	0.00111	49,532	149	901
Beverton-Holt	55,702.281	273.910	55,702	203	∞

It is important to note that the population capacity estimates are based on the number of smolts produced entirely within the Chiwawa River watershed. As noted earlier, there are spring Chinook fry and parr that move out of the Chiwawa River watershed during spring, early summer, and fall (Hillman et al. 2017). Fall emigration is common and occurs even when densities of juveniles are very low, indicating that fall emigration is a life-history characteristic. Regardless of why the fish emigrate as fry and parr, some of these fish survive and rear in the Wenatchee or Columbia rivers. Some survive to smolt (unpublished WDFW data), but are not included in the smolt capacity estimates shown in Table 5.

As with parr, the capacity estimates for spring Chinook smolts apply only to the Chiwawa River watershed. As before, we can extrapolate smolt capacity estimates from the Chiwawa River watershed to the entire Wenatchee River basin using intrinsic potential (IP). In this case, we multiply the smolt capacity per intrinsic potential within the Chiwawa River watershed by the total intrinsic potential within the Wenatchee River basin. This yields an estimate of smolt capacity for the Wenatchee River basin (Table 6).

Table 6. Estimates of Wenatchee River basin smolt capacity based on intrinsic potential (IP). The amount of IP within the Chiwawa River watershed is 0.481 km^2; the total amount of IP within the Wenatchee River basin is 1.798 km^2.

Model	Chiwawa smolt capacity	Chiwawa smolts/IP	Wenatchee smolt capacity
Beverton-Holt	55,702	115,805	208,218
Smooth Hockey Stick	45,161	93,891	168,816
Ricker	49,532	102,976	185,152

Using this simple method, we estimate the population capacity for the Wenatchee River basin at 168,816-208,218 smolts depending on which model is used. Based on smolt trapping in the lower Wenatchee River over a 13-year period, total smolt abundance has ranged from 36,752 to 302,116 smolts (average = 107,300 smolts) (Table 2).[14] Thus, recent (2000-2014) smolt production appears to be below capacity estimates for most years but higher in some years.

An important assumption of this simple method is that each unit of IP supports the same number of smolts. As we noted earlier, this is not the case given that the quality of habitat within each unit of IP can vary greatly. Nevertheless, the ratio of smolts to IP comes from the Chiwawa River watershed, which contains some of the highest quality habitat within the Wenatchee River basin. Therefore, the estimated total smolt capacity for the entire Wenatchee River basin is likely biased high. If habitat conditions throughout the Wenatchee River basin are enhanced to conditions similar to those in the Chiwawa River watershed, we may expect smolt abundance to approach those estimated with this simple method.

Wenatchee River Spring Chinook Smolts

Rather than extrapolate results from the Chiwawa River watershed to the entire Wenatchee River basin, we can fit stock-recruitment models to the smolt data collected in the lower Wenatchee River and estimate population capacity directly from the population models. We successfully fit the three stock-recruitment curves to the Chiwawa spring Chinook smolt data; although, the models explained little of the variation in the stock-recruitment data ($R^2 < 0.05$) (Figure 3).

[14] It is important to point out that the trapping location has changed over time. During the period 2000-2008 and 2011-2012, the trap was located near the Town of Monitor. During the period 2013-present, the trap was located near the Town of Cashmere.

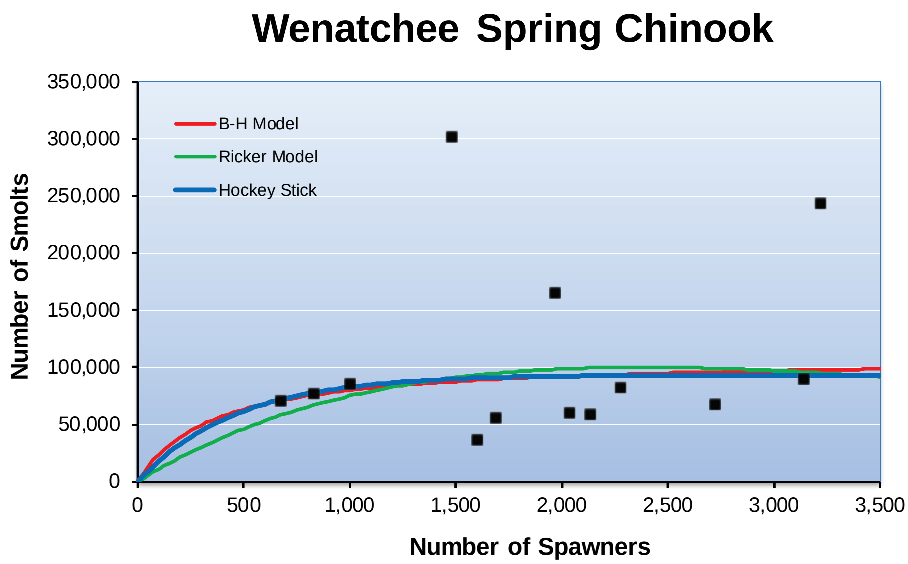

Figure 4. Relationship between numbers of spring Chinook smolts and numbers of spawners in the Wenatchee River basin, 2000-2014 (no data were collected in 2009 or 2010). Figure shows the fit of the Beverton-Holt, Ricker, and smooth hockey stick models to the data.

For yearling smolts produced within the Wenatchee River basin, the use of AIC_c indicated that the Beverton-Holt model best approximated the information in the productivity data. The estimated structural parameters for this model were:

$$Smolts = \frac{(108{,}696 \times Spawners)}{(359 + Spawners)}$$

where the bootstrap estimated standard errors for the two parameters were 49,948 and 836, respectively. The adjusted $R^2 = 0.026$.

The second-best model was the smooth hockey stick model, which was 0.112 AIC_c units from the best model. The estimated parameters for this model were:

$$LN(Smolts) = 11.4 + LN\left(1 - e^{-\left(\frac{20.72}{93{,}560}\right)Spawners}\right)$$

where the bootstrap estimated standard errors of the two parameters were 30.74 and 225.43, respectively, and the $R^2 = 0.017$.

The third-best model was the Ricker model, which was 0.0.808 AIC_c units from the best model. The estimated parameters for this model were:

$$Smolts = 114.10 \times Spawners(\mathrm{e}^{-0.00042 \times Spawners})$$

where the bootstrap estimated standard errors of the two parameters were 56.16 and 0.00021, respectively, and the $R^2 = 0.001$.

The AIC_c difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for all three models. Relative to the best model, the other two models had evidence ratios less than 2.0.

Depending on the stock-recruitment model used, population capacity for the Wenatchee River basin ranged from 93,560 to 108,696 smolts (Table 7). The Beverton-Holt model estimated the highest capacity, while the smooth hockey stick model estimated the lowest. The number of spawners needed to produce the population capacity of smolts ranged from 1,389-2,381 (Table 7).

Table 7. Estimates of Beverton-Holt, smooth hockey stick, and Ricker model parameters, smolt capacity (K), smolt productivity (smolts per spawner), and the number of spawners needed to produce the maximum number of smolts for Wenatchee River spring Chinook.

Model	Parameter		Population capacity (K)	Intrinsic productivity	Spawners
	A	B			
Smooth hockey stick	11.446	201.724	93,560	202	1,389
Ricker	114.104	0.00042	99,944	114	2,381
Beverton-Holt	108,696.009	358.616	108,696	303	∞

The population capacity estimates reported here are based on the number of smolts produced within the Wenatchee River basin. It is likely that some juvenile spring Chinook rear in the Columbia River and survive to smolt. Those fish are not included in these estimates of capacity.

Habitat Capacity

Habitat capacity can be estimated using fish-habitat models and creative modeling of stock-recruitment data. As we noted earlier, there are several different fish-habitat models that can be used to estimate habitat capacity. In this paper, we explore the use of two different methods, quantile regression applied to stock-recruitment functions and the Quantile Regression Random Forest model. The former relies on simple stock and recruitment data, while the latter requires estimates of habitat quality and quantity, and functional relationships between maximum fish density and habitat conditions.

Quantile Regression Analysis of Stock-Recruitment Data

To estimate population capacity, we used non-linear regression techniques to fit stock-recruitment functions to the data. These techniques approximate the conditional mean of the recruitment data given the range of stock sizes. As such, the functions (curves) estimated from the analyses lie near the center of the distribution of data resulting in data points above and below the curve. Although this technique is useful for estimating population capacity, it is not appropriate for estimating habitat capacity. The fact that there are actual recruitment data above the estimated population capacity indicates that habitat capacity must be greater than the population capacity, or that measurement error is high. The former explanation is more likely than the latter.

One way to possibly estimate habitat capacity with stock-recruitment data is to fit stock-recruitment functions to the juvenile spring Chinook data using quantile regression techniques. Quantile regression estimates quantiles of the recruitment data given the range of stock sizes. Thus,

we can use quantile regression to fit a stock-recruitment function to, say, the upper 90% or 95% of the recruitment distribution. In other words, we fit a stock-recruitment function to the upper limits of the recruitment data given the range of stock sizes. In this case, the resulting stock-recruitment curve is above most of the recruitment data and therefore few data points lie above the curve. Calculation of capacity from these functions should more closely represent habitat capacity, provided there is an adequate range of stock sizes. Quantile regression gives results similar to those obtained from calculating reference intervals (RI).

In this exercise, we calculated the upper 90% RI for the Beverton-Holt and Ricker functions. We assume the 90% RI will closely represent the habitat capacity for juvenile spring Chinook. We calculated the 90% RI only for the Beverton-Holt and Ricker models, because these functions can be transformed into linear function (see Hilborn and Walters 1992). RIs are easier to calculate on linear functions than non-linear functions. We were unable to transform the smooth hockey stick model into a linear function and therefore we did not calculate RIs for this function.

Chiwawa River Spring Chinook Parr—We calculated 90% RIs for Chiwawa Chinook parr data for both the Ricker and Beverton-Holt models (Figure 5). The estimated parameters for the 90% RI for the Ricker model were:

$$\log\left(\frac{Parr}{Spawners}\right) = 6.152 - \frac{6.152}{5{,}984.436}(Spawners)$$

This resulted in an estimated habitat capacity of 168,071 parr, which is about 1.4 times greater than the population capacity estimated with the Ricker model.

The estimated parameters for the 90% RI for the Beverton-Holt model were:

$$\frac{Spawners}{Parr} = \frac{196.91}{181{,}818} + \frac{1}{181{,}818}(Spawners)$$

This function resulted in an estimated habitat capacity of 181,818 parr, which was about 1.2 times greater than the population capacity estimated with the Beverton-Holt model.

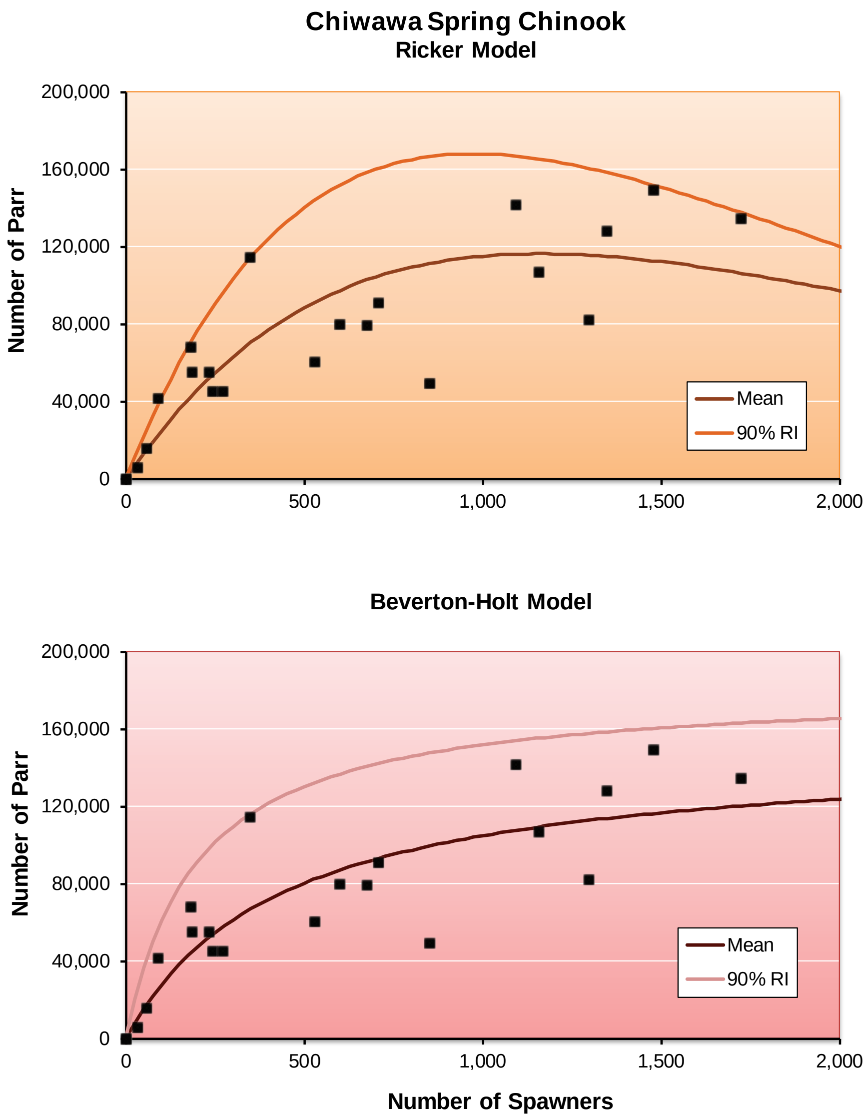

Figure 5. Relationship between numbers of spring Chinook parr and numbers of spawners in the Chiwawa River watershed, 1992-2016. Upper figure shows the fit of the Ricker model and its 90% reference interval to the data; lower figure shows the fit of the Beverton-Holt model and its 90% reference interval.

If we extrapolate the habitat capacity estimates for Chiwawa spring Chinook parr to the entire Wenatchee River basin (using the IP method described earlier), we estimate the habitat capacity for the Wenatchee River basin to be 628,256 parr from the Ricker model and 679,645 parr from the Beverton-Holt model.

Chiwawa River Spring Chinook Smolts—As with parr, we calculated 90% RIs for Chiwawa Chinook smolt data for both the Ricker and Beverton-Holt models (Figure 6). The estimated parameters for the 90% RI for the Ricker model were:

$$\log\left(\frac{Smolts}{Spawners}\right) = 5.687 - \frac{5.687}{4{,}687.964}(Spawners)$$

This resulted in an estimated habitat capacity of 89,425 smolts, which is about 1.8 times greater than the population capacity estimated with the Ricker model.

The estimated parameters for the 90% RI for the Beverton-Holt model were:

$$\frac{Spawners}{Smolts} = \frac{102.129}{64{,}516} + \frac{1}{64{,}516}(Spawners)$$

This function resulted in an estimated habitat capacity of 64,516 smolts, which was about 1.2 times greater than the population capacity estimated with the Beverton-Holt model.

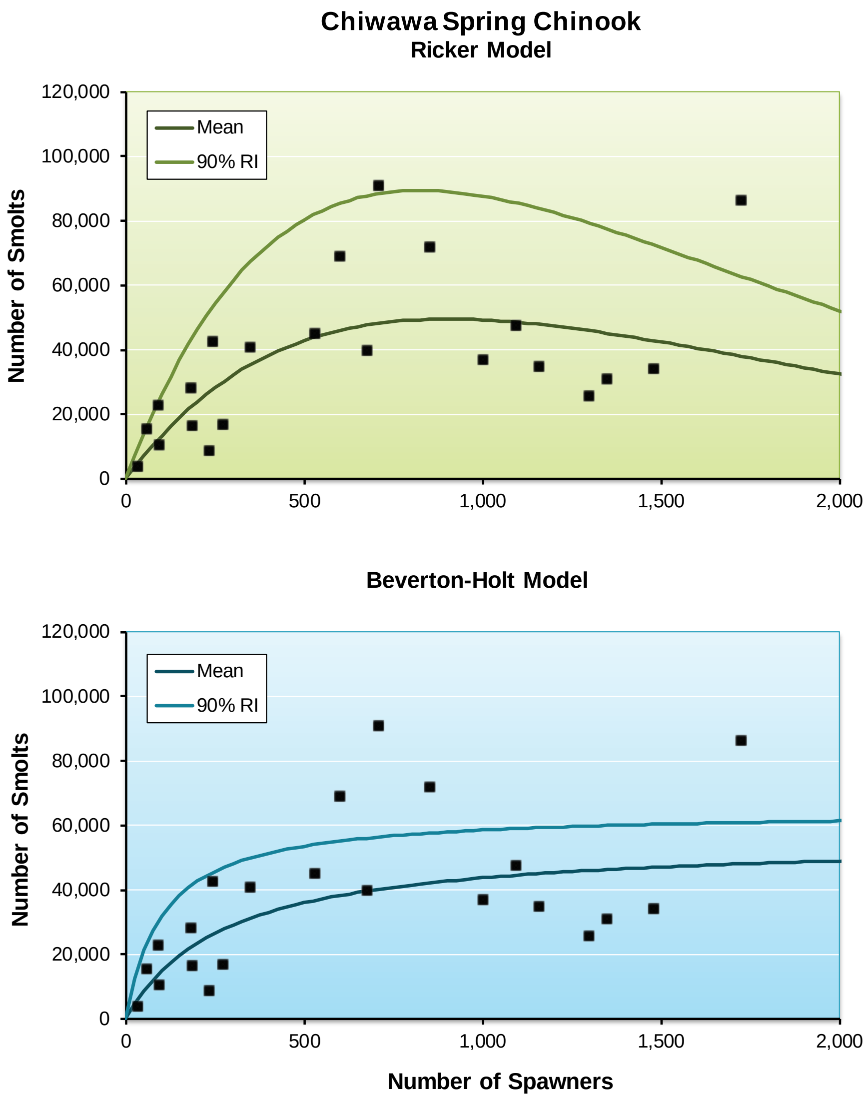

Figure 6. Relationship between numbers of spring Chinook smolts and numbers of spawners in the Chiwawa River watershed, 1992-2015. Upper figure shows the fit of the Ricker model and its 90% reference interval to the data; lower figure shows the fit of the Beverton-Holt model and its 90% reference interval.

If we extrapolate the habitat capacity estimates for Chiwawa spring Chinook smolts to the entire Wenatchee River basin (using the IP method described earlier), we estimate the habitat capacity

for the Wenatchee River basin to be 334,276 smolts based on the Ricker model and 241,164 smolts from the Beverton-Holt model.

Wenatchee River Spring Chinook Smolts—We calculated 90% RIs for Wenatchee River Chinook smolt data for both the Ricker and Beverton-Holt models (Figure 7). The estimated parameters for the 90% RI for the Ricker model were:

$$\log\left(\frac{Smolts}{Spawners}\right) = 5.320 - \frac{5.320}{16{,}642.420}(Spawners)$$

This resulted in an estimated habitat capacity of 235,131 smolts, which is about 2.4 times greater than the population capacity estimated with the Ricker model.

The estimated parameters for the 90% RI for the Beverton-Holt model were:

$$\frac{Spawners}{Smolts} = \frac{357.593}{186{,}567} + \frac{1}{186{,}567}(Spawners)$$

This function resulted in an estimated habitat capacity of 186,567 smolts, which was about 1.7 times greater than the population capacity estimated with the Beverton-Holt model.

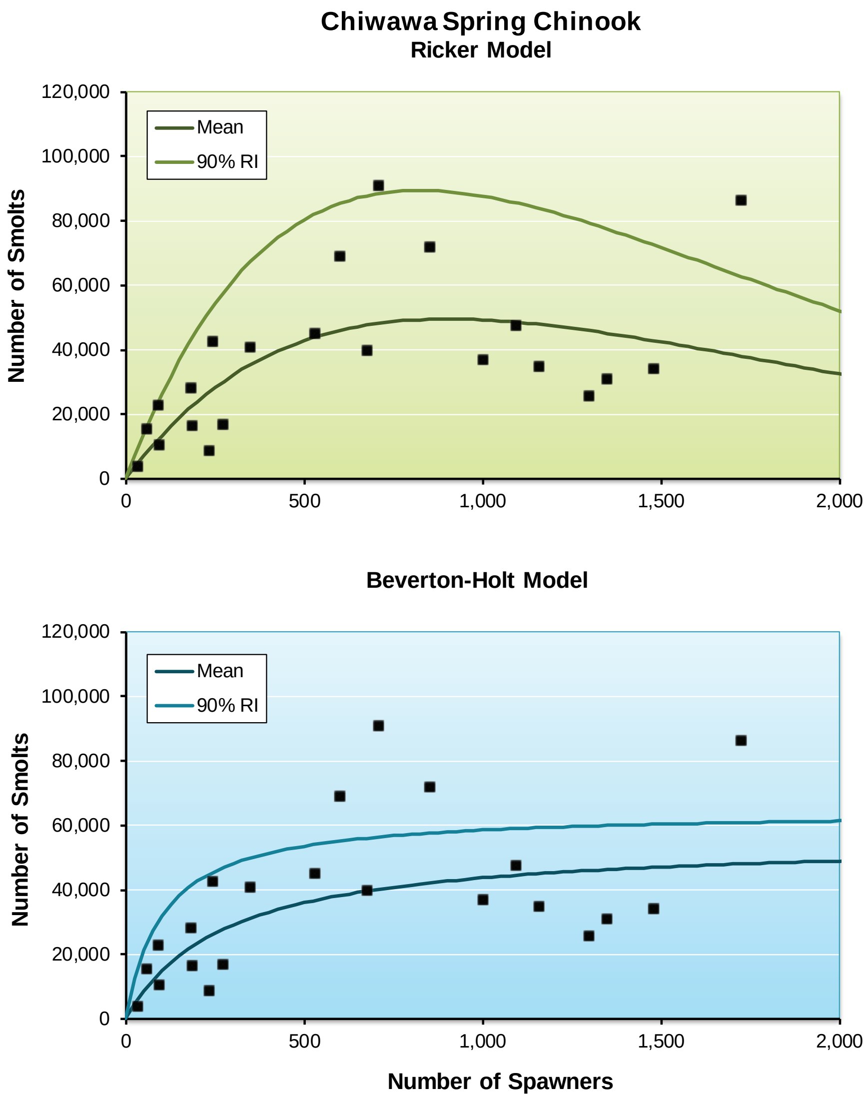

Figure 7. Relationship between numbers of spring Chinook smolts and numbers of spawners in the Wenatchee River basin, 2000-2015 (no data were collected in 2009 or 2010). Upper figure shows the fit of the Ricker model and its 90% reference interval to the data; lower figure shows the fit of the Beverton-Holt model and its 90% reference interval.

Quantile Regression Random Forest Model

Researchers with the Integrated Status and Effectiveness Monitoring Program (ISEMP) developed a model that estimates Chinook parr habitat capacity based on fish-habitat relationships (ISEMP/CHaMP 2015). Based on extensive sampling throughout the Columbia River basin, these researchers developed relationships between maximum densities of Chinook parr (summer estimates) and various habitat variables. Quantile regression forest (QRF) models use these relationships to estimate carrying capacities for juvenile Chinook. Very simply, QRF analysis develops non-linear relationships between fish density and different habitat variables. In this case, however, QRF analysis predicts the 90% quantile of fish density rather than the mean or median density. The researchers assume that the 90% quantile represents habitat capacity. This is important because the numbers of fish counted in some field sampling sites may not have been at maximum capacity. That is, it is likely that not all sites sampled were fully "seeded" with Chinook salmon. Thus, using the mean or median (50% quantile) would not represent habitat capacity, but some level below habitat capacity.

Researchers fit the QRF model to parr density data and 12 habitat variables that were collected from 227 sites within the distribution of Chinook throughout the Columbia River basin (within CHaMP/ISEMP watersheds). These variables were selected to represent a variety of types of habitat variables (e.g., substrate, riparian, complexity, temperature, etc.), contain the most "fish information," and be as uncorrelated as possible (ISEMP/CHaMP 2015). The 12 habitat variables and their relative importance are shown in Figure 8.

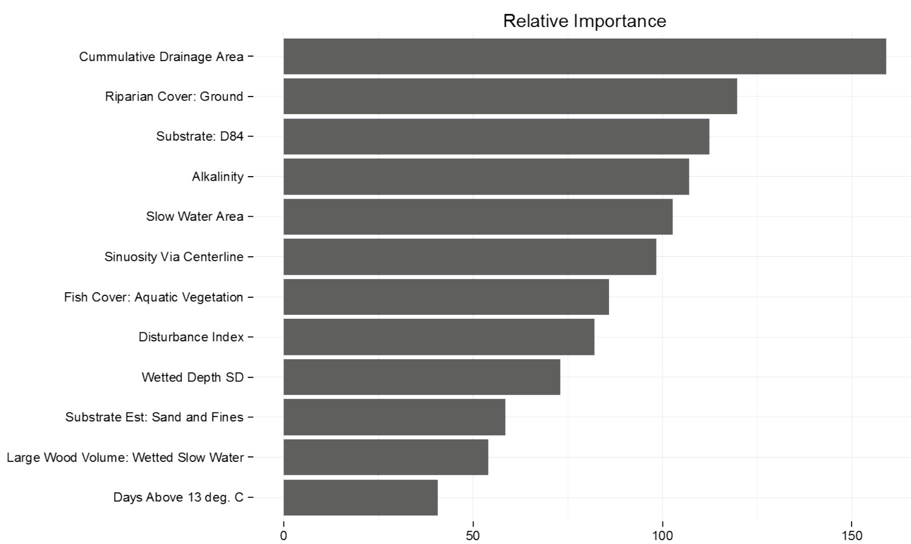

Figure 8. Relative importance of habitat variables included in juvenile Chinook salmon quantile regression forest models (Figure is from ISEMP/CHaMP 2015).

As a way of testing the model, ISEMP researchers used their QRF model to estimate Chinook parr capacities in different watersheds, including the Chiwawa River watershed, and compared their

estimates to those generated from fish population data using stock-recruitment modeling. Figure 9 shows the relationship between the QRF model results and population model results for the Chiwawa River watershed. The red curve was generated using the QRF model and the blue curve was generated using the Beverton-Holt model. At the time of this analysis, the Beverton-Holt model was fit to 21 years of parr data, not the 24 years of data used in the analyses above.

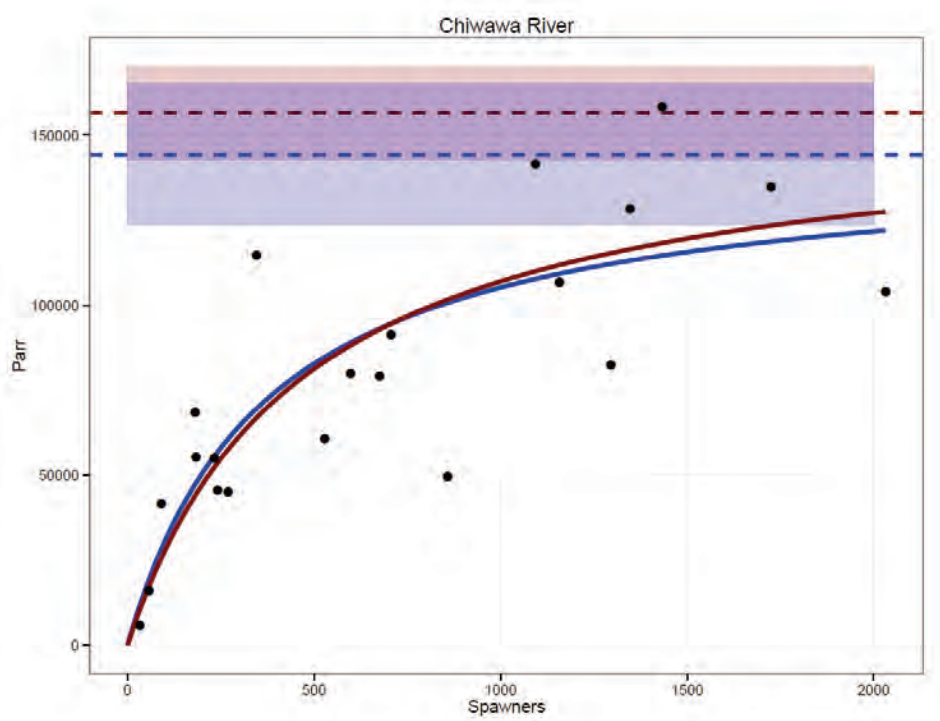

Figure 9. Comparison of productivity curves for Chiwawa spring Chinook parr generated from the QRF model (red line) and Beverton-Holt model (blue line). Dashed horizontal lines represent carrying capacity estimates. Shading about the capacity estimates represent the 95% confidence bounds. Figure is from ISEMP/CHaMP (2015).

The comparison shows that although the curves are very similar, the carrying capacity estimates (dashed horizontal lines) differed, with the habitat capacity generated from the QRF model being larger than the population capacity generated from the population data. That is, the QRF model estimated a habitat capacity of about 164,000 spring Chinook parr, while the population model estimated a population capacity of about 145,000 parr. Including more recent parr data in the Beverton-Holt model indicates that the population capacity estimate is about 151,000 parr for the Chiwawa River watershed. The 90% RI for the Beverton-Holt model estimated a habitat capacity of about 182,000, which is 1.1 times greater than the estimate from the QRF model. Note that the 90% RI for the Ricker model estimated a habitat capacity of about 168,000, which is close to the QRF model estimate.

Comparing Results

We estimated capacities for both spring Chinook parr and smolts for the Chiwawa River watershed and the entire Wenatchee River basin using different analytical tools. In this section, we compare the results from the different approaches.

Parr Capacity

Depending on the population model used, population capacity estimates for the Chiwawa River watershed ranged from 113,801 to 150,902 parr (Table 8). Not surprisingly, the Beverton-Holt model generally predicts the highest capacity estimates, while the smooth hockey stick model predicts the lowest. As expected, the population capacity estimates for Chiwawa parr were less than the habitat capacity estimates for parr. Habitat capacity estimates were about 1.2 to 1.5 times greater than the population capacity estimates (Table 8). Importantly, the fish-habitat model (QRF model) calculated a habitat capacity estimate that was close to that estimated from calculating 90% RI for the population models. Extrapolating Chiwawa capacity estimates to the entire Wenatchee River basin resulted in population capacities of 425,395 to 564,079 parr and habitat capacity estimates of 613,040 to 679,645 parr (Table 8).

Table 8. Comparison of spring Chinook parr capacity estimates for the Chiwawa River watershed and the Wenatchee River basin. Population capacities were estimated directly from the stock-recruitment functions; habitat capacities were estimated by calculating 90% reference intervals (using quantile regression; QR) for the stock-recruitment models and using a fish-habitat model (Quantile Regression Forest Model; QRF). Capacities for the Wenatchee River basin were estimated by extrapolating Chiwawa capacities using intrinsic potential.

Capacity type	Model	Chiwawa parr capacity	Wenatchee parr capacity
Population capacity	Beverton-Holt	150,902	564,079
	Smooth Hockey Stick	113,801	425,395
	Ricker	116,650	436,043
Habitat capacity	QR Beverton-Holt	181,818	679,645
	QR Ricker	168,071	628,256
	QRF Model	164,000	613,040

The number of spawners needed to achieve parr capacity also varied depending on the population model used (Table 9). For the Chiwawa River watershed, maximum spawners needed to achieve population capacity for parr ranged from 1,089 to 1,163 adults. Extrapolating Chiwawa results to the entire Wenatchee River basin resulted in maximum spawner estimates of 4,070 to 4,347 adults. We were able to estimate habitat capacity only with the Ricker model (Table 9). Using quantile regression to calculate the 90% RI for the Ricker model resulted in a maximum spawner abundance of 973 adults, which is less than the number needed to achieve population capacity. This is because the 90% RI for the Ricker function estimates a higher intrinsic productivity, which shifts the "hump" of the curve to the left resulting in a higher capacity estimate but a lower maximum spawner estimate (see Figure 5).

Table 9. Comparison of the number of spawners needed to achieve parr capacities in the Chiwawa River watershed and the Wenatchee River basin. For the Chiwawa River watershed, maximum spawners were estimated directly from the stock-recruitment functions. Maximum spawners for the entire Wenatchee River basin were estimated as the product of the extrapolated parr numbers times the ratio of maximum spawners to parr capacity for Chiwawa spring Chinook. Because of the nature of the Beverton-Holt model, no maximum spawners can be calculated from that model.

Capacity type	Model	Spawners need to achieve parr capacity	
		Chiwawa	Wenatchee
Population capacity	Smooth Hockey Stick	1,089	4,070
	Ricker	1,163	4,347
Habitat capacity	QR Ricker	973	3,636

Smolt Capacity

As with parr estimates, population capacity estimates for smolts varied depending on the population model used. For Chiwawa spring Chinook smolts, population capacities ranged from 45,161 to 55,702 smolts, with the smooth hockey stick providing the lowest estimate and the Beverton-Holt model providing the highest (Table 10). The population capacity estimates were about 55 to 86% of the habitat capacity estimates. Extrapolating Chiwawa capacity estimates to the entire Wenatchee River basin resulted in population capacities of 168,816 to 208,218 smolts and habitat capacity estimates of 241,164 to 334,276 smolts (Table 10). These were greater than those estimated using smolt and spawner data for the entire Wenatchee River basin. Fitting population models to smolt and spawner data for the entire basin resulted in population capacities of 93,560 to 108,696 smolts and habitat capacities of 186,567 to 235,131 smolts (Table 10).

Table 10. Comparison of spring Chinook smolt capacity estimates for the Chiwawa River watershed and the Wenatchee River basin. Population capacities were estimated directly from the stock-recruitment functions; habitat capacities were estimated by calculating 90% reference intervals (using quantile regression; QR) for the stock-recruitment models. Capacities for the Wenatchee River basin were estimated by extrapolating Chiwawa capacities using intrinsic potential and by fitting population models to the smolt and spawner data for the entire basin.

Capacity type	Model	Chiwawa smolt capacity	Wenatchee smolt capacity	
			Chiwawa extrapolation	Wenatchee data
Population capacity	Beverton-Holt	55,702	208,218	108,696
	Smooth Hockey Stick	45,161	168,816	93,560
	Ricker	49,532	185,152	99,944
Habitat capacity	QR Beverton-Holt	64,516	241,164	186,567
	QR Ricker	89,425	334,276	235,131

The number of spawners needed to achieve smolt capacity varied depending on the population model used (Table 11). For the Chiwawa River watershed, maximum spawners needed to achieve

population capacity for smolts ranged from 777 to 901 adults. Note that the maximum number of adults needed to achieve population capacity for smolts is less than those needed to achieve population capacity for parr. Extrapolating Chiwawa results to the entire Wenatchee River basin resulted in maximum spawner estimates of 2,904 to 3,368 adults. These estimates are considerably higher than those estimated from fitting population models to Wenatchee River basin data. The latter estimated maximum spawners ranging from 1,389 to 2,381 adults. We were able to estimate habitat capacity only with the Ricker model (Table 11). Using quantile regression to calculate the 90% RI for the Ricker model resulted in a maximum spawner abundance of 824 adults for the Chiwawa River watershed and 3,129 adults for the entire Wenatchee River basin. Extrapolating Chiwawa results to the entire Wenatchee River basin resulted in a maximum spawner estimate of 3,080, which is close to the estimate generated by fitting the model to Wenatchee River basin data.

Table 11. Comparison of the number of spawners needed to achieve smolt capacities in the Chiwawa River watershed and the Wenatchee River basin. Maximum spawners were estimated directly from the stock-recruitment functions. Maximum spawners for the entire Wenatchee River basin were also estimated as the product of the extrapolated smolt numbers times the ratio of maximum spawners to smolt capacity for Chiwawa spring Chinook. Because of the nature of the Beverton-Holt model, no maximum spawners can be calculated from that model.

Capacity type	Model	Spawners need to achieve smolt capacity		
		Chiwawa	Wenatchee	
			Chiwawa extrapolation	Wenatchee data
Population capacity	Smooth Hockey Stick	777	2,904	1,389
	Ricker	901	3,368	2,381
Habitat capacity	QR Ricker	824	3,080	3,129

As an additional exercise, we calculated smolt capacities and maximum spawners generated from fitting population models to smolt and spawner data in the Chiwawa River, Nason Creek, and White River watersheds, and compared the sum of those estimates to the Wenatchee River basin estimates. Only the Ricker model could be fit to the White River and Nason Creek data (see Hillman et al. 2017). Estimated population capacities from the Ricker model were 49,532 smolts in the Chiwawa, 4,412 smolts in Nason Creek, and 4,659 smolts in the White River, resulting in a cumulative population capacity of 58,603 smolts (1,550 spawners are needed to achieve this cumulative smolt capacity). The cumulative population capacity estimate is nearly 60% of the total population capacity calculated from fitting the Ricker model to the entire Wenatchee River basin data. If these estimates are correct, this means that about 40% of the current Wenatchee River basin smolt capacity is outside the Chiwawa River, Nason Creek, and White River watersheds. Hillman et al. (2017) report that over the period 1989 to 2016, on average, 76% of spring Chinook spawning occurs in the three watersheds. Thus, a large percentage of smolt capacity is generated outside the major spawning areas. We believe this highlights the importance of the mainstem Wenatchee River as a rearing area for juvenile spring Chinook.

Recommendations

Based on the simple analyses conducted in this report, we offer the following recommendations:

1. Where sufficient stock and recruitment data are available, and the data have sufficient contrast, then use population (stock-recruitment) modeling as the primary method to calculate population capacity and the number of spawners needed to achieve capacity for each spawning aggregate or population of interest. Select the best fitting stock-recruitment model based upon AIC_c, unless other factors suggest otherwise, such as evidence for a biological mechanism. A biological mechanism supporting a Ricker function, for example, would be that there is a stock-dependent effect on the mortality of eggs and juveniles (i.e., mortality is proportional to the initial cohort size). When AIC_c values are not appreciably different, then select the model that is most useful (e.g., Ricker and smooth hockey stick models are easier to work with than the Beverton-Holt model).
2. Adult-to-adult data are the most relevant because they account for all life stages and delayed effects in freshwater (e.g., small size at migration), but they are also the most variable (i.e., low R^2). Therefore, adult-to-juvenile data (e.g., parr, yearling smolts, total migrants) are likely the most useful for determining freshwater population capacity. Where data are available, pre-spawn adult to spawning adult survival can also be assessed using population models to evaluate density dependence and pre-spawn adult capacity.
3. The population models used to estimate population capacity should also be used in reference streams so one can make comparisons of carrying capacities and density-corrected productivities. Unless there are good reasons for selecting a different juvenile life-stage, the default should be to use yearling smolts because they represent the capacity of the tributaries to produce yearlings and it is also a clear identification and quantification of a migrant life-stage.
4. In the absence of fish-habitat models, quantile regression can be used to estimate habitat capacity by calculating reference intervals for the population models. The percentage of the reference interval should be set using the error in the estimation of the recruits and the level of desire to exclude anomalous data. For example, if the 95% confidence interval is approximately 10% of the recruitment estimate, then the reference interval should be set at 90% (e.g., RI = 100% - C.I.%).
5. Where sufficiency conditions in (1) are not met, use habitat-based expansion of density at capacity for the most ecologically similar population. For example, use Twisp capacity estimates for habitat-based expansions in the Methow. The habitat expansion metric should be "total stream area weighted by intrinsic potential and temperature limited," unless there are good reasons for a different expansion. The primary idea is to exclude areas that are known to not produce fish because of passage, temperature, or other limitations.
6. Capacity estimates should be described within the context of the information that was used to derive estimates. For example, spawner distribution of hatchery-origin fish could influence estimates of capacity if they are within poor habitat. However, the capacity estimates do reflect the historic and current hatchery practices. It is unknown how the capacity estimates would change if a different hatchery program that produced different spawning distributions was to be implemented. However, if those data do become available, then capacity estimates can be revised. Similarly, significant enhancements (e.g.,

improved passage) or degradations (e.g., fire) in habitat can also change capacity and can be incorporated into future estimates of capacity.

7. Regardless of the method used to estimate capacity, always describe the limitations of the data and assumptions of the models. Note where assumptions are violated and how these violations could affect the results of the analysis.

APPENDIX 2: HATCHERY REPLACEMENT RATES

Based on ideas developed by the HETT, in February 2016, the HCP Hatchery Committees and PRCC Hatchery Subcommittee agreed to the following rules and HRR targets:

1. Use the estimated 40% HRR Target during 5-year statistical evaluation periods.
2. Use varying degrees of action depending on the numbers of years that annual HRR deviates from Target.
   a. Green Light (below Target for ≤ 2 years).
   b. Red Light (below Target for > 2 years).
3. Each program will have its own HRR target with the following exceptions.
   a. Nason Creek spring Chinook will use the Chiwawa Target (there are currently no data to calculate a target for Nason Creek spring Chinook).
   b. Methow and Chewuch spring Chinook will use the greater of their two Targets (they are MetComp stock and evaluated similarly).

Table 1. Release numbers and 5-year hatchery replacement rates (HRR) targets for Upper Columbia River Hatchery Programs.

Species	Owner	Program (Hatchery)	Basin (Purpose)	Smolts released[1]	5-Year HRR[2]
Steelhead	CPUD	Eastbank (Chiwawa)	Wenatchee (Conservation)	123,650	6.9

[3] Harvest not included.

APPENDIX 3: PNI and pHOS Targets and Sliding Scales

Select CPUD, DPUD, and GPUD funded hatchery mitigation programs have PNI management targets, while others do not. Table 1 summarizes management strategies by species and population. Detailed information can be found in the sections that follow. Descriptions provided in the following sections are taken directly from HGMPs and/or issued and draft permits.

Table 1. Summary of management strategies by species and population.

Species	Population	Management Strategy	Comments
Spring Chinook	Wenatchee	Sliding Scale of PNI management	Details can be found in Section 2.0
	Methow	Two—population sliding scale PNI management	Details can be found in Section 3.0
	Okanogan	None Currently	Details can be found in Section 4.0
Steelhead	Wenatchee	Two-zone management.	Details can be found in 5.0
	Methow	In-development	Details forthcoming; Section 6.0
	Okanogan	None Currently	Details can be found in Section 7.0
Summer Chinook	Wenatchee	None Currently	Details can be found in Section 9.0
	Methow	None Currently	Details can be found in Section 10.0
	Okanogan	0.67; pHOS 0.30	Details can be found in Section 11.0
	Upper Columbia River	None Currently	Details can be found in Section 12.0
Fall Chinook	Hanford Reach	0.67	Details can be found in Section 13.0

2.0 Wenatchee Spring Chinook

Wenatchee spring Chinook will be managed according to the sliding scale identified in the Wenatchee Spring Chinook Management Plan (2010) and Permit Numbers 18118 and 18121. The sliding scale is based upon the estimated number of natural origin spring Chinook over Tumwater Dam. As more information becomes available the sliding scale may be adjusted as a result of gaining a better understanding of the pre-spawn mortality rate and carrying capacity.

Table 2. Sliding scale of PNI goals based on natural origin spring Chinook run size expected to the Wenatchee River basin. Percentiles are based on adult returns observed between 1999 and 2008.

Percentile	NOR Run Size				PNI
	Chiwawa	Nason Creek	White	Wenatchee River (above TWD)	
>75th	>372	>350	>87	>910	≥ 0.80
50% - 75%	278-372	259-349	68-86	631-909	≥ 0.67
25% - 50%	209-277	176-258	41-67	525-630	≥ 0.50
10%-25%	176-208	80-175	20-40	400-524	≥ 0.40

<10th	<175	<80	<20	<400	Any PNI

3.0 Methow/ Chewuch Spring Chinook

The following sliding scale (Table 3) is presented in the April 14, 2016 draft Methow Hatchery Spring Chinook Section 10-Draft. It is anticipated that no further changes will be made to the sliding scale prior to issuance of the final permits.

Table 3. PUD PNI sliding scale calculations for a range of natural run sizes.

Natural Origin Returns	PUD pHOS	WNFH pHOS	PUD pNOB	2-Pop PNI	PUD PNI (equation)
<300	Ensure minimum of 500 total spawners				
300	0.40	0.2	0.75	0.67	0.67
500	0.40	0.2	0.80	0.68	0.76
900	0.30	0.15	1.00	0.78	0.80
1500	0.25	0.1	1.00	0.8	0.80
2000	0.25	0.1	1.00	0.8	0.80
2500	0.25	0.1	1.00	0.8	0.80

4.0 Okanogan Spring Chinook

The Okanogan spring Chinook program is a re-introduction effort implemented as a non-essential experimental population under ESA Section 10j to re-introduce spring Chinook into the Okanogan River. As a non-essential experimental population targeting re-introduction and establishment of a local population of spring Chinook, the Okanogan spring Chinook program will not conduct adult management actions to reduce the proportion of 10j hatchery fish on the spawning grounds or conduct broodstocking efforts in the Okanogan for a 10-year period (2014 – 2023), as such, no PNI or pHOS objectives have been identified for this program in this 10-year period.

CJH Program segregated production released into the mainstem Columbia River are non-listed Leavenworth stock released reared/acclimated/released at CJH. Although no PNI or pHOS targets are identified for the Okanogan 10j population, minimizing strays from the CJH segregated spring Chinook program is a program objective, as such, returning segregated program fish will be subject to directed harvest and aggressive adult surplusing at CJH to minimize straying to the Okanogan River Basin as well as other extant upper Columbia River spring Chinook populations. Stray targets for the segregated program are 5% or less stray rate (i.e. spawning contribution to other upper Columbia River spring Chinook populations).

5.0 Wenatchee Steelhead

Interim escapement goal for Wenatchee River steelhead will be 1,500 spawners with an additional goal of attaining an average PNI of 0.67 for the Wenatchee River basin population as a whole. To achieve the stated goal, the Wenatchee steelhead program will use a two-zone management approach wherein the upper basin (above TWD) will be managed for recovery using an integrated recovery program, a separate spawning escapement goal, and a PNI standard to achieve the overall basin goal of an average PNI over time of 0.67 (Table 4). Areas below TWD will be managed to minimize hatchery supplementation with a pHOS goal of < 0.10.

Steelhead returning upstream of TWD will be managed as an integrated recovery program with a pNOB goal of 1.0. The above TWD escapement goal will be 1,094 spawners. Working within this framework, pNOB will be maximized above TWD while pHOS will be minimized.

Table 4. Wenatchee steelhead two-zone management and PNI targets.

Location	Run Escapement Goal	pNOB Conservation Program	pNOB Safety Net Program	pHOS	PNI
Above TWD	1,094	1.0	0.0	Varies	Varies
Below TWD	406	N/A	N/A	< 0.10	< 0.67
Basin Total	1,500	N/A	N/A	Minimal	Average = 0.67

6.0 Methow Steelhead

Methow steelhead PNI targets are currently in development.

7.0 Okanogan Steelhead

Current program has no PNI goal. CTCR submitted an Okanogan steelhead HGMP to NOAA Fisheries on February 4, 2014. Within the HGMP provisions were included to allow a greater collection of natural-origin broodstock and multiple adult management strategies to address over-escapement of hatchery-origin steelhead to the spawning grounds. The HGMP also identified a near-term (1-4 years) and a long-term PNI objectives of 0.50 and > 0.67, respectively. Once NOAA has completed the consultation and issued a new permit, providing the opportunity to increase the proportion of natural-origin fish in the broodstock and additional adult management strategies, the program will adopt the PNI objectives and this Appendix can be amended accordingly.

8.0 Wells Columbia Mainstem Safety-net Steelhead

The Safety-Net Mainstem Columbia component released below Wells Dam will be managed primarily at the Wells Hatchery volunteer channel. The objective of the adult management of the Safety-Net Mainstem Columbia component is to prevent runs of this component from moving into natural spawning areas. This will be accomplished through in-river harvest and removal of volunteers at the Wells Hatchery outfall. There are no PNI goals for this component.

9.0 Wenatchee Summer Chinook

No PNI goals are established.

10.0 Methow Summer Chinook

No PNI goals are established.

11.0 Okanogan Summer Chinook

Okanogan summer/fall Chinook will be managed to achieve a 5-year rolling average PNI of 0.67 and pHOS of 0.30. Strategies to achieve that PNI target include up to 100% pNOB, aggressive removal of hatchery-origin Chinook in selective fisheries, at the Okanogan weir, and during surplusing at CJH ladder. Reduction in the number of juveniles released in the Okanogan River Basin (integrated program) is also a management option, should adult management actions be unable to control the proportion of hatchery fish on the spawning grounds to achieve that PNI target.

CJH segregated summer/fall Chinook program rears/acclimates/releases smolts into the mainstem Columbia River at CJH. Broodstock are 100% hatchery-origin, as such no PNI target for this production component. Stray rate (i.e. contribution to upper Columbia summer/fall Chinook populations) is 5% or less. Adult management on returning adults from the segregated program include fisheries, removal at the Okanogan weir, and removal at the CJH ladder.

12.0 Upper Columbia Summer Chinook (Chelan Falls and Wells)

No PNI goals are established. Chelan Falls and Wells FH summer Chinook programs are segregated harvest programs designed to provide opportunity for harvest. Adult returns are not intended to spawn naturally; therefore, there is no escapement goal for natural spawning areas. Adult returns will be managed to meet program objectives. Chelan Falls and Wells Hatchery summer Chinook are available for harvest in the ocean and Columbia River commercial, tribal, and recreational fisheries.

13.0 Priest Rapids Fall Chinook

The Hanford Reach fall Chinook population is intentionally supplemented by Grant PUD at the Priest Rapids Hatchery and the ACOE at the Priest Rapids and Ringold Springs hatcheries. Managers desire to achieve a population level PNI that includes all hatchery programs of $\geq$0.67. Grant PUD and the HSC do not have control over operation or expansion of the ACOE program and therefore will strive to operate the Priest Rapids Hatchery fall Chinook program in a way that does its fair share of achieving a population level PNI of 0.67.

APPENDIX 4: SPATIAL DISTRIBUTION OF SPAWNERS OR REDDS

Strategies for conservation programs typically intend that hatchery and naturally produced fish spawn together and in similar locations. However, in some cases, strategies may differ from this paradigm. In Table 1, conservation programs that have a spatial distribution management plan that deviates from similar to the natural spawning spatial distributions are presented. Otherwise, conservation programs are intended to have a spawning distribution similar to the natural origin spawning spatial distributions, as described by M&E Objective 5.3.

Table 1. Management targets for the spatial distribution of hatchery-origin redds for conservation programs that deviate from Objective 5.3.

Program	Target	Rational	Source
Carlton Summer Chinook	The observed spawning distribution of hatchery origin Methow summer Chinook from 2005-2010 represents the base-line spawner distribution for evaluating the performance of the hatchery program (i.e., M&E plan check-ins). It is acknowledged that this distribution is lower in the River than the spawning distribution of natural origin summer Chinook salmon.	Based upon an assessment of summer Chinook and ESA-listed spring Chinook abundance and spawner distribution, it was determined that an increase in summer Chinook spawning abundance in the upper most range of natural origin summer Chinook distribution or potentially above the current range may pose an unknown and potentially adverse impact to ESA listed spring Chinook. Due to the concern for spring Chinook, the HSC has endorsed an acclimation site in the Methow Basin that is lower in the basin than may be required to attain exact replication of natural and hatchery origin summer Chinook spawner distribution.	SOA 2011-02 Priest Rapids Coordinating Committee Hatchery Subcommittee Statement of Agreement on Monitoring & Evaluation (M&E) Objective for Spawning Distribution of Hatchery-Origin Summer Chinook
Dryden Summer Chinook	The observed spawning distribution of hatchery origin Wenatchee summer Chinook from 2008-2013 (previous 5 years to the current M&E check-in cycle) represents the base-line spawner distribution for evaluating the performance of the	The primary site endorsed by the HSC for Grant PUD overwinter acclimation of summer Chinook is the Dryden Pond, and is the current acclimation and release site for the existing summer Chinook supplementation program	Adapted from SOA 2011-02 Priest Rapids Coordinating Committee Hatchery Subcommittee Statement of Agreement on Monitoring & Evaluation (M&E) Objective for Spawning Distribution of Hatchery-Origin Summer Chinook

	hatchery program (i.e., M&E plan check-ins).	funded and owned by Chelan PUD. Because current data indicates that spawning distribution of hatchery summer Chinook from the existing program is lower in the Wenatchee River than natural origin spawners, expectations are that acclimation of Grant PUD's summer Chinook at Dryden Pond would continue to return hatchery origin summer Chinook that result in different spawning distributions for hatchery and natural summer Chinook.	

APPENDIX 5: WITHIN HATCHERY REARING TARGETS

Rearing Targets for Upper Columbia River Hatchery Programs. K-factor or fork length targets will be determined based on data from the pending "Five-Year Report."

Table 1. Numbers, fish per pound (fpp), coefficient of variation (CV), and condition factor (K) targets at release of Upper Columbia River Hatchery Programs.

Hatchery	Species	Life Stage	Basin	Release number	FPP	CV	K-factor

Priest	Fall Chinook	Subyearling	Columbia	7.3 M[8]	50	<10	TBD
Ringold	Fall Chinook	Subyearling	Columbia	3.5 M	50	<10	TBD

[1] The total release includes the release of 108,249 into the Methow River at the Methow Fish Hatchery, 25,000 into the Methow River at the Goat Wall site, and 60,516 into the Chewuch River at the Chewuch Acclimation Facility.

[2] These fish come from Winthrop National Fish Hatchery (MetComp) eyed eggs.

[3] The total release includes 125,000 conservation fish and 98,670 safety net fish.

[4] The combined Okanogan and Omak steelhead release number is 100,000.

[5] The total release includes 66,771 fish into Nason Creek, 53,170 into the Chiwawa River, 102,359 into the Wenatchee River, and 25,000 into Blackbird Pond.

[6] The Wells subyearling Chinook are not reared to achieve a specific size target. The fish are released on a date to optimize survival and are grown to the largest size possible before release.

[7] The total release is divided equally among the Omak, Riverside, and Similkameen Acclimation Ponds.

[8] The total release consists of 5.6 m fall Chinook for the Grant PUD program and 1.7 M fall Chinook for the Army Corps of Engineers program.

APPENDIX 6: IDENTIFYING AND ANALYZING REFERENCE POPULATIONS

An important goal of supplementation is to increase spawning abundance and natural-origin recruitment of the supplemented population, and not reduce the productivity of the supplemented population. Indeed, a successful supplementation program must increase spawning abundance and natural-origin recruitment to levels above those that would have occurred without supplementation. There are several methods that can be used to test the effects of supplementation programs on these population metrics. One important method is to compare the performance of population metrics (e.g., spawning abundance, natural-origin recruitment, and productivity) in the supplemented population to those in un-supplemented (reference) populations. By comparing supplemented populations to reference populations, one can determine if the supplementation programs benefit, harm, or have no effect on the supplemented populations. These comparisons, however, are only valid if the performance of the reference populations is similar to the performance of the supplemented population prior to the period of supplementation. If the performance of the two populations differs significantly before any supplementation occurs, then any results from comparing the two populations after supplementation will be suspect. It is therefore important to select reference populations that are as similar as possible to the supplemented populations.

One of the goals of the Conceptual Approach to Monitoring and Evaluating the Chelan County PUD Hatchery Programs (Murdoch and Peven 2005) is to use reference populations to analyze the potential effects of hatchery supplementation programs on natural-origin salmon and steelhead spawner abundance and productivity[15]. Murdoch and Peven (2005) identified specific objectives to evaluate the performance of the program. For example, Objective 1 determines if the supplementation programs have increased the number of naturally spawning and naturally produced adults of the target population (supplemented population) relative to a reference population. Objective 7 determines if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity (e.g., number of juveniles per redd) of supplemented streams when compared to reference streams. The relevant questions tested under each objective are as follows:

Objective 1:

- Is the annual change in the number of natural-origin recruits produced from the supplemented populations greater than or equal to the annual change in natural-origin recruits in an un-supplemented population?
- Is the change in natural replacement rates within the supplemented population greater than or equal to the change in natural replacement rates in an un-supplemented population?

Objective 7:

[15] Productivity is defined as adult recruits per spawner, where recruits are the number of adults produced from a given brood year (i.e., spawners plus adults harvested).

- Is the change in numbers of juveniles (smolts, parr, or emigrants) per redd in the supplemented population greater than or equal to that in an un-supplemented population?[16]

In this paper, we describe methods used to identify suitable reference streams and statistical techniques that can be used to compare reference populations with supplemented populations. Although we apply the methods described in this paper to Chiwawa spring Chinook salmon (hereafter referred to as Chinook), the methods should also apply to steelhead and other supplemented salmon stocks in the Upper Columbia Basin.

Identification of Reference Populations

Reference populations are an important component of an effectiveness monitoring design because they provide the standard by which treatment conditions are compared (ISRP and ISAB 2005; Murdoch and Peven 2005; Galbreath et al. 2008). Selecting appropriate reference areas and maintaining them over long periods of time is needed to establish the effectiveness of supplementation programs.

We developed a three-step process for identifying suitable reference populations (Figure 1). Each step serves as a filter. That is, potential reference populations are evaluated based on specific criteria under each step. Populations that pass through each step are considered suitable reference populations for a specific supplemented population.

[16] In this paper, we only address adult recruits, not juvenile recruits. This is because we were unable to find suitable reference populations for analysis of juveniles. However, the methods described in this paper would also apply to juveniles.

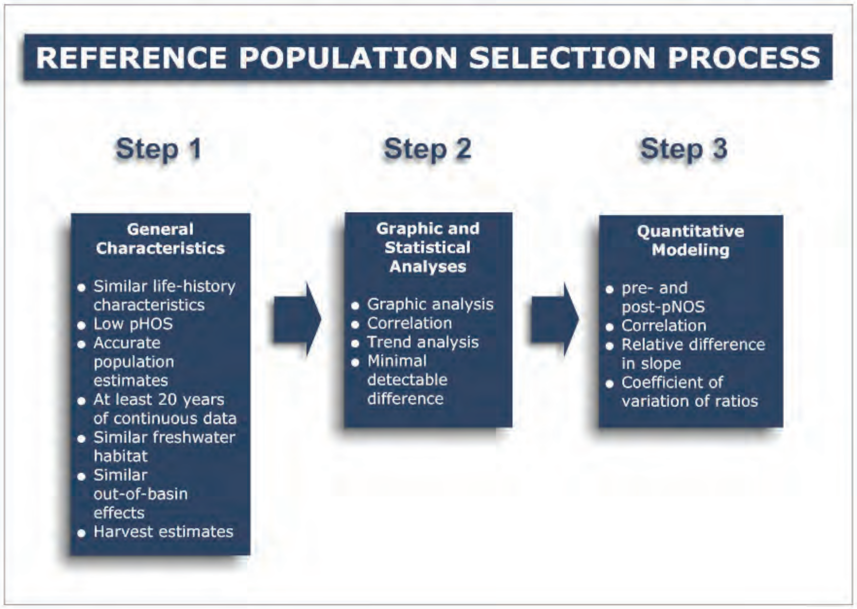

Figure 1. Criteria evaluated during each step in the process of identifying suitable reference populations.

Step 1: General Characteristics

Under step 1, potential reference populations are evaluated based on several general criteria. When compared to the supplemented population, potential reference populations should have:

- Similar life-history characteristics (e.g., run timing, migration characteristics, etc.).
- No or few hatchery fish in the reference area (pHOS < 10%).
- Accurate abundance estimates.
- Long time series of natural-origin abundance and productivity estimates (at least 20 years of continuous data).
- Similar trends in freshwater habitat.
- Similar out-of-basin effects (i.e., similar migration and ocean survivals).
- Harvest estimates for adjusting escapement estimates.

We used these criteria to begin the process of selecting suitable reference populations for the Chiwawa spring Chinook program. We began by identifying stream-type Chinook populations within the Columbia Basin. Galbreath et al. (2008; their Table 1) identified stream-type Chinook populations within the Columbia River Basin that may serve as suitable reference populations for hatchery programs. Supplementing their work with data from the NOAA Fisheries Salmon Population Summary Database, we identified 18 candidate stream-type Chinook populations that may serve as reference populations for the Chiwawa supplementation program (Table 1).

Table 1. Populations of stream-type Chinook salmon and their comparison to Chiwawa spring Chinook.

Population	Similar life-history	No or few hatchery fish	Accurate abundance estimates	Long time series (at least 20 years)	Similar freshwater habitat impairments	Similar out-of-basin effects	Comments
Deschutes River	Yes	Yes	Yes	Yes	No	No	
John Day mainstem	Yes	Yes	Yes	Yes	No	No	
Middle Fk John Day	Yes	Yes	Yes	Yes	No	No	
North Fk John Day	Yes	Yes	Yes	Yes	No	No	
Granite Creek	Yes	Yes	Yes	Yes	No	No	
Wenaha River	Yes	No	Yes	Yes	Yes	No	Hatchery strays (>10%)
Minam River	Yes	No	Yes	Yes	Yes	No	Hatchery strays (>10%)
Slate Creek	Yes	Yes	Yes	No	No	No	
Secesh River	Yes	Yes	Yes	Yes	Yes	No	
Middle Fk Salmon River	Yes	Yes	Yes	No	No	No	Fair productivity est.
Big Creek	Yes	Yes	Yes	Yes	No	No	
Camas Creek	Yes	Yes	Yes	Yes	No	No	Fair productivity est.
Loon Creek	Yes	Yes	Yes	Yes	No	No	Fair productivity est.
Sulphur Creek	Yes	Yes	Yes	Yes	No	No	
Bear Valley Creek	Yes	Yes	Yes	Yes	No	No	
Marsh Creek	Yes	Yes	Yes	Yes	Yes	No	
North Fk Salmon River	Yes	Yes	No	No	Yes	No

East Fk Salmon River	Yes	No	Yes	Yes	No	No	Hatchery strays (>10%)
Valley Creek	Yes	No	Yes	Yes	No	No	Hatchery strays (>10%)
Chamberlain Creek	Yes	Yes	Yes	No	Yes	No	
Naches River	Yes	Yes	Yes	Yes	Yes	No	
Little Wenatchee River	Yes	No	Yes	Yes	Yes	Yes	Hatchery strays (>10%)
Entiat River	Yes	No	Yes	Yes	No	No	Hatchery release ending

We then assessed the accuracy and length of the series of abundance estimates. We assumed that abundance estimates generated from expanded redd counts or adjusted weir counts would compare well with estimates in the Chiwawa Basin, which were based on expanded redd counts. In addition, we looked for populations that had an abundance data series that extended from at least 1981 to present. Based on this analysis, we identified 18 populations with abundance estimates that could be compared to those from the Chiwawa Basin (Table 1).

Next, we determined if the potential reference populations came from watersheds with habitat conditions similar to those in the Chiwawa Basin. For this exercise, we searched recovery plans and draft recovery plans to identify tributary factors that limit Chinook abundance, productivity, and survival within the reference populations. We compared these factors with those limiting

Chinook salmon in the Chiwawa Basin. Based on this analysis, we identified eight populations with habitat impairments similar to those in the Chiwawa Basin (Table 1).

Finally, we examined the potential reference populations to see if they experienced out-of-basin effects similar to spring Chinook from the Chiwawa Basin. In this case, we compared the number of mainstem dams that each potential reference population passes during migration. Six of the potential reference populations pass less than six mainstem dams; the other populations pass eight mainstem dams (Table 1). Only the Little Wenatchee population passes seven dams, similar to the Chiwawa population.

In sum, there were no reference populations that matched the Chiwawa spring Chinook population on all the criteria identified above. Differential out-of-basin effects and freshwater habitat conditions prevented most reference populations from matching with Chiwawa spring Chinook. However, some of the potential reference populations were similar to the Chiwawa population on several criteria and warranted further investigation. We selected the following populations for further investigation: Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River.

We included the Little Wenatchee because it is within the Wenatchee River basin and experiences similar out-of-basin effects and has the same climatic and environmental conditions as the Chiwawa. A confounding effect with the Little Wenatchee is that Chiwawa hatchery fish have strayed into the Little Wenatchee. However, straying of Chiwawa hatchery fish should decrease with the change in source water to the Chiwawa acclimation ponds in 2006. We also included the Entiat River because it is an adjacent basin to the Chiwawa and experiences similar climatic and environmental conditions. The spring Chinook hatchery program that has operated in the Entiat since 1975 has been discontinued. Therefore, this population offers a unique opportunity to compare the Chiwawa population to a population in which the hatchery program has been discontinued.

Step 2: Graphic and Statistical Analysis

Graphic Analysis

Although we were unable to find potential reference populations that matched with the Chiwawa population on all criteria considered under Step 1, spawner abundance, natural-origin recruits (NORs), and productivity of some of the potential reference populations may nevertheless track closely with the Chiwawa population. If the time series of abundance, NORs, and productivity of a potential reference population tracks closely with the abundance, NORs, and productivity of the Chiwawa population, the reference population may provide a reasonable reference condition for testing the effects of supplementation on the Chiwawa population.

Under Step 2, we used graphing techniques to examine the relationship of abundance, NORs, and productivity between the Chiwawa population and the five reference populations (Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River). We compiled spawner abundance, NORs, and productivity data from local biologists and the NOAA Fisheries Salmon Population Summary Database. We then compared time series plots of spawner abundance, NORs, and productivity data of potential reference populations with the Chiwawa population (Figures 2, 3, and 4; plots on the left side of figures). The time series only included the period 1981 to 1992, which represented the period before supplementation of the Chiwawa population (pre-treatment period). We also plotted the relationship between the abundance, NORs, and productivity of each

potential reference population to the Chiwawa population (Figures 2, 3, and 4; plots on right side of figures). These plots show whether the reference populations closely tracked the Chiwawa population. As a point of reference, data points that fall along the dashed line would represent a perfect relationship between the two populations (i.e., both populations have identical abundance, NORs, and productivity estimates). While a perfect relationship between two independent populations is unrealistic, a strong linear relationship between the two populations indicates populations with similar trends.

Based on analysis of spawner abundance, the Naches River time series tracked more closely with the abundance of Chiwawa spring Chinook than did the other potential reference populations. The poor relationship with the other potential reference streams was largely because of the relatively high abundance of Chiwawa spring Chinook during the mid-1980s. As with spawner abundance, analyses of NORs indicated a close relationship between the Naches and Chiwawa populations. The other potential reference populations tracked poorly with the Chiwawa. The analyses of productivity indicated close relationships between potential reference populations and the Chiwawa population. The Naches, Sesech, and Little Wenatchee populations tracked the closest with the Chiwawa population.

When analyzing the potential effects of a supplementation program on fish performance, it is common to transform the data to meet various assumptions of statistical analysis. The most common transformation used to adjust abundance, NORs, and productivity data is the natural logarithm (LN or $\log_e$). We therefore transformed the spawner abundance, NORs, and productivity data using LN and re-plotted the relationships between the potential reference populations and the Chiwawa population (Figures 5, 6, and 7). We added 1 to each observation before taking its logarithm to avoid taking the logarithm of 0, which is undefined (note that the LN of 1 is 0).

By transforming spawner abundance, NORs, and productivity data, most of the potential reference populations tracked more closely with the Chiwawa population. The Naches, Entiat, and Little Wenatchee abundance data tracked the closest with the Chiwawa abundance data (Figure 5). For NORs, Marsh Creek and the Little Wenatchee populations tracked the closest with the Chiwawa (Figure 6). For productivity, the Naches, Sesech, and Little Wenatchee tracked the closest with the Chiwawa (Figure 7).

Attachment E

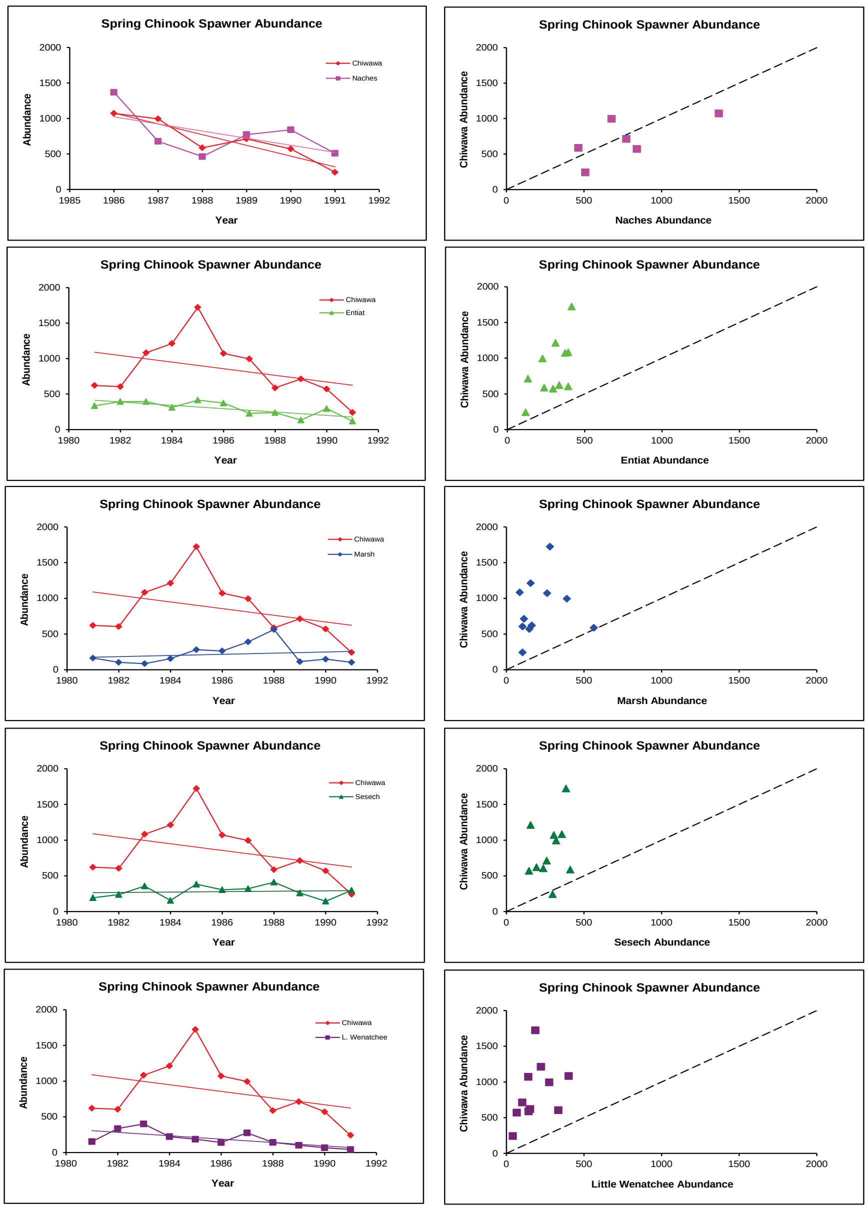

Figure 2. Time series of spawner abundance of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

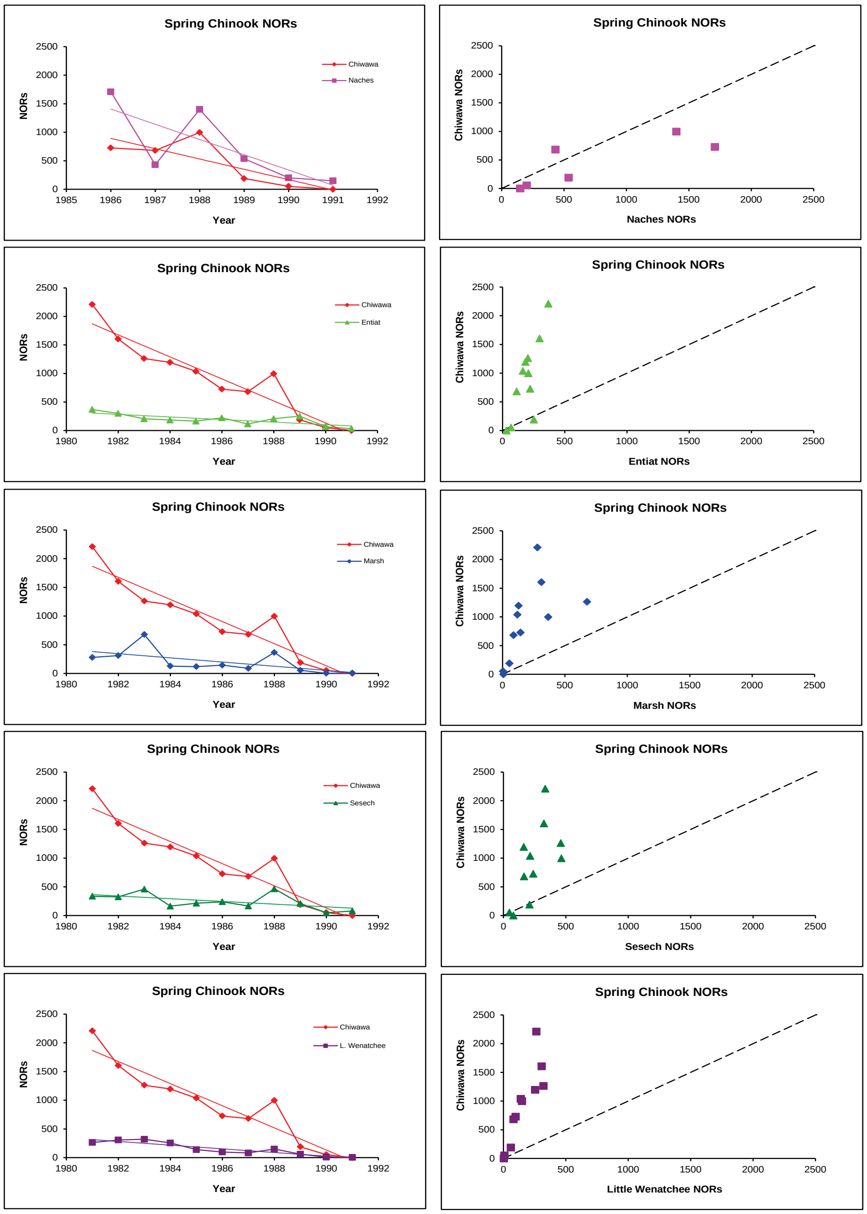

Figure 3. Time series of natural-origin recruits (NORs) of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

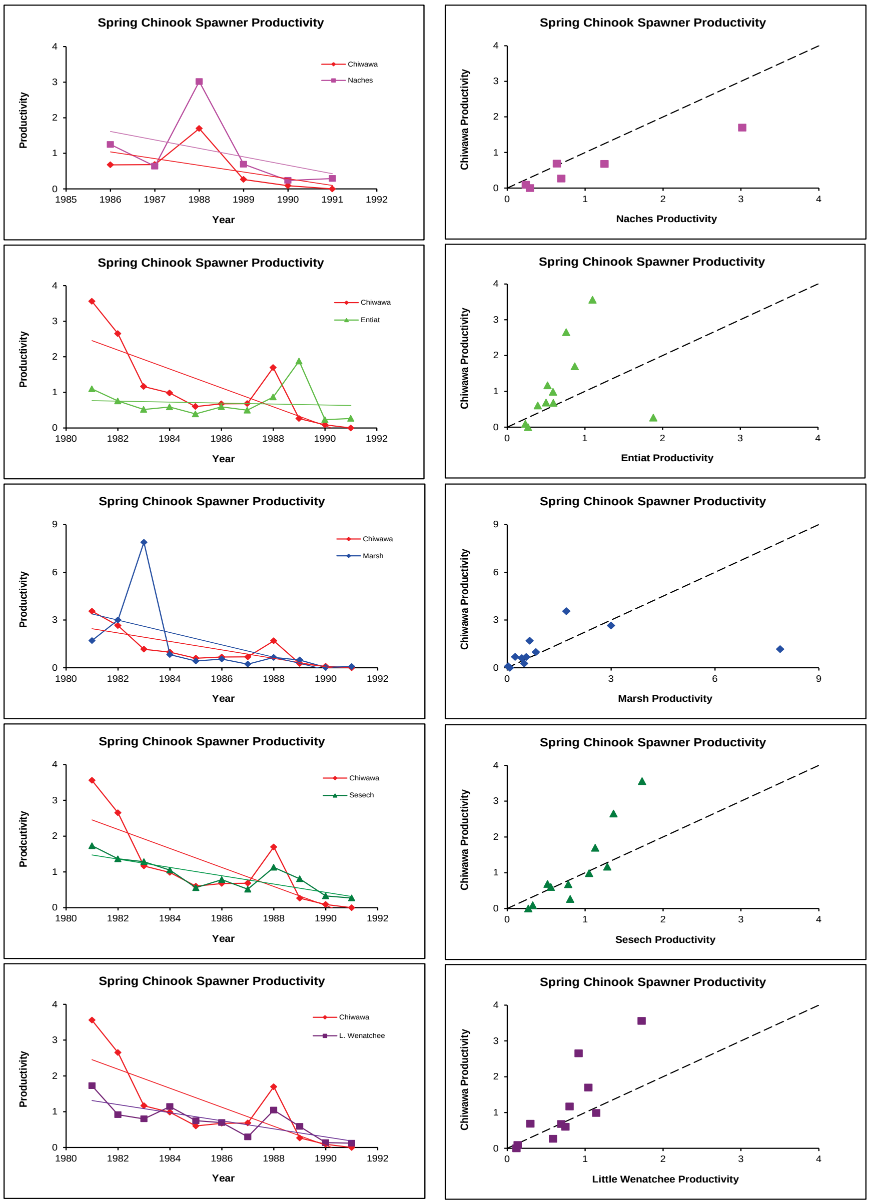

Figure 4. Time series of adult productivity of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

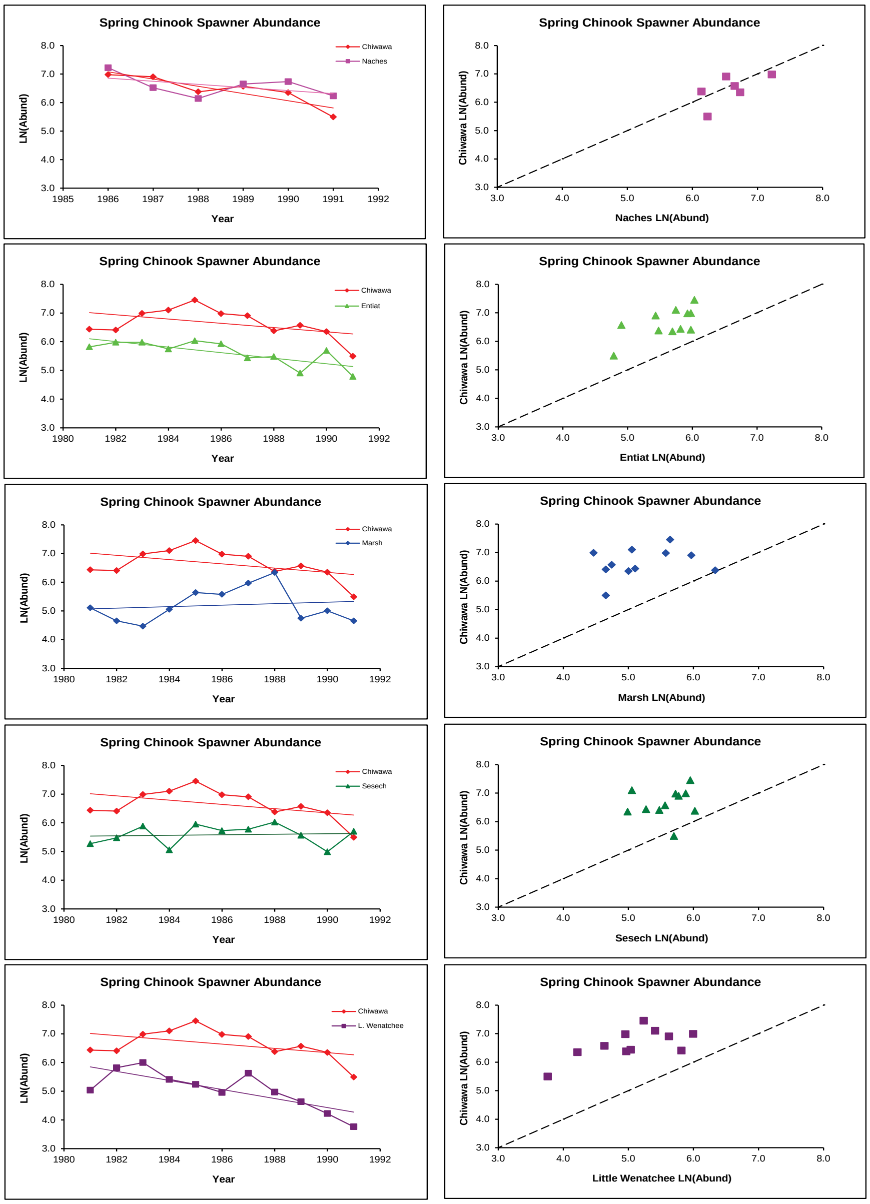

Figure 5. Time series of natural log spawner abundance of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

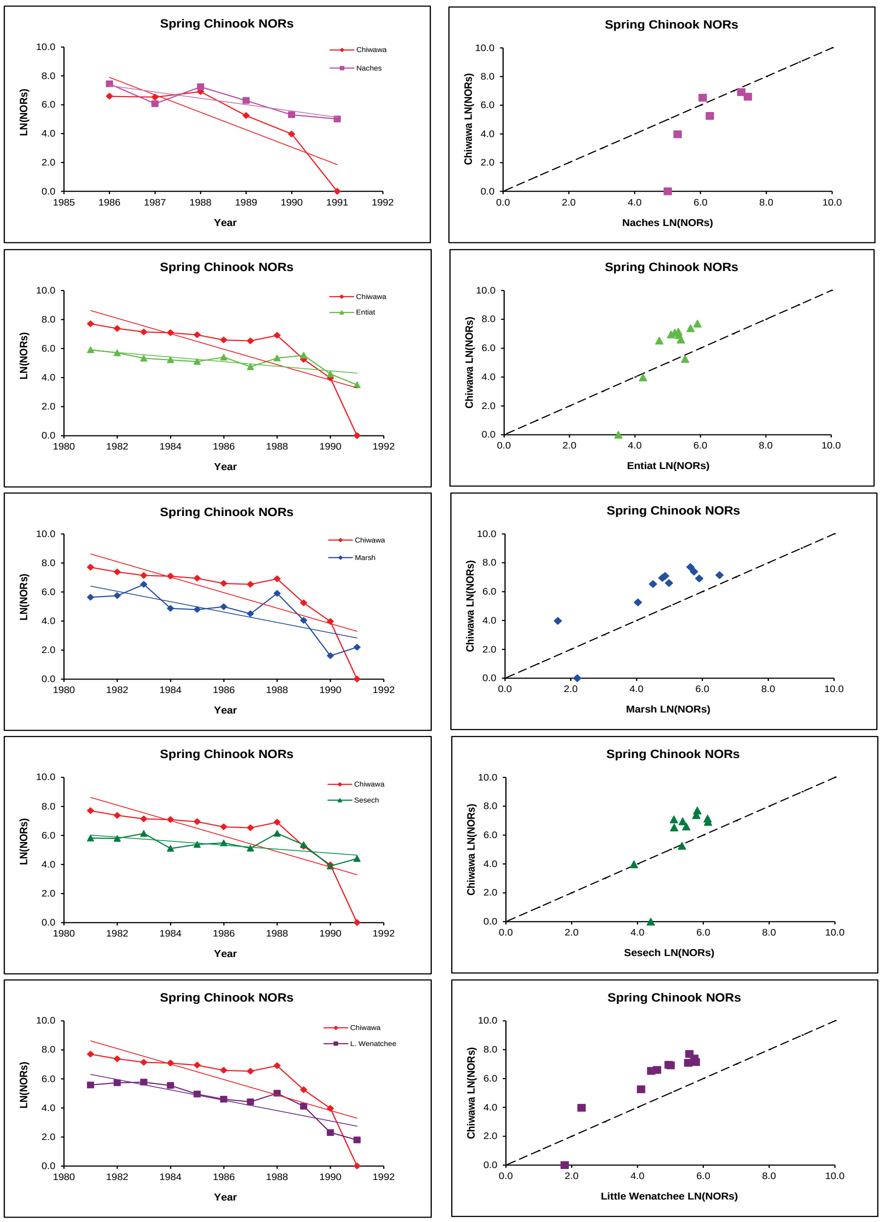

Figure 6. Time series of natural log natural-origin recruits (NORs) of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

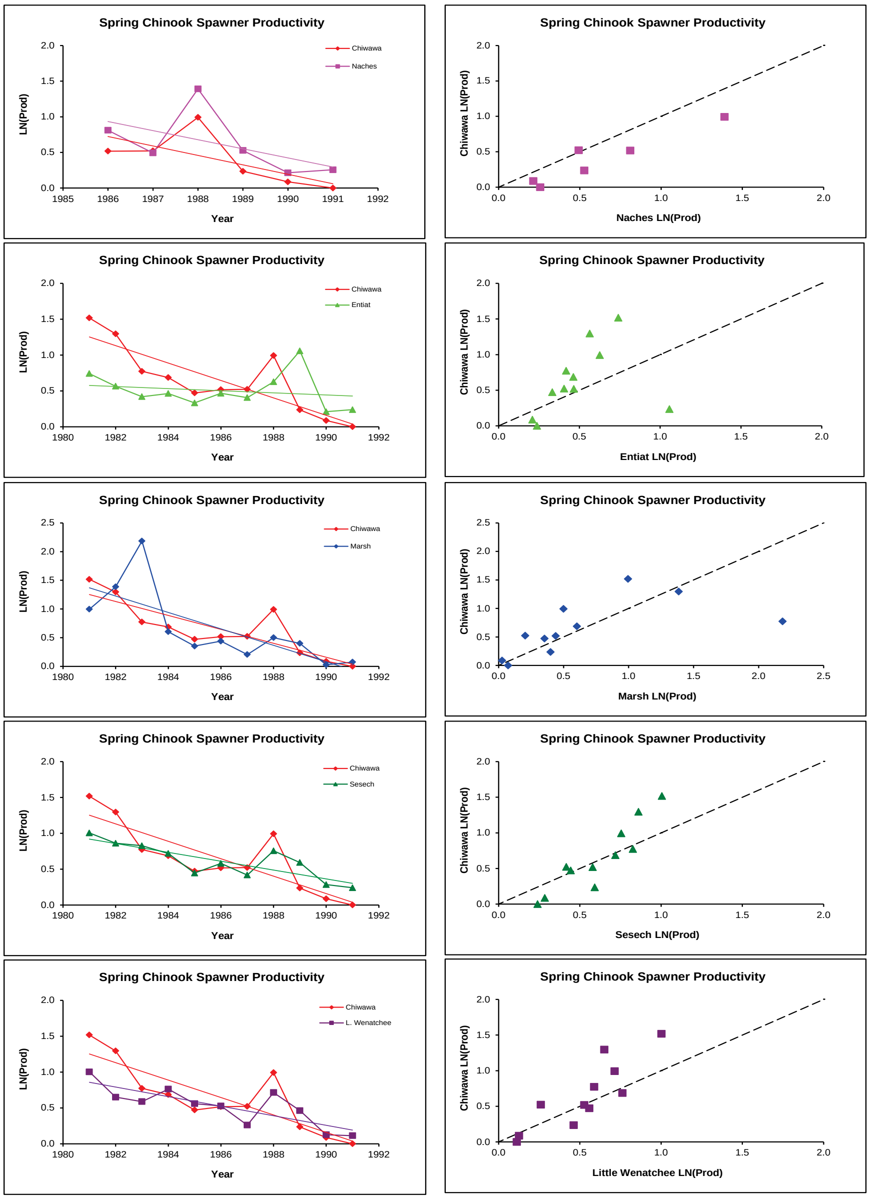

Figure 7. Time series of natural log adult productivity of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

Correlations and Trends

Other methods for evaluating the suitability of potential reference populations under Step 2 include correlation and trend analyses. For correlation analysis, we simply calculated the Pearson correlation coefficient, which is an index of the strength of the association between the potential reference populations and the Chiwawa population. The coefficient ranges from -1 to 1, where a value near 1 or -1 represents that strongest association between the populations. A value of 0 means no association. We used only spawner abundance, NORs, and productivity data during the pre-treatment period (1981-1992). We assumed that populations with coefficients greater than 0.6 represented reasonable reference conditions.

For trend analyses, we used least squares techniques to compute a straight-line trend through the spawner abundance and productivity data for the potential reference populations and the Chiwawa population. Trends were fit to the pre-treatment time series data (1981-1992). We then used t-tests to determine if the slopes of the trends between potential reference populations and the Chiwawa population differed significantly.

It is important to note that time-series trend analyses are susceptible to temporal correlations in the data. Autoregressive integrated moving average (ARIMA) models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). However, these models require a long time series (N > 40) and therefore we could not use them to model the spring Chinook data. As such, we were unable to correct for any temporal correlation that may exist within the time series.

Tests of correlation with spawner abundance data indicated that the Naches River closely correlated with the Chiwawa population (Table 2). There was no difference in abundance trends between the potential reference populations and the Chiwawa population (Table 2; Figure 2). For NORs, all potential reference populations correlated with the Chiwawa population (Table 2). However, trends in NORs of all reference populations, except Naches, differed significantly from the Chiwawa population (Table 2; Figure 3). For productivity, the Naches, Sesech, and Little Wenatchee correlated with the Chiwawa population (Table 2). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 2; Figure 4).

Table 2. Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (*) indicates significance at P < 0.05.

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Spawner Abundance Data				
Naches	0.684*	-0.659	8	0.528
Entiat	0.598*	-0.596	18	0.559
Marsh	0.147	-1.341	18	0.197
Sesech	0.274	-1.265	18	0.222
Little Wenatchee	0.399	-0.591	18	0.562
Natural-Origin Recruits				
Naches	0.803*	0.666	8	0.524
Entiat	0.795*	-7.495	18	0.000

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Marsh	0.605*	-5.786	18	0.000
Sesech	0.648*	-6.874	18	0.000
Little Wenatchee	0.880*	-7.206	18	0.000
Productivity Data				
Naches	0.960*	0.169	8	0.870
Entiat	0.272	-3.057	18	0.007
Marsh	0.320	0.605	18	0.553
Sesech	0.903*	-2.059	18	0.054
Little Wenatchee	0.848*	-2.065	18	0.054

We also ran correlation and trend analyses on natural-log transformed spawner abundance, NORs, and productivity data. These analyses indicated that the Naches, Entiat, and Little Wenatchee abundance data correlated with the Chiwawa population data (Table 3). None of the abundance trends of the potential reference populations differed significantly from the Chiwawa population trend (Table 3; Figure 5). For NORs, all potential reference populations correlated with the Chiwawa population (Table 3). Only trends in NORs of the Entiat and Sesech differed significantly from the Chiwawa population (Table 2; Figure 6). For productivity, the Naches, Marsh, Sesech, and Little Wenatchee correlated with the Chiwawa population data (Table 3). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 3; Figure 7).

Table 3. Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (*) indicates significance at P < 0.05. Analyses were conducted on natural-log transformed abundance and productivity data.

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
LN Spawner Abundance Data				
Naches	0.642*	-1.323	8	0.222
Entiat	0.652*	0.412	18	0.685
Marsh	0.294	-1.324	18	0.202
Sesech	0.149	-1.431	18	0.170
Little Wenatchee	0.670*	1.325	18	0.202
LN Natural-Origin Recruits				
Naches	0.824*	-1.985	8	0.082
Entiat	0.886*	-2.563	18	0.019

Sesech	0.730*	-2.664	18	0.016
Little Wenatchee	0.927*	-1.150	18	0.265
LN Productivity Data				

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Naches	0.944*	-0.042	8	0.968
Entiat	0.373	-3.043	18	0.007
Marsh	0.610*	0.428	18	0.674
Sesech	0.913*	-2.050	18	0.055
Little Wenatchee	0.862*	-1.811	18	0.087

In summary, based on correlation, trend, and graphic analyses, the Naches, Entiat, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. For NORs, the Naches, Marsh, and Little Wenatchee appear to be reasonable reference populations. For productivity, the Naches, Marsh, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for the Chiwawa population.

Minimal Detectable Differences (MDD)

Given a suite of potential reference populations, it is important to conduct power analyses to determine the minimum differences that can be detected when comparing the reference populations to the supplemented population. As a final exercise under Step 2, we examined potential reference populations for the smallest minimal detectable differences. Before conducting power analyses, several decisions needed to be made, including what statistical procedures will be used to analyze the data, the desired level of statistical power (probability of rejecting a false null hypothesis), the size of the type-I error (the probability of rejecting a true null hypothesis of no difference), and the number of samples (i.e., years) included in the analysis. In this case, the number of samples represents the number of treatment (supplementation) years. The number of pre-treatment years (1981-1992) was based on the number of years of quality data available for Chiwawa spring Chinook and potential reference populations.

We designed the study as a modified BACI (Before-After, Control-Impact) design, which includes replication before and after supplementation in both the treated (T) population and the reference (R) populations. A common approach used to analyze data from BACI designs includes analysis of difference scores (Stewart-Oaten et al. 1992; Smith et al. 1993). Differences are calculated between paired treatment and reference population scores (i.e., T-R). Another approach is to calculate ratios (treatment/reference; T/R) for paired treatment and reference population scores (Skalski and Robson 1992). Finally, differences in annual changes in paired treatment and reference population scores can be calculated (i.e., ΔT-ΔR) (Murdoch and Peven 2005; Hays et al. 2006).[17] These derived difference and ratio scores are then analyzed for a before-after treatment effect with a two-sample t-test, Aspin-Welch modification of the t-test, or a randomization test. For power analyses, we calculated minimal detectable differences assuming the use of an independent two-sample t-test with a type-I error rate of 0.05, power of 0.80 (beta or type-II error rate of 0.20), and sample sizes (treatment years) of 5, 10, 15, 20, 25, and 50 years.

[17] The difference of annual difference scores was estimated by first subtracting the population parameter (e.g., spawner abundance) in year 2 from year 1. This continues for all years in the data series for both treatment ($T_{t+1} – T_t$) and reference populations ($R_{t+1} – R_t$). We then calculated differences between paired treatment and reference annual difference scores [($T_{t+1} – T_t$) - ($R_{t+1} – R_t$) = ΔT-ΔR].

The power analysis calculated the minimal detectable difference between mean difference or ratio scores before and during supplementation. We used existing data to calculate variances for the pre-supplementation and supplementation periods. Thus, variances were known and unequal. For both spawner abundance and NORs, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was less than the mean difference during supplementation (one-tail test; Difference < 0). For productivity, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was greater than the mean difference during supplementation (one-tail test; Difference > 0).

Based on spawner abundance data, power analysis indicated that the Sesech-Chiwawa pairing consistently produced the smallest detectable differences (Table 4). However, when the abundance data were transformed using natural logs, the Entiat-Chiwawa pairing produced the smallest detectable difference (Table 5). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 334 to 394 adult spawners; transformed data ranged from 0.479 to 1.010. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

Table 4. Minimal detectable differences between mean difference and ratio scores before and during supplementation. Analyses were conducted on spawner abundance data.

	50	0.600	0.564	1.038	0.670	0.585

Based on NORs, power analysis indicated that the Entiat-Chiwawa, Marsh-Chiwawa, and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 6). When NORs were transformed using natural logs, the Little Wenatchee-Chiwawa pairing produced the smallest detectable difference (Table 7). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 483 to 640 NORs; transformed data ranged from 0.958 to 2.262. These analyses indicate that the Entiat, Marsh, and Little Wenatchee populations appear to be reasonable reference populations for comparing NORs with Chiwawa data.

Using untransformed productivity data, power analysis indicated that the Little Wenatchee-Chiwawa pairing consistently produced the smallest detectable differences (Table 8). The Marsh-Chiwawa pairings produced the largest detectable differences. When we analyzed natural-log transformed productivity data, the Naches-Chiwawa and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 9). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 0.754 to 1.839; transformed data ranged from 0.277 to 0.477. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing productivity data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

Table 8. Minimal detectable differences between mean difference and ratio scores before and during supplementation. Analyses were conducted on productivity data.

Response variable	Treatment years	Minimal detectable differences by reference population

Step 3: Quantitative Method for Ranking Selection Criteria

Not surprisingly, different selection criteria produced different results (Table 10). Determining whether a given population is or is not a suitable reference population based on selection criteria such as graphic analysis can be subjective. In addition, treating each selection criterion as equally important may not be appropriate. For example, using the information in Table 10, is it appropriate to select a reference population that has two or three "Yes" entries, or should only populations with four "Yes" entries be selected as suitable reference populations? This approach does not allow certain selection criteria to carry more weight in the overall selection process. That is, correlation may be more important than graphic analysis in the overall selection process. In order to reduce

subjectivity, we developed a method of scoring and weighting each selection criterion. This method allows a more quantitative process for selecting suitable reference populations.

Table 10. Summary of results from graphic analysis, correlations, trend analysis, and power analysis (minimal detectable differences). "Yes" indicates that the population is a suitable reference population for the Chiwawa population; "No" indicates that it may not be a suitable reference population.

Potential reference populations	Graphic analysis	Correlation	Trends	Minimal detectable differences
Spawner Abundance				
Naches	Yes	Yes	Yes	Yes
Entiat	Yes	Yes	Yes	Yes
Marsh	No	No	Yes	No
Sesech	No	No	Yes	Yes
Little Wenatchee	Yes	Yes	Yes	Yes
Natural-Origin Recruits				
Naches	Yes	Yes	Yes	No
Entiat	No	Yes	No	Yes
Marsh	Yes	Yes	Yes	Yes
Sesech	No	Yes	No	No
Little Wenatchee	Yes	Yes	Yes	Yes
Productivity				
Naches	Yes	Yes	Yes	Yes
Entiat	No	No	No	Yes
Marsh	No	Yes	Yes	No
Sesech	Yes	Yes	Yes	Yes
Little Wenatchee	Yes	Yes	Yes	Yes

We developed scoring methods for each of the following five selection criteria:

(1) The proportion of natural-origin spawners (pNOS) in the reference population for the period before supplementation (pre-pNOS);

(2) pNOS in the reference population for the period following supplementation (post-pNOS);

(3) The correlation between the reference and supplemented populations before supplementation;

(4) The relative difference in slopes between the reference and supplemented populations before supplementation; and

(5) The coefficient of variation (CV) of the ratio of supplemented to reference populations before the period of supplementation.

Each selection criteria was scored from 0 to 1, with 0 being the worst possible score and 1 being the best.

The pre- and post-pNOS values were calculated as the average pNOS values before and after supplementation, respectively. Because pNOS values range from 0-1, we did not need to rescale

these values. When using reference populations to evaluate the effects of supplementation programs, it is important that the reference populations maintain high values of pNOS throughout the life of the monitoring program. Therefore, we heavily weighted the mean pNOS scores. We assigned weights of 30 and 40 to the mean pre- and post-pNOS scores, respectively. The relatively larger weight for the post-supplementation period is to reduce the likelihood of retaining a reference population that becomes influenced by hatchery fish during the supplementation period.

We assessed the association between the reference and supplemented populations during the pre-supplementation period by calculating the Pearson correlation coefficient, which ranges from -1 to 1. To scale the coefficient between 0 and 1, we took the absolute value of the coefficient. Thus, a coefficient of -0.92 would be reported as 0.92. For our analyses, we were not concerned with the direction of the relationship, only the strength of the relationship. The correlation coefficient was given a weight of 12.5.

As noted earlier, we used least squares to fit a linear trend to each of the reference populations and the supplemented population during the pre-supplementation period. Using the slope estimates for each trend line, we calculated the relative difference in slopes as the slope of the supplemented population minus the slope of the reference population, divided by the slope of the reference population. To scale this value between 0 and 1, we used absolute values, and depending on the direction of the slopes, we subtracted the relative difference from 1. The latter was needed to make sure a larger relative difference value indicated a small difference in slopes between the supplemented and reference populations. The relative difference score was given a weight of 7.5.

Finally, as a means to score effect size, we calculated the CV of the ratio of supplemented to reference population parameters (i.e., T/R). The CV was calculated as the standard deviation of the ratios divided by the absolute value of the mean ratios. The CV was subtracted from 1. This scaled the value from 0 to 1 with larger values representing the best condition. The CV was given a weight of 10, which is greater than the weight for trend, but less than the weight for correlation.

The total score for a reference population was calculated by multiplying the estimated value, which ranged from 0 to 1, by its weight. The sum of the five weighted values provided a total score, which ranged from 0 to 100. Based on several simulations, we set the cut-off score at 81. That is, if the total score for a given reference population equaled or exceeded 81, the population was included as a suitable reference population. If the total score fell below 81, the population was not considered a suitable reference. Based on the distribution of all scores possible, a score of 81 or greater represented only 3% of the total distribution. Thus, a cut-off of 81 is quite conservative.

Under Step 3, we used this method to select the final suite of suitable reference populations. Table 11 shows results from scoring each of the reference populations using the quantitative method. Using the cut-off criterion of 81, only the Naches, Marsh, and Sesech populations would be considered suitable reference populations for the Chiwawa supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values).

Table 11. Results from scoring potential reference populations using the selection criteria (pNOS, correlation, trend, and effect size). Populations with scores less than 81 were considered unsuitable as reference populations. Populations with scores equal to or greater than 81 were considered suitable references. These results were based on natural-log transformed data.

Potential reference populations	Population metric		
	Abundance	NORs	Productivity
Naches	85	88	91
Entiat	23	21	16
Marsh	79	91	87
Sesech	84	85	88
Little Wenatchee	51	53	49

An important benefit from scoring the different selection criteria is that the total scores can be used to weight the outcome of differing statistical results. For example, analyses may show that when three suitable reference populations are compared to the supplemented population, two of the reference populations may indicate a significant treatment effect, while the third indicates no effect. Under this scenario it is not clear if the supplementation program has or has not affected the abundance or productivity of the supplemented population. If, however, the two reference populations that produced a significant result had higher total scores than the reference population that did not indicate a significant result, one can place more weight on the results from populations with higher total scores.

Conclusions

The purpose of this exercise was to develop a method for selecting suitable reference populations that could be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity. The selection process included a three-step process (Figure 8). Step 1 identified populations with similar life-history characteristics, few or no hatchery spawners, a long time series of accurate abundance and productivity estimates, and similar freshwater habitat impairments and out-of-basin effects. Populations that met these criteria were then examined for their graphical and statistical relationship with the supplemented population (Step 2). The statistical analysis under Step 2 were converted to a quantitative model (Step 3) that was used to generate a weighted score for pNOS, correlation, trends, and effect sizes for each potential reference population. Reference populations with total scores of 81 or greater were selected as suitable reference populations.

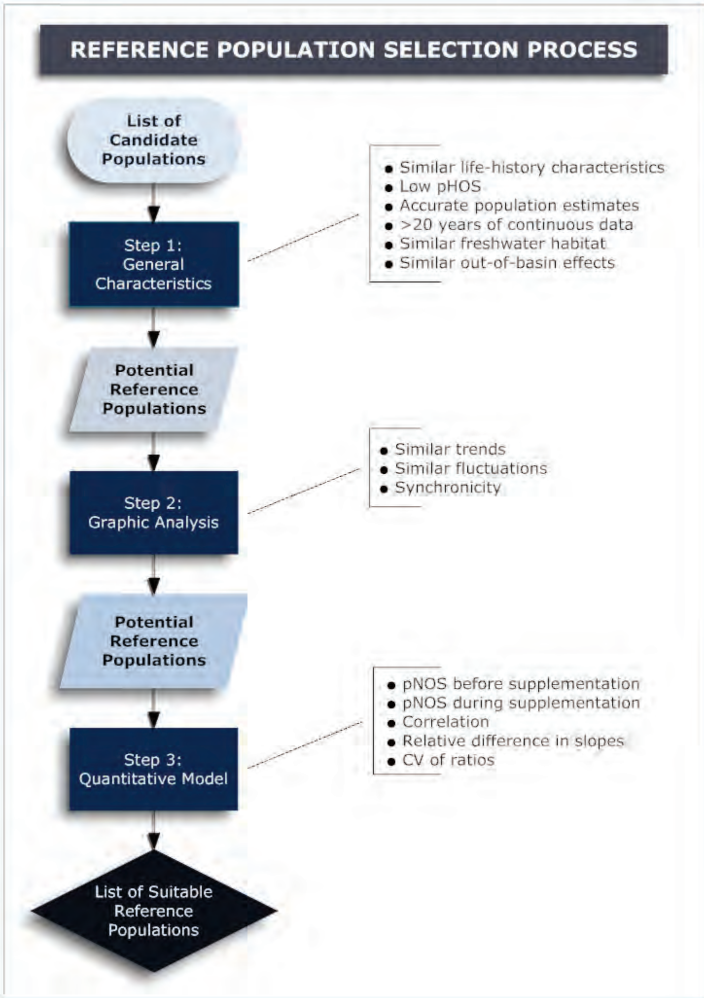

Figure 8. Three-step process for selecting suitable reference populations for supplemented populations.

We used this approach to select suitable reference populations for analyzing the effects of the Chiwawa spring Chinook supplementation program on fish abundance and productivity. The method indicated that the Naches, Marsh, and Sesech populations would serve as suitable reference populations for the Chiwawa spring Chinook supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values). However, because the presence of hatchery spring Chinook within those populations should decrease, they may serve as unique reference populations in which the comparisons change from all populations receiving

hatchery fish to only the Chiwawa population receiving hatchery fish. Therefore, we will continue to include both the Little Wenatchee and Entiat populations in future analyses.

An important assumption in the use of reference populations is that the supplemented and reference populations that tracked each other before supplementation would continue to track each other in the absence of supplementation. Given that the reference populations did not match the Chiwawa population on all criteria examined (Table 1) and some reference populations tracked the Chiwawa population more poorly than others (Figures 2-7; Tables 2-4), there may be some uncertainty as to whether differences observed between the Chiwawa and reference populations during the supplementation period are associated with the hatchery program, "nuisance" factors[18], or a combination of both. In addition, we have no ability to regulate or control activities in reference areas. Any large-scale change (man-made or natural) in reference areas could affect our ability to assess the effectiveness of the supplementation program.

Because we have no ability to maintain reference areas for long periods of time and may not be able to control all activities even within the supplemented populations, we propose the use of a "causal-comparative" approach to strengthen the certainty of our inferences (Pearsons and Temple 2010). The causal-comparative approach relies on correlative data to try and make a case for causal inference.[19] Correlation is used to rule out alternative hypotheses (note that we make our case as much if not more by disproving plausible alternatives as we do by showing that the data are consistent with a hypothesis). For example, large scale land-use activities or natural events can affect stream flows, fine sediment recruitment, and water temperatures. Changes in these factors can affect the freshwater survival and productivity of fish independently of supplementation programs. If changes in habitat, migratory, and ocean conditions do not affect reference and treatment populations similarly, inferences associated with supplementation programs may be confounded. By measuring and tracking these extraneous factors within reference and treatment areas, we can assess the effects of these state variables on population conditions independent of the supplementation programs. This allows us to more effectively assess the influence of supplementation programs on populations.

To that end, we recommend that the following state variables be measured and tracked within the Chiwawa Basin and each of the reference areas: mean annual precipitation, total and riparian forest cover, road density, impervious surface, and alluvium. These variables can be used to describe differences in water temperatures at different life stages (pre-spawning, egg incubation, and summer rearing) and substrate characteristics, including fine sediments and embeddedness (Jorgensen et al. 2009). They can be used to assess possible changes in spawner abundance, NORs, and productivity that are independent of supplementation.

18 A "nuisance" factor is any factor that is outside the control of the experimenter and can affect the response variable (spawner abundance or productivity). In this case, nuisance factors may include differences in freshwater habitat trends and conditions, out-of-basin effects (e.g., migration and ocean survival), and hatchery strays that affect the Chiwawa and reference populations differently.

19 It is important to point out that correlation does not demonstrate cause-and-effect. It only suggests a relationship between variables. Thus, inferences based on correlation lack the certainty that is associated with a design-based approach.

Analyses with Reference Populations

Once suitable reference populations are selected, methods for analyzing the supplemented and reference populations need to be identified. What follows is a description of different analyses that can be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity using reference populations. Later in this report we describe methods for assessing supplementation effects when reference populations are not available.

We used some of the reference populations selected for the Chiwawa program to illustrate the different methods for evaluating the effects of the supplementation program on spawner abundance, NORs, and productivity. For abundance, we selected the Naches, Entiat, Little Wenatchee, and Sesech populations as suitable references for the Chiwawa population. For NORs, we selected the Naches, Entiat, Marsh, and Little Wenatchee populations as suitable references. For productivity, we selected the Naches, Sesech, Little Wenatchee, and Marsh Creek as suitable references for the Chiwawa. As noted earlier, we included the Little Wenatchee and Entiat populations, even though they did not meet all the criteria for suitable reference populations.

Analysis of Trends

As a first step, we used trend analyses to assess the effects of the Chiwawa supplementation program on spring Chinook spawner abundance, NORs, and productivity. Here, we compared the slopes of the trends between each treatment/reference pair before and during supplementation using t-tests. If the hatchery program is successfully supplementing the natural spring Chinook population, trends in spawner abundance and NORs should deviate significantly (i.e., the slope of the supplemented population should be greater than the slopes of the reference populations during the supplementation period). For productivity, the slope of the supplemented population, relative to the reference population, should increase or remain the same.

Trend analysis indicated that the relationship of slopes of spawner abundance between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 9; Table 12). This was true for both transformed and untransformed abundance data. Before supplementation, spawner abundances trended down in both the Chiwawa and reference populations (Figure 9). During the period of supplementation, abundances in both the Chiwawa and reference populations trended upward. Interestingly, in nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the supplementation period than in the pre-supplementation period (Table 12). This was most evident in the transformed abundance data (Figure 9).

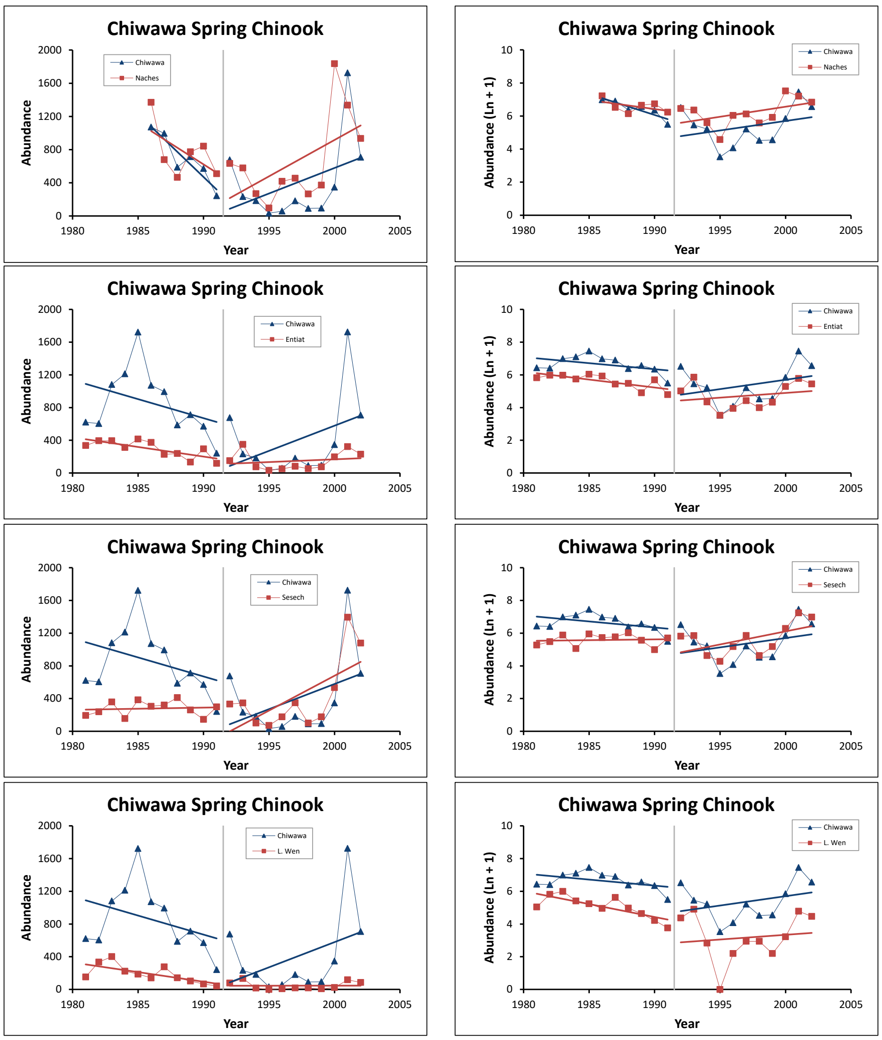

Figure 9. Trends in spring Chinook spawner abundance in the Chiwawa and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed spawner abundance data; those on the right include natural-log transformed data.

Table 12. Pearson correlation coefficients and t-test results comparing slopes of spawner abundance trends between reference populations and the Chiwawa spring Chinook population before and during the supplementation periods; for correlation coefficients, an asterisk (*) indicates significance at P < 0.05. Analyses include both untransformed and natural-log transformed spawner abundance data.

Trend analysis indicated that the relationship of slopes of NORs between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 10; Table 13). Before supplementation, Chiwawa NORs trended downward more strongly than the reference populations (Figure 10). However, during the supplementation period, both the Chiwawa and reference population NORs trended upward in parallel. In nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the pre-supplementation period than in the supplementation period (Table 13).

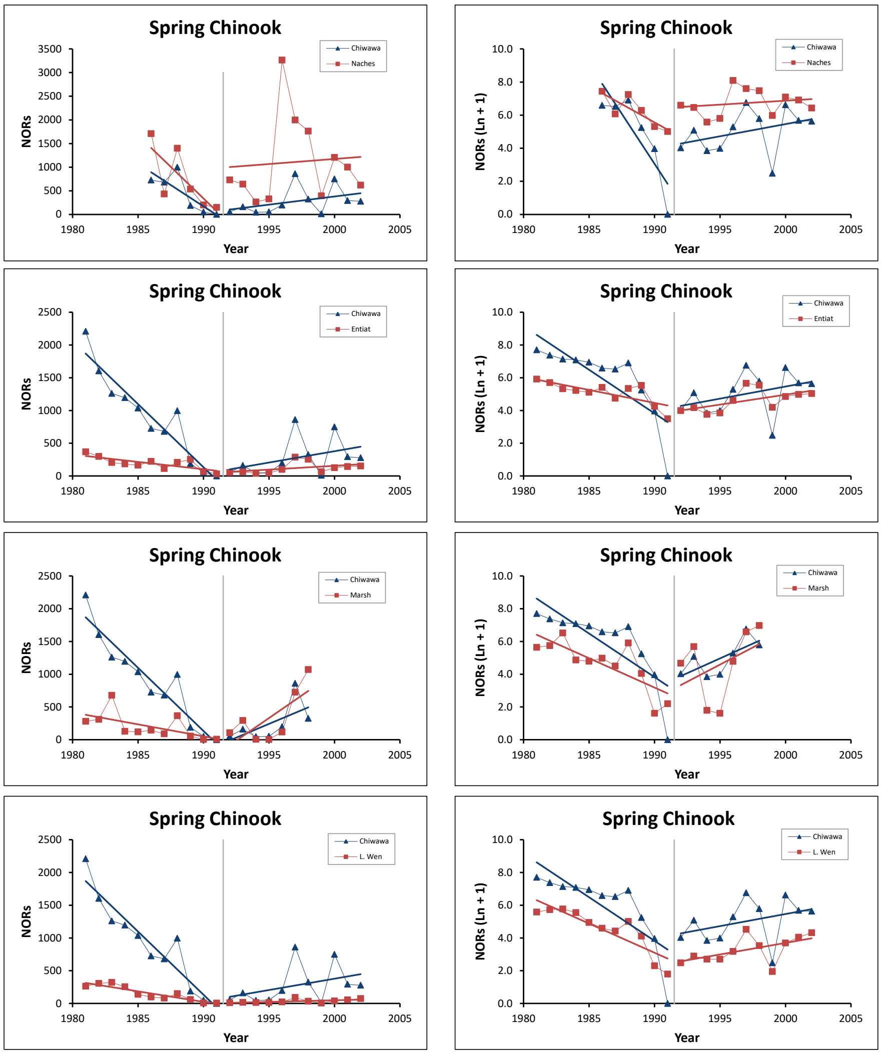

Figure 10. Trends in spring Chinook natural-origin recruits (NORs) in the Chiwawa and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed NORs; those on the right include natural-log transformed data.

Table 13. Pearson correlation coefficients and t-test results comparing slopes of natural-origin recruits trends between reference populations and the Chiwawa spring Chinook population before and during the supplementation periods; for correlation coefficients, an asterisk (*) indicates significance at P < 0.05. Analyses include both untransformed and natural-log transformed natural-origin recruits.

Little Wenatchee	0.927*	0.898*	-1.150	0.046	0.265	0.964

As with NORs and spawner abundance data, trend analysis indicated that the relationship of slopes of productivity (recruits/spawner) between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 11; Table 14). This was true for both transformed and untransformed productivity data. Before supplementation, productivities trended down in both the Chiwawa and reference populations (Figure 11). During the period of supplementation, productivities fluctuated widely in both the Chiwawa and reference populations. Nevertheless, during the supplementation period, productivities generally increased in both the reference and Chiwawa populations. Unlike with spawner abundance, the Pearson correlation coefficients resulting from analysis of productivity data were generally higher in the pre-supplementation period than during the supplementation period (Table 14).

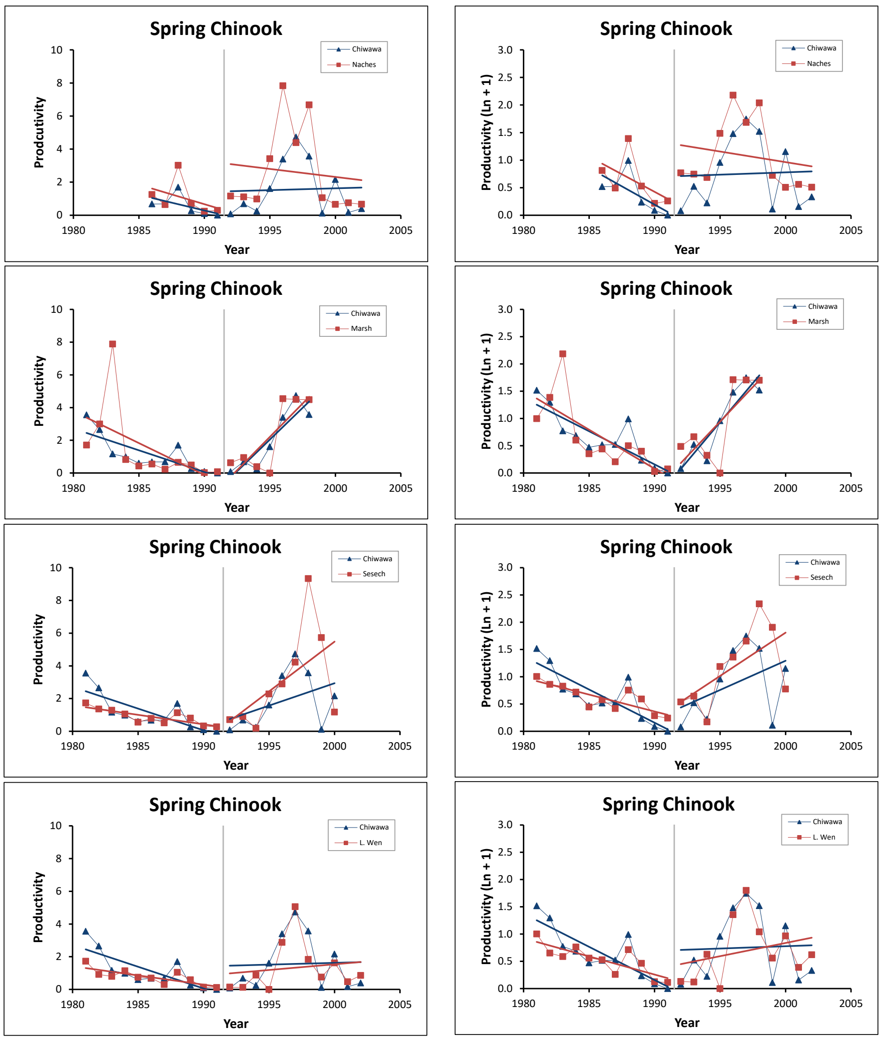

Figure 11. Trends in spring Chinook productivity (recruits/spawner) in the Chiwawa (supplemented) and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed productivity data; those on the right include natural-log transformed data.

Table 14. Pearson correlation coefficients and t-test results comparing slopes of productivity (recruits/spawner) trends between reference populations and the Chiwawa spring Chinook population before and during the supplementation periods; for correlation coefficients, an asterisk (*) indicates significance at $P < 0.05$. Analyses include both untransformed and natural-log transformed productivity data.

Using trend analysis, we found no evidence that the supplementation program has significantly increased the spawner abundance and NORs of spring Chinook in the Chiwawa Basin. Even though we documented an increasing trend in spawner abundance and NORs during the supplementation period, a similar increase in spawner abundance and NORs was observed in the reference populations. In addition, we found no evidence that the supplementation program has increased the productivity of spring Chinook in the Chiwawa Basin. Importantly, the productivity of spring Chinook in the Chiwawa Basin did not trend downward during the supplementation period. Thus, based on trend analysis, it appears that the supplementation program has not increased or decreased the abundance and productivity of spring Chinook in the Chiwawa Basin.

We note that this exercise only tests the slopes of the trend lines. It does not test for differences in elevations of the trend lines. A supplementation program could increase spawner abundance, NORs, and productivity of the target population without changing the slopes of the trend lines. That is, supplementation could cause the elevation of the trend line to be greater during the supplementation period than during the pre-supplementation period. In the next section we evaluate elevation differences by testing mean differences before and after supplementation.

Analysis of Mean Differences, Ratios, and Rates

For assessing mean differences between supplemented and reference populations, we derived three different response variables using transformed and untransformed spawner abundance, NORs, and productivity data. The first included difference scores, which were calculated as the difference between paired treatment and reference data (T-R). The second included ratios, which were calculated as the ratio of paired treatment and reference data (T/R). Finally, we calculated the differences in annual changes in paired treatment and reference population data (ΔT-ΔR; see footnote #2).

If the hatchery program is successfully supplementing the natural spring Chinook population, the mean difference or ratio score of paired spawner abundance data and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean difference or ratio score during the supplementation period should be equal to or higher than the pre-supplementation period. We tested the following statistical hypotheses.

Spawner Abundance and NORs:

> Ho: Mean Difference (or Ratio) before supplementation ≥ Mean Difference (or Ratio) during supplementation.
>
> Ha: Mean Difference (or Ratio) before supplementation < Mean Difference (or Ratio) during supplementation (i.e., μ_{pre} - $\mu_{post} < 0$).

Productivity (Recruits/Spawner):

> Ho: Mean Difference (or Ratio) before supplementation ≤ Mean Difference (or Ratio) during supplementation.
>
> Ha: Mean Difference (or Ratio) before supplementation > Mean Difference (or Ratio) during supplementation (i.e., μ_{pre} - $\mu_{post} > 0$).[20]

For each set of response variables, we tested before/after supplementation effects using a one-tailed Aspin-Welch unequal-variance test. We used the Aspin-Welch unequal-variance test instead of Student's t-test, because in nearly every case, the variances of response variables in the pre-treatment and supplementation periods were unequal.[21] This was true even for natural-log transformed variables. We used the modified Levene equal-variance test to assess the equality of variance. In some cases, the distributions of response variables were not normal (based on the Omnibus Normality test and examination of histograms, normal probability plots, and box plots). Therefore, we also used a randomization test, based on 10,000 Monte Carlo simulations, to assess differences in response variables before and during supplementation. The randomization procedure only allowed the testing of two-tailed hypotheses. Therefore, we generated 95% confidence intervals on the mean difference (μ_{pre} - μ_{post}) using bootstrapping methods to determine the direction of the difference. We generated 5,000 bootstrap samples to calculate confidence intervals.

All these statistical methods assume that the samples of derived difference or ratio scores from the pre-supplementation and supplementation periods were independent. However, BACI designs, like time-series trend analysis, are repeated-measures designs and therefore are susceptible to temporal correlations in the data. This means that the two samples of difference or ratio scores may not be independent. Under this scenario, ARIMA models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). ARIMA models can be fit individually to the reference and supplemented time series data, or to a derived data series created by taking the ratio or difference of the supplemented/reference data at each time step. ARIMA models, however, require a long time series (N > 40) and therefore we could not use them to model

20 Because of the logic of null hypothesis testing, the rejection of the null hypothesis of no difference in productivity would mean that the supplementation program has reduced the productivity of the target population (here rejection of the null indicates "harm"). Notice that the rejection of the null hypothesis of no difference in spawner abundance means that the supplementation program has improved the spawner abundance in the target population (here rejection of the null indicates "benefit").

21 In cases in which the variances were equal, both the Aspin-Welch test and Student's t-test gave the same result.

the spring Chinook data. Thus, we acknowledge that our analyses may be confounded if the samples are not independent.

Difference Scores (T-R)

Analysis of supplementation effects on spawner abundance using difference scores indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 15; Figure 12). Only the Little Wenatchee-Chiwawa pairing using transformed abundance data indicated a significant increase in spawning abundance following supplementation. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction (i.e., CIs > 0). That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 12).

Table 15. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed spawner abundance data. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

Ratio Scores (T/R)

As with difference scores, analysis of supplementation effects on spawner abundance using ratios indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 18; Figure 13). Only the Little Wenatchee-Chiwawa pairing indicated a significant increase in spawning abundance following supplementation. Analysis with both transformed and untransformed Little Wenatchee-Chiwawa data indicated a significant effect. In contrast, only difference scores derived from transformed data indicated a significant effect. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction. That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 13).

Analysis of supplementation effects on productivity (adult recruits/spawner) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 20; Figure 13). Although the Aspin-Welch test indicated a significant effect when comparing the Chiwawa to the Marsh Creek population, both the randomization test and the bootstrap CI did not indicate a significant effect. These tests indicate that supplementation has probably not negatively affected the productivity of spring Chinook salmon in the Chiwawa Basin.

We believe results from analysis of mean differences of annual change (ΔT-ΔR) in spawning abundance, NORs, and productivity are difficult to interpret and may be insensitive to treatment effects. A simpler analysis, which is also easier to interpret, is the use of trend analysis. Therefore, we recommend that analyses using differences of annual change be replaced with trend analysis.

Corrections for Density Dependence and Carrying Capacity

The analyses described above assume that the density of spawners or recruits does not affect the survival and productivity of fish. However, it is well known that the density of fish can affect the number of recruits as well as the productivity of the population. This occurs through the relationship between density and mortality. Mortality of fish can be generally classified as density independent and density dependent. In general, when densities are low, the mortality is density independent, but as densities increase, the amount of density-dependent mortality increases. Monitoring programs can make use of this information to derive density-corrected estimates of productivity. In this section, we describe two different methods for deriving density-corrected estimates of productivity.

The first method controlled the effects of density on productivity (adult recruits/spawner; R/S) by partitioning observed productivities into density-independent and density-dependent productivity. When abundance is below the minimum number of spawners (S) needed to produce the maximum number of recruits (K_{sp}), the observed productivity is used in statistical tests. However, when the abundance is equal to or above K_{sp}, the modeled value of productivity (R/K_{sp}) is used in statistical tests.

$$\boldsymbol{Adj\ R/S} = \begin{cases} \boldsymbol{R/S,} & \boldsymbol{if\ S < K_{sp}} \\ \boldsymbol{R/K_{sp},} & \boldsymbol{if\ S \geq K_{sp}} \end{cases}$$

The density-independent and density-dependent productivities were then combined in a single test.

The second method was based on one of the goals of supplementation, which is to fill the capacity of the environment with fish. This method corrects for differences in carrying capacities between the supplemented and reference populations. We did this by calculating the percent saturation of NORs. That is, we calculated the fraction of the habitat (τ) that was filled with NORs by dividing the observed NOR by the modeled maximum number of NORs (K_R) that the habitat could support.

$$\boldsymbol{\tau = \frac{NOR_{obs}}{K_R}}$$

Note that 1-τ represents the unused portion of the carrying capacity and is the term that is multiplied by the exponential growth equation to derive the logistic growth equation. We included τ in the statistical analyses.

These two methods require the estimation of carrying capacity (K_R) and the spawning abundance that produces the maximum number of recruits (K_{sp}). We estimated these parameters for both reference populations and the supplemented population using Ricker, Beverton-Holt, and smooth hockey stick stock-recruitment models. We used only spawner abundance as a predictor of subsequent brood recruitment. We made the following assumptions in proceeding with the analysis:

- *Density-dependent mortality*—For some time period before recruitment, the brood instantaneous mortality rate is proportional to the number of parent spawners (Ricker 1954).
- *Lognormal variation*—At any particular spawning stock size, the variation in recruitment is log-normally distributed about its average, and acts multiplicatively (Quinn and Deriso 1999).
- *Measurement error*—Error in spawning stock size estimates (measurement error) is small relative to the range of spawning stock sizes observed (Hilborn and Walters 1992). Variation in realized recruitment at any particular spawning stock size (process error) dominates recruitment measurement error.
- *Stationarity*—The average stock-recruitment relationship is constant over time (Hilborn and Walters 1992). That is, environmental conditions randomly affect survival independent of stock size or time.

In general, the methods we used to fit the models to the data followed those outlined in Hilborn and Walters (1992) and Froese (2008). The Ricker model, which assumes that the number of recruits increases to a maximum and then declines as the number of spawners increases, takes the form:

$$\boldsymbol{E(R) = \alpha S e^{-\beta S}}$$

where E(R) is the expected recruitment, S is spawner abundance, α is the number of recruits per spawner at low spawning levels, and β describes how quickly the recruits per spawner drop as the number of spawners increases. We estimated K_R as:

$$\boldsymbol{K_R = \left(\frac{\alpha}{\beta}\right) e^{-1}}$$

and K_{sp} as:

$$\boldsymbol{K_{sp} = \frac{1}{\beta}}$$

The Beverton-Holt model assumes that the number of recruits increases constantly toward an asymptote as the number of spawners increases. After the asymptote is reached, the number of recruits neither increases nor decreases. The asymptote represents the maximum number of recruits the system can support (i.e., carrying capacity for the system; K_R). The Beverton-Holt curve takes the form:

$$\boldsymbol{E(R) = \frac{(\alpha S)}{(\beta + S)}}$$

where E(R) and S are as above, α is the maximum number of recruits produced (K_R), and β is the number of spawners needed to produce (on average) recruits equal to one-half the maximum number of recruits. Because $K_{sp} = \infty$ in the Beverton-Holt model, we estimated K_{sp} as the number of spawners needed to produce $0.99(K_R)$.

Like the Beverton-Holt model, the smooth hockey stick model assumes that the number of recruits increases toward an asymptote (carrying capacity; K_R) as the number of spawners increases. After the carrying capacity is reached, the number of recruits neither increases nor decreases. The carrying capacity represents the maximum number of recruits the system can support. This curve

takes the form (Froese 2008):

$$E(R) = R_{\infty}\left(1 - e^{-\left(\frac{\alpha}{R\infty}\right)S}\right)$$

where E(R) and S are as above, α is the slope at the origin of the spawner-recruitment curve, and R_{∞} is the carrying capacity of recruits (note that $R_{\infty} = K_R$). As with the Beverton-Holt model, we estimated K_{sp} as the number of spawners needed to produce $0.99(K_R)$.

We used non-linear regression to fit the three models to spawner-recruitment data. Before fitting the models, we transformed recruitment data using natural logs. We estimated bias and uncertainty measures (95% CI) for the model parameters using bootstrap procedures, which assumed that the {R, S} sample represented or approximated the population. The number of bootstrap samples was 3,000. We computed and stored the non-linear regression results for each bootstrap sample. We then calculated the bootstrap 95% CI by arranging the 3,000 bootstrap parameter values in sorted order and selected the 2.5 and 97.5 percentiles from the list.

We used Akaike's Information Criterion for small sample size (AIC_c) to determine which model(s) best explained the relationship between spawners and recruitment in the supplemented and reference populations. AIC_c was estimated as:

$$AIC_c = -2log\left(£(\theta|data)\right) + 2K + \left(\frac{2K(K+1)}{n-K-1}\right)$$

where $log(£(\theta|data))$ is the maximum likelihood estimate, K is the number of estimable parameters (structural parameters plus the residual variance parameter), and n is the sample size (Burnham and Anderson 2002). We used least-squares methods to estimate $log(£(\theta|data))$, which was calculated as $log(\sigma^2)$, where σ^2 = residual sum of squares divided by the sample size ($\sigma^2 = RSS/n$). AIC_c assessed model fit in relation to model complexity (number of parameters). The model with the smallest AIC_c value represented the "best approximating" model within the model set. Remaining models were ranked relative to the best model using AIC_c difference scores (ΔAIC_c), Akaike weights (w_i), and evidence ratios. Models with ΔAIC_c values less than 2 indicated that there is substantial support for these models as being the best-fitting models within the set (Burnham and Anderson 2002). Models with values greater than 2 had less support. Akaike weights are probabilities estimating the strength of the evidence supporting a particular model as being the best model within the model set. Models with small w_i values are less plausible as competing models (Burnham and Anderson 2002). If no single model could be specified as the best model, a "best subset" of competing models was identified using (1) AIC_c differences to indicate the level of empirical support each model had as being the best model, (2) evidence ratios based on Akaike weights to indicate the relative probability that any model is the best model, and (3) coefficients of determination (R^2) assessing the explanatory power of each model.

Stock-Recruitment Analysis

We successfully fit stock-recruitment models to the Chiwawa and reference population data. The span of spawner data for the Chiwawa and reference populations was greater than 14 times the minimum observed spawners, which should provide sufficient contrast for estimation of model parameters. In addition, the span of recruitment data was greater than 12 times the minimum observed recruitment, again providing sufficient contrast for estimation of parameters. The relationship between natural log R/S and spawners indicated that some of the highest productivities occurred at the lower spawner levels and the lowest productivities generally occurred at the highest spawner levels (Figure 15). This is consistent with the assumption of density-dependent mortality.

Although model fits were generally poor, explaining less than 40% of the residual variation in natural-log recruitment data, we were able to estimate average maximum recruitment levels (K_R) and the spawning levels needed to produce maximum recruitment (K_{sp}) (Table 24; Figure 15). For all populations examined, Akaike information criterion was unable to identify a best approximating model (i.e., ΔAIC_c values were less than 2, indicating support for all three models). However, evaluation of 95% CIs and the asymptotic correlation coefficients indicated that the smooth hockey stick model may be the best approximating model for each population. Therefore, we used estimates of K_R and K_{sp} derived from the smooth hockey stick model to correct for density dependence and different carrying capacities in treatment-reference comparisons.

As part of the regression diagnostics, we examined the dependence of the model residuals on time and found a significant ($P < 0.05$), positive, one-year-lag autocorrelation for the Entiat (0.562), Marsh (0.551), Sesech (0.564), and Little Wenatchee (0.629) populations. For the purposes of our work here, we did not attempt to correct for this one-year-lag correlation in the residuals. Future analyses will explore the use of autoregressive models (e.g., AR1; Noakes et al. 1987) to correct for autocorrelation.

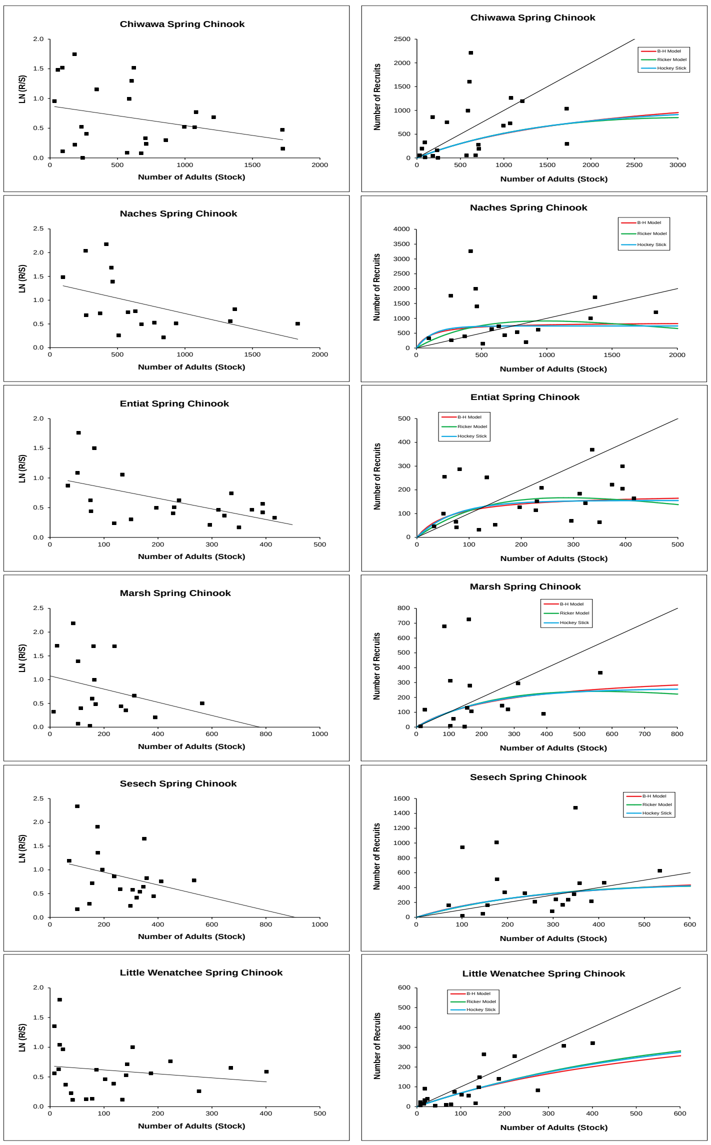

Figure 15. Relationships between natural log recruits/spawner (LN R/S) and spawners (Stock) in the Chiwawa and reference populations (figures on the left) and relationships between numbers of untransformed recruits and spawners in the Chiwawa and reference populations (figures on the right). Figures on the right also show the fit of the Ricker, Beverton-Holt, and the smooth hockey stick models to the data (black straight line represents R=S).

Table 24. Results from fitting Ricker, Beverton-Holt, and smooth hockey stick models to stock-recruitment data from the Chiwawa and reference populations. 95% CI on parameter estimates are based on 3,000 bootstrap trials; Corr coef = asymptotic correlation of the parameter estimates; K_R = maximum natural origin recruits (recruits at carrying capacity); K_{sp} = number of spawners needed to produce K_R; AICc = Akaike's Information Criterion for small sample size; Adj R^2 = coefficient of determination that is adjusted for the number of parameters in the model.

Method 1: Productivity Data Adjusted for Density Dependence

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects based on the smooth hockey stick model) using difference scores indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 25; Figure 16). All tests, regardless of treatment-reference pairs, indicated that productivity did not change significantly during the supplementation period, even though productivity did decrease during the supplementation period (Figure 16). These results are consistent with those based on unadjusted productivity data (Table 17). This is because most abundance estimates were below the level of assumed density dependence.

Table 25. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

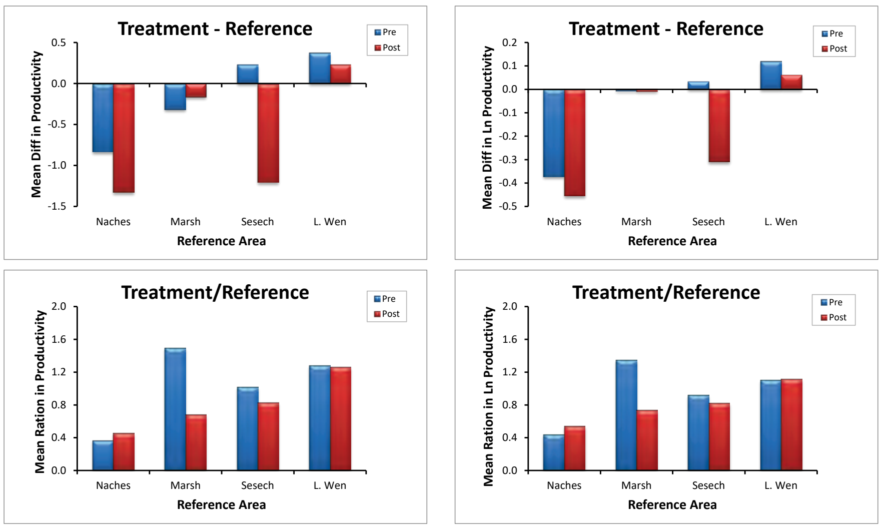

Figure 16. Mean differences (Treatment – Reference; figures on the top) and mean ratios (Treatment/Reference; figures on the bottom) of transformed and untransformed productivity data (adjusted for density dependence) before (pre) and after (post) spring Chinook supplementation in the Chiwawa Basin. Negative effects of supplementation on productivity are indicated when the pre-supplementation (blue) bars are greater than their corresponding post-supplementation (red) bars.

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 26; Figure 16). The Aspin-Welch test and the 95% CIs did indicate a significant effect when comparing the Chiwawa to the Marsh Creek population. These results are consistent with those using unadjusted productivity data (Table 20). Again, this is because most abundance estimates were below the level of assumed density dependence.

Table 26. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean ratios during the supplementation period were less than mean ratios during the pre-supplementation period.

Little Wenatchee	-0.034	0.513	0.015	0.980	-0.697 – 0.852

Our analyses assume that there is a spawner abundance (K_{sp}) at which density-independent effects end and density-dependent effects begin. In reality, density-dependent effects occur at low spawning abundance and intensify as spawning abundance increases (evident in the changing slope of the three stock-recruitment curves used in our analyses). We did not account for these increasing density-dependent effects at spawner abundances less than K_{sp}. If we accounted for the increasing effects of density dependence at spawning abundances less than K_{sp}, the analysis with and without productivity adjustments may give different results.

Method 2: Fraction of Carrying Capacity Filled with NORs

We analyzed the effects of supplementation on filling the capacity of the habitat with natural-origin recruits. The smooth hockey stick model derived the carrying capacity (K_R) estimates for the Chiwawa and reference populations. The fraction of the carrying capacity filled with Chinook recruits before and during supplementation for the Chiwawa and reference populations is provided in Table 27. These data indicate that for the Chiwawa population, the mean fraction of the K_R filled with fish decreased significantly from the pre-supplementation period through the supplementation period (Table 27). Likewise, the Entiat and Little Wenatchee populations showed a significant decline in the mean fraction of K_R filled with adult recruits. In contrast, the mean fraction of K_R in the Naches and Marsh Creek populations increased during the same period (Table 27).[22] Interestingly, the fraction of K_R filled with adult recruits for all populations trended downward during the pre-supplementation period (Figure 17). During the supplementation period, however, the fraction of K_R filled with adult recruits trended upward for all populations. These results suggest that agents of mortality outside the Chiwawa and reference populations were reducing recruitment to the populations.

22 Although we do not show the results here, statistical analysis of the mean fraction of carrying capacity filled by adult recruits using natural-log transformed data produced the same result as using untransformed data. This was true for all populations.

Table 27. Fraction of the carrying capacity that was filled with Chinook salmon adult recruits in the Chiwawa and reference populations before (pre) and during (post) supplementation in Chiwawa Basin. The smooth hockey stick model estimated carrying capacity for each population. Statistical results from comparing the pre and post mean scores using the Aspin-Welch unequal-variance test are provided at the bottom of the table.

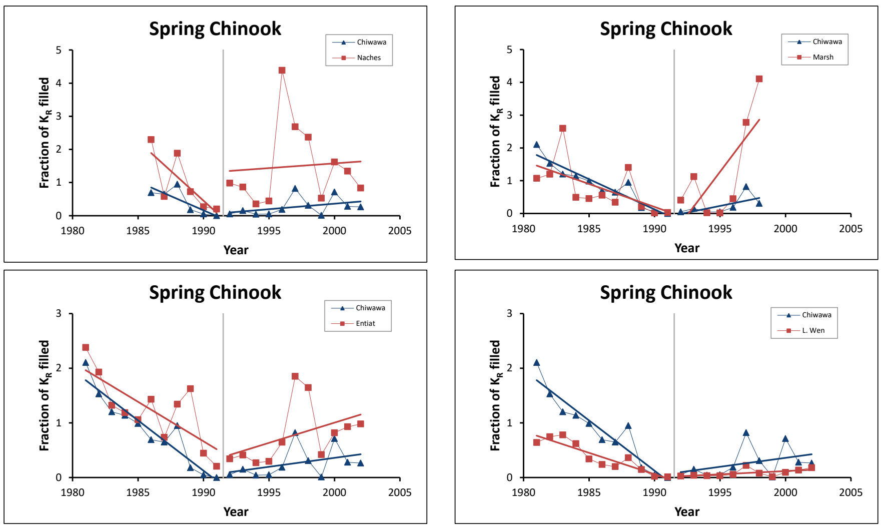

Figure 17. Trends in the fraction of the carrying capacity that was filled with Chinook salmon adult recruits in the Chiwawa and reference populations before (pre) and during (post) supplementation in Chiwawa Basin. The vertical lines in the figures separate the pre- and post-supplementation periods. The smooth hockey stick model estimated carrying capacity for each population.

We then compared the mean difference scores and ratios between the Chiwawa and reference populations before and during supplementation using data representing the fraction of K_R filled with adult recruits. In most of the Chiwawa-reference population comparisons, the absolute value of the mean difference between the fraction of K_R filled with recruits was greater in the supplementation period than during the pre-supplementation period; two of the four pairings were significant (Table 28; Figure 18). Analysis of difference scores using natural-log transformed data indicated that three of the four pairings were significant (Table 28).

Results from analyses using ratios were similar to results using difference scores. Mean ratio scores were generally smaller during the supplementation period than during the pre-supplementation period (Figure 18). This indicated that the mean fraction of K_R filled by adult recruits in most reference populations was greater during the supplementation period than during the pre-supplementation period (i.e., the denominator in the ratio increased between the pre- and post-supplementation periods). In contrast, the fraction of K_R filled by adult recruits in the Chiwawa decreased from the pre- to post-supplementation period (i.e., the numerator in the ratio decreased between the pre- and post-supplementation periods). Thus, unlike the Chiwawa population, the capacity of most reference populations was becoming more saturated during the period when the Chiwawa was being supplemented. Statistical analysis with mean ratios indicated that two of the four pairings were significant (Table 29).

Analyses comparing the Little Wenatchee with the Chiwawa indicate that adult recruits to the Little Wenatchee have been well below its carrying capacity. During the pre-supplementation period, the capacity of the Little Wenatchee was on average 37% saturated with adult recruits. During the supplementation period, the capacity of the Little Wenatchee declined to 8% saturation

with adult recruits (a 22% decline). The Chiwawa, during the pre-supplementation period, was on average 86% saturated. During the supplementation period, percent saturation in the Chiwawa decreased to 26% (a 30% decrease). During the same time periods, the capacity of the Entiat population, which until recently has been supplemented, declined from 124% to 78% saturation (a 63% decline).

Table 28. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on the fraction of the habitat capacity (K_R) that is filled with natural origin recruits. Analyses include both transformed and untransformed data. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

Comparing Stock-Recruitment Curves

As a final set of treatment and reference population comparisons, we compared the stock-recruitment curves of the Chiwawa population (using {R, S} data only from the supplementation period) to the reference populations (using all available {R, S} data). Specifically, we tested whether the regression parameters were equal between the Chiwawa population and the reference populations, and whether the fitted curves coincided between populations. Earlier in this report we described the data, methods, and results of fitting the Ricker, Beverton-Holt, and smooth hockey stick curves to the data. Because AIC_c was unable to identify a best approximating model, here we included all three models in our analyses. We tested the following hypotheses.

Parameter equivalence:

Ho: Stock-recruitment parameters (α and β) of the Chiwawa population = Stock-recruitment parameters of the reference populations.

Ha: Stock-recruitment parameters (α and β) of the Chiwawa population ≠ Stock-recruitment parameters of the reference populations.

Curve equivalence:

Ho: Modeled stock-recruitment curves of the Chiwawa population = Modeled stock-recruitment curves of the reference populations.

Ha: Modeled stock-recruitment curves of the Chiwawa population ≠ Modeled stock-recruitment curves of the reference populations.

We used two-sided randomization tests to test the null hypotheses of equal model parameters and that fitted curves coincided. Because the total number of permutations was in the millions, we used a Monte Carlo approach to randomly select 10,000 permutations. The test statistic for comparing the model parameters was formed by summing the difference between the population parameter estimates for each pair of populations. The test statistic for comparing the whole curve was formed by summing the difference between the estimated predicted values for each pair of populations at 500 equally spaced points along the curve.

Ricker Relationships

Ricker curves differed significantly between the Chiwawa and reference populations (Figure 19; Table 30). Interestingly, however, the parameters in the Ricker model did not differ significantly among most populations (Table 30). Only the β parameter differed significantly between the Chiwawa and Entiat populations.

In the Ricker model, the α parameter represents intrinsic productivity (i.e., recruits per spawner at low spawner densities). In this analysis, there was not enough evidence in the stock-recruitment data to reject the hypothesis of inequality in intrinsic productivity. Thus, this test was unable to demonstrate that supplementation, based on the Ricker curve, affected productivity in the Chiwawa population.

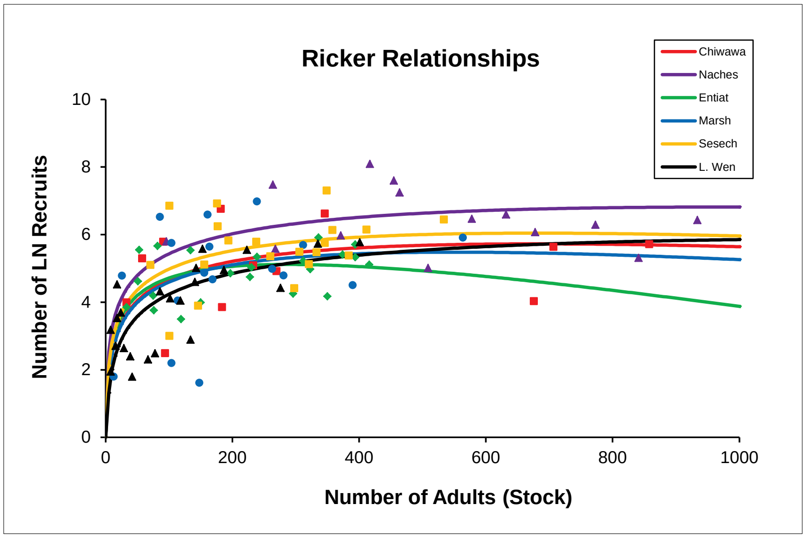

Figure 19. Scatter plot of the number of spawners and natural log adult recruits and fitted Ricker curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

Table 30. Randomization test results comparing the equality of Ricker curves and equality of parameter values (α and β). Randomization tests were based on 10,000 Monte Carlo samples. Equality or curves was based on 500 points along the x-axis (spawner abundance axis).

Curves tested	Curve inequality randomization P-value	Parameter inequality		
		Model Parameter		Randomization P-value
		Chiwawa	Reference	
Chiwawa v. Naches	0.008	α = 1.2247	α = 2.5267	0.236
		β = 0.0015	β = 0.0010	0.600
Chiwawa v. Entiat	0.004	α = 1.2247	α = 1.5836	0.978

		β = 0.0015	β = 0.0008	0.203

Beverton-Holt Relationships

Beverton-Holt curves differed significantly only between the Chiwawa and Naches populations (Figure 20; Table 31). There was no significant difference in curves between the Chiwawa and the other reference populations. The parameters in the Beverton-Holt model did not differ significantly among any of the populations (Table 31). This was true even for the Chiwawa and Naches populations.

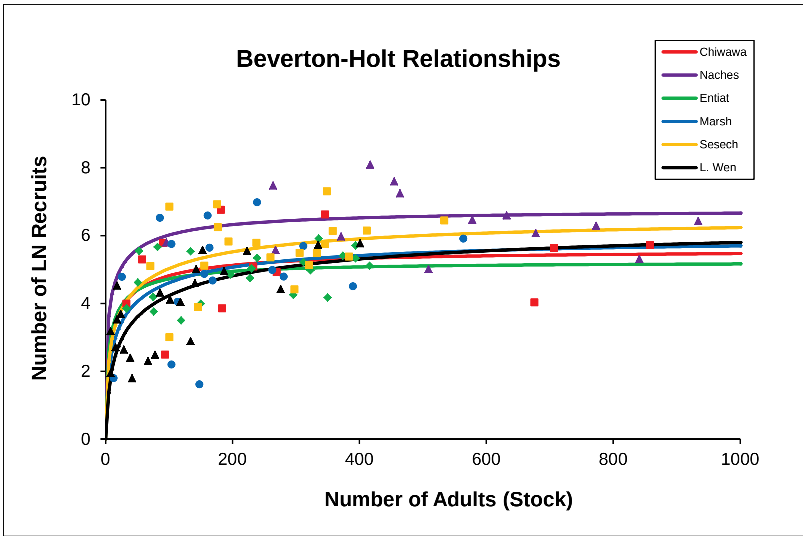

Figure 20. Scatter plot of the number of spawners and natural log adult recruits and fitted Beverton-Holt curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

Table 31. Randomization test results comparing the equality of Beverton-Holt curves and equality of parameter values (α and β). Randomization tests were based on 10,000 Monte Carlo samples. Equality or curves was based on 500 points along the x-axis (spawner abundance axis).

Curves tested	Curve inequality randomization P-value	Parameter inequality

Smooth Hockey Stick Relationships

Smooth hockey stick curves differed significantly between the Chiwawa and Naches populations and the Chiwawa and Sesech populations (Figure 21; Table 32). There was no significant difference in curves between the Chiwawa and the other reference populations. Most of the parameters in the smooth hockey stick model did not differ significantly among the populations (Table 32). However, the productivity parameter β did differ significantly between the Chiwawa and the Naches and the Chiwawa and Little Wenatchee populations. The β parameter for the Naches was significantly greater than the Chiwawa, while the β parameter for the Little Wenatchee was significantly less than the Chiwawa.

Comparing different stock-recruitment curves and their parameters did not provide strong evidence that the supplementation program has negatively affected the productivity of the Chiwawa population.

Analysis without Reference Populations

In some cases, suitable reference populations may not exist to compare with supplemented populations. It is therefore important to have alternative analyses to assess supplementation effects. In this section, we describe methods that can be used to assess supplementation effects when suitable reference populations are not available. We discuss before-after comparisons, correlation analysis, and comparisons to standards as alternatives when reference populations are unavailable.

Before-After Comparisons

Before-after analyses compare population metrics (spawner abundance, NORs, and productivity) before supplementation to those during supplementation. In this case, data collected before supplementation represent the reference condition. The assumption is that population trajectories measured during the pre-supplementation period would continue in the absence of supplementation. We compared trends in abundance and productivity, mean abundance and productivity, and stock-recruitment relationships before and after supplementation.

Trend Analysis

Comparing trends before and after supplementation can be used to assess the effects of supplementation. Here, we compared the slopes of trends of spawner abundance, NORs, and productivity before and during supplementation using t-tests. If the hatchery program is successfully supplementing the natural spring Chinook population, the trend for spawner abundance and NORs during supplementation should be greater than the slope during the pre-supplementation period. For productivity, the slope during the supplementation period should increase or remain the same as that during the pre-supplementation period.

Visual examination of trends of Chiwawa data indicates that spawner abundance, NORs, and productivity decreased during the pre-supplementation period, but increased during the supplementation period (Figure 22). Only the changes in NOR trends were significant (Figure 22). This was true for both transformed and untransformed data.

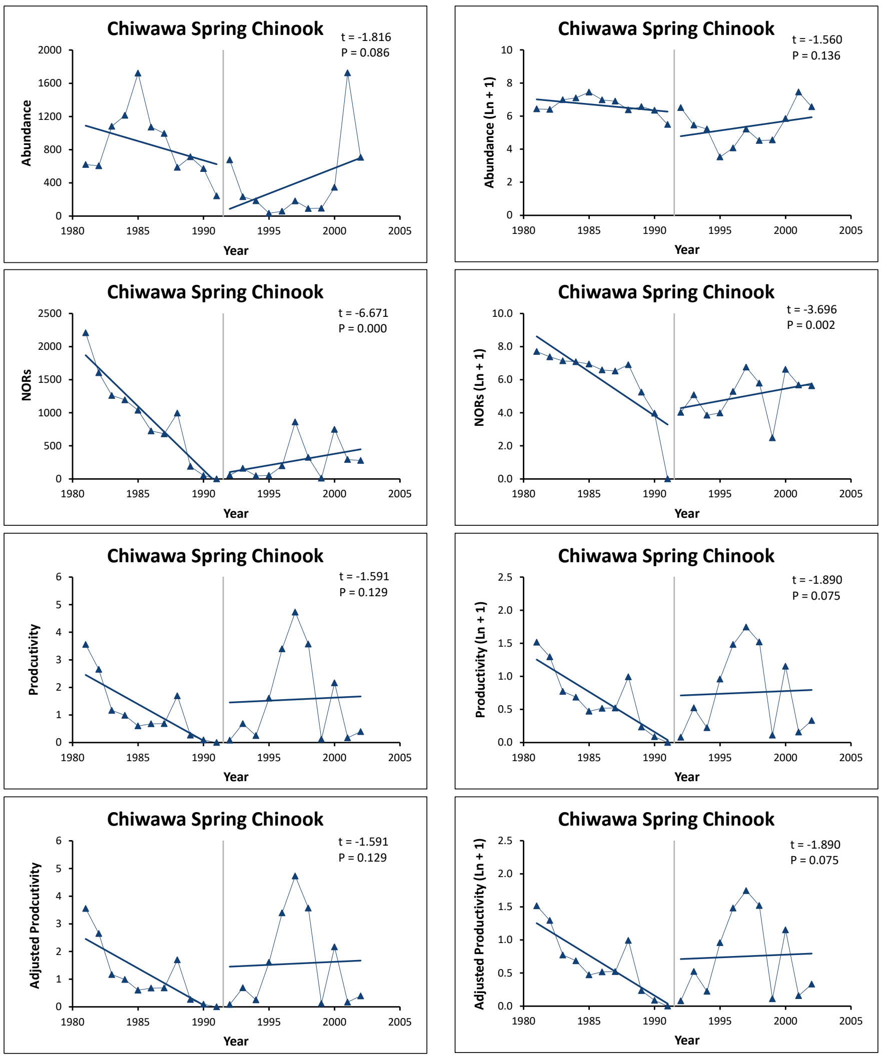

Figure 22. Trends in Chiwawa spring Chinook spawner abundance, natural-origin recruits (NORs), productivity (adults recruits per spawner), and adjusted productivity (adjusted for density dependence) before and during supplementation. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left show untransformed data; figures on the right include natural-log transformed data. Figures include results of t-tests comparing slope of trends before and during supplementation.

Analysis of Mean Scores

We also compared mean spawner abundance, NORs, and productivity data before and after supplementation. If the hatchery program is successfully supplementing the natural spring Chinook population, mean spawner abundance and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean productivity during the supplementation period should be equal to or higher than the pre-supplementation period. We tested the following statistical hypotheses.

Spawner Abundance and NORs:

Ho: Mean spawner abundance and NORs before supplementation ≥ Mean spawner abundance and NORs during supplementation.

Ha: Mean spawner abundance and NORs before supplementation < Mean spawner abundance and NORs during supplementation.

Productivity (Recruits/Spawner):

Ho: Mean productivity before supplementation ≤ Mean productivity during supplementation.

Ha: Mean productivity before supplementation > Mean productivity during supplementation.

We tested before-after supplementation effects using a one-tailed Aspin-Welch unequal-variance test. We also used a randomization test, based on 10,000 Monte Carlo simulations, to assess differences in spawner abundance and productivity before and during supplementation. The randomization procedure only allowed the testing of two-tailed hypotheses. Therefore, we generated 95% confidence intervals on the mean difference (μ_{pre} - μ_{post}) using bootstrapping methods to determine if the significant result from the randomization test was in the right direction. We generated 5,000 bootstrap samples to calculate confidence intervals.

Mean spawner abundance during the supplementation period was significantly less than the pre-supplementation spawner abundance (Table 33). Mean spawner abundance decreased 46% between the pre- and post-supplementation periods. Likewise, mean NORs decreased significantly between the two periods (Table 33). On the other hand, productivity increased slightly, but not significantly, between the pre- and post-supplementation periods (Table 33). This was true for both adjusted and transformed productivity data.

Table 33. Statistical results comparing mean scores of spawner abundance, natural-origin recruits (NORs), and productivity (using both untransformed and natural-log transformed) before and during supplementation of Chiwawa spring Chinook. Randomization tests were based on 10,000 Monte Carlo samples and 95% CI were based on 5,000 bootstrap samples.

Population metric	Mean scores		Test on means			
			Aspin-Welch test		Random test P-value	Bootstrap 95% CI

LN Adj Productivity	0.64	0.75	-0.450	0.671	0.652	-0.57 – 0.34

Analysis of Stock-Recruitment Curves

The third method compared stock-recruitment curves of the Chiwawa population during supplementation with those generated before supplementation. Specifically, we tested whether the regression parameters were equal between the pre- and post-supplementation periods, and whether the fitted curves coincided between the two time periods. We used the methods described earlier to fit the Ricker, Beverton-Holt, and smooth hockey stick curves to the two data sets. We tested the following hypotheses.

Parameter equivalence:

Ho: Stock-recruitment parameters (α and β) of the pre-supplementation period = Stock-recruitment parameters of the supplementation period.

Ha: Stock-recruitment parameters (α and β) of the pre-supplementation period $\neq$ Stock-recruitment parameters of the supplementation period.

Curve equivalence:

Ho: Modeled stock-recruitment curves from the pre-supplementation period = Modeled stock-recruitment curves from the pre-supplementation period.

Ha: Modeled stock-recruitment curves from the pre-supplementation period $\neq$ Modeled stock-recruitment curves from the pre-supplementation period.

We were only able to fit stock-recruitment curves to the post-supplementation data. Non-linear regression was unable to converge on a solution using only pre-supplementation data. Therefore, we were unable to use this method to test supplementation effects on the Chiwawa spring Chinook population. If we could have fit curves to both the pre- and post-supplementation periods, we would have used two-sided randomization tests to evaluate the null hypotheses of equal model parameters and that fitted curves coincided.

Before describing correlation approaches, it is important to note that comparing before-after data can sometimes be misleading. For example, the spawner abundance, NORs, and productivity data presented in Figure 22 suggest that supplementation is increasing the abundance and productivity of spring Chinook in the Chiwawa Basin. However, when we compared these trends to those from reference populations during the same time periods (Figures 9-11), it becomes clear that supplementation was not responsible for increasing the trends in spawner abundance, NORs, and productivity of the Chiwawa population. Thus, whenever possible, it is wise to compare before-after data with a reference population.

Correlation Analyses

A simple way to see if the supplementation program is increasing or decreasing productivity is to assess the association between the proportion of adult spawners that are made up of hatchery adults (pHOS) and productivity (recruits/spawner). If the supplementation program is working as planned, the increase in hatchery fish spawning naturally should increase the productivity of the population. It should not decrease the productivity of the population.

We tested the association between pHOS and adult productivity[23] using Pearson correlation. During the pre-supplementation period, productivity averaged 1.13 recruits/spawner; during the supplementation period, productivity averaged 1.39 recruits/spawner. This increase in productivity did not appear to be strongly correlated to pHOS (Figure 23). Correlation analysis showed that there was no significant association between pHOS and productivity, even though productivity increased with increasing pHOS.

[23] Note that the analysis could also include juvenile productivity (e.g., smolts/spawner).

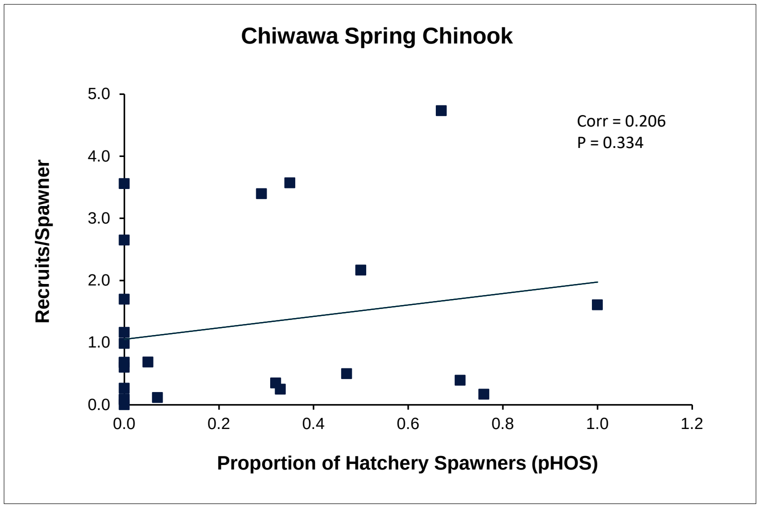

Figure 23. Association between the proportion of spawners that are made up of hatchery adults (pHOS) and the number of natural-origin recruits. The Pearson correlation coefficient (Corr) and its P-value (P) are shown in the figure.

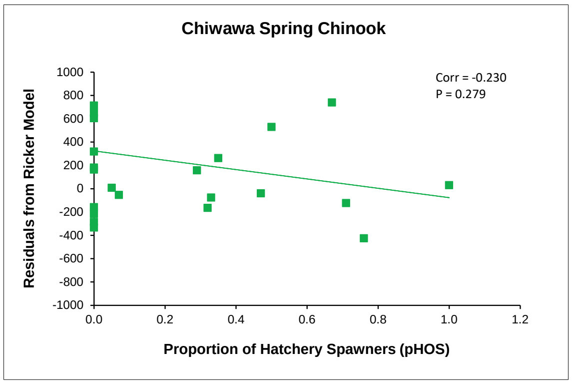
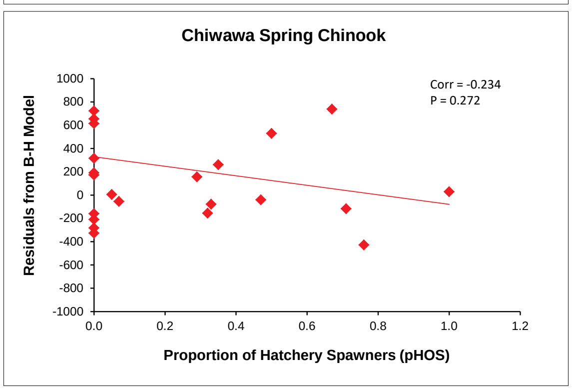
The association between pHOS and productivity can also be assessed by testing the correlation between pHOS and the residuals from stock-recruitment curves fitted to the Chiwawa spawner and natural-origin recruitment data. This approach removes the effects of density dependence on the relationship between pHOS and productivity. A significant negative association provides evidence that hatchery-origin spawners may not be as productive as natural-origin spawners.

The Ricker, Beverton-Holt, and smooth hockey stick models were fit to the Chiwawa stock and recruitment data (including {S, R} data from both the pre- and post-supplementation period, 1981-2004) using methods described earlier. Residuals were calculated by subtracting the predicted recruitment values from the observed (modeled) values. Pearson correlation then tested the association between pHOS and the residuals from each model.

Although there was a negative trend in residuals with increasing pHOS, suggesting that hatchery-origin spawners may not be as productive as natural-origin spawners, the association was not significant (Figure 24). Thus, based on these analyses, there is no strong evidence that the supplementation program has significantly benefited or harmed the natural spring Chinook population.





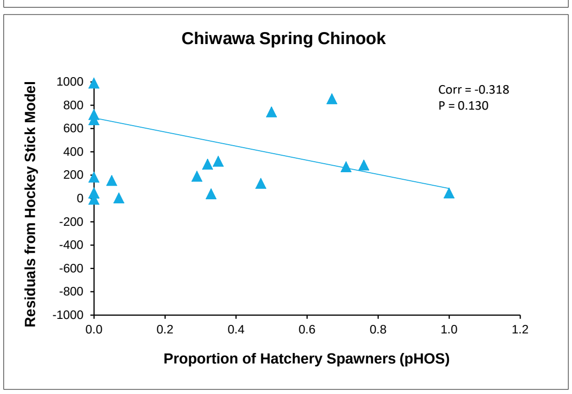


Figure 24. Association between the proportion of spawners that are made up of hatchery adults (pHOS) and the residuals from Ricker, Beverton-Holt (B-H), and smooth hockey stick stock-recruitment models. The Pearson correlation coefficient (Corr) and its P-value (P) are shown in the figures.

Comparison to Standards

In those cases in which suitable reference populations are not available and there are no pre-supplementation data, the investigator is left with comparing population parameters to relevant standards. Standards can include performance of natural-origin fish in similar environments (a type of reference condition), mitigation requirements, quantitative objectives of the program, Biological Assessment and Management Plan (BAMP) values, or other appropriate standards. An example of a statistical hypothesis would be:

Ho: Productivity (Recruits/Spawner) of the supplemented population ≥ standard productivity.

Ha: Productivity (Recruits/Spawner) of the supplemented population < standard productivity.

For these analyses to be useful, the standards must be based on biological reality.

Conclusions and Recommendations

Hatcheries are an important component of fish production within the Upper Columbia Basin. The goal of some of these programs is to supplement natural production in declining populations. The supplementation programs generally use both hatchery and natural (spawned and reared in nature from either wild or hatchery parents) adults for hatchery broodstock. These programs are designed to supplement natural populations by increasing natural reproduction while preventing the establishment of a domesticated hatchery stock. Thus, the programs should increase total spawning escapement and NORs, and not reduce the productivity of the natural population. Measuring the success of these programs is challenging and expensive.

In this paper, we described methods that can be used to determine if supplementation programs are achieving some of their goals. This paper focused on the use of reference populations to determine if the supplementation programs increase total spawning escapement, NORs, and maintain or increase productivities. In some cases, suitable reference populations may not be available (e.g., we found no suitable reference populations for Upper Columbia steelhead and sockeye). In these cases, alternative methods are needed to assess supplementation effects. We also described these alternative methods in this paper.

Identification of Reference Populations

Finding suitable reference populations that match well with supplemented populations is a difficult and time-consuming process. Our three-step selection process included identification of populations with similar life-history characteristics, few or no hatchery spawners, a long time series of accurate abundance and productivity estimates, and similar freshwater habitat impairments and out-of-basin effects. Those populations that met these criteria were then examined for their relationship with the supplemented population (in this case, the Chiwawa spring Chinook population). Several criteria were scored, including pNOS, correlation, trend, and effect size. Reference populations with total weighed scores of 81 or greater were selected as suitable reference populations.

This selection process provided a valuable framework for selecting suitable reference populations for supplemented populations. Interestingly, we found that a given reference population may match well with one parameter of the supplemented population (e.g., spawning escapement), but not for all parameters (e.g., not NORs or productivity). The reason for this may be related to errors

in the estimation of population parameters and/or differential factors limiting population parameters of supplemented and reference populations. Therefore, depending on the parameter analyzed, a different suite of reference populations may be needed.

An important assumption in the use of reference populations is that the supplemented and reference populations that tracked each other before supplementation would continue to track each other in the absence of supplementation. Given that the reference populations did not match the Chiwawa population on all criteria examined, and some reference populations tracked the Chiwawa population more poorly than others, there may be some uncertainty as to whether differences observed between the supplemented and reference populations during the supplementation period are associated with the hatchery program, or other unaccounted factors. For example, any large-scale change (man-made or natural) within the reference or supplemented population could affect our ability to assess the effectiveness of the supplementation program.

To account for some of these uncontrollable factors, we recommend the use of a "causal-comparative" approach to strengthen the certainty of our inferences. This approach relies on correlative data to try and make a case for causal inference. We recommend that the following state variables be measured and tracked within the supplemented and reference populations: mean annual precipitation, total and riparian forest cover, road density, impervious surface, and alluvium. These variables can be used to describe differences in water temperatures at different life stages (pre-spawning, egg incubation, and summer rearing) and substrate characteristics, including fine sediments and embeddedness. These state variables can be used to help explain possible changes in spawner abundance, NORs, and productivity that are independent of supplementation. In addition, the use of multiple reference streams reduces the possibility that man-made changes to a single reference stream will influence the interpretation of the results.

Analyses with Reference Populations

Using reference populations, we evaluated the effects of supplementation on natural-log transformed and untransformed total spawning escapement, NORs, and productivity by comparing trends, analyzing mean differences, ratios, and rates, and comparing stock-recruitment curves and their parameters. For trend analysis, we compared the slopes of the trends between each supplemented/reference pair before and during supplementation. If the hatchery program is successfully supplementing the natural population, trends in spawner abundance and NORs should deviate significantly during the supplementation period (i.e., the slope of the supplemented population should be greater than the slopes of the reference populations during the supplementation period), but not during the pre-supplementation period. For productivity, the slope of the supplemented population, relative to the reference population, should increase or remain the same.

Because trend analysis only tests the slopes of the trend lines, it does not test for differences in elevations of the trend lines, additional analyses were needed to determine if supplementation increased spawner abundance, NORs, and productivity of the target population without changing the slopes of the trend lines. To do this, we derived three different response variables using natural-log transformed and untransformed spawner abundance, NORs, and productivity data. The first derived variable included difference scores, which were calculated as the difference between paired treatment and reference data (T-R). The second included ratios, which were calculated as the ratio of paired treatment and reference data (T/R). Finally, we calculated the differences in annual changes in paired treatment and reference population data (ΔT-ΔR). If the hatchery

program is successfully supplementing the natural population, the mean difference or ratio score of paired spawner abundance data and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean difference or ratio score during the supplementation period should be equal to or higher than the pre-supplementation period.

As a final set of analyses, we compared the stock-recruitment curves of the supplemented population (using stock and recruitment data only from the supplementation period) to the reference populations (using all available stock and recruitment data). Specifically, we tested whether the regression parameters were equal between the supplemented population and the reference populations, and whether the fitted curves coincided between populations. Here, we were most interested in comparing the productivity parameters in the models.

Surprisingly, these different analyses yielded similar results when they were applied to the Chiwawa spring Chinook and reference population data. Trend analysis was unable to detect a significant difference in trends between the supplemented and reference populations during the supplementation period. Even though we measured an increasing trend in spawner abundance, NORs, and productivity in the supplemented population during the supplementation period, these same parameters trended upward in the reference populations. Likewise, we were unable to detect a significant supplementation effect using difference scores, ratios, and differences in annual changes. However, we found the results from analysis of mean differences of annual change difficult to interpret and they may be insensitive to treatment effects. A simpler analysis, which is also easier to interpret, is to use trend analysis. Finally, comparing stock-recruitment curves and their parameters did not provide strong evidence that supplementation has affected the productivity of the natural population.

Based on these results, we do not recommend using difference scores of annual change (ΔT-ΔR), nor do we recommend comparing stock-recruitment curves and their parameters. As noted above, difference scores of annual change are difficult to interpret and may be redundant with trend analysis. Testing stock-recruitment curves and their parameters appears redundant with testing differences in productivity using difference scores or ratios. In addition, the analyses are computer intensive and do not appear to be very sensitive to changes.

There was little difference in results using difference scores and ratios. It appears that ratios may be more sensitive to change than difference scores (e.g., we found significant differences in some comparisons using ratios but not with difference scores), but ratios can be more difficult to interpret than difference scores. Nevertheless, we recommend the use of ratios in future analyses.

Correcting for Density Dependence and Carrying Capacity

The analyses described so far assumed that the density of spawners or recruits did not affect the survival and productivity of fish. However, without controlling for density effects, productivity of the population would continue to decline with increasing abundance. This scenario could occur in supplementation programs that increase the number of spawners, and could result in lower productivities relative to reference populations. In addition, lower productivities may be caused by differential environmental carrying capacities rather than the capacity of the supplemented fish to produce offspring. Therefore, we described two different methods for deriving density-corrected estimates of productivity. The first controlled the effects of density on productivity by partitioning observed productivities into density-independent and density-dependent productivity. These productivities were then combined in a single test. The second method corrected for differences in carrying capacities between the supplemented and reference populations. This was accomplished

by calculating the percent saturation of NORs, which was estimated as the ratio of observed NORs to the maximum number of NORs that the habitat could support.

We fit Ricker, Beverton-Holt, and smooth hockey stick models to stock and recruitment data to estimate the maximum number of NORs (NORs at carrying capacity) and the maximum number of spawners needed to produce maximum NORs. We fit models to the supplemented and reference populations. Using information-theoretic criterion and evaluating the precision of estimated parameters, we found that the smooth hockey stick model provided the best estimates of maximum NORs and spawners. We used these modeled values to estimate density-independent and density-dependent productivities, and saturation of NORs.

Statistical analyses, using difference scores and ratios of adjusted Chiwawa spring Chinook productivity data, found no significant effects of supplementation on the productivity of the supplemented population. Indeed, the results from correcting for density dependence were similar to those without correcting for density dependence. This is in part because the abundance of the supplemented and reference populations has been below their respective carrying capacities in most years. This was clearly demonstrated in the analyses of NORs corrected for carrying capacity. In the supplemented population, the mean fraction of the carrying capacity filled with NORs decreased significantly during the supplementation period. In other words, the carrying capacity was filled with more NORs during the pre-supplementation period than during the supplementation period, which is contrary to the goal of supplementation. By comparison, two of the reference populations showed a similar decrease in saturation, while the other two reference populations actually increased in saturation. Analyzing the saturation scores using BACI-design analyses indicated that two of the four pairings differed significantly. That is, the percent saturation of the supplemented population decreased significantly relative to two reference populations.

Because productivity can be affected by the abundance of spawners and recruits, we recommend that future analyses comparing supplemented and reference populations adjust for density-dependent effects and differential carrying capacities. Although we detected only slight differences between adjusted and unadjusted results, as supplemented stocks recover, it will become more important to adjust productivities to account for density dependence. Importantly, the analyses using percent saturation placed NORs in the context of the carrying capacity of the environment. This will help managers determine if supplementation programs are filling or over-filling the capacity of the habitat with NORs.

As we noted earlier, analyses using productivities adjusted for density dependence assume that there is a spawner abundance at which density-independent effects end and density-dependent effects begin. In reality, density-dependent effects occur at low spawning abundance and intensify as spawning abundance increases. We did not account for these increasing density-dependent effects at lower spawner abundances. This is an area that needs additional attention.

Analyses without Reference Populations

Because of the rigorous criteria we used to select reference populations, it is likely that reference populations may not exist for making comparisons with supplemented populations. For example, we used the criteria described in this paper to identify reference populations for supplemented steelhead and sockeye populations in the Upper Columbia Basin. We were unsuccessful in identifying any suitable reference populations. Therefore, in the absence of suitable reference populations, it is important to have alternative methods for assessing supplementation effects. We described three different types of analyses one can use to assess supplementation effects in the

absence of reference populations. They include before-after comparisons, correlation analysis, and comparisons to standards.

Before-after analyses compare population metrics before supplementation with those during supplementation. In this case, data collected before supplementation represent the reference condition. The assumption is that population trajectories measured during the pre-supplementation period would continue in the absence of supplementation. We compared trends in spawner abundance, NORs, and productivity before and after supplementation. In addition, we compared mean scores in these three parameters before and after supplementation. Finally, we attempted to compare stock-recruitment parameters before and after supplementation. The hypotheses examined were that the spawner abundance and NORs would be greater during the supplementation period, and that productivities would not decline during the supplementation period.

Trend analysis indicated that the all three Chiwawa spring Chinook population parameters trended downward during the pre-supplementation period, but trended upward during supplementation. On the other hand, mean spawner abundance and NORs were lower during the supplementation period than during the pre-supplementation period. Mean productivities increased, but not significantly, during the supplementation period. We were unable to compare pre- and post-supplementation stock-recruitment curves because we were unable to fit stock-recruitment models to the pre-supplementation data.

We used correlation analyses to determine if the proportion of hatchery-origin fish that spawn naturally on the spawning grounds (pHOS) increased productivity. In addition, we used correlation to assess the association between pHOS and the residuals from stock-recruitment relationships. A significant negative association provides evidence that hatchery-origin spawners may not be as productive as natural-origin spawners. The analysis indicated that the productivity of Chiwawa spring Chinook increased with increasing pHOS, but the association was not significant. In contrast, there was a negative association between pHOS and the stock-recruitment residuals, but again the association was not significant. The latter analysis accounts for density-dependent effects.

In concert, the before-after comparisons and correlation analyses do not provide conclusive evidence that the supplementation program has increased spawner abundance and NORs, or that it has significantly reduced the productivity of the supplemented population. Although increasing the number of hatchery fish on the spawning grounds appears to reduce NORs and productivity, mean productivity actually increased during the supplementation period compared to the pre-supplementation period.

It is important to note that relying on only one set of analysis could result in drawing a wrong conclusion. For example, if we had only conducted trend analysis, we may have concluded wrongly that the Chiwawa spring Chinook supplementation program significantly increased spawner abundance, NORs, and productivity in the supplemented population. The analysis of mean scores and correlations indicates that the supplementation program has not increased spawner abundance or NORs in the supplemented population. Therefore, in the absence of suitable reference populations, we recommend that analyses include the evaluation of trends, means scores, and correlations. By conducting more than one set of analyses, one can use weight-of-evidence to assess the effects of supplementation programs.

Under the scenario that there are no reference populations or pre-supplementation data, one is left with comparing population parameters to relevant standards. These standards could come from mitigation requirements, quantitative objectives, or published or unpublished standards. One could also use correlation to evaluate the association between productivity and pHOS, but this requires a wide range in pHOS values to be most effective. A more extreme approach, which probably would not gain much traction with managers, is to shutoff the supplementation program for some time and then evaluate the effects of the program in a before-after design. The Entiat spring Chinook hatchery program provides a unique opportunity to evaluate this type of management decision.

Some Concerns and Limitations

No matter how hard we try to explain different sources of variation in population data, we are limited by the quality of the data. Teasing out the effects of supplementation requires long time series of population data. Because funding levels and methods change over time, the quality (i.e., accuracy and precision) of the data also changes over time. Importantly, the population parameters examined in this paper (spawner abundance, NORs, and productivity) are rarely measured directly in the field. That is, other population metrics, such as numbers of redds, number of fish counted at weirs or dams, scales, tags, etc., are sampled in the field. These metrics are then used to calculate spawner abundance[24], NORs, and productivity, often based on assumptions about fish/redd, pre-spawning loss, marking rates, and sampling rates. This has a tendency to increase the variability in the data independent of supplementation programs. In our studies, we can only control sampling within the supplemented populations, and even that is limited by available funding. We have no control over the sampling within reference populations. Thus, we have to assume that sampling within the reference populations will continue and that sampling effort will remain comparable to that in the supplemented populations.

In our analyses, we included both the Entiat and Little Wenatchee populations as references for the Chiwawa population. In the analyses, we treated them as equivalent to the other reference populations. That is, the statistical procedures used to compare the supplemented population to each reference population were identical. This is appropriate. However, the interpretation of the results must be different when comparing the Entiat and Little Wenatchee to the supplemented population, because they are populations that were influenced by hatchery fish. As noted earlier, the Entiat spring Chinook hatchery program has been discontinued. Therefore, it provides a unique type of reference where the comparison changes from both populations being supplemented to only one population being supplemented. For the Little Wenatchee, nearly all the strays came from the Chiwawa program. Straying should stop or be greatly reduced with the change in water supply to the Chiwawa Rearing Ponds. In sum, one must be careful in how they interpret these test-reference results.

Finally, it is important to point out that for this paper, we conducted 463 statistical tests. Because we set our Type I error rate at 0.05, by random chance alone, we may have incorrectly rejected about 23 null hypotheses. Inasmuch as this work was designed to evaluate different ways to analyze test-reference data, the number of future analyses will be greatly reduced based on the results from this work. However, if the Type I error rate is a concern to managers, researchers can

---

24 The smooth hockey stick model, which we used to estimate density-dependent correction factors for productivity and NORs, is sensitive to errors in spawner escapement estimates. Therefore, it is important to use accurate and precise estimates of spawner escapement.

use a lower error rate, such as α = 0.01. Another option is to analyze test-reference data graphically. Although this is subjective, there are no statistical analyses and therefore no concerns with violating assumptions of statistical tests, including temporal correlation. We believe researchers should use the statistical procedures recommended in this report to support graphic analysis.

Wenatchee Spring Chinook Hatchery Programs
Leavenworth Hatchery first release of spring Chinook
Leavenworth Hatchery releases spring Chinook annually (2.2 M release goal). Broodstock mostly from Carson, Little White Salmon, and Cowlitz hatcheries.
Leavenworth Hatchery releases spring Chinook mostly from Icicle Creek broodstock.
Leavenworth Hatchery Release Goal changed to 1.6 M Smolts
White River Captive Broodstock Programs began
Nason Creek Captive Broodstock Programs began
First release of F2 Chinook from the White River Captive Program
Nason Creek Supplementation Program began with a release goal of 223,670 smolts (125,000 for conservation and 98,670 for safety net)
First release of Nason Creek Chinook smolts

ANCHOR QEA

Memorandum

To: Wells, Rocky Reach, and Rock Island HCP Hatchery Committees

Date: January 21, 2018

From: Tracy Hillman, HCP Hatchery Committees Chairman

cc: Sarah Montgomery, Anchor QEA, LLC

Re: Final Minutes of the November 15, 2017 HCP Hatchery Committees Meeting

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plan (HCP) Hatchery Committees meeting was held at the Grant PUD office in Wenatchee, Washington, on Wednesday, November 15, 2017, from 9:00 to 11:45 a.m. Attendees are listed in Attachment A to these meeting minutes.

Action Item Summary

- Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A). *(Note: this item is ongoing.)*
- Mike Tonseth will coordinate with Todd Seamons (WDFW) to produce an outline or recommended approach for genetic monitoring (Item I-A). *(Note: this item is ongoing.)*
- Bill Gale, Matt Cooper, Charlie Snow (WDFW), Tom Kahler, and Greg Mackey will develop management alternatives for the Twisp River and Winthrop National Fish Hatchery steelhead programs (Item I-A). *(Note: this item is ongoing.)*
- Greg Mackey will revise the Douglas PUD steelhead surplus document and send it to the Hatchery Committees (Item III-A). *(Note: Mackey sent the revision to Sarah Montgomery, which she forwarded to the Hatchery Committees following the meeting on November 15, 2017.)*
- Greg Mackey will provide an update on the Wells and Methow fish hatcheries transition process, particularly regarding fish health and marking strategies, near the end of the transition period (Item III-C). *(Note: Mackey provided this update via email on December 7, 2017.)*
- Greg Mackey will provide an update on summer Chinook salmon spawning numbers for the Douglas PUD programs to the Hatchery Committees (Item IV-A).
- Tracy Hillman will revise non-target taxa of concern language in the draft Monitoring and Evaluation (M&E) Plan for PUD Hatchery Programs (2017 Update) and provide the final approved version to the Hatchery Committees, the Independent Scientific Advisory Board (ISAB), and Greer Maier (Upper Columbia Salmon Recovery Board [UCSRB]; Item V-C). (*Note: Hillman revised and sent the final Plan to Sarah Montgomery, which she distributed to the*

Hatchery Committees and Maier on November 17, 2017. Hillman also sent the plan to the ISAB on November 17, 2017.)

- Tracy Hillman will distribute the draft timelines for Wenatchee and Methow spring Chinook salmon programs for Hatchery Committees review (Item V-D). *(Note: Hillman sent the timelines to Sarah Montgomery, which she forwarded to the Hatchery Committees on November 15, 2017.)*
- Tracy Hillman will draft timelines for summer Chinook salmon, steelhead, and sockeye salmon, and for hatchery programs in the Entiat River basin (Item V-D).
- Sarah Montgomery will distribute Greer Maier's presentation, "Integrated Recovery," from the November 15, 2017 Hatchery Committees meeting (Item IV-E). *(Note: Montgomery sent the presentation to the Hatchery Committees following the meeting on November 15, 2017.)*

Decision Summary

- The Rocky Reach and Rock Island Hatchery Committees approved Chelan PUD's Statement of Agreement (SOA), "Regarding District's Coho Obligation" as follows: Colville Confederated Tribes (CCT) approved via email on November 14, 2017, and Chelan PUD, WDFW, U.S. Fish and Wildlife Service (USFWS), Yakama Nation (YN), and National Marine Fisheries Service (NMFS) approved on November 15, 2017 (Item II-A). *(Note: Sarah Montgomery distributed the Final SOA to the Hatchery Committees on November 16, 2017.)*
- The Hatchery Committees approved the draft M&E Plan for PUD Hatchery Programs (2017 Update), contingent on one edit to the non-target taxa of concern section, as follows: CCT approved via email on November 15, 2017, and Chelan PUD, Douglas PUD, WDFW, USFWS, NMFS, and YN approved on November 15, 2017. Grant PUD (PRCC HSC) also indicated approval of the Plan during the joint HCP-HC/PRCC HSC section of the meeting (Item V-C). (*Note: Sarah Montgomery distributed the final Plan to the Hatchery Committees on November 17, 2017.*)

Agreements

- Wells Hatchery Committee representatives agreed to the following items regarding the surplus of brood year 2017 steelhead for Douglas PUD's program:
  - Release all Twisp no-net-impact and inundation program fish on-station at time of release (55,620 or fewer).
  - Release all Methow inundation program fish on-station at time of release (72,768 or fewer).
  - Retain 210,412 Columbia Safety-Net program fish on-station for release.

 - Release the target of 160,000 Columbia Safety-Net program fish plus a surplus (50,412 or fewer) to make up the shortfall (27,232 or more fish) in the Methow inundation program release, for a total release of 338,800 fish or less.
 - Remove additional surplus fish (37,034 or fewer) from the Columbia Safety-Net program and release in non-anadromous waters under direction of WDFW (Item III-A).

Review Items

- Sarah Montgomery sent an email to the Hatchery Committees on November 27, 2017, notifying them that the *Draft Upper Columbia River Summer/Fall and Fall Chinook Biological Opinion* (BiOp) is available for review with edits and comments due to Emi Kondo by December 11, 2017.

Finalized Documents

- Sarah Montgomery sent an email to the Hatchery Committees on November 7, 2017, notifying them that the *Douglas PUD Final Transition Plan for Wells and Methow Fish Hatcheries* is now available for download from the Hatchery Committees Extranet site.
- Sarah Montgomery sent an email to the Hatchery Committees on November 15, 2017, notifying them that the *Douglas PUD Final 2016 M&E Annual Report* is now available for download from the Hatchery Committees Extranet site.
- Sarah Montgomery sent an email to the Rocky Reach and Rock Island Hatchery Committees on November 16, 2017, notifying them that the Final SOA, *Regarding District's Coho Obligation*, is now available for download from the Hatchery Committees Extranet site.
- Sarah Montgomery sent an email to the Hatchery Committees and PRCC HSC on November 17, 2017, notifying them that the *Final M&E Plan for PUD Hatchery Programs (2017 Update)* is now available for download from the Hatchery Committees Extranet site.
- Sarah Montgomery sent an email to the Hatchery Committees on December 7, 2017 , notifying them that Douglas PUD's *Final 2018 M&E Implementation Plan* is now available for download from the Hatchery Committees Extranet site.

I. Welcome

A. Review Agenda, Review Last Meeting Action Items, and Approve the October 18, 2017 Meeting Minutes (Tracy Hillman)

Tracy Hillman welcomed the Hatchery Committees and asked for any additions or changes to the agenda. Greg Mackey added Douglas PUD items for a steelhead surplus discussion, the Douglas PUD Draft 2018 M&E Implementation Plan, and a discussion about the Wells and Methow fish hatcheries transition. Mike Tonseth added an item for summer Chinook salmon spawning at Wells Fish Hatchery.

The Hatchery Committees representatives reviewed the revised draft October 18, 2017 meeting minutes. Sarah Montgomery said there are a few outstanding comments, and representatives revised the meeting minutes. Hatchery Committees representatives present approved the draft October 18, 2017 meeting minutes as revised.

Action items from the Hatchery Committees meeting on October 18, 2017, and follow-up discussions were addressed *(note: italicized text below corresponds to agenda items from the meeting on October 18, 2017)*:

- *Andrew Murdoch (Washington Department of Fish and Wildlife [WDFW]) will write an overview of proposed expanded sampling at the off-ladder fish trap (OLAFT) at Priest Rapids Dam (Item I-A).*
  This item is ongoing. Mike Tonseth indicated expanded sampling is likely not implementable in 2018.
- *Mike Tonseth will coordinate with Todd Seamons (WDFW) to produce an outline or recommended approach for genetic monitoring (Item I-A).*
  This item is ongoing. Tonseth indicated it will be addressed at the beginning of 2018.
- *Kirk Truscott will discuss internally and coordinate with Keely Murdoch on potential edits to Chelan PUD's Draft Statement of Agreement (SOA) Regarding District's Coho Obligation (Item I-A).*
  This item is complete.
- *Sarah Montgomery and Mike Tonseth will coordinate to revise and finalize the September 20, 2017 Hatchery Committees meeting minutes (Item I-A).*
  This item is complete.
- *Sarah Montgomery will distribute Barry Berejikian's (Northwest Fisheries Science Center [NWFSC]) presentation, "Potential to improve the conservation benefits of steelhead hatcheries," to the Hatchery Committees (Item II-C).*
  This item is complete.
- *Bill Gale, Matt Cooper, Charlie Snow (WDFW), Tom Kahler, and Greg Mackey will develop management alternatives for the Twisp River and Winthrop National Fish Hatchery (NFH) steelhead programs (Item II-C).*
  This item is ongoing.
- *Sarah Montgomery will notify the Hatchery Committees that the Draft Monitoring and Evaluation Plan for PUD Hatchery Programs (2017 Update) will be a decision item at the Hatchery Committees November 15, 2017 meeting (Item III-C).*

This item will be discussed today.

- *Tracy Hillman will distribute the draft timelines for Wenatchee and Methow spring Chinook salmon programs for Hatchery Committees review (Item III-D).*
  This item is complete.

II. Chelan PUD

A. Decision: Coho Salmon SOA (Catherine Willard)

Catherine Willard shared the document, "Draft SOA Regarding District's Coho Obligation," which Sarah Montgomery distributed to the Hatchery Committees on November 3, 2017. Willard said this version of the draft SOA includes the methodology for meeting Chelan PUD's coho salmon obligation, but not the funding arrangement with YN, which will be determined later in a separate SOA after further coordination with YN and CCT.

Bill Gale asked when the second SOA will be brought to the committees. Willard said in order to meet the obligation in 2018, the second agreement should be decided in early 2018, and said contracting can be completed quickly in order to arrange funding shortly after the agreement is made. Gale asked why the original SOA, including the funding arrangement, has been separated into two SOAs. Willard said Chelan PUD wants to record that the methods for calculating the District's obligation are agreed to now, then later agree to the funding arrangement. The Rocky Reach and Rock Island Hatchery Committees approved the SOA as follows: Chelan PUD, YN, WDFW, USFWS, and NMFS approved during the meeting on November 15, 2017, and CCT approved via email on November 14, 2017. (Note: the final version was distributed on November 16, 2017 [Attachment B]).

III. Douglas PUD

A. Steelhead Program Surplus Brood Year 2017 (Greg Mackey)

Greg Mackey shared the document, "Douglas PUD Steelhead Program Surplus BY 2017," which Sarah Montgomery distributed to the Hatchery Committees on November 14, 2017. (Note: a revised version was distributed following the meeting on November 15, 2017 [Attachment C]).

Mackey said the Douglas PUD steelhead program has an excess of 7,620 fish in the Twisp program, an excess of 87,446 in the Columbia program, and a shortage of 27,232 fish in the Methow program. Mike Tonseth said the numbers he received regarding the surplus are different, and Mackey said he would check accuracy and distribute a final document with the numbers; regardless, there is a surplus and the committees need to discuss how to meet obligations and release excess fish. Tonseth said long-term commitments are to manage programs to 100%, not 110% of targets, based on input from Craig Busack (NMFS). Keely Murdoch agreed and said the programs should be managed to 100% of the target, but if an overage up to 110% occurs, those fish should be released. Murdoch recommended keeping 110% of the targeted level of fish, because some fish will die during the winter. Mackey agreed that the program should not purposefully release 110% of the target level of fish.

Mackey said the Twisp program has an overage of wild-by-wild fish, and asked if those fish should be kept even though the current number is above 110% of the target. Bill Gale asked if the Twisp program fish are different than other groups and said the Winthrop and Twisp programs have similar brood stock. Tonseth advocated maintaining the Twisp program at its current level (overage), in order not to disrupt tagging and smolt-to-adult return estimates. Murdoch asked if the permit for these programs is written such that the 100% target pertains to the program combined, or to each release group. Tonseth said the targets are for the program as a whole. Gale said he thinks it is acceptable to manage the program target with a combined approach this year, but the Hatchery Committees should not set the precedent of managing release groups in aggregate due to long-term unintended consequences. Tonseth said sufficient broodstock were collected for each release component, and the overage is due in part to collection of 2-salt fish, while the shortage is related to a water issue at the hatchery resulting in some steelhead dying. Tonseth said the situation in 2017 is unique, and the programs are not set up to automatically backfill each other. Mackey agreed and said there was no issue with broodstock collection, and if there had been, it would have been addressed earlier.

Mackey said one option is to maintain the Twisp program as-is with the overage, release all the Methow program fish that are available, and backfill the release up to 110% with the Columbia program overage. Tonseth said the broodstock collection protocols and BiOp are specific as to which broodstock comprise the safety-net program. He said due to the parental origin of surplus hatchery fish being unknown, those should not be used for safety-net releases. Tonseth said Mackey's proposition will likely meet the 100% target, though with a different make-up than planned. Murdoch asked if other steelhead programs are short. Tonseth said Okanogan and Ringold programs are not short, and Matt Cooper said the Winthrop program is also not short.

Tracy Hillman asked why the Methow program is short. Mackey said the shortage is due to a power outage at Wells Fish Hatchery that occurred in early summer 2017. When power was out, the water supply diminished and an airlock in the pipes resulted in steelhead fry (mostly Methow program) being siphoned out of start tanks.

Mackey summarized that the programs combined have a targeted release of 308,000 fish, not to exceed the 110% level of 338,800 fish. He said by keeping the Twisp overage, releasing all the Methow program fish available, and backfilling with Columbia program fish to meet the total mitigation obligation, the Hatchery Committees should discuss whether to maintain only the 308,000-targeted fish or to maintain 338,800 fish at a 10% overage. Gale suggested maintaining the 308,000 fish plus an estimate for winter mortality. Tonseth reminded the representatives that the estimates presented today are from the time the fish are tagged, and some will die before release. Tonseth estimated that if 338,800 fish are maintained, approximately 325,000 would be released, which he said is a reasonable buffer.

Gale said at those numbers, the Columbia program would be at an approximate 15% overage, and fish from that release that stray into the Methow River might be an issue and should be considered. Murdoch said with a year of poor steelhead survival, strays into the Methow River may not be an issue. Tonseth said the Columbia program has the greatest likelihood of adults being removed upon return, which also helps to minimize straying into the Methow River.

Brett Farman said overages are generally considered by each release location, not as an aggregate of programs. He said if the Hatchery Committees agree to the deviation as a group, that is acceptable for this occasion. Farman asked about the marking strategy for these releases, and if they can be differentiated upon return. Mackey said the Columbia program release is ad-clipped only, the Methow release is ad-clipped only, and the Twisp release is CWT only. Tonseth noted that the BiOp for Methow steelhead programs indicates that if shortages or overages occur in one component, the difference is made up by the Columbia release, as proposed today to meet the production obligation for Douglas PUD.

Mackey said surplus fish are usually put into non-anadromous waters as determined by WDFW. Douglas PUD, YN, WDFW, USFWS, and NMFS came to agreement about the surplus, and CCT provided input via email. Wells Hatchery Committee representatives agreed to the following items regarding the surplus of brood year 2017 steelhead for Douglas PUD's program:

- Release all Twisp no-net-impact and inundation program fish that are on-station at time of release (55,620 or fewer).
- Release all Methow inundation program fish that are on-station at time of release (72,768 or fewer).
- Retain 210,412 Columbia Safety-Net program fish on-station for release.
- Release the target of 160,000 Columbia Safety-Net program fish plus a surplus (50,412 or fewer) to make up the shortfall (27,232 or more fish) in the Methow inundation program release, for a total release of 338,800 fish or less.
- Remove additional surplus fish (37,034 or fewer) from the Columbia Safety-Net program and release in non-anadromous waters under direction of WDFW.

B. M&E Implementation Plan 2018 (Greg Mackey)

Greg Mackey said Douglas PUD has not yet received any substantial comments on their draft 2018 Implementation Plan, which is available for review until December 1, 2017.

C. Wells and Methow Fish Hatcheries Transition (Greg Mackey)

Greg Mackey said Douglas PUD has fully staffed both the Wells and Methow fish hatcheries. Mackey said the transition is on track to be complete within 90 days as planned, and Douglas PUD is working to finalize paperwork and responsibilities. Bill Gale asked if anyone has been hired for the fish health position. Mackey said not yet, and Douglas PUD has not decided yet to hire for the position or contract it with WDFW. Mike Tonseth asked if contracts for fish marking will also be decided soon. Mackey said the contracts would be separate [from fish health], and Douglas PUD has requested quotes from entities capable of marking fish for these hatcheries, including WDFW, CCT, USFWS, and others. Gale noted the 90-day transition period ends before the next Hatchery Committees meeting, and asked for an update on remaining items towards the end of the transition period. Mackey said he will provide an update.

IV. WDFW

A. Summer Chinook Salmon Spawning Update (Mike Tonseth)

Greg Mackey said Mike Tonseth asked for an update on spawning for the Douglas PUD summer Chinook salmon program. Mackey said staff acquired the full program egg take, with a possible surplus. He said staff collected an additional 18 females to augment losses during an outbreak of columnaris.The Yakima River restoration program receives eggs through the Wells broodstsock collection and spawning. YN staff participates in spawning on days when the Yakima River program receives eggs. He said because late females were not sexually maturing as expected, it is not currently known how many eggs went directly to the Yakima River restoration program. He said as of November 13, all fish were spawned and the remainder were killed because they were either gong to die form the Columnaris infection or were so sexually immature that they were not likely to mature at all. Tonseth asked for a second update when Douglas PUD has revised numbers. Mackey said he will provide an update.

V. Joint HCP-HC/PRCC HSC

A. NMFS Consultation Update (Emi Kondo)

Emi Kondo provided an update on consultation for the unlisted programs in the upper Columbia River. Kondo said she received the official initiation of consultation request, and now NMFS will respond with letters of sufficiency to the applicants. She confirmed to whom the letters should be addressed for Douglas PUD, Grant PUD, Chelan PUD, and WDFW.

She said the Draft Upper Columbia River summer/fall and fall Chinook salmon BiOp will go to General Counsel review soon, then back to the applicants for review. She said this BiOp is a regional priority to finish by the end of 2017, and asked for the Hatchery Committees to be aware that it will be available for review soon.

Alene Underwood asked for an update on the steelhead draft permit. Kondo said she is not sure on the status of the steelhead draft permit, and said Charlene Hurst would have more information about that permit.

B. USFWS Bull Trout Consultation Update (Matt Cooper)

Matt Cooper said Karl Halupka provided him an update on USFWS bull trout consultations, which he summarized as follows:

- Halupka is finalizing editorial pieces and working to get the BiOp for the batch of Wenatchee subbasin programs signed this week.
- Halupka is making progress on the Methow steelhead consultation, and is using the memorandum format developed for Methow spring Chinook salmon. He expects this to be complete by the end of November.
- Halupka received additional information for the unlisted programs in the upper Columbia River, which will inform the effects analysis. He said the schedule for completing a letter of concurrence depends on when NMFS is able to initiate consultation.

Mike Tonseth added that the USFWS consultation for the unlisted batch of Columbia River programs will likely only require a letter of concurrence.

C. Decision: M&E Plan for PUD Hatchery Programs, 2017 Update (Tracy Hillman)

Tracy Hillman shared the revised document, M&E Plan for PUD Hatchery Programs (2017 Update), which Sarah Montgomery distributed to the Hatchery Committees on October 19, 2017. Hillman said the sections about non-target taxa of concern and adaptive management have been recently updated, and Andrew Murdoch also provided edits to Appendix 1, Estimation of Carrying Capacity.

He asked if the Hatchery Committees approve the revised document. Chelan PUD, Douglas PUD, YN, USFWS, NMFS, and WDFW approved during the meeting, and CCT approved via email. Grant PUD (PRCC HSC) also indicated approval.

Hillman said he will finalize and distribute the document to the committees, Greer Maier, and the ISAB. (Note: Montgomery distributed the final version on October 17, 2017 [Attachment D]).

D. Timeline of Changes in Spring Chinook Salmon Programs (Tracy Hillman)

Tracy Hillman shared the document, Draft Hatchery Program Timelines, which Sarah Montgomery distributed to the Hatchery Committees on October 18, 2017 (Attachment E). Hillman said he received feedback from USFWS and Chelan PUD on the timelines. He said once the timelines have all the needed information, statistical break periods can be decided. Hillman said he will revise the timelines based on further input from Douglas PUD, and also prepare draft timelines for steelhead and summer Chinook salmon. Once the timelines are complete, the best way to complete the statistical and comprehensive reports can be decided.

Bill Gale asked if a timeline should be created for the Entiat. He said there is no PUD hatchery production there, but it could be related to analyses for statistical and comprehensive reports. Hillman said he will make a timeline for the Entiat and asked representatives to send him input for it. Mike Tonseth said spring and summer Chinook salmon programs have been in the Entiat River, and steelhead used to be released there too. Gale suggested developing a timeline for sockeye. Hillman said he can do that. Gale suggested also displaying the timelines by basin as well as species. Todd Pearsons suggested also displaying the timelines in table format, and also including exact dates as well as years whenever possible. Mackey suggested identifying year and brood year whenever possible. Hillman said he would incorporate these suggestions and continue revising the timelines.

E. Discuss UCSRB Hatchery Report (Greer Maier)

Tracy Hillman welcomed Greer Maier to the meeting, and said Maier will be discussing the UCSRB's draft Hatchery Summary. Maier shared a presentation, "Integrated Recovery" (Attachment F), which Sarah Montgomery distributed to the Hatchery Committees on November 15, 2017. Maier said the UCSRB implements the Upper Columbia Salmon and Steelhead Recovery Plan along with their partners, including the Integrated Recovery Technical Advisory Group (IRTAG), and the plan identifies actions across the four H's, hydropower, hatcheries, habitat, and harvest. Maier reviewed the process of writing the Habitat Report and Hatchery Summary, and discussed the contents of the Hatchery Summary.

Maier said the next steps for the Hatchery Report include a meeting next week to edit and review the report with the IRTAG, then it will hopefully be approved at the board meeting in December. In 2018, the UCSRB plans to share the report and knowledge from it through meetings and conferences. Then, the UCSRB will develop summaries for hydropower and harvest. Maier said the UCSRB is always looking to partner with other entities in order to move along initiatives that benefit recovery.

Questions and Comments

Bill Gale asked about the delineation between the hatchery report and the harvest report. He said with the Leavenworth programs, for example, there are unlisted hatchery programs that produce fish for harvest, but these programs are described in the Hatchery Summary. Maier said the harvest report has not been started yet, and the hatchery report focuses on hatchery fish interacting with listed species. She said there is overlap, and a clear line has not been drawn yet. She said she is open to suggestions on which programs to discuss in which report. Mike Tonseth suggested describing a clear linkage between the harvest and hatchery reports. He said harvest programs such as summer Chinook, fall Chinook, and sockeye salmon have impacts to listed fish. Maier agreed and said those will be addressed in the harvest report. Gale suggested being very clear about which programs and topics are included in each report.

Gale also suggested providing more clarity in the adult straying section, where he said hatchery escapement and straying are somewhat conflated. He said the Hatchery Committees discuss strays as out-of-population strays, and if a hatchery fish returns to its intended population (such as Wenatchee, Methow, or Okanogan), then it is not a stray; rather, it is a hatchery movement and escapement issue. Maier said the National Oceanic and Atmospheric Administration thinks that there are consequences to within-population straying, and within-population straying is reported in documents prepared by or for the Hatchery Committees. Gale suggested separating the types of straying more clearly. Greg Mackey said out-of-population straying is a genetic issue, and within-population straying is a management issue. Keely Murdoch said the level of concern for each type of stray depends on the program and species because they are all managed differently. Maier said the section discussing straying includes a general overview, and she will add more information about within-basin and out-of-basin strays. Mackey said that information is provided in PUD reports. Hillman suggested organizing that section by the recovery plan objectives and goals. He said the recovery plan mainly discusses out-of-population straying, but also discusses within-population straying. Maier liked this approach, and Hillman said she can find appropriate language and terms in the Hatchery M&E Plan. Gale said data for within-population straying are hard to compile, and so it might be best to show out-of-population stray data and describe that within-population straying also occurs. Maier said the document currently shows brood-year stray rates. Todd Pearsons said viable salmon population (VSP) criteria include within- and between-population stray rates, and said brood-year stray rates are different. He suggested focusing primarily on VSP-related stray rates. Hillman suggested reporting return-year stray rates instead of brood-year stray rates, because the recovery plan discusses return-year stray rates. Tonseth agreed and said examining brood-year stray rates can help determine if rearing practices or release strategies may contribute to stray rates, but it is more for management than evaluation. Mackey suggested reporting the number of fish along with the stray rate percentage, as percentages can be misleading depending on the size of the recipient program. Maier said she would consider these suggestions and review the Hatchery M&E Plan (2017 Update) for further content.

Mackey said for assessing habitat or hatchery performance, or for setting a management strategy, one could examine percent improvement for each generation or each year, then compile years and examine improvement over time. He said some improvements cannot be detected in year-to-year evaluations, but over a longer period of time they would be detected, as in a life cycle model. Maier said Jeff Jorgensen (NWFSC) included life cycle modeling scenarios with improvements over time (i.e., increasing natural-origin adults), and the results are included in the original Hatchery Summary draft, but not the most recent version. Mackey said the life cycle model will be useful for examining expected changes over time and will help with long-term planning and expectations. Hillman asked if Jorgensen's results showing that hatchery programs are very important to reducing the threat of extinction are included in the Hatchery Summary. Maier said those results are not included in the most recent version of the summary, but the life cycle model includes a robust hatchery module that should be considered especially considering realistic increases in natural-origin returns.

Hillman asked if non-target taxa of concern species are addressed in the Hatchery Summary. Tom Kahler said the BiOps contain information about non-target taxa of concern species that could be used in the summary. Mackey recommended contacting Craig Busack and Charlene Hurst for more information about non-target taxa of concern topics. Pearsons said there is published information about the non-target taxa of concern model, which could also be used in the summary.

Maier summarized that the UCSRB will start working on the hydro report next, then harvest. Peter Graf (Grant PUD) asked what the UCSRB's goals are for shared learning and discussions. He asked who will be participating in these discussions. Maier said shared learning will involve presentations to the Board from members of the IRTAG or Hatchery Committees. She said the Board should understand the relationship between management sections and recovery, and the goal is for the Board to engage on hatchery topics and understand the programs and management concepts.

Maier summarized that any further comments should be provided to her by Monday, November 20, 2017, so the IRTAG can address any outstanding issues. She asked representatives present for any further input on this summary. Catherine Willard said the summary is much improved from the previous draft, and Murdoch agreed. Maier asked what representatives think of this summary format, and said the hydro summary will likely focus on direct life stage interactions with the hydro system. Willard said she thinks the summaries will be useful for habitat and hydro managers.

Gale asked what the timeline is for reexamining the four H's once the reports are completed. Maier said for the Habitat Report, the UCSRB maintains a database of important information for tracking habitat projects. She said the Board tracks certain metrics and reports on them yearly. She said she expects the Hatchery Summary will also result in a database that is updated and reported annually. Gale suggested finalizing which data will be reported on and maintained before the report is finalized, so that the report points to and focuses on which data will be tracked.

Matt Cooper asked if there will be a report or modeling effort that will tie the four H reports together. Maier said the Board has discussed writing a synthesis report, but has not decided yet, and the discussion will likely continue during the sharing sessions when the most important data for interactions between the H's are identified.

Hatchery Committees representatives present thanked Maier for her presentation.

VI. HCP Administration

A. Next Meetings

Tracy Hillman asked if the Hatchery Committees plan to meet in December. Bill Gale said the committees might need to discuss consultations at the December meeting. Hillman summarized that the Hatchery Committees might have a conference call or meet in person in December, depending on what needs to be discussed.

The next Hatchery Committees meetings are on December 20, 2017 (TBD), and January 17, 2018 (Grant PUD), and February 14, 2018 (Grant PUD).

Rocky Reach and Rock Island HCP Hatchery Committees
FINAL Statement of Agreement
Regarding District's Coho Obligation
November 15th, 2017

Approved as follows: CCT approved via email on November 14, 2017, and Chelan PUD, WDFW, USFWS, NMFS, and YN approved on November 15, 2017.

Statement

The Rocky Reach and Rock Island HCP Hatchery Committees (hereafter "Committees") agree that Chelan PUD shall provide coho compensation for the Methow River and Wenatchee River sub-basins at a rate equivalent to 7.0% at each project to meet Chelan PUD's No Net Impact hatchery obligations for brood years 2017 to 2021 (release years 2019 to 2023); therefore, 7.0% will be used as the coho hatchery compensation rate until the next scheduled hatchery compensation recalculation (2023). Methodology described in the SOA Regarding the 2013 No Net Impact Recalculation Methodology (dated July 20th, 2011) will be used to calculate hatchery compensation levels for coho.

Background

On June 20, 2007, the Committees agreed to implement coho hatchery compensation as detailed in Section 8.4.3.a of the Rocky Reach and Rock Island HCPs and agreed that the District shall begin providing hatchery compensation no later than October 1, 2007. On March 28, 2017, the Rocky Reach and Rock Island Coordinating Committees agreed to use Chelan PUD's yearling Chinook acoustic tag survival estimates and coho PIT-tag based survival estimates to estimate juvenile coho survival of 93.98% at Rock Island and 92.94% at Rocky Reach (Skalski and Townsend 2017) which culminated in a 93% survival value at both projects.

Calculations for the Methow Sub-basin Coho Reintroduction Project

Compensation for **hatchery-origin smolts** will be determined by multiplying the Program's annual release targets from the Methow sub-basin coho reintroduction project by the unavoidable project mortality (1-(0.93 x 0.93)) for Rocky Reach and Rock Island.

Compensation for **natural-origin smolts** produced is determined by:

- Mean NOR[1] to Rocky Reach (return years 2008 to 2011 and 2013 to 2015) = 43
- Mean NOR in absence of project mortality: 43/0.9300 = 46
- Adult equivalents to meet NNI: 46-43=3
- Mean 8-year SAR (release years 2008-2015 Methow sub-basin hatchery program) = 0.59%
- Compensation for natural-origin smolts: 3/0.0059 = 508 smolts

Calculations for the Wenatchee Sub-basin Coho Reintroduction Project

Compensation for **hatchery-origin smolts** will be determined by multiplying the Program's annual release targets from the Wenatchee sub-basin coho reintroduction project by the unavoidable project mortality (1-0.93) for Rock Island.

Compensation for **natural-origin smolts** is determined by:

- Mean NOR to Rock Island (return years 2007-2016) = 529
- Mean NOR in absence of project mortality: 529/0.9300 = 569
- Adult equivalents to meet NNI: 569-529 = 40
- Mean 10 year SAR[2] (release years 2006-2015 Wenatchee sub-basin hatchery program) = 0.75%
- Compensation for natural-origin smolts: 40/0.0075 = 5,333 smolts

[1]Natural-origin return=NOR
[2]SAR=releases from the Wenatchee hatchery programs and returns to Priest Rapids Dam (versus Rock Island Dam due to historic variable PIT tag detection efficiency at the adult ladders).

November 2017

HCP-HC

Douglas PUD Steelhead Program Surplus BY 2017

Quick Description:

The Twisp program has excess, the Methow Program is short, and the Columbia program has substantial excess fish. However, if the program + 10% overage is considered, the Twisp is 2,820 over and the Columbia is 71,232 over. The Methow is 27,232 under the 100,000 release target.

The Twisp includes 8,000 NNI (this obligation is met first). If we use the Columbia release to absorb the shortfall in the Methow Inundation and the overage in the Twisp Inundation, we can meet the mitigation obligations. This results in 37,034 surplus Columbia Inundation fish while maintaining +10 % across the DPUD programs in aggregate.

The 37,034 surplus would be provided to WDFW to release in non-anadromous waters.

Breakdown of the numbers:

	NNI	Inundation	Target	Target+10%	Difference	Diff at +10%
Twisp	8,000	47,620	48,000	52,800	7,620	2,820
Methow	0	72,768	100,000	110,000	-27,232	-37,232
Columbia	0	247,446	160,000	176,000	87,446	71,446
Total	8,000	367,834	308,000	338,800	67,834	37,034

Adjust Columbia to compensate for low Methow, high Twisp and High Columbia

Surplus Columbia = 37,034

Under this scenario the total release would be:

Twisp	55,620	
Methow	72,768	
Columbia	210,412	
Total	338,800	Matches the overall target of 308,000 + 10% = 338,800

SECTION 1: INTRODUCTION

This document is an update of the monitoring and evaluation (M&E) plan of the salmon and steelhead hatchery programs funded by Douglas, Chelan, and Grant County Public Utility Districts (PUDs). Programmatic changes, evaluation of data collection methods, and M&E results from the past several years, along with shifting management paradigms affect M&E needs, all of which have occurred under advancing fish culture and monitoring techniques. As required by the programs, this document is a result of a five-year review intended to expand on and coalesce previous M&E documents (BAMP 1998; Cates et al. 2005; Murdoch and Peven 2005; Hays et al. 2006; Pearsons and Langshaw 2009a, 2009b; Hillman et al. 2013) with inclusion of new information.

Fishery management agencies developed the following general goal statements for hatchery programs, which were adopted by the HCPs Hatchery Committees and PRCC Hatchery Sub-Committee (hereafter, Hatchery Committees):

1. Support the recovery of ESA-listed species by increasing the abundance of the natural adult population, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity.
2. Increase the abundance of the natural adult population of unlisted plan species, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity. In addition, provide harvest opportunities in years when spawning escapement is sufficient to support harvest.
3. Provide salmon for harvest and increase harvest opportunities, while segregating returning adults from natural tributary spawning populations.

Following the development of Hatchery and Genetic Management Plans (HGMPs), artificial supplementation programs are now characterized into three categories. The first type, integrated conservation programs, are intended to support or restore natural populations. These programs focus on increasing the natural production of targeted fish populations. A fundamental assumption of this strategy is that hatchery fish returning to the spawning grounds are reproductively similar to naturally produced fish. The second type, safety-net programs, are extensions of conservation programs, but are intended to function as reserve capacity for conservation programs in years of low returns. The safety-net provides a demographic and genetic reserve for the natural population. That is, in years of abundant returns they function like segregated programs, and in low return years they can be managed as conservation programs. Lastly harvest augmentation programs are intended to increase harvest opportunities while limiting interactions with wild-origin counterparts.

Monitoring is needed to determine if the hatchery programs are meeting the intended management objectives of conservation, safety-net, or harvest augmentation programs. Objectives for hatchery programs are generally grouped into three categories of performance indicators:

1. In-Hatchery: Is the program meeting the hatchery production objectives?
2. In-Nature: How do fish from the program perform after release?
    a. Conservation Program:

- How does the program affect target population abundance and productivity?
- How does the program affect target population long-term fitness?

b. Safety-Net Program:
- How does the program affect target population long-term fitness?

c. Harvest Augmentation Program:
- Does the program provide harvest opportunities?

3. Risk Assessment: Does the program pose risks to other populations?

Objectives in this plan have been organized in a hierarchy where productivity indicators are the primary metrics used to assess if conservation and safety-net program goals have been met; harvest rates and effects on non-targeted populations are used for harvest programs. In cases where productivity indicators are not available or results are equivocal, monitoring indicators may be used to help evaluate the performance of the program. Evaluations of monitoring indicators may not provide sufficiently powerful conclusions on which to base management actions, although they may provide insight as to why a productivity indicator did or did not meet the program goal. Therefore, the relationship between hatchery programs and indicators can be viewed in a chain-of-causation: management actions within the hatchery programs affect the status of monitoring indicators, which in turn influence productivity indicators (Figure 1).

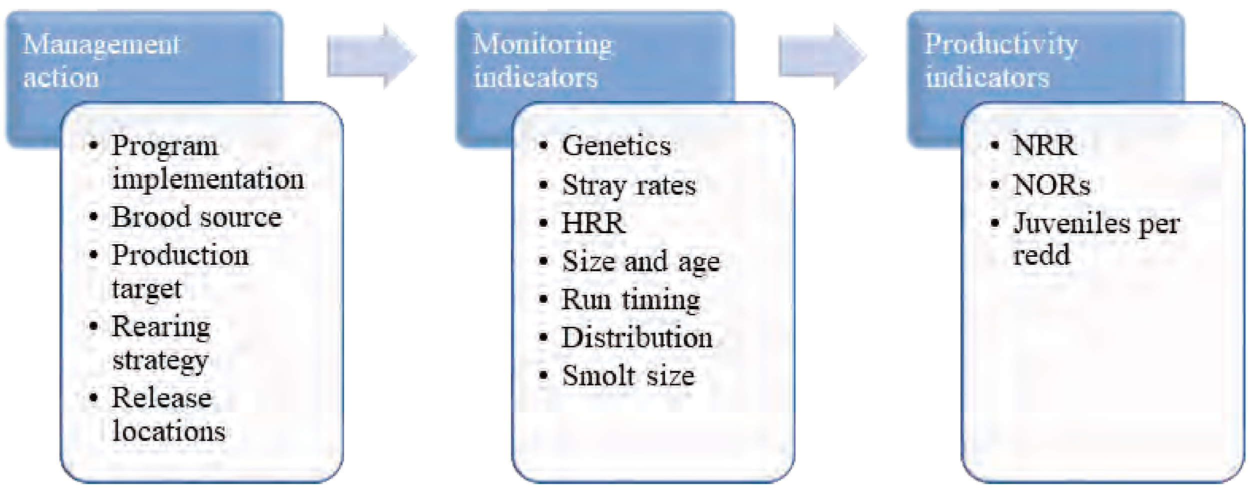

Figure 1. Relationship of indicators to the assessment of supplementation programs. Management actions affect monitoring indicators, which influence productivity indicators. Monitoring indicators may be used to hypothesize the magnitude of influence on productivity.

The primary goal of a conservation program is to contribute to the rebuilding and recovery of naturally reproducing populations within their native habitat. In this plan, natural replacement rates (NRR), recruitment of naturally-produced fish (NOR), and juvenile productivity (juveniles per redd) are important indicators for assessing the success of supplementation. These indicators are difficult to measure precisely and are quite variable in space and time. Therefore, monitoring indicators can be evaluated to help assess if productivity was related to the hatchery programs or other factors (Table 1).

Table 1. Program objectives, indicators, and goals for conservation hatchery programs including productivity and monitoring indicators (also applies to safety-net programs when used to support a conservation program).

	Objective	Indicator	Target	Program goals: Rebuild natural populations	Program goals: Maintain genetic diversity	Program goals: Opportunity for harvest
Productivity indicators	Determine if the program has increased the number of naturally spawning adults	Abundance of natural spawners	Increase	✓		✓
		Adult productivity (NRR)	No decrease	✓		
	Determine if the proportion of hatchery fish affects freshwater productivity	Residuals vs. pHOS	No relationship	✓		
		Juveniles per redd vs. pHOS	No relationship	✓		
Monitoring indicators	Determine if run timing and distribution meets objectives	Migration timing	No difference	✓	✓	
		Spawn timing[1]	No difference	✓	✓	
		Redd distribution[2]	No difference	✓	✓	
	Determine if program has affected genetic diversity and population structure	Allele frequency (hatchery vs. wild)	No difference		✓	
		Genetic distance between populations	No difference		✓	
		Effective population size	Increase		✓	
		Age and size at maturity	No difference		✓	
	Determine if hatchery survival meets expectations	HRR	HRR > NRR	✓		
		HRR	HRR ≥ Goal[3]	✓		
	Determine if recipient stray rate of hatchery fish is acceptable	Out of basin	≤ 5%	✓	✓	
		Within basin	≤ 10%	✓	✓	
	Determine if hatchery fish were released at program targets	Size and number	= Target[4]	✓		
	Provide harvest opportunities when appropriate	Harvest	Escapement goals			✓

[1] Hatchery and natural-origin fish should spawn at the same time across the range of elevations within the spawning distribution of each stock.

[2] Hatchery and natural-origin fish should spawn in the same locations. Exceptions are the Carlton and Dryden Summer Chinook programs (see Appendix 4).

[3] HRR targets are identified in Appendix 2.

[4] Number and size targets are identified in Table 3 and Appendix 5.

A flow of information following sequential, logical steps will be employed to evaluate supplementation programs, consistent with the indicators described in Table 1. For example, a hatchery program, at a minimum, must be able to produce more adults per spawner than would occur in the natural environment. Should the program fail this test, hatchery operations should be evaluated to determine if improvements can correct the problem. If a program successfully replaces the required number of adults, it is then evaluated against a reference population or condition, if available, to determine if it has increased the overall number of naturally spawning fish (including both hatchery- and natural-origin adults), increased the number of natural-origin spawners, and to test if productivity of the natural population has changed. When these goals are met, the program is considered successful. When these goals are not met, monitoring indicators may infer why the program is not achieving its goals

If suitable reference populations are not available, other comparisons can be used to help evaluate treatment responses. Evaluation of programs may pursue the following approaches:

- Comparison to reference population(s) that do not contain pre-treatment data.
- Before treatment and after treatment comparisons.
- Comparison to standard(s).
- Comparison to other suitable reference conditions.

Methodologies for selecting reference streams, analyzing data from treatment and reference stream comparisons, and other comparisons are presented in Hillman et al. (2012) (see Appendix 6).

The primary goals of a safety-net program are to provide demographic and genetic reserves for a population that is supplemented by a conservation program (Table 2). Harvest and adult management may be used to control escapement of spawners when appropriate. Monitoring focuses on estimating the number of fish that escape to spawn naturally and stray rates and in-hatchery performance evaluation.

Table 2. Program objectives, indicators, and goals for segregated harvest augmentation hatchery programs including monitoring indicators.

				Program goals		
	Objective	**Indicator**	**Target**	**Rebuild natural populations**	**Maintain genetic diversity**	**Opportunity for harvest**
Monitoring indicators	Determine if hatchery survival meets expectations	HRR	HRR > NRR			✓
		HRR	HRR ≥ Goal[1]			✓
	Determine if stray rate of hatchery fish is acceptable	Out of basin	≤ 5%		✓	
		Within basin	≤ 10%		✓	
	Determine if hatchery fish were released at program targets	Size and number	= Target[2]			✓
	Provide harvest opportunities when appropriate	Harvest	When greater than escapement goals			✓

[1] HRR targets are identified in Appendix 2.

[2] Number and size targets are identified in Table 3 and Appendix 5.

The primary goal of a harvest augmentation program is to increase harvest opportunities, while segregating adults from natural spawning populations. In this plan, harvest opportunity, survival rates, and stray rates are important indicators for assessing the success of harvest augmentation. These indicators are more readily quantified compared to productivity indicators (Table 2). A flow of information will be employed to evaluate harvest augmentation programs. Since harvest augmentation programs are typically segregated, monitoring indicators will be used to determine the success of a program.

Both monitoring and productivity indicators will be used to evaluate the success of hatchery programs. In the event that the statistical power of tests that involve productivity indicators is insufficient to inform sound management decisions, some of the monitoring indicators may be used to guide management. Figure 2 show the categories of indicators associated with each component of monitoring.

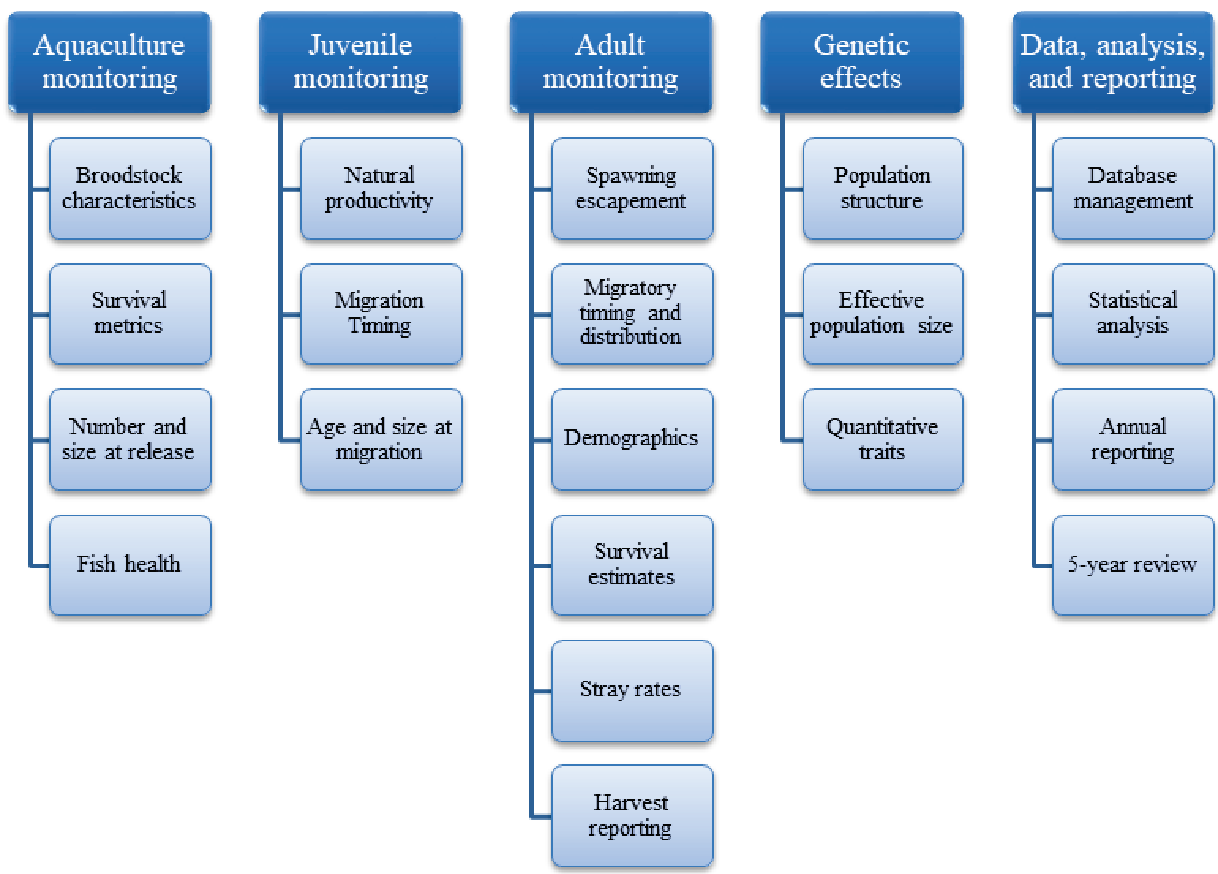

Figure 2. Overview of Monitoring and Evaluation Plan Categories and Components (not including regional objectives).

The overarching goals of conservation, safety-net, and harvest augmentation programs, as described above, are shown in detail in Figure 3. The flow chart (Figure 3) shows the relationship of overarching program goals, the strategies used to meet the goals, the monitoring and evaluation objectives used to evaluate the strategies and determine if goals are being met, and the adaptive

management cycle associated with the programs (see Tables 1 and 2 for the indicators under each objective). The logic depicted in this flow chart shall be used to assess M&E results and apply those results to management decisions. Table 3 presents the current hatchery programs releasing fish in the Upper Columbia Basin.

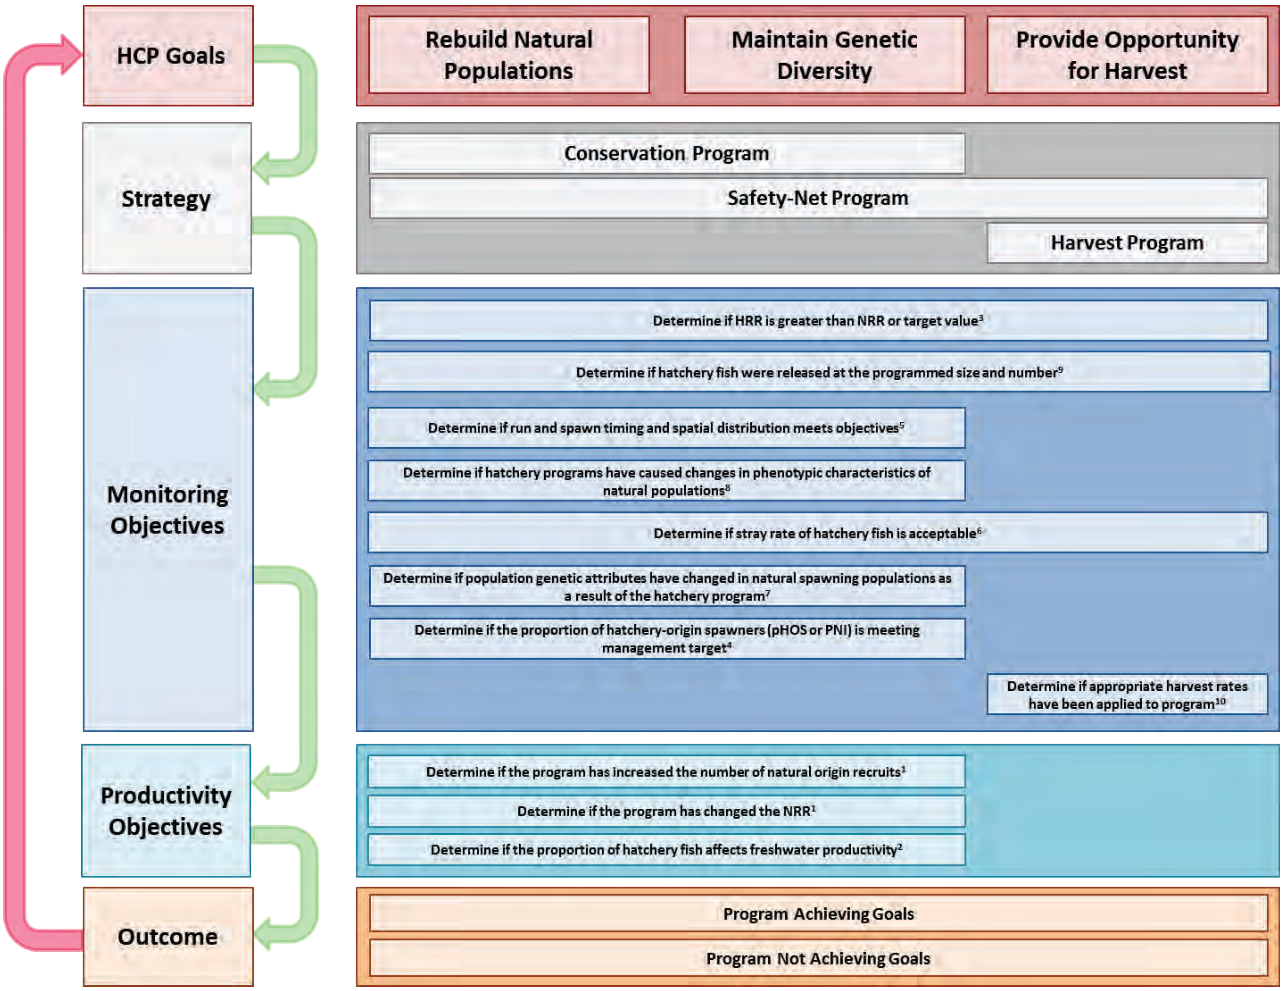

Figure 3. Adaptive management flow chart depicting HCP goals, associated strategies to meet the goals, the monitoring and evaluation objectives (indicated in superscript), and the adaptive management feedback cycle. The strategies, objectives, and outcomes are aligned vertically under the corresponding goals.

Table 3. Hatchery programs in the mid-Columbia River Basin, 2012. Funding entities included Douglas PUD (D), Chelan PUD (C), Grant PUD (G), Bonneville Power Administration (B), Bureau of Reclamation (O), and Army Corps of Engineers (A) and are listed in order of contribution. Total artificial production targets in the mid-Columbia River exceeds 20 million juveniles annually.

[1] Species listed under the Endangered Species Act.
[2] Segregated program.
[3] Sub-yearling production.
[4] Fry production.
[5] Program covered by this M&E Plan.
[6] Program also partially covered by CCT M&E Plan.
[7] Program affects PUD-funded programs covered by this plan.
[8] Planned to increase to 1,000,000.
[9] Part of the Mitchell Act suite of mitigation programs under the FCRPS BiOp.

SECTION 2: ADULT PRODUCTIVITY

2.1 Natural Replacement Rates of Supplemented Populations[1]

Objective 1: Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.

At the core of a conservation program is the objective of increasing the number of spawning adults (i.e., the combined number of naturally produced and hatchery fish) in order to affect a subsequent increase in the number of returning naturally produced fish or natural-origin recruits (NOR). In order for the natural population to remain stable or to increase, the Natural Replacement Rate (NRR), or the ratio of NORs to the parent spawning population, must be at a level where parents are being replaced by their offspring as spawners in the next generation. It is possible to affect an increase in natural-origin spawners through supplementation with a stable or decreasing NRR. However, if the NRR is below replacement (NRR<1.0), termination of the supplementation program will result in a declining natural population should that state of NRR persist. The proportion of the hatchery-origin spawners (pHOS) that will increase natural production without creating adverse effects to the genetic diversity or reproductive success rate of the natural population is unknown, and may be dependent on how individual hatchery programs are operated, as well as available spawning and rearing habitat. Some programs restrict pHOS to reduce the risk to the natural population with the intent of optimizing productivity, concomitantly reducing the overall number of spawners. All other objectives of the M&E Plan either directly support this objective or seek to minimize negative effects of the conservation programs on non-target stocks of concern.

Differences in carrying capacities of supplemented and non-supplemented streams can confound the analysis of the effects of supplementation on total number of spawners returning to the streams. For example, if the supplemented population is at carrying capacity and the non-supplemented population is not, the total number of spawners returning to the non-supplemented population may show an increasing trend over time, while the supplemented population would show no increasing trend. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on total spawners, density corrections should be included in the analyses. Hypotheses that may require density corrections are noted under each monitoring question. Appendix 1 describes methods for estimating carrying capacities.

Monitoring Questions:

Q1.1.1 Has the supplementation program changed the adult productivity (NRRs) of the supplemented populations?[2]

Target Species/Populations:

[1] Supplementation programs may include a safety-net component.

[2] Because adult productivity is affected by the abundance of the population (i.e., productivity decreases with increasing abundance), the goal of supplementation is to increase or maintain productivity, but not decrease it.

- Q1.1.1 applies to all conservation and safety-net stocks.

Statistical Hypotheses 1.1.1[3]:

- $Ho_{1.1.1.1}$: Slope in NRRs before supplementation ≤ slope in NRRs after supplementation.
- $Ho_{1.1.1.2}$: Differences in slopes in NRRs between supplemented and reference populations before supplementation ≤ differences in slopes in NRRs between supplemented and reference populations after supplementation.
- $Ho_{1.1.1.3}$: Mean NRRs before supplementation ≤ mean NRRs after supplementation.
- $Ho_{1.1.1.4}$: Mean ratio scores in NRRs before supplementation ≤ Mean ratio scores in NRRs during supplementation.
- $Ho_{1.1.1.5}$: Mean ratio scores in NRRs (adjusted for density dependence) before supplementation ≤ Mean ratio scores in NRRs (adjusted for density dependence) during supplementation. [This hypothesis adjusts NRRs for density-dependent effects (see Hillman et al. 2012 for details; Appendix 6).]
- $Ho_{1.1.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds
- Number of naturally produced fish harvested

Derived Variables:

- Number of naturally produced recruits by brood year for both naturally produced parents and hatchery parents (≥age-3).
- NRRs (calculated as NORs/spawner).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NRRs (requires reference population[s]).
- Includes calculation of ratios NORs (requires reference population).
- Appendix 1: Spawning escapement and carrying capacity information (as applicable)

Spatial/Temporal Scale:

- Calculated annually based on brood year.
- Time series.

Possible Statistical Analysis:

---

3 Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 6) for details.

- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 6). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NRRs.
- On a five-year period, correlate productivity with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

2.2 Natural-Origin Recruits of Supplemented Populations

Monitoring Questions:

Q1.2.1: Has the supplementation program changed the abundance of NORs within the supplemented population?

Target Species/Populations:

- Q1.2.1 applies to all supplemented or safety net stocks.

Statistical Hypotheses 1.2.1[4]:

- $Ho_{1.2.1.1}$: Slope in NORs[5] before supplementation ≥ slope in NORs after supplementation.
- $Ho_{1.2.1.2}$: Differences in slopes in NORs between supplemented and reference populations before supplementation ≥ differences in slopes in NORs between supplemented and reference populations after supplementation.
- $Ho_{1.2.1.3}$: Mean NORs before supplementation ≥ mean NORs after supplementation.
- $Ho_{1.2.1.4}$: Mean ratio scores in NORs before supplementation ≥ Mean ratio scores in NORs during supplementation.
- $Ho_{1.2.1.5}$: Mean ratio scores in NORs/Maximum Recruitment before supplementation ≥ Mean ratio scores in NORs/Maximum Recruitment during supplementation. [This hypothesis adjusts NORs for the capacity of the habitat; it tests the fraction of the habitat saturated with NORs (see Hillman et al. 2012 for details).]
- $Ho_{1.2.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and NORs; rho = 0. [If there is a significant negative association between

4 Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 7) for details.

5 “Slope in NORS” refers to abundance of NORs across time (years).

pHOS and NORs, then hatchery fish may be reducing the reproductive success of the wild population.]

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish taken for broodstock.
- Number of hatchery and naturally produced fish taken in harvest (if recruitment is to the Columbia).

Derived Variables:

- NORs (number of naturally produced recruits (total recruits) by brood year for both naturally produced parents and hatchery parents [≥age-3]).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NORs (requires reference population[s]).
- Estimates of carrying capacity (see Appendix 1).

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NORs.
- On a five-year period, correlate NORs with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

SECTION 3: JUVENILE PRODUCTIVITY

3.1 Freshwater Juvenile Productivity

Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.

Out-of-basin effects (e.g., smolt passage through the hydro system, harvest, and ocean productivity, etc.) influence the survival of smolts after they migrate from the tributaries. These effects introduce substantial variability into the adult-to-adult survival rates (NRRs and HRRs) and may mask in-basin effects (e.g., habitat quality, density-dependent mortality, and differential reproductive success of hatchery and naturally produced fish). Therefore, an estimate of freshwater productivity may help inform the performance of hatchery and natural-origin spawners.

The objective of estimating freshwater productivity in the Upper Columbia ESU/DPS is to estimate the survival from egg to a critical juvenile life stage(s) of target stocks. Smolt or juvenile production models generated from the information obtained through these programs will provide a level of predictability with greater sensitivity to in-basin effects than spawner-recruitment models that consider all effects.

Differences in the current carrying capacities of supplemented and non-supplemented streams can confound the effects of supplementation on numbers of juveniles per redd. For example, if the supplemented population is at or above carrying capacity and the non-supplemented population is not, numbers of juveniles per redd in the non-supplemented population may be significantly greater than the number of juveniles per redd in the supplemented population. In addition, pHOS may be correlated with overall spawner abundance. In these cases, it is difficult or impossible to separate density-dependent effects from the influence of pHOS on freshwater productivity. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on juveniles per redd, the capacity of the habitats must be included in the analyses. The Supplementary Hypotheses presented below are designed to address the confounding effects of different densities on the analyses.

Monitoring Questions:

Q2.1.1: Has the supplementation program changed the number of juveniles (smolts, parr, and/or emigrants) per redd within the supplemented population?

Q2.2.1: Does the number of juveniles per redd decrease as the proportion of hatchery spawners increases?[6]

Target Species/Populations:

- Both Q2.1.1 and Q2.2.1 apply to all conservation stocks.

Statistical Hypotheses for 2.1.1[7]:

[6] Information is needed to estimate the effects of density dependence on these questions. Consider spatial distribution of redds.

[7] Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. (2012) for details.

- $Ho_{2.1.1.1}$: Slope in juveniles/redd before supplementation ≤ slope in juveniles/redd after supplementation.
- $Ho_{2.1.1.2}$: Differences in slopes in juveniles/redd between supplemented and reference populations before supplementation ≤ differences in slopes in juveniles/redd between supplemented and reference populations after supplementation.
- $Ho_{2.1.1.3}$: Mean juveniles/redd before supplementation ≤ mean juveniles/redd after supplementation.
- $Ho_{2.1.1.4}$: Mean ratio scores in juveniles/redd before supplementation ≤ Mean ratio scores in juveniles/redd during supplementation.
- $Ho_{2.1.1.5}$: Mean ratio scores in juveniles/redd (adjusted for density dependence) before supplementation ≤ Mean ratio scores in juveniles/redd (adjusted for density dependence) during supplementation. [This hypothesis adjusts juveniles/redd for density-dependent effects (see Hillman et al. 2012 for details; Appendix 6).]
- $Ho_{2.1.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

Statistical Hypotheses for 2.2.1:

- $Ho_{2.2.1.1}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]
- $Ho_{2.2.1.2}$: The slope between proportion of hatchery spawners and juveniles/redd is ≥ 0.

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Numbers of redds.
- Number of juveniles (smolts, parr [where appropriate], and emigrants).

Derived Variables:

- Number of juveniles per spawner.
- Number of juveniles per redd.
- Carrying capacity (see Appendix 1).

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- These analyses shall be performed every five-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 6). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and juveniles/redd.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

Attachment D

SECTION 4: NATURAL ENVIRONMENT MONITORING INDICATORS

4.1 Hatchery Replacement Rates (HRRs)

<u>Objective 3</u>: **Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.**

The survival advantage from the hatchery (i.e., egg-to-smolt) must be sufficient to produce a greater number of returning adults than if broodstock were left to spawn naturally. If a hatchery program cannot produce a greater number of adults than naturally spawning fish, then the program should be modified or discontinued. Production levels were initially developed using historical run sizes and smolt-to-adult survival rates (BAMP 1998). Using the stock specific NRR and agreed upon target values (see Appendix 2), comparisons to actual survival rates will be made to ensure the expected level of survival has been achieved.

Monitoring Questions:

Q3.2.1: Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the adult-to-adult survival rate (NRR) of naturally produced fish?

Q3.2.2: Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the Target Value identified in Appendix 2[8]?

Target Species/Populations:

- Q3.2.1 applies to all conservation stocks.
- Q3.2.2 applies to all stocks.

Statistical Hypothesis 3.2.1:

- $Ho_{3.2.1.1}$: $HRR_{\text{Year x}} \geq NRR_{\text{Year x}}$

Statistical Hypothesis 3.2.2:

- $Ho_{3.2.2.1}$: HRR ≥ Target Value identified in Appendix 2

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish harvested.
- Number of hatchery and naturally produced fish collected for broodstock.
- Number of broodstock used by brood year (hatchery and naturally produced fish).

Derived Variables:

- Number of hatchery and naturally produced adults by brood year (≥age-3).

[8] Target values may be adjusted by the hatchery committees.

- HRR (number of returning adults per brood year/broodstock)
- NRR (from Objective 1)
- Appendix 2: HRR targets identified in Appendix 2

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- For Q3.2.1 use graphic analysis and paired-sample quantile tests to compare HRR to NRR
- For Q3.2.2 use graphic analysis and one-sample quantile tests to compare HRR to the target value.
- On a five-year period, correlate HRRs with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.2 Proportion of Hatchery-Origin Spawners (pHOS or PNI)

<u>Objective 4</u>: **Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.**

Certain hatchery programs have pHOS or PNI targets, while other do not. HGMPs and permits inform the selection of targets, which are identified in Appendix 3.

Monitoring Questions:

Q4.1.1: Is the estimated proportion of hatchery-origin spawners (pHOS) less than or equal to the management target, and/or, is the estimated Percent Natural Influence (PNI) greater than or equal to the management target identified in Appendix 3?

Target Species/Populations:

- Q4.1.1 applies to all conservation and safety-net stocks that have a defined pHOS or PNI target or sliding scale (see Appendix 3).

Statistical Hypothesis 4.1.1:

- $Ho_{4.1.1.1}$: pHOS > target value or $PNI_{\text{Supplemented population}}$ < target value identified in Appendix 3

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds

Derived Variables:

- pHOS or PNI
- Appendix 3: PNI and pHOS targets and sliding scales identified in Appendix 3

Spatial/Temporal Scale:

- Calculate annually.
- Analyzed as time series.

Possible Statistical Analysis:

- Use graphic analysis and summary statistics to compare pHOS or PNI to the target value in Appendix 3.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

4.3 Run Timing, Spawn Timing, and Spawning Distribution

Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.

Strategies for conservation programs typically intend that hatchery and natural-origin fish spawn together and in similar locations. However, in some cases, strategies may differ from this paradigm (e.g., summer Chinook salmon in the Wenatchee and Methow rivers; see Appendix 4). Phenotypic plasticity or selection resulting from the hatchery environment (i.e., domestication) may affect run (migration) timing, spawn timing, and spawning distribution. If conservation programs do not adequately represent the genetic diversity of the natural population, and if phenotypic traits in supplementation fish related to fitness deviate from the naturally produced spawning population, the goals of supplementation may not be achieved. Hatchery adults that migrate and/or spawn at different times or are spatially segregated from natural-origin fish may be subject to reduced fitness. Hatchery adults that spawn at different times or locations than natural-origin fish would be reproductively isolated from the natural population. The extent of such isolation, ranging from no isolation to substantial isolation, may be exploited for management purposes in some cases.

Migration Timing

Monitoring Questions:

Q5.1.1: Is the migration timing of hatchery and natural-origin fish from the same age class similar?

Target Species/Populations:

- Q5.1.1 applies to all conservation stocks.

Statistical Hypotheses 5.1.1:

- $Ho_{5.1.1.1}$: Migration timing $_{\text{Hatchery Age X}}$ = Migration timing $_{\text{Naturally produced Age X}}$

- $Ho_{5.1.1.2}$: The cumulative frequency of migration timing of hatchery-origin fish = the cumulative frequency of migration timing of natural-origin fish.
- $Ho_{5.1.1.3}$: The 10th percentile, 50th percentile (mode), 90th percentile, and mean migration timing of hatchery-origin fish = the 10th percentile, 50th percentile (median), 90th percentile, and mean migration timing of natural-origin fish.

Measured Variables:

- Ages of hatchery and natural-origin fish sampled via PIT tags or stock assessment monitoring.
- Time (Julian date) of arrival at mainstem projects and within tributaries (e.g., traps, PIT arrays) with the intent to identify biologically significant differences.

Derived Variables:

- Mean Julian date for a given age class.

Spatial/Temporal Scale:

- Calculate annually based on return year and age class.
- Time series.

Possible Statistical Analysis:

- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Spawn Timing

Monitoring Questions:

Q5.2.1: Is the timing of spawning similar for conservation hatchery and natural-origin fish?

Target Species/Populations:

- Q5.2.1: Applies to all semelparous species and populations supplemented by conservation programs. Steelhead can only be assessed for natural spawning in situations where hatchery and natural-origin fish can be appropriately marked and detected.

Statistical Hypotheses 5.2.1:

- $Ho_{5.2.1.1}$: The cumulative frequency of spawn timing of hatchery-origin fish = the cumulative frequency of spawn timing of natural-origin fish.
- $Ho_{5.2.1.2}$: The 10th percentile, 50th percentile (mode), 90th percentile, and mean spawn timing of hatchery-origin fish = the 10th percentile, 50th percentile (mode), 90th percentile, and mean spawn timing of natural-origin fish.

- $Ho_{5.2.1.3}$: The relationship between elevation and spawn timing of hatchery-origin fish = the relationship between elevation and spawn timing of natural-origin fish.

Measured Variables:

- Time (Julian date) and elevation (m) of hatchery and natural-origin salmon carcasses or marked steelhead detected on spawning grounds within defined reaches.
- Time (Julian date) of ripeness of hatchery and natural-origin steelhead captured for broodstock.

Derived Variables:

- Mean Julian date.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.
- Use graphic analyses, ANCOVA, and/or regression analysis to assess relationships between elevation and spawn timing.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Spatial Distribution of Redds

Monitoring Questions:

Q5.3.1: Is the distribution of redds similar for conservation hatchery and natural-origin fish?

Q5.3.2: Is the distribution of redds similar to defined management targets (see Appendix 4)?

Target Species/Populations:

- Q5.3.1 applies to all conservation program stocks.
- Q5.3.2 applies only to conservation program stocks with specific spawning distribution targets (Carlton and Dryden summer Chinook programs; Appendix 4).

Statistical Hypothesis 5.3.1:

- $Ho_{5.3.1.1}$: The distribution of hatchery-origin redds (hatchery females) = the distribution of natural-origin redds (natural-origin females).

Statistical Hypothesis 5.3.2:

- $Ho_{5.3.2.1}$: The distribution of hatchery-origin redds (hatchery females) = the target distribution identified in Appendix 4.

Measured Variables:

- Location (GPS coordinate) of female salmon carcasses observed on spawning grounds. The distribution of hatchery and naturally produced steelhead redds may be evaluated if marking or tagging efforts provide reasonable results.

Derived Variables:

- Location of female salmon carcass at the historic reach scale and at the 0.1 km scale.
- Calculate percent overlap in distribution across available spawning habitat or historical reaches.
- Appendix 4: Management targets for spatial distribution of spawners or redds (as applicable).

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates' Chi-square analysis for both Q5.3.1 and Q5.3.2.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.4 Stray Rates

Objective 6: Determine if the recipient stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.

Maintaining locally adapted traits among independent fish populations requires that returning hatchery fish have a high rate of site fidelity to the target population or stream. Hatchery practices (e.g., imprinting on water sources at key life history stages, release methodology, release location, age at return, broodstock used, spawner density, spawning habitat quality and access, and environmental conditions) are the main variables thought to affect stray rates. Regardless of the magnitude of homing of adult returns, if adult hatchery fish do not contribute to the natural population, the program will not meet the basic condition of a supplementation program.

Independent populations are populations that are genetically differentiated from other populations. In some cases, genetic differentiation may be assumed based on phenotypic traits or geographic isolation when molecular genetics analyses are not available. When populations are not independent, straying among them does not pose a risk of genetic homogenization. In addition, stray rates of hatchery-origin fish cannot be expected to be lower than for natural-origin fish. When estimates of stray rates for natural-origin fish are available and if they exceed the 5% among population stray rate or 10% within population stray rate thresholds identified in this plan, analysis

and interpretation of stray rates must take into account the concept that hatchery programs may be held to unattainable standards based on the natural stray rate. Current criteria established by the ICBTRT (2005) and the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) indicate that fish that do stray to other non-target populations should not comprise greater than 5% of the non-target spawning population. Likewise, fish that stray into non-target spawning areas within an independent population should not comprise greater than 10% of the non-target spawning aggregate (see Tables 6.1 and 6.2).

This plan identifies three stray rate metrics; brood-year stray rate, among population return-year stray rate, and within population return-year stray rate. The return-year stray rates have specific targets that are from the ICBTRT (2005) and Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007), and are linked to extinction risk. That is, hatchery strays from other populations cannot make up more than 5% of the spawning escapement within a non-target, recipient population. In addition, hatchery strays from other spawning aggregations within a population (e.g., Chiwawa spring Chinook) cannot make up more than 10% of the spawning escapement within a non-target, recipient spawning aggregate (e.g., White River). Brood-year stray rate, on the other hand, is not discussed in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) or ICBTRT (2005) and therefore has no specific target. Nevertheless, it is important to track brood-year stray rates to determine if hatchery operations affect the homing and straying of specific brood years. These data support the return-year stray metrics and are used to inform possible changes in genetic variation among stocks.

Brood-Year Stray Rates

Monitoring Questions:

Q6.1.1: What is the brood-year stray rate of hatchery fish?

Target Species/Populations:

- Q6.1.1 applies to all hatchery stocks.

Statistical Hypothesis 6.1.1:

- $Ho_{6.1.1.1}$: None.

Measured Variables:

- Number of hatchery carcasses found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.
- Number of hatchery fish collected for broodstock.
- Number of hatchery fish taken in fishery.
- Locations of live and dead strays (used to tease out overshoot).

Derived Variables:

- Total number of hatchery carcasses and take in fishery estimated from expansion analysis.
- Percent of the total brood return that strays.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphical analysis to track brood-year stray rates over time.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Among-Population Return-Year Stray Rates

Monitoring Questions:

Q6.2.1: Do hatchery strays make up less than 5% of the spawning escapement within their non-target independent populations?

Target Species/Populations:

- Q6.2.1 applies to all hatchery stocks.

Statistical Hypothesis 6.2.1:

- $Ho_{6.2.1.1}$: Stray hatchery fish make up ≥ 5% of the spawning escapement (based on run year) within other independent populations [9]

Measured Variables:

- Number of hatchery carcasses (PIT-tagged steelhead) found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

Derived Variables:

- Total number of hatchery salmon carcasses (PIT-tagged steelhead, spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target population that is made up of hatchery strays.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

[9] This stray rate is suggested based on a literature review and recommendations by the ICBTRT (2005) and is identified in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007). It can be re-evaluated as more information on naturally-produced Upper Columbia salmonids becomes available. This will be evaluated on a species and program specific basis and decisions made by the HCP HC and PRCC HSC. It is important to understand the actual spawner composition of the population to determine the potential effect of straying.

- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (5%) stray rate.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Within-Population Return-Year Stray Rates

Monitoring Questions:

Q6.3.1: Do hatchery strays make up less than 10% of the spawning aggregate within non-target spawning areas within the target population?

Target Species/Populations:

- Q6.3.1 applies to all hatchery stocks.

Statistical Hypothesis 6.3.1:

- $Ho_{6.3.1}$: Stray hatchery fish make up ≥ 10% of spawning escapement (based on run year) within non-target spawning areas within the target population

Measured Variables:

- Number of hatchery carcasses (possibly PIT-tagged steelhead) found in non-target and target spawning aggregates or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

Derived Variables:

- Total number of hatchery salmon carcasses (possibly PIT-tagged steelhead or spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target spawning aggregate that is made up of hatchery strays.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (10%) stray rate.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.5 Population Genetics

Objective 7: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.

The genetic component of the M&E Plan specifically addresses the potential for changes in genetic diversity in natural populations as a result of a hatchery program(s). The long-term fitness of populations is assumed to be related to maintaining the genetic diversity of natural populations. However, hatchery programs select a subset of individuals from the population to pass on genetic material to the next generation. This is often a relatively small number of individuals that produce a large number of offspring, and can result in changes in allele frequencies and reductions of effective population size. Therefore, it is important to monitor the genetic status of the natural populations to determine if there are signs of changes in genetic distance among populations, changes in allele frequencies, and to estimate effective population size. Assessing the genetic effects of the hatchery program does not require annual sampling, but does require regular sampling at generational scales. Meeting stray-rate targets (hypotheses tested under Objective 5) should reduce significant changes in population genetics. Stray rates may inform population genetic analyses. Testing statistical hypotheses associated with genetic components (Hypotheses 3.1, 3.2, and 3.3) should be conducted every ten years or two generations.

Allele Frequency

Monitoring Questions:

Q7.1.1: Is the allele frequency of hatchery fish similar to the allele frequency of naturally produced and donor (broodstock) fish?

Target Species/Populations:

- Q7.1.1 applies to all conservation stocks.

Statiscial Hypotheses 7.1.1:

- $Ho_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ = Allele frequency $_{\text{Naturally produced}}$ = Allele frequency $_{\text{Donor pop.}}$
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ ≠ Allele frequency $_{\text{Naturally produced}}$ = Allele frequency $_{\text{Donor pop.}}$ or
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ = Allele frequency $_{\text{Naturally produced}}$ ≠ Allele frequency $_{\text{Donor pop.}}$ or
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ ≠ Allele frequency $_{\text{Naturally produced}}$ ≠ Allele frequency $_{\text{Donor pop.}}$

Measured Variables:

- SNP genotypes

Derived Variables:

- Allele frequency

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples within drainages.

Possible Statistical Analysis:

- Population differentiation tests, analysis of molecular variance (AMOVA), and relative genetic distances.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Genetic Distance Between Populations

Monitoring Questions:

Q7.2.1: Does the genetic distance among subpopulations within a supplemented population remain the same over time?

Target Species/Populations:

- Q7.2.1 applies to all conservation and safety-net stocks.

Statistical Hypothesis 7.2.1:

- $Ho_{7.2.1.1}$: Genetic distance between subpopulations $_{\text{Year x}}$ = Genetic distance between subpopulations $_{\text{Year y}}$

Measured Variables:

- SNP genotypes

Derived Variables:

- Allele frequencies

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples among spawning aggregates.

Possible Statistical Analysis:

- Population differentiation tests, AMOVA, and relative genetic distances.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Effective Spawning Population

Monitoring Questions:

Q7.3.1: Is the ratio of effective population size (N_e) to spawning population size (N) constant over time?

Target Species/Populations:

- Q7.3.1 applies to all supplemented stocks.

Statistical Hypothesis 3.3:

- $Ho_{7.3.1.1}$: $(N_e/N)_{t0} = (N_e/N)_{t1}$ for each population

Measured Variables:

- SNP genotypes

Derived Variables:

- Allele frequencies

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.

Possible Statistical Analysis:

- Population differentiation tests, relative genetic distances, statistics to calculate effective population size (e.g., harmonic means).

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.6 Phenotypic Traits

Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

Fitness, or the ability of individuals to survive and pass on their genes to the next generation in a given environment, includes genetic, physiological, and behavioral components.[10] Maintaining the long-term fitness of supplemented populations requires a comprehensive evaluation of genetic and phenotypic characteristics. Evaluation of some phenotypic traits (i.e., run timing, spawn timing, spawning location, and stray rates) is addressed under Objective 5. Objective 8 assess the potential effects of domestication, including size at maturity, age at maturity, sex ratio, and fecundity. Age and size at maturity shall be assessed for both fish arriving in the Columbia system, and those recovered on the spawning grounds. Size (or age) selective mortality during migration through the Columbia system, such as through fisheries, could alter the age and size of fish on the spawning grounds.

[10] These metrics are difficult to measure, and phenotypic expression of these traits may be all we can measure and evaluate.

Age at Maturity

Monitoring Questions:

Q8.1.1: Is the age at maturity of hatchery and natural-origin fish similar at the time they enter the Columbia River and when they spawn?

Target Species/Populations:

- Q8.1.1 applies to all conservation program stocks.

Statistical Hypotheses 8.1.1:

- $Ho_{8.1.1.1}$: Age at Maturity $_{\text{Hatchery produced spawners Gender X}}$ = Age at Maturity $_{\text{Naturally produced spawners Gender X}}$
- $Ho_{8.1.1.2}$: Age at Maturity $_{\text{All hatchery produced adults Gender X}}$ = Age at Maturity $_{\text{All naturally produced adults Gender X}}$

Measured Variables:

- Total and salt (ocean) age of hatchery and natural-origin salmon carcasses collected on spawning grounds.
- Total and salt age of broodstock.
- Total and salt age of fish at stock assessment locations (e.g., Dryden, Tumwater, Wells, Priest Rapids).
- Whenever possible, age at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).
- Assess age of fish, including harvested fish.

Derived Variables:

- Total age and saltwater age
- Age of fish entering the Columbia River.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates' Chi-square.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Size at Maturity

Monitoring Questions:

Q8.2.1: Is the size (length) at maturity of a given age and sex of hatchery fish similar to the size at maturity of a given age and sex of natural-origin fish?

Target Species/Populations:

- Q8.2.1 applies to all conservation and safety-net stocks.

Statistical Hypothesis 8.2.1:

- $Ho_{8.2.1.1}$: Size (length) at Maturity $_{\text{Hatchery Age X and Gender Y}}$ = Size (length) at Maturity $_{\text{Naturally produced Age X and Gender Y}}$
- $Ho_{8.2.1.2}$: Size (length) at Maturity $_{\text{All hatchery adults Gender X}}$ = Size (length) at Maturity $_{\text{All naturally produced adults Gender X}}$

Measured Variables:

- Size (length), age, and gender of hatchery and natural-origin salmon carcasses collected on spawning grounds.
- Size (length), age, and gender of broodstock.
- Size (length), age, and gender of fish at stock assessment locations (e.g., Priest Rapids, Dryden, Tumwater, Wells, Twisp Weir).
- Whenever possible, size at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).

Derived Variables:

- Total age and saltwater age

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and three-way ANOVA by origin, gender, and age

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Fecundity at Size[11]

Monitoring Questions:

Q8.3.1: Is the fecundity vs. size relationship of hatchery and natural-origin fish similar?

[11] May not apply to all programs.

Q8.3.2: Is the gonadal mass vs. size relationship of hatchery and natural-origin fish similar?

Target Species/Populations:

- Both Q8.3.1 and Q8.3.2 apply to all conservation stocks using both natural- and hatchery-origin broodstock.

Statistical Hypothesis 8.3.1:

- $Ho_{8.3.1.1}$: Slope of Fecundity vs. Size $_{\text{Hatchery}}$ = Slope of Fecundity vs. Size $_{\text{Naturally produced}}$

Statistical Hypothesis 8.3.2:

- $Ho_{8.3.2.1}$: Gonadal Mass vs. Size $_{\text{Hatchery}}$ = Gonadal Mass vs. Size $_{\text{Naturally produced}}$

Measured Variables:

- Length, weight, and age (covariate) of hatchery and natural-origin broodstock after eggs have been removed.
- Number and weight of eggs

Derived Variables:

- Total age and saltwater age.
- Mean weight per egg.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis, regression, t-test, and ANCOVA.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Sex Ratio

Monitoring Questions:

Q8.4.1: Is the sex ratio of hatchery and natural-origin fish similar?

Target Species/Populations:

- Q8.4.1 applies to all conservation stocks.

Statistical Hypothesis 8.4.1:

- $Ho_{8.4.1.1}$: Sex Ratio $_{\text{Hatchery}}$ = Sex Ratio $_{\text{Naturally produced}}$

Measured Variables:

- Age and sex of hatchery and natural-origin salmon carcasses collected on spawning grounds or sampled at dams or weirs.
- Whenever possible sex ratio will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling or ultrasound on live fish).

Derived Variables:

- Ratio of sexes based on brood year returns

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates'Chi-square.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 5: HATCHERY ENVIRONMENT MONITORING INDICATORS

5.1 Release Targets

Objective 9: Determine if hatchery fish were released at the programmed size and number.

The HCP outlines the number and size of fish that are to be released to meet NNI and inundation compensation levels. The size of the fish at release may be altered according to an adaptive management process in the Hatchery Committee(s), and the number of fish can be altered by survival study results and adjustment of hatchery production for population dynamics. Size of fish at release can affect survival, sex ratios, age at return, stray rate, and fecundity. In addition, the variation in size at release may affect performance of the fish.

The coefficient of variation (CV) will be evaluated to ascertain if program performance is related to variation in size at release. Note also that variation in a population is a natural condition and striving to control this variation could result in directional or stabilizing artificial selection that could have unforeseen long-term consequences. Attaining uniform or multi-modal growth in a hatchery environment may not be adaptive for fitness in the wild. Therefore, pursuit of a CV target should be seen as an informative exercise, but is not in itself indicative of success or failure of a hatchery program. Furthermore, growth regimes may prove to be important in affecting adult returns and age structure. Although many factors can influence both the size and number of fish released, past hatchery cultural experience with these stocks should assist in meeting program production levels. Appendix 5 presents the target size at release and CVs for the programs. These targets shall be assessed annually to ensure they are optimized to inform management decisions.

Size at Release of Hatchery Fish

Monitoring Questions:

Q9.1.1: Is the size (fish per pound; fpp) of hatchery fish released equal to the program goal identified in Appendix 5?

Target Species/Populations:

- Q9.1.1 applies to all hatchery stocks.

Statistical Hypothesis 9.1.1:

- $Ho_{9.1.1}$: Hatchery fish $_{\text{fpp at release}}$ = Programmed $_{\text{fpp at release}}$ (see Appendix 5)

Measured Variables:

- Fork length and weights of random samples of hatchery juveniles at release.

Derived Variables:

- Mean length (FL), mean weight, and fish per pound
- Appendix 5: Rearing targets

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated fpp of hatchery fish at time of release with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Coefficient of Variation (CV) of Hatchery Fish Released

Monitoring Questions:

Q9.2.1: Is the CV of hatchery fish released equal to the program target identified in Appendix 5?

Target Species/Populations:

- Q9.2.1 applies to all hatchery stocks.

Statistical Hypothesis 9.2.1:

- $Ho_{9.2.1.1}$: Hatchery fish $CV_{\text{at release}}$ = Programmed CV in Appendix 5

Measured Variables:

- Length and weights of random samples of hatchery smolts.

Derived Variables:

- Coefficient of Variation: $cv = (1 + 1/4n) \times (s/x)$ (where s = standard deviation, x = estimated mean, n = sample size)
- Appendix 5: Rearing targets

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated CV of size of hatchery fish released with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Condition Factor (K) of Hatchery Fish Released

Monitoring Questions:

Q9.3.1: Is the K of hatchery fish released equal to the program target identified in Appendix 5?

Target Species/Populations:

- Q9.3.1 applies to all hatchery stocks.

Statistical Hypothesis 9.3.1:

- $Ho_{9.3.1.1}$: Hatchery fish $K_{\text{at release}}$ = Programmed K identified in Appendix 5

Measured Variables:

- Monthly individual lengths and weights of random samples of hatchery juveniles.

Derived Variables:

- Condition Factor: $K = W/L^3 \times 10^5$

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated K of released hatchery fish with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Number of Hatchery Fish Released

Monitoring Questions:

Q9.4.1: Is the number of hatchery fish released equal to the program goal identified in Appendix 5?

Target Species/Populations:

- Q9.4.1 applies to all hatchery stocks.

Statistical Hypothesis 9.4.1:

- $Ho_{9.4.1.1}$: Hatchery Fish Number = Programmed Number identified in Appendix 5

Measured Variables:

- Numbers of smolts released from the hatchery.

Derived Variables:

- Appendix 5: Rearing targets

Spatial/Temporal Scale:

- Calculate annually.

- Time series.

Possible Statistical Analysis:

- Use graphic analysis and one-sample quantile tests to compare the estimated number of hatchery fish released with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 6: HARVEST MONITORING INDICATORS

6.1 Harvest Rates

<u>Objective 10</u>: **Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.**

Harvest will be applied to different types of programs in an effort to achieve the management objectives of those programs. Programs designed to augment harvest should routinely contribute to harvest at a rate that greatly reduces the incidence of straying to natural spawning grounds, but also allows the program to be sustained. Safety-net programs may be harvested as part of an adult management strategy to minimize excessive escapement of hatchery-origin fish to spawning grounds. Similarly, conservation programs may undergo harvest to manage returning adults, but the emphasis for these programs should be to achieve escapement goals. In all cases, harvest effort should not have the unintended consequence of removing excessive numbers of conservation or natural-origin fish. In years when the expected returns of hatchery adults are above the level required to meet program goals (i.e., supplementation of spawning populations and/or brood stock requirements), surplus fish may be available for harvest. The M&E Plan specifically addresses harvest and harvest opportunities upstream of Priest Rapids Dam. Harvest or removal of surplus hatchery fish from the spawning grounds may assist in reducing potential adverse ecological and genetic impacts to natural populations (e.g., loss of genetic variation within and between populations, loss of fitness, reduced effective population size, and density-dependent effects).

Monitoring Questions:

Q10.1.1: Conservation Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of conservation hatchery fish but low enough to sustain the hatchery program?

Q10.1.2: Safety-Net Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of safety-net hatchery fish but low enough to sustain the hatchery program?

Q10.1.3: Is the harvest on hatchery fish produced from harvest-augmentation programs high enough to manage natural spawning but low enough to sustain the hatchery program?

Q10.1.4: Is the escapement of fish from conservation and safety-net programs in excess of broodstock and natural production[12] needs to provide opportunities for terminal harvest?

Target Species/Populations:

- Q10.1.1 applies to conservation programs.
- Q10.1.2 applies to safety-net programs.

[12] The current best estimates of carrying capacity (maximum recruits) will be used, as available.

- Q10.1.3 applies harvest augmentation programs.
- Q10.1.4 applies to conservation and safety-net programs.

Statistical Hypothesis 10.1.1:

- $Ho_{10.1.1.1}$: Harvest rate ≤ Maximum level to meet program goals

Statistical Hypothesis 10.1.2:

- $Ho_{10.1.2.1}$: Harvest rate ≤ Maximum level to meet program goals

Statistical Hypothesis 10.1.3:

- $Ho_{10.1.3.1}$: Escapement ≤ Maximum level to meet supplementation goals

Statistical Hypothesis 10.1.4:

- $Ho_{10.1.4.1}$: Harvest rate ≤ Maximum level to meet program goals

Measured Variables:

- Numbers of hatchery fish taken in harvest.
- Numbers of natural-origin fish taken in harvest.

Derived Variables:

- Total harvest by fishery estimated from expansion analysis.

Spatial/Temporal Scale:

- Calculated annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and one-sample quantile tests to compare the estimated harvest of hatchery fish with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 7: REGIONAL OBJECTIVES

Hatchery programs have the potential to increase diseases that typically occur at low levels in the natural environment (Objective 9). In addition, hatchery fish can reduce the abundance, size, or distribution of non-target taxa through ecological interactions (Objective 10). In this section, we address incidence of disease and non-target taxa of concern.

7.1 Incidence of Disease

Objective 11: Determine if the incidence of disease has increased in the natural and hatchery populations.

The hatchery environment has the potential to amplify diseases that are typically found at low levels in the natural environment. Amplification could occur within the hatchery population (i.e., vertical and horizontal transmission) or indirectly from the hatchery effluent or commingling between infected and non-infected fish (i.e., horizontal transmission). Potential impacts to natural populations have not been extensively studied, but should be considered for programs in which the hatchery fish are expected to commingle with natural fish. This is particularly important for supplementation type programs. Specifically, the causative agent of bacterial kidney disease (BKD), *Renibacterium salmoninarum* (Rs), could be monitored at selected acclimation ponds, both in the water and fish, in which the risk and potential for transmission from the hatchery is highest. Although it is technologically possible to measure the amount of Rs in water or Rs DNA in smolts and adults non-lethally sampled, the biological meaning of these data are uncertain. Currently, the only metric available for M & E purposes is measuring the antigen level from kidney/spleen samples (i.e., ELISA, PCR). When available, non-lethal sampling may replace or be used in concert with lethal sampling.

Implementation of this objective will be conducted in a coordinated approach within the hatchery and natural environment. BKD management within the hatchery population (e.g., broodstock or juveniles) has the potential to reduce the prevalence of disease through various actions (e.g., culling or reduced rearing densities). BKD management must also take into account and support other relevant objectives of the M & E program (e.g., Hatchery Return Rate [HRR], number of smolts released). Hence, the goal of BKD management is to decrease the prevalence of disease and maintain hatchery production objectives (i.e., number and HRR).

As previously discussed, disease transmission from hatchery to naturally produced fish may occur at various life stages and locations. Of these, horizontal transmission from hatchery effluent, vertical transmission on the spawning grounds, and horizontal transmission in the migration corridor have been identified as disease interactions that could be examined under this objective, although others may also be relevant. Experimental designs addressing this objective may require technology not yet available, although in some instances samples may be collected, but not analyzed until a link can be established between bacteria levels in samples and disease prevalence.

Developing a complete set of questions and hypotheses statements for this objective may not be practical at this time, because there is currently no BKD Management Plan. However, while developing experimental designs for this objective, it may be feasible to incorporate both hatchery and natural environment monitoring under a single study design. Integration of the different

aspects of the objective would likely result in a more robust approach into understanding the effectiveness of disease management strategies.

Proposed Tasks:

T1: Assemble fish health data for fish used as brood (e.g., ELISA results).

T2: Conduct data exploration exercise to identify potential relationships between pathogen profiles and likely causative variables (e.g., rearing conditions and management actions).

T3: Develop hypotheses for potential testing to meet objective.

7.2 Non-Target Taxa of Concern (NTTOC)

Objective 12: Determine if the release of hatchery fish affects non-target taxa of concern (NTTOC) within acceptable limits.

Hatchery programs have the potential to affect non-target taxa through various types of interactions (e.g., competition and predation). These interactions can reduce the distribution, size, and abundance of non-target species. The non-target taxa of concern (NTTOC) ecological risk assessment was developed as a regional objective that would addressed ecological interactions on non-target taxa.

In 2008, the Wells HCP, Rocky Reach HCP, Rock Island HCP Hatchery Committees, and the Priest Rapids Hatchery Sub-Committee agreed to an approach to evaluate the potential effects of hatchery programs on NTTOC. The committees originally planned to convene a panel of experts to conduct a preliminary evaluation of the potential effects of Plan supplemented species on NTTOC. At the 15 October 2008 Hatchery Committees meeting, the members agreed to convene an expert panel to conduct a preliminary evaluation of potential effects of supplemented Plan Species on non-target taxa using an approach similar to that used in the Yakima Basin (Pearsons and Hopley 1999; Ham and Pearsons, 2001). The Committees agreed to convene the panel in spring or early summer 2009, and focus this initial effort on HCP Plan Species and the two non-Plan Species, westslope cutthroat trout and lamprey. The Committees identified species interactions, containment objectives for non-target species, and fisheries professionals who possessed the expertise to contribute as panel members. The Committees directed the Hatchery Evaluation Technical Team (HETT) to pursue assessment of the hatchery programs potential effects on NTTOC.

The HETT evaluated methods to conduct a risk assessment on NTTOC, and proposed using a combined modeling and a Delphi panel approach, whereby the modeling results would be compared and correlated with the Delphi panel results. The HETT identified the PCD Risk 1 model (Busack et al., 2005; Pearsons and Busack, 2012) to conduct the modeling evaluation. The PCD Risk 1 model is a data intensive, individual-based stochastic model. The HETT determined that the assembled data to be used as inputs for the PCD Risk 1 model would also serve to provide expert panelists the necessary data for them to conduct risk assessments. Hence, the HETT embarked on an extensive effort to gather, organize, and extract the required data from existing datasets, literature, and biologists familiar with the programs and/or particular NTTOC. Ultimately, the input data were assembled in a relational database that allowed the data to be output in user-friendly formats for modeling or Delphi panel use. The database also served to hold the modeling results, which could be extracted and summarized as needed. Following the modeling work, the Committees decided not to assemble the expert panel, because the panel would not be able to evaluate adequately the very large number of possible interactions.

A report titled *Ecological Risk Assessment of Upper-Columbia Hatchery Programs on Non-Target Taxa of Concern* was drafted in 2013 and finalized in 2014, which included the modeling results to date. The results in the report represent a very extensive effort to model the risk of all the upper Columbia hatchery programs for the identified NTTOC for which data and model runs were available. Should new information become available, the Committees agreed to assess the suitability of the data as it relates to conducting future NTTOC evaluations as a regional objective.

SECTION 8: ADAPTIVE MANAGEMENT

One of the challenges of evaluating PUD hatchery programs is that hatchery programs are modified resulting in hatchery treatments that are uneven throughout the duration of the hatchery program. Modifications occur as a result of recalculating hatchery release numbers every 10 years and also through adaptive management. To solve this evaluation challenge, we propose to conduct two scales of analysis. First, the entire duration of the program will be analyzed using the entire data set. This evaluation will analyze whether the overall adaptively managed program achieved objectives. Second, where appropriate, analyses will be compared across periods or programs to determine if major program changes have resulted in hypothesized changes to key response variables. We acknowledged that partitioning data into shorter periods will likely result in reduced statistical power so only the biggest changes will be evaluated. In the future, the hatchery committees will develop a table or figure that identifies major program changes in fish culture or M&E.

In the past, hatchery programs have been evaluated at the hatchery program scale (e.g., Nason Creek, Carlton summer Chinook). In some cases, it may be worthwhile to evaluate supplementation programs at different spatial scales. For example, the Nason Creek spring Chinook salmon program can be evaluated at the scale of Nason Creek, the combined effects of spring Chinook hatchery programs in the Wenatchee basin at the Wenatchee basin scale, and then all of the spring Chinook programs in the upper Columbia at the upper Columbia basin scale.

Comparisons of supplemented populations (treatments) to in-basin reference populations are the best way to evaluate whether treatments have caused changes to variables such as natural-origin recruits or productivity. Many suitable out-of-basin references are available (see Appendix 6), but these references do not control for unique factors that may be happening in the upper Columbia or areas outside the upper Columbia. For example, large fires that occur in the Upper Columbia may not occur at similar times in areas outside of this area. Candidate in-basin reference populations are not ideal for spring Chinook salmon because they are small and are above a lake (e.g., Little Wenatchee River) or they have had a long history of hatchery stocking (e.g., Entiat River). Every population of upper Columbia summer and fall Chinook is supplemented so in-basin references are not currently available. Without a suitable number of in-basin reference populations that are similar in size and distribution to treated populations, it will be difficult to unambiguously assess hatchery effects on certain variables. Although not ideal, the only way to increase in-basin reference comparisons is to strategically reduce the number of places where hatchery fish are released such as was done for the Entiat River.

Previous stocking history will lessen the value of reference populations; however, they can still be of value. For instance, the Committees can still test whether NORs are increased under supplementation compared to periods when other populations are not supplemented (i.e., a reverse BACI analysis).

SECTION 10: GLOSSARY

Adult-to-Adult survival (Ratio)	The number of parent broodstock relative to the number of returning adults.
Age at maturity	The age of fish at the time of spawning (hatchery or naturally).
Augmentation	A hatchery strategy where fish are released for the sole purpose of providing harvest opportunities.
Broodstock	Adult salmon and steelhead collected for hatchery fish egg harvest and fertilization.
Donor population	The source population for supplementation programs before hatchery fish spawned naturally.
Effective population size (Ne)	The number of reproducing individuals in an ideal population (i.e., Ne = N) that would lose genetic variation due to genetic drift or inbreeding at the same rate as the number of reproducing adults in the real population under consideration (Hallerman 2003).
ESA	Endangered Species Act passed in 1973. The ESA-listed species refers to fish species added to the ESA list of endangered or threatened species and are covered by the ESA.
Expected value	The number of smolts or adults derived from survival rates agreed to in the Biological Assessment and Management Plan (BAMP 1998).
Extraction rate	The proportion of the spawning population collected for broodstock.
Genetic diversity	All the genetic variation within a species of interest, including both within and between population components.
Genetic stock structure	A type of assortative mating, in which the gene pool of a species is composed of a group of subpopulations, or stocks, that mate panmictically within themselves.
Genetic variation	All the variation due to different alleles and genes in an individual, population, or species.
HCP	Habitat Conservation Plan is a plan that enables an individual or organization to obtain a Section 10 Permit which outlines what will be done to “minimize and mitigate” the impact of the permitted take on a listed species.

HCP-HC	Habitat Conservation Plan Hatchery Committee is the committee that directs actions under the hatchery program section of the HCP's for Chelan and Douglas PUDs.
HRR	Hatchery Replacement Rate is the ratio of the number of returning hatchery adults relative to the number of adults taken as broodstock, both hatchery and naturally produced fish (i.e., adult-to-adult replacement rate).
Long-term fitness	Long-term fitness is the ability of a population to self-perpetuate over successive generation.
Naturally produced	Progeny of fish that spawned in the natural environment, regardless of the origin of the parents.
Mean Ratio	The ratio between a treatment and control population, with the mean taken across a time period, such as years. Used in analysis in Before-After-Control-Impact studies.
Ne	Effective population size.
Non-target taxa of concern (NTTOC)	Species, stocks, or components of a stock with high value (e.g., stewardship or utilization) that may suffer negative effects because of a hatchery program.
NRR	Natural replacement rate is the ratio of the number of returning naturally produced adults relative to the number of adults that naturally spawned, both hatchery and naturally produced.
NTTOC	Non-target taxa of concern.
pHOS	Proportion of Hatchery Origin Spawners.
PNI	Proportionate Natural Influence.
pNOB	Proportion of Natural Origin Broodstock.
PRCC HSC	Priest Rapids Coordinating Committee Hatchery Subcommittee.
Productivity	The capacity in which juvenile fish or adults can be produced.
Reference population	A population in which no directed artificial propagation is currently directed, although may have occurred in the past. Reference populations are used to monitor the natural variability in survival rates and out of basin impacts on survival.
Smolt-to-adult survival rate (SAR)	Smolt-to-adult survival rate is a measure of the number of adults that return from a given smolt population.
Segregated	A type of hatchery program in which returning adults are spatially or temporally isolated from other populations.

Size at maturity	The length or weight of a fish at a point in time during the year in which spawning will occur.
Smolts per redd	The total number of smolts produced from a stream divided by the total number of redds from which they were produced.
SNP or single-nucleotide polymorphism	A single-nucleotide polymorphism is a variation in a single nucleotide that occurs at a specific position in the genome, where each variation is present to some appreciable degree within a population.
Spawning Escapement	The number of adult fish that survive to spawn.
Stray rate	The rate at which fish spawn outside of natal rivers or the stream in which they were released.
Supplementation	A hatchery strategy where the main purpose is to increase the relative abundance of natural spawning fish without reducing the long-term fitness of the population.
Target population	A specific population in which management actions are directed (e.g., artificial propagation, harvest, or conservation).

APPENDIX 1: ESTIMATION OF CARRYING CAPACITY

In the ecological literature, carrying capacity is often defined as the maximum population size that can be supported indefinitely by the environment (Cain et al. 2014). Said another way, carrying capacity is the maximum number or biomass of a species that a given habitat can support. This maximal environment load is often referred to as "habitat capacity" and is identified with the letter "C." In contrast, the carrying capacity parameter "K" in population models (e.g., logistic equation, Beverton-Holt model, hockey stick model, and the Ricker model) defines a maximum equilibrium population size. Maximum equilibrium population size is generated from density dependent mechanisms that reduce population growth rates as population size increases (negative density dependence). This is referred to as compensation. Population size fluctuates about the maximum equilibrium size because of variability in vital rates that are unrelated to density (density independent factors) and measurement error. Maximum equilibrium population size is often referred to as "population capacity." The two capacities (habitat capacity and population capacity) are related but not identical and therefore should not be confused. Habitat capacity will usually be greater than population capacity.

Estimation of carrying capacity is important because hatchery managers use it to inform supplementation programs, harvest managers use it to set appropriate harvest and escapement levels, modelers use it in life-cycle models to predict the effects of different recovery scenarios, and restoration practitioners use it to guide restoration actions. The purpose of this paper is to describe methods that can be used to estimate carrying capacity for stocks within the Upper Columbia River basin. We apply these methods to Wenatchee and Chiwawa River spring Chinook salmon.[13] Data used in this exercise are shown in Tables 1 and 2 and come from Hillman et al. (2017). We begin by identifying simple methods used to detect density dependence. We then describe the use of population models to estimate population capacity. We also discuss the use of habitat models and quantile regression to estimate habitat capacity. We end by comparing results of different methods and offering recommendations for estimating carrying capacity.

Table 1. Numbers of redds, adult spawners (estimated from redd surveys), eggs (estimated as the number of redds times average brood-year fecundity), summer parr (estimated using snorkel surveys), and yearling smolts (estimates using a rotary screw trap) by brood year for spring Chinook salmon in the Chiwawa River watershed. Smolts represent the number of yearling Chinook produced entirely within the Chiwawa River watershed. Date are from Hillman et al. (2017). NS = not sampled.

Brood year	Numbers of Chiwawa spring Chinook				
	Redds	Spawners	Eggs	Parr	Smolts
1991	104	242	478,400	45,483	42525
1992	302	676	1,570,098	79,113	39723

* From 2000-2010 the smolt trap operated near the Town of Monitor; from 2013 to present the trap operated near the Town of Cashmere.

Evidence of Density Dependence

To calculate population capacity, the size of the population or stock must be influenced to a large degree by density-dependent factors. That is, population growth is affected by mechanisms whose effectiveness increases as population size increases. As population density increases, factors such as competition, predation, and disease (and parasites) cause birth rates to decrease, death rates to increase, and dispersal to increase. When densities decrease, the opposite occurs; birth rates increase and death and emigration rates decrease. In general, when the density of the population becomes high enough, density-dependent factors decrease population size because food or space are in short supply (Chapman 1966). In the ecological literature, this is referred to as “population regulation.”

A simple way to determine if density-dependent factors regulate population size is to plot population growth rate (or appropriate surrogate) against population size. If population regulation is occurring, the relationship between population size and population growth rate decreases exponentially (decreases linearly if data are log-transformed). Surrogates for population growth rate include survival rates, natality (birth rates), productivity, recruits, individual growth rates, and movement. Figure 1 shows the relationship between productivity (parr/spawner and smolts/spawner) and spawning escapement for Wenatchee River and Chiwawa River spring Chinook. One could use redd counts as a surrogate for spawning abundance. Because most female spring Chinook construct only one redd (Murdoch et al. 2009), redd counts reflect the number of female spawners in the population. In this report, we use number of spawners (spawning escapement) because most management decisions are based on spawning escapement.

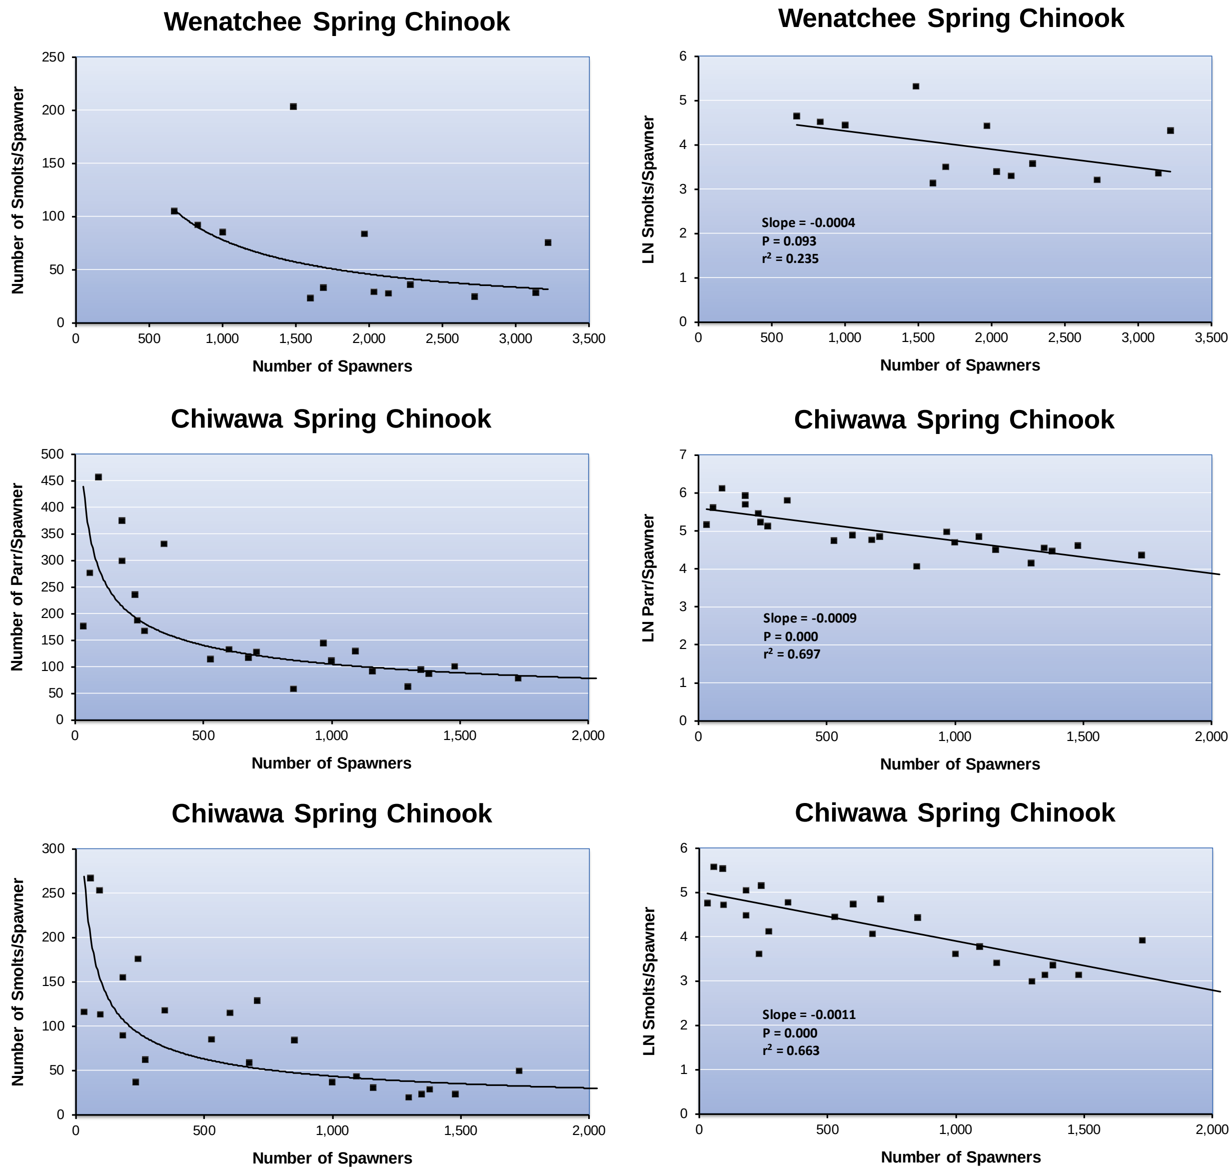

Figure 1. Relationship between spawner abundance and smolts/spawner for Wenatchee spring Chinook (top figures), spawner abundance and parr/spawner for Chiwawa spring Chinook (middle figures), and spawner abundance and smolts/spawner for Chiwawa spring Chinook (bottom figures). Figures on the right show natural log transformed productivity data.

The negative relationship between spawner abundance and juvenile productivity indicates the presence of density dependence in Chiwawa spring Chinook. Although there is a hint of density dependence in the Wenatchee River productivity data, the relationship was not significant statistically. This in part may be related to changes in sampling over the 13-year period. The negative relationship was significant for both summer parr and yearling smolts in the Chiwawa River watershed. We caution, however, that there may be a bias in the simple regression analysis presented in the figures. That is, the dependent (productivity) and independent (abundance) variables are not independent and this can produce a negative bias in regression estimates of slope. Nevertheless, the decline in juvenile productivity with increasing spawner abundance indicates the

presence of density dependence. Given the presence of density dependence, we should be able to estimate population capacity.

Estimating Carrying Capacity

Several different methods can be used to estimate population capacity. For example, time series analyses, including the logistic or Gompertz functions, or stock-recruitment models can be used to estimate population capacity. Common stock-recruitment models include Ricker, Beverton-Holt, and smooth hockey stick models. These models incorporate environmental variability and can be used to estimate the size of the spawning population needed to produce the maximum number of recruits. Habitat capacity, on the other hand, can be estimated using fish-habitat models. In general, these models estimate habitat capacity as the product of habitat area and fish/habitat relationships. These range from simple models such as percent habitat saturation models to more complex models including habitat suitability, quantile regression forest models, dynamic food-web models, and bioenergetic or net rate of energy intake models. In this report, we explore the use of stock-recruitment models to estimate population capacity. We apply quantile regression to stock-recruitment models to estimate habitat capacity and compare those results to a habitat model, the quantile regression forest model.

Population Capacity

To estimate population capacity, we evaluated the fit of three different stock-recruitment models to Chiwawa and Wenatchee River spring Chinook data: Ricker, Beverton-Holt, and smooth hockey stick models. In using these models, we assume:

- *Density-dependent mortality*—For some time period before recruitment, the brood instantaneous mortality rate is proportional to the number of parent spawners (Ricker 1954).
- *Lognormal variation*—At any particular spawning stock size, the variation in recruitment is log-normally distributed about its average, and acts multiplicatively (Quinn and Deriso 1999).
- *Measurement error*—Error in spawning stock size estimates (measurement error) is small relative to the range of spawning stock sizes observed (Hilborn and Walters 1992). Variation in realized recruitment at any particular spawning stock size (process error) dominates recruitment measurement error.
- *Stationarity*—The average stock-recruitment relationship is constant over time (Hilborn and Walters 1992). That is, environmental conditions randomly affect survival independent of stock size or time.

In general, the methods we used to fit the models to the data followed those outlined in Hilborn and Walters (1992) and Froese (2008). The Ricker model, which assumes that the number of recruits increases to a maximum and then declines as the number of spawners increases, takes the form:

$$\boldsymbol{E(R) = \alpha S e^{-\beta S}}$$

where E(R) is the expected recruitment, S is spawner abundance, α is the number of recruits per spawner at low spawning levels, and β describes how quickly the recruits per spawner drop as the number of spawners increases. We estimated population capacity (K) as:

$$K = \left(\frac{\alpha}{\beta}\right) e^{-1}$$

and the number of spawners (SP) needed to produce the maximum number of recruits as:

$$SP = \frac{1}{\beta}$$

The Beverton-Holt model assumes that the number of recruits increases constantly toward an asymptote as the number of spawners increases. After the asymptote is reached, the number of recruits neither increases nor decreases. The asymptote represents the maximum number of recruits the system can support (i.e., population capacity for the system; K). The Beverton-Holt curve takes the form:

$$E(R) = \frac{(\alpha S)}{(\beta + S)}$$

where E(R) and S are as above, α is the maximum number of recruits produced (i.e., α = K), and β is the number of spawners needed to produce (on average) recruits equal to one-half the maximum number of recruits. The number of spawners needed to produce the maximum number of recruits is ∞ in the Beverton-Holt model.

Like the Beverton-Holt model, the smooth hockey stick model assumes that the number of recruits increases toward an asymptote (population capacity; K) as the number of spawners increases. After the carrying capacity is reached, the number of recruits neither increases nor decreases. The carrying capacity represents the maximum equilibrium number of recruits the system can support. This curve takes the form (Froese 2008):

$$E(R) = R_{\infty}\left(1 - e^{-\left(\frac{\alpha}{R\infty}\right)S}\right)$$

where E(R) and S are as above, α is the slope at the origin of the spawner-recruitment curve, and R_{∞} is the carrying capacity of recruits (i.e., $R_{\infty} = K$). There is no direct estimate of SP in the smooth hockey stick model. Therefore, we estimated SP as the number of spawners needed to produce 0.95(K).

We used non-linear regression to fit the three models to spawner-recruitment data. Before fitting the models, we transformed recruitment data using natural logs. We estimated bias and uncertainty measures (95% CI) for the model parameters using bootstrap procedures, which assumed that the {R, S} sample represented or approximated the population. The number of bootstrap samples was 3,000. We computed and stored the non-linear regression results for each bootstrap sample. We then calculated the bootstrap 95% CI by arranging the 3,000 bootstrap parameter values in sorted order and selected the 2.5 and 97.5 percentiles from the list.

We used Akaike's Information Criterion for small sample size (AIC_c) to determine which model(s) best explained the relationship between spawners and recruitment in the supplemented and reference populations. AIC_c was estimated as:

$$AIC_c = -2log\left(£(\theta|data)\right) + 2K + \left(\frac{2K(K+1)}{n-K-1}\right)$$

where $log(£(\theta|data))$ is the maximum likelihood estimate, K is the number of estimable parameters (structural parameters plus the residual variance parameter), and n is the sample size (Burnham and Anderson 2002). We used least-squares methods to estimate $log(£(\theta|data))$, which was calculated as $log(\sigma^2)$, where σ^2 = residual sum of squares divided by the sample size ($\sigma^2 = RSS/n$). AIC_c assessed model fit in relation to model complexity (number of parameters). The model with the smallest AIC_c value represented the "best approximating" model within the model set. Remaining models were ranked relative to the best model using AIC_c difference scores (ΔAIC_c), Akaike weights (w_i), and evidence ratios. Models with ΔAIC_c values less than 2 indicated that there is substantial support for these models as being the best-fitting models within the set (Burnham and Anderson 2002). Models with values greater than 2 had less support. Akaike weights are probabilities estimating the strength of the evidence supporting a particular model as being the best model within the model set. Models with small w_i values are less plausible as competing models (Burnham and Anderson 2002). If no single model could be specified as the best model, a "best subset" of competing models was identified using (1) AIC_c differences to indicate the level of empirical support each model had as being the best model, (2) evidence ratios based on Akaike weights to indicate the relative probability that any model is the best model, and (3) coefficients of determination (R^2) assessing the explanatory power of each model.

Chiwawa River Spring Chinook Parr

We successfully fit the three stock-recruitment curves to the Chiwawa spring Chinook parr data (Figure 2).

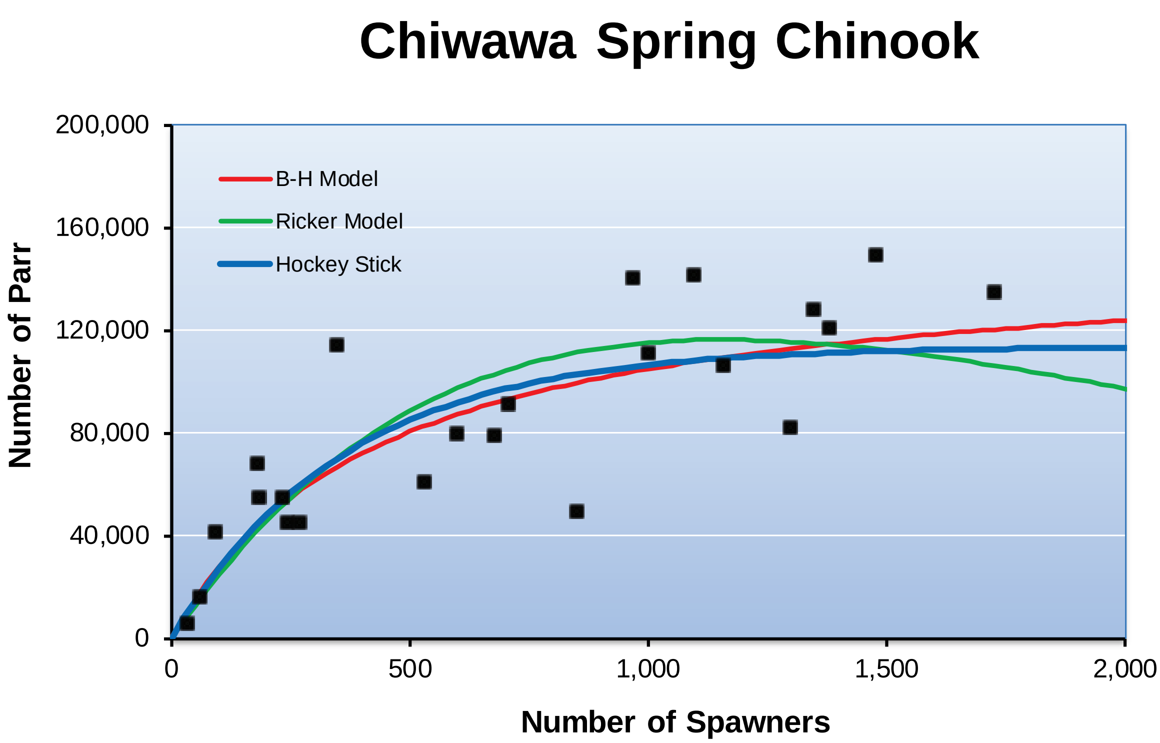

Figure 2. Relationship between numbers of spring Chinook parr and numbers of spawners in the Chiwawa River watershed, 1992-2016 (no sampling occurred in 2000). Figure shows the fit of the Beverton-Holt, Ricker, and smooth hockey stick models to the data.

For summer parr, the use of AIC_c indicated that the Beverton-Holt model best approximated the information in the productivity data. The estimated structural parameters for this model were:

$$Parr = \frac{(150{,}902 \times Spawners)}{(438 + Spawners)}$$

where the bootstrap estimated standard errors for the two parameters were 21,142 and 145, respectively. The adjusted $R^2 = 0.812$.

The second-best model was the smooth hockey stick model, which was 0.245 AIC_c units from the best model. The estimated parameters for this model were:

$$LN(Parr) = 11.6 + LN\left(1 - e^{-\left(\frac{312.9}{113{,}801}\right)Spawners}\right)$$

where the bootstrap estimated standard errors of the two parameters were 0.097 and 57.578, respectively, and the $R^2 = 0.810$.

The AIC_c difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for both the Beverton-Holt and smooth hockey stick models. There was less support for the Ricker model, which was > 2 AIC_c units from the best models. This was further supported by the fact that, relative to the best models, the Ricker model had an evidence ratio greater than 3.

Depending on the stock-recruitment model used, population capacity ranged from 113,801 to 150,902 parr (Table 3). The Beverton-Holt model estimated the highest capacity, while the smooth hockey stick model estimated the lowest. The number of spawners needed to produce the population capacity of parr ranged from 1,089 to 1,163 (Table 3).

Table 3. Estimates of Beverton-Holt, smooth hockey stick, and Ricker model parameters, parr capacity (K), parr productivity (parr per spawner), and the number of spawners needed to produce the maximum number of parr for Chiwawa River spring Chinook.

Model	**Parameter**		**Population capacity (K)**	**Intrinsic productivity**	**Spawners**
	A	**B**			
Beverton-Holt	150,902.145	437.655	150,902	345	∞
Smooth Hockey Stick	11.642	312.913	113,801	313	1,089
Ricker	272.696	0.0009	116,650	273	1,163

It is important to note that the population capacity estimates are based on the number of parr counted in the Chiwawa River watershed during August. There are spring Chinook fry and parr that move out of the Chiwawa River watershed during spring and early summer (Hillman et al. 2017). It is unknown if these fish leave because of density-dependent pressures, they are flushed out during high flows, it is a life-history characteristic, or a combination of these. Regardless of the mechanism or reason, some of these fish may survive and rear in the Wenatchee or Columbia rivers. These emigrants are not included in the capacity estimates shown in Table 3.

The capacity estimates for spring Chinook parr apply only to the Chiwawa River watershed, a watershed within the Wenatchee River basin. Estimating parr capacity for the entire Wenatchee River basin using stock-recruitment models is difficult because there is no long-term time series of parr data for the entire basin. However, we can extrapolate parr capacity estimates from the

Chiwawa River watershed to the entire Wenatchee River basin using intrinsic potential (IP). Multiplying the parr capacity per intrinsic potential within the Chiwawa River watershed by the total intrinsic potential within the Wenatchee River basin yields an estimate of parr capacity for the Wenatchee River basin (Table 4). The Interior Columbia Basin Technical Recovery Team estimated IP based on wetted width, valley width (confinement), and gradient (see Cooney and Holzer 2006). They used sedimentation and temperature to refine IP for each 200-m long reach. We used the total stream area (km^2) weighted by intrinsic potential and temperature limited to extrapolate parr capacity to the entire Wenatchee River basin.

Table 4. Estimates of Wenatchee River basin parr capacity based on intrinsic potential (IP). The amount of IP within the Chiwawa River watershed is 0.481 km^2; the total amount of IP within the Wenatchee River basin is 1.798 km^2.

Model	Chiwawa parr capacity	Chiwawa parr/IP	Wenatchee parr capacity
Beverton-Holt	150,902	313,726	564,079
Smooth Hockey Stick	113,801	236,593	425,395
Ricker	116,650	242,516	436,043

Using this simple method, we estimate the Wenatchee River basin supports about 425,395-564,079 parr depending on which model is used. An important assumption of this simple method is that each unit of IP supports the same number of parr. This is clearly not true given that the quality of habitat within each unit of IP can vary greatly. That is, one unit of IP may contain more habitat structure (e.g., wood and cover) than another unit of IP. Importantly, the ratio of parr to IP comes from the Chiwawa River watershed, which contains some of the highest quality habitat within the Wenatchee River basin. Therefore, the estimated total parr capacity for the entire Wenatchee River basin is likely biased high. If habitat conditions throughout the Wenatchee River basin are enhanced to conditions similar to those in the Chiwawa River watershed, we may expect parr abundance to approach those estimated with this simple method.

Chiwawa River Spring Chinook Smolts

We successfully fit the three stock-recruitment curves to the Chiwawa spring Chinook smolt data (Figure 3). This information allows us to better understand the quality and quantity of overwintering habitat in the Chiwawa River basin.

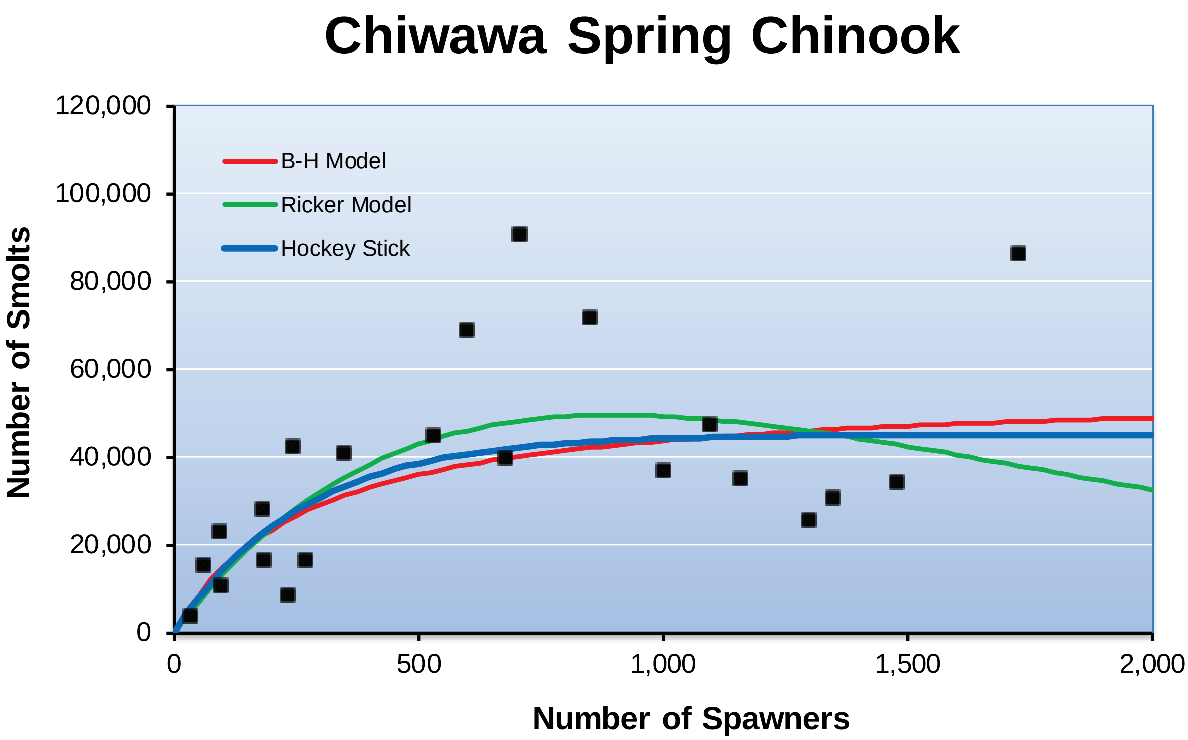

Figure 3. Relationship between numbers of spring Chinook smolts and numbers of spawners in the Chiwawa River watershed, 1992-2015. Figure shows the fit of the Beverton-Holt, Ricker, and smooth hockey stick models to the data.

For yearling smolts produced entirely within the Chiwawa River watershed, the use of AIC_c indicated that the smooth hockey stick model best approximated the information in the productivity data. The estimated structural parameters for this model were:

$$LN(Smolts) = 10.7 + LN\left(1 - e^{-\left(\frac{174.1}{45,161}\right)Spawners}\right)$$

where the bootstrap estimated standard errors for the two parameters were 0.13 and 41.29, respectively. The adjusted $R^2 = 0.569$.

The second-best model was the Ricker model, which was 0.234 AIC_c units from the best model. The estimated parameters for this model were:

$$Smolts = 149.45 \times Spawners(\mathrm{e}^{-0.00111 \times Spawners})$$

where the bootstrap estimated standard errors of the two parameters were 26.23 and 0.00018, respectively, and the $R^2 = 0.573$.

The third-best model was the Beverton-Holt model, which was 0.725 AIC_c units from the best model. The estimated parameters for this model were:

$$Smolts = \frac{(55,702 \times Spawners)}{(273 + Spawners)}$$

where the bootstrap estimated standard errors of the two parameters were 10,421.9 and 123.0, respectively, and the $R^2 = 0.560$.

The AIC_c difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for all three models. Relative to the best model, the other two models had evidence ratios less than 1.5.

Depending on the stock-recruitment model used, population capacity ranged from 45,161 to 55,702 smolts (Table 5). The Beverton-Holt model estimated the highest capacity, while the smooth hockey stick model estimated the lowest. The number of spawners needed to produce the population capacity of smolts ranged from 777 to 901 (Table 5).

Table 5. Estimates of Beverton-Holt, smooth hockey stick, and Ricker model parameters, smolt capacity (K), smolt productivity (smolts per spawner), and the number of spawners needed to produce the maximum number of smolts for Chiwawa River spring Chinook.

Model	Parameter		Population capacity (K)	Intrinsic productivity	Spawners
	A	B			
Smooth hockey stick	10.718	174.077	45,161	174	777
Ricker	149.452	0.00111	49,532	149	901
Beverton-Holt	55,702.281	273.910	55,702	203	∞

It is important to note that the population capacity estimates are based on the number of smolts produced entirely within the Chiwawa River watershed. As noted earlier, there are spring Chinook fry and parr that move out of the Chiwawa River watershed during spring, early summer, and fall (Hillman et al. 2017). Fall emigration is common and occurs even when densities of juveniles are very low, indicating that fall emigration is a life-history characteristic. Regardless of why the fish emigrate as fry and parr, some of these fish survive and rear in the Wenatchee or Columbia rivers. Some survive to smolt (unpublished WDFW data), but are not included in the smolt capacity estimates shown in Table 5.

As with parr, the capacity estimates for spring Chinook smolts apply only to the Chiwawa River watershed. As before, we can extrapolate smolt capacity estimates from the Chiwawa River watershed to the entire Wenatchee River basin using intrinsic potential (IP). In this case, we multiply the smolt capacity per intrinsic potential within the Chiwawa River watershed by the total intrinsic potential within the Wenatchee River basin. This yields an estimate of smolt capacity for the Wenatchee River basin (Table 6).

Table 6. Estimates of Wenatchee River basin smolt capacity based on intrinsic potential (IP). The amount of IP within the Chiwawa River watershed is 0.481 km^2; the total amount of IP within the Wenatchee River basin is 1.798 km^2.

Model	Chiwawa smolt capacity	Chiwawa smolts/IP	Wenatchee smolt capacity
Beverton-Holt	55,702	115,805	208,218
Smooth Hockey Stick	45,161	93,891	168,816
Ricker	49,532	102,976	185,152

Using this simple method, we estimate the population capacity for the Wenatchee River basin at 168,816-208,218 smolts depending on which model is used. Based on smolt trapping in the lower Wenatchee River over a 13-year period, total smolt abundance has ranged from 36,752 to 302,116 smolts (average = 107,300 smolts) (Table 2).[14] Thus, recent (2000-2014) smolt production appears to be below capacity estimates for most years but higher in some years.

An important assumption of this simple method is that each unit of IP supports the same number of smolts. As we noted earlier, this is not the case given that the quality of habitat within each unit of IP can vary greatly. Nevertheless, the ratio of smolts to IP comes from the Chiwawa River watershed, which contains some of the highest quality habitat within the Wenatchee River basin. Therefore, the estimated total smolt capacity for the entire Wenatchee River basin is likely biased high. If habitat conditions throughout the Wenatchee River basin are enhanced to conditions similar to those in the Chiwawa River watershed, we may expect smolt abundance to approach those estimated with this simple method.

Wenatchee River Spring Chinook Smolts

Rather than extrapolate results from the Chiwawa River watershed to the entire Wenatchee River basin, we can fit stock-recruitment models to the smolt data collected in the lower Wenatchee River and estimate population capacity directly from the population models. We successfully fit the three stock-recruitment curves to the Chiwawa spring Chinook smolt data; although, the models explained little of the variation in the stock-recruitment data ($R^2 < 0.05$) (Figure 3).

[14] It is important to point out that the trapping location has changed over time. During the period 2000-2008 and 2011-2012, the trap was located near the Town of Monitor. During the period 2013-present, the trap was located near the Town of Cashmere.

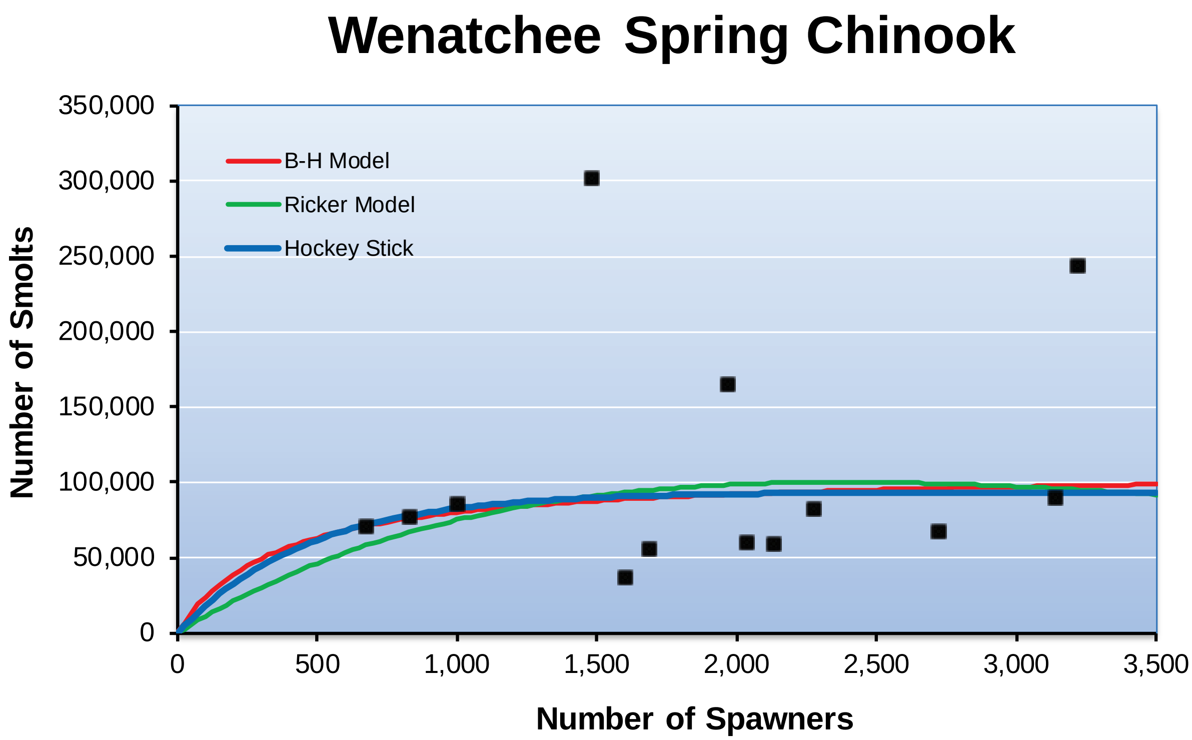

Figure 4. Relationship between numbers of spring Chinook smolts and numbers of spawners in the Wenatchee River basin, 2000-2014 (no data were collected in 2009 or 2010). Figure shows the fit of the Beverton-Holt, Ricker, and smooth hockey stick models to the data.

For yearling smolts produced within the Wenatchee River basin, the use of AIC$_c$ indicated that the Beverton-Holt model best approximated the information in the productivity data. The estimated structural parameters for this model were:

$$Smolts = \frac{(108{,}696 \times Spawners)}{(359 + Spawners)}$$

where the bootstrap estimated standard errors for the two parameters were 49,948 and 836, respectively. The adjusted $R^2 = 0.026$.

The second-best model was the smooth hockey stick model, which was 0.112 AIC$_c$ units from the best model. The estimated parameters for this model were:

$$LN(Smolts) = 11.4 + LN\left(1 - e^{-\left(\frac{20.72}{93{,}560}\right)Spawners}\right)$$

where the bootstrap estimated standard errors of the two parameters were 30.74 and 225.43, respectively, and the $R^2 = 0.017$.

The third-best model was the Ricker model, which was 0.0.808 AIC$_c$ units from the best model. The estimated parameters for this model were:

$$Smolts = 114.10 \times Spawners(\mathrm{e}^{-0.00042 \times Spawners})$$

where the bootstrap estimated standard errors of the two parameters were 56.16 and 0.00021, respectively, and the $R^2 = 0.001$.

The AIC_c difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for all three models. Relative to the best model, the other two models had evidence ratios less than 2.0.

Depending on the stock-recruitment model used, population capacity for the Wenatchee River basin ranged from 93,560 to 108,696 smolts (Table 7). The Beverton-Holt model estimated the highest capacity, while the smooth hockey stick model estimated the lowest. The number of spawners needed to produce the population capacity of smolts ranged from 1,389-2,381 (Table 7).

Table 7. Estimates of Beverton-Holt, smooth hockey stick, and Ricker model parameters, smolt capacity (K), smolt productivity (smolts per spawner), and the number of spawners needed to produce the maximum number of smolts for Wenatchee River spring Chinook.

Model	Parameter		Population capacity (K)	Intrinsic productivity	Spawners
	A	B			
Smooth hockey stick	11.446	201.724	93,560	202	1,389
Ricker	114.104	0.00042	99,944	114	2,381
Beverton-Holt	108,696.009	358.616	108,696	303	∞

The population capacity estimates reported here are based on the number of smolts produced within the Wenatchee River basin. It is likely that some juvenile spring Chinook rear in the Columbia River and survive to smolt. Those fish are not included in these estimates of capacity.

Habitat Capacity

Habitat capacity can be estimated using fish-habitat models and creative modeling of stock-recruitment data. As we noted earlier, there are several different fish-habitat models that can be used to estimate habitat capacity. In this paper, we explore the use of two different methods, quantile regression applied to stock-recruitment functions and the Quantile Regression Random Forest model. The former relies on simple stock and recruitment data, while the latter requires estimates of habitat quality and quantity, and functional relationships between maximum fish density and habitat conditions.

Quantile Regression Analysis of Stock-Recruitment Data

To estimate population capacity, we used non-linear regression techniques to fit stock-recruitment functions to the data. These techniques approximate the conditional mean of the recruitment data given the range of stock sizes. As such, the functions (curves) estimated from the analyses lie near the center of the distribution of data resulting in data points above and below the curve. Although this technique is useful for estimating population capacity, it is not appropriate for estimating habitat capacity. The fact that there are actual recruitment data above the estimated population capacity indicates that habitat capacity must be greater than the population capacity, or that measurement error is high. The former explanation is more likely than the latter.

One way to possibly estimate habitat capacity with stock-recruitment data is to fit stock-recruitment functions to the juvenile spring Chinook data using quantile regression techniques. Quantile regression estimates quantiles of the recruitment data given the range of stock sizes. Thus,

we can use quantile regression to fit a stock-recruitment function to, say, the upper 90% or 95% of the recruitment distribution. In other words, we fit a stock-recruitment function to the upper limits of the recruitment data given the range of stock sizes. In this case, the resulting stock-recruitment curve is above most of the recruitment data and therefore few data points lie above the curve. Calculation of capacity from these functions should more closely represent habitat capacity, provided there is an adequate range of stock sizes. Quantile regression gives results similar to those obtained from calculating reference intervals (RI).

In this exercise, we calculated the upper 90% RI for the Beverton-Holt and Ricker functions. We assume the 90% RI will closely represent the habitat capacity for juvenile spring Chinook. We calculated the 90% RI only for the Beverton-Holt and Ricker models, because these functions can be transformed into linear function (see Hilborn and Walters 1992). RIs are easier to calculate on linear functions than non-linear functions. We were unable to transform the smooth hockey stick model into a linear function and therefore we did not calculate RIs for this function.

Chiwawa River Spring Chinook Parr—We calculated 90% RIs for Chiwawa Chinook parr data for both the Ricker and Beverton-Holt models (Figure 5). The estimated parameters for the 90% RI for the Ricker model were:

$$\log\left(\frac{Parr}{Spawners}\right) = 6.152 - \frac{6.152}{5{,}984.436}(Spawners)$$

This resulted in an estimated habitat capacity of 168,071 parr, which is about 1.4 times greater than the population capacity estimated with the Ricker model.

The estimated parameters for the 90% RI for the Beverton-Holt model were:

$$\frac{Spawners}{Parr} = \frac{196.91}{181{,}818} + \frac{1}{181{,}818}(Spawners)$$

This function resulted in an estimated habitat capacity of 181,818 parr, which was about 1.2 times greater than the population capacity estimated with the Beverton-Holt model.

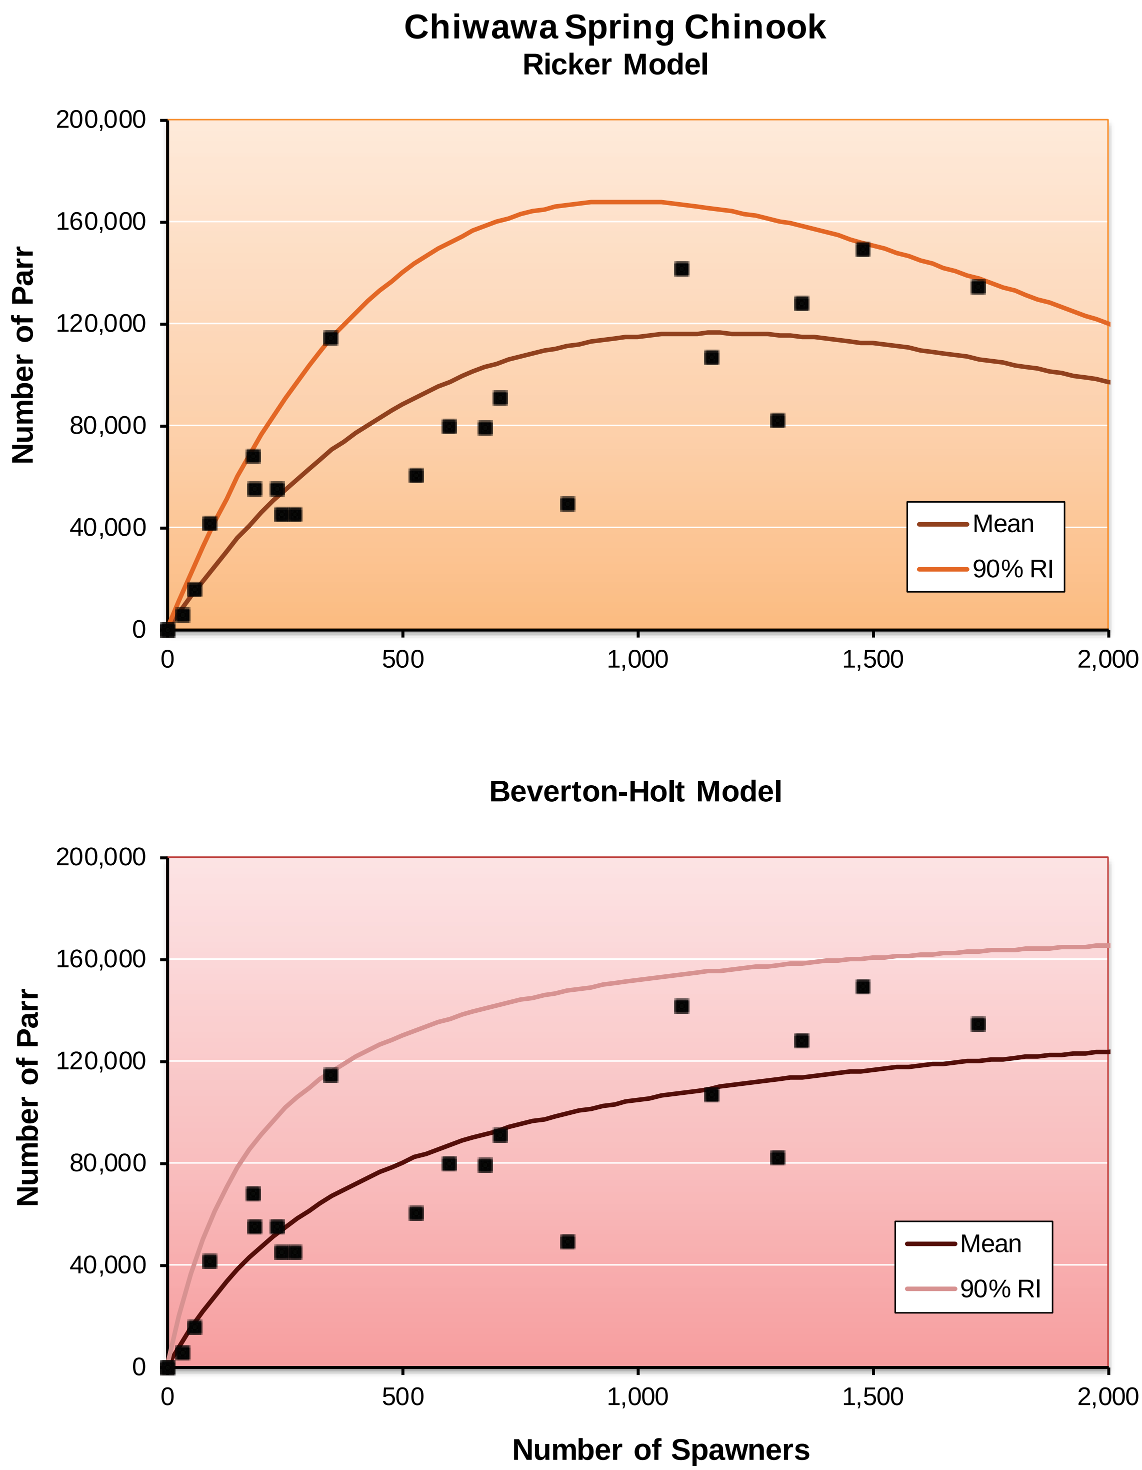

Figure 5. Relationship between numbers of spring Chinook parr and numbers of spawners in the Chiwawa River watershed, 1992-2016. Upper figure shows the fit of the Ricker model and its 90% reference interval to the data; lower figure shows the fit of the Beverton-Holt model and its 90% reference interval.

If we extrapolate the habitat capacity estimates for Chiwawa spring Chinook parr to the entire Wenatchee River basin (using the IP method described earlier), we estimate the habitat capacity for the Wenatchee River basin to be 628,256 parr from the Ricker model and 679,645 parr from the Beverton-Holt model.

Chiwawa River Spring Chinook Smolts—As with parr, we calculated 90% RIs for Chiwawa Chinook smolt data for both the Ricker and Beverton-Holt models (Figure 6). The estimated parameters for the 90% RI for the Ricker model were:

$$\log\left(\frac{Smolts}{Spawners}\right) = 5.687 - \frac{5.687}{4{,}687.964}(Spawners)$$

This resulted in an estimated habitat capacity of 89,425 smolts, which is about 1.8 times greater than the population capacity estimated with the Ricker model.

The estimated parameters for the 90% RI for the Beverton-Holt model were:

$$\frac{Spawners}{Smolts} = \frac{102.129}{64{,}516} + \frac{1}{64{,}516}(Spawners)$$

This function resulted in an estimated habitat capacity of 64,516 smolts, which was about 1.2 times greater than the population capacity estimated with the Beverton-Holt model.

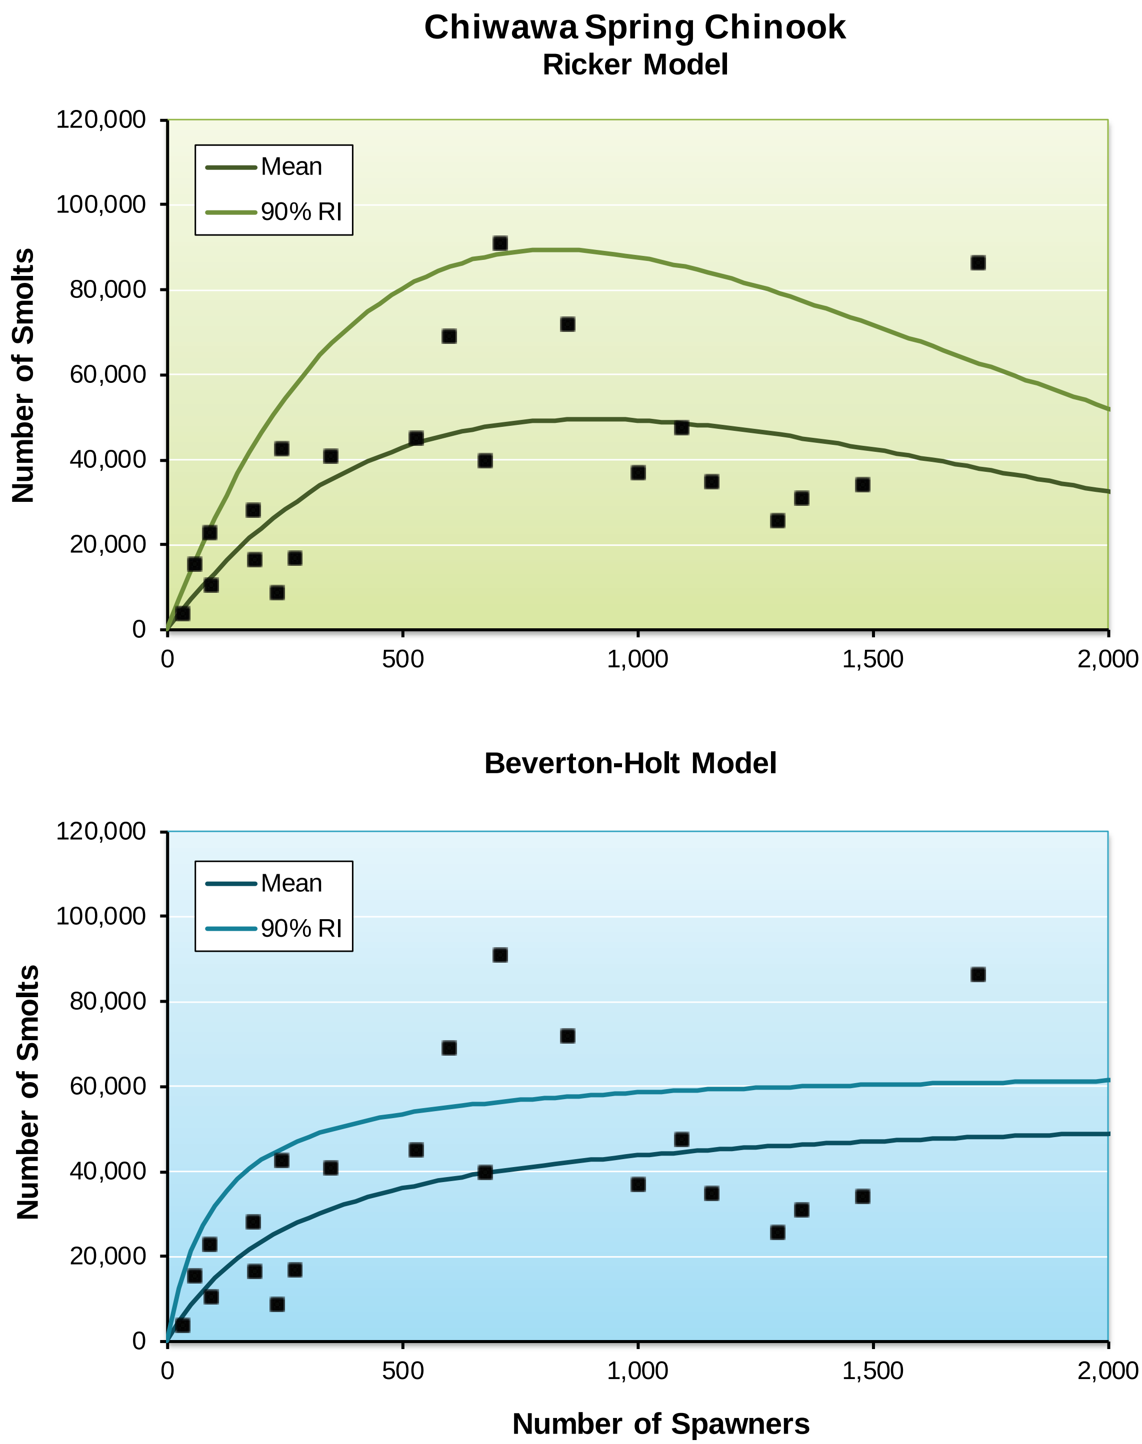

Figure 6. Relationship between numbers of spring Chinook smolts and numbers of spawners in the Chiwawa River watershed, 1992-2015. Upper figure shows the fit of the Ricker model and its 90% reference interval to the data; lower figure shows the fit of the Beverton-Holt model and its 90% reference interval.

If we extrapolate the habitat capacity estimates for Chiwawa spring Chinook smolts to the entire Wenatchee River basin (using the IP method described earlier), we estimate the habitat capacity

for the Wenatchee River basin to be 334,276 smolts based on the Ricker model and 241,164 smolts from the Beverton-Holt model.

Wenatchee River Spring Chinook Smolts—We calculated 90% RIs for Wenatchee River Chinook smolt data for both the Ricker and Beverton-Holt models (Figure 7). The estimated parameters for the 90% RI for the Ricker model were:

$$\log\left(\frac{Smolts}{Spawners}\right) = 5.320 - \frac{5.320}{16{,}642.420}(Spawners)$$

This resulted in an estimated habitat capacity of 235,131 smolts, which is about 2.4 times greater than the population capacity estimated with the Ricker model.

The estimated parameters for the 90% RI for the Beverton-Holt model were:

$$\frac{Spawners}{Smolts} = \frac{357.593}{186{,}567} + \frac{1}{186{,}567}(Spawners)$$

This function resulted in an estimated habitat capacity of 186,567 smolts, which was about 1.7 times greater than the population capacity estimated with the Beverton-Holt model.

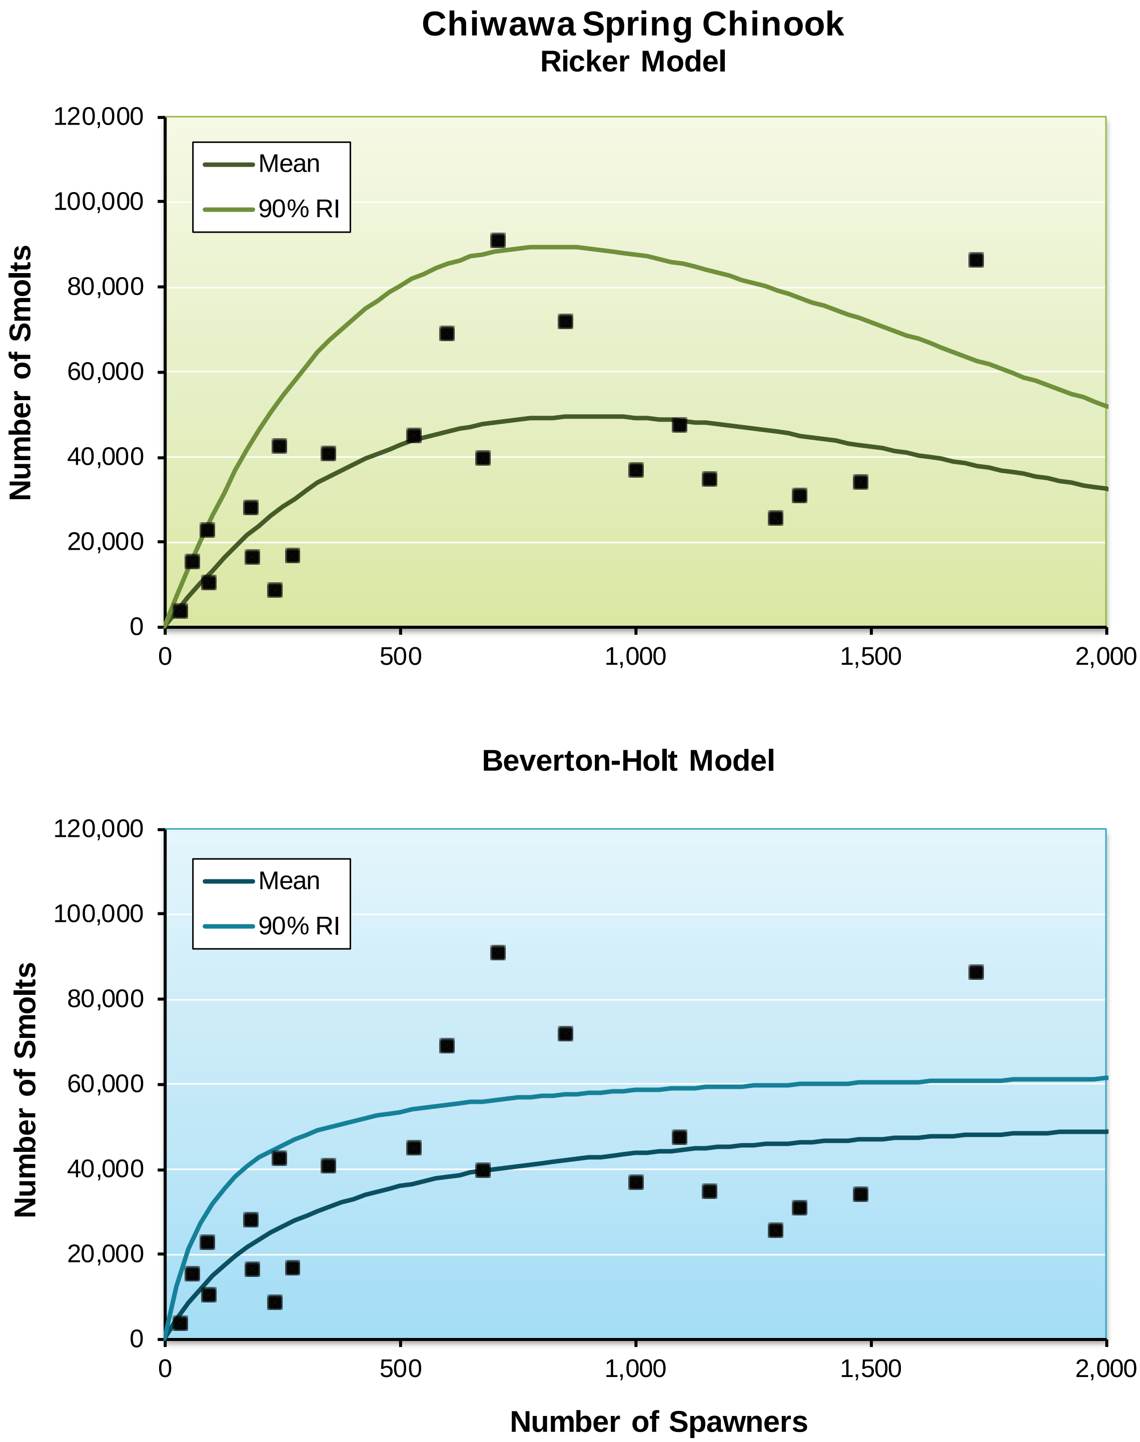

Figure 7. Relationship between numbers of spring Chinook smolts and numbers of spawners in the Wenatchee River basin, 2000-2015 (no data were collected in 2009 or 2010). Upper figure shows the fit of the Ricker model and its 90% reference interval to the data; lower figure shows the fit of the Beverton-Holt model and its 90% reference interval.

Quantile Regression Random Forest Model

Researchers with the Integrated Status and Effectiveness Monitoring Program (ISEMP) developed a model that estimates Chinook parr habitat capacity based on fish-habitat relationships (ISEMP/CHaMP 2015). Based on extensive sampling throughout the Columbia River basin, these researchers developed relationships between maximum densities of Chinook parr (summer estimates) and various habitat variables. Quantile regression forest (QRF) models use these relationships to estimate carrying capacities for juvenile Chinook. Very simply, QRF analysis develops non-linear relationships between fish density and different habitat variables. In this case, however, QRF analysis predicts the 90% quantile of fish density rather than the mean or median density. The researchers assume that the 90% quantile represents habitat capacity. This is important because the numbers of fish counted in some field sampling sites may not have been at maximum capacity. That is, it is likely that not all sites sampled were fully "seeded" with Chinook salmon. Thus, using the mean or median (50% quantile) would not represent habitat capacity, but some level below habitat capacity.

Researchers fit the QRF model to parr density data and 12 habitat variables that were collected from 227 sites within the distribution of Chinook throughout the Columbia River basin (within CHaMP/ISEMP watersheds). These variables were selected to represent a variety of types of habitat variables (e.g., substrate, riparian, complexity, temperature, etc.), contain the most "fish information," and be as uncorrelated as possible (ISEMP/CHaMP 2015). The 12 habitat variables and their relative importance are shown in Figure 8.

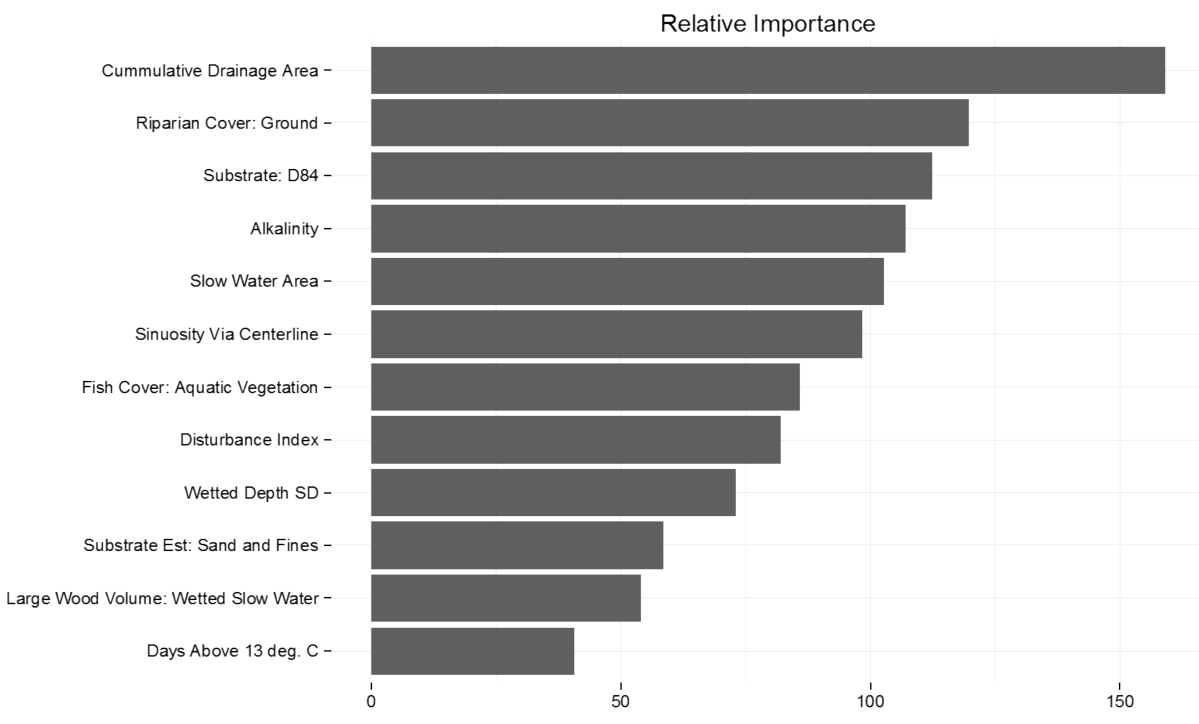

Figure 8. Relative importance of habitat variables included in juvenile Chinook salmon quantile regression forest models (Figure is from ISEMP/CHaMP 2015).

As a way of testing the model, ISEMP researchers used their QRF model to estimate Chinook parr capacities in different watersheds, including the Chiwawa River watershed, and compared their

estimates to those generated from fish population data using stock-recruitment modeling. Figure 9 shows the relationship between the QRF model results and population model results for the Chiwawa River watershed. The red curve was generated using the QRF model and the blue curve was generated using the Beverton-Holt model. At the time of this analysis, the Beverton-Holt model was fit to 21 years of parr data, not the 24 years of data used in the analyses above.

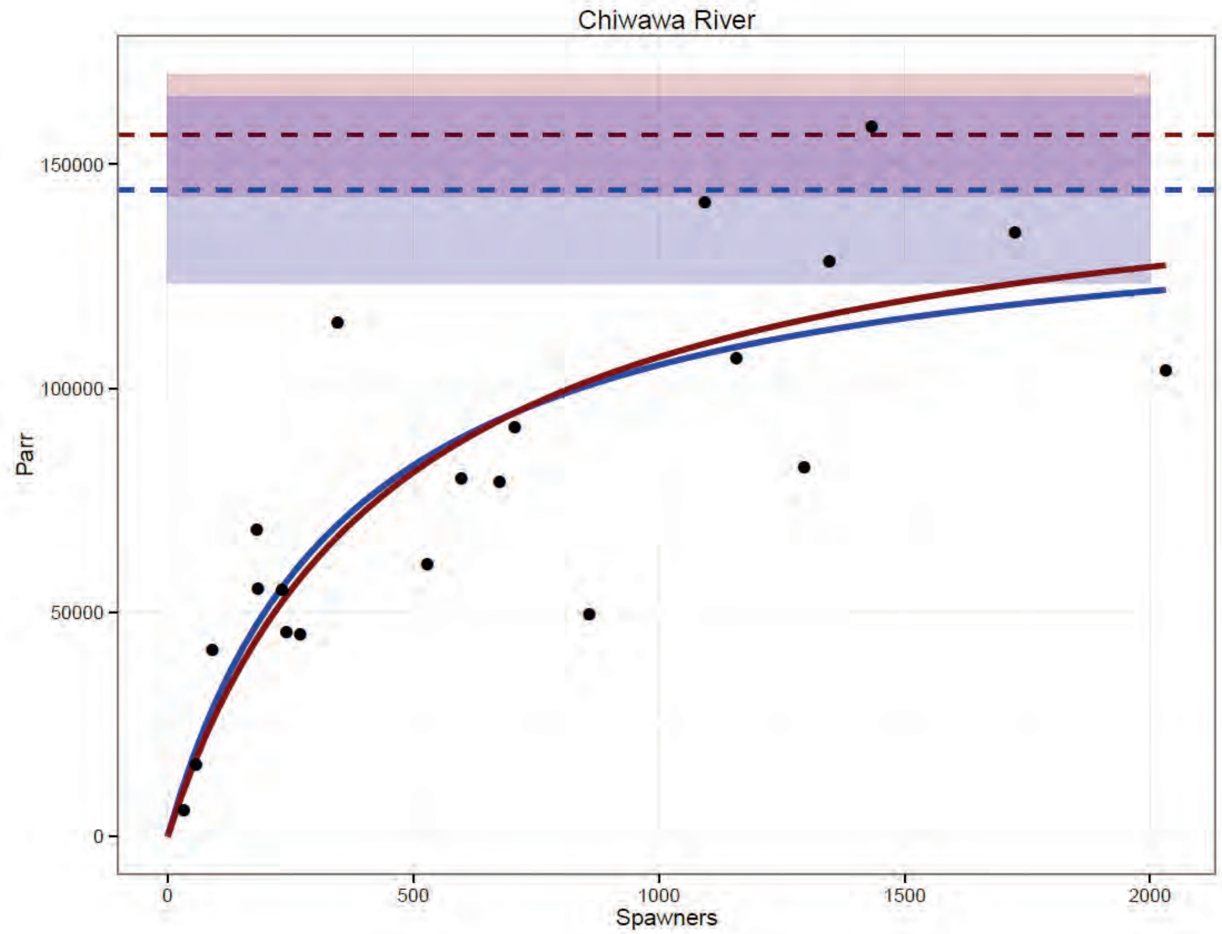

Figure 9. Comparison of productivity curves for Chiwawa spring Chinook parr generated from the QRF model (red line) and Beverton-Holt model (blue line). Dashed horizontal lines represent carrying capacity estimates. Shading about the capacity estimates represent the 95% confidence bounds. Figure is from ISEMP/CHaMP (2015).

The comparison shows that although the curves are very similar, the carrying capacity estimates (dashed horizontal lines) differed, with the habitat capacity generated from the QRF model being larger than the population capacity generated from the population data. That is, the QRF model estimated a habitat capacity of about 164,000 spring Chinook parr, while the population model estimated a population capacity of about 145,000 parr. Including more recent parr data in the Beverton-Holt model indicates that the population capacity estimate is about 151,000 parr for the Chiwawa River watershed. The 90% RI for the Beverton-Holt model estimated a habitat capacity of about 182,000, which is 1.1 times greater than the estimate from the QRF model. Note that the 90% RI for the Ricker model estimated a habitat capacity of about 168,000, which is close to the QRF model estimate.

Comparing Results

We estimated capacities for both spring Chinook parr and smolts for the Chiwawa River watershed and the entire Wenatchee River basin using different analytical tools. In this section, we compare the results from the different approaches.

Parr Capacity

Depending on the population model used, population capacity estimates for the Chiwawa River watershed ranged from 113,801 to 150,902 parr (Table 8). Not surprisingly, the Beverton-Holt model generally predicts the highest capacity estimates, while the smooth hockey stick model predicts the lowest. As expected, the population capacity estimates for Chiwawa parr were less than the habitat capacity estimates for parr. Habitat capacity estimates were about 1.2 to 1.5 times greater than the population capacity estimates (Table 8). Importantly, the fish-habitat model (QRF model) calculated a habitat capacity estimate that was close to that estimated from calculating 90% RI for the population models. Extrapolating Chiwawa capacity estimates to the entire Wenatchee River basin resulted in population capacities of 425,395 to 564,079 parr and habitat capacity estimates of 613,040 to 679,645 parr (Table 8).

Table 8. Comparison of spring Chinook parr capacity estimates for the Chiwawa River watershed and the Wenatchee River basin. Population capacities were estimated directly from the stock-recruitment functions; habitat capacities were estimated by calculating 90% reference intervals (using quantile regression; QR) for the stock-recruitment models and using a fish-habitat model (Quantile Regression Forest Model; QRF). Capacities for the Wenatchee River basin were estimated by extrapolating Chiwawa capacities using intrinsic potential.

Capacity type	Model	Chiwawa parr capacity	Wenatchee parr capacity
Population capacity	Beverton-Holt	150,902	564,079
	Smooth Hockey Stick	113,801	425,395
	Ricker	116,650	436,043
Habitat capacity	QR Beverton-Holt	181,818	679,645
	QR Ricker	168,071	628,256
	QRF Model	164,000	613,040

The number of spawners needed to achieve parr capacity also varied depending on the population model used (Table 9). For the Chiwawa River watershed, maximum spawners needed to achieve population capacity for parr ranged from 1,089 to 1,163 adults. Extrapolating Chiwawa results to the entire Wenatchee River basin resulted in maximum spawner estimates of 4,070 to 4,347 adults. We were able to estimate habitat capacity only with the Ricker model (Table 9). Using quantile regression to calculate the 90% RI for the Ricker model resulted in a maximum spawner abundance of 973 adults, which is less than the number needed to achieve population capacity. This is because the 90% RI for the Ricker function estimates a higher intrinsic productivity, which shifts the "hump" of the curve to the left resulting in a higher capacity estimate but a lower maximum spawner estimate (see Figure 5).

Table 9. Comparison of the number of spawners needed to achieve parr capacities in the Chiwawa River watershed and the Wenatchee River basin. For the Chiwawa River watershed, maximum spawners were estimated directly from the stock-recruitment functions. Maximum spawners for the entire Wenatchee River basin were estimated as the product of the extrapolated parr numbers times the ratio of maximum spawners to parr capacity for Chiwawa spring Chinook. Because of the nature of the Beverton-Holt model, no maximum spawners can be calculated from that model.

Capacity type	Model	Spawners need to achieve parr capacity	
		Chiwawa	Wenatchee
Population capacity	Smooth Hockey Stick	1,089	4,070
	Ricker	1,163	4,347
Habitat capacity	QR Ricker	973	3,636

Smolt Capacity

As with parr estimates, population capacity estimates for smolts varied depending on the population model used. For Chiwawa spring Chinook smolts, population capacities ranged from 45,161 to 55,702 smolts, with the smooth hockey stick providing the lowest estimate and the Beverton-Holt model providing the highest (Table 10). The population capacity estimates were about 55 to 86% of the habitat capacity estimates. Extrapolating Chiwawa capacity estimates to the entire Wenatchee River basin resulted in population capacities of 168,816 to 208,218 smolts and habitat capacity estimates of 241,164 to 334,276 smolts (Table 10). These were greater than those estimated using smolt and spawner data for the entire Wenatchee River basin. Fitting population models to smolt and spawner data for the entire basin resulted in population capacities of 93,560 to 108,696 smolts and habitat capacities of 186,567 to 235,131 smolts (Table 10).

Table 10. Comparison of spring Chinook smolt capacity estimates for the Chiwawa River watershed and the Wenatchee River basin. Population capacities were estimated directly from the stock-recruitment functions; habitat capacities were estimated by calculating 90% reference intervals (using quantile regression; QR) for the stock-recruitment models. Capacities for the Wenatchee River basin were estimated by extrapolating Chiwawa capacities using intrinsic potential and by fitting population models to the smolt and spawner data for the entire basin.

Capacity type	Model	Chiwawa smolt capacity	Wenatchee smolt capacity	
			Chiwawa extrapolation	Wenatchee data
Population capacity	Beverton-Holt	55,702	208,218	108,696
	Smooth Hockey Stick	45,161	168,816	93,560
	Ricker	49,532	185,152	99,944
Habitat capacity	QR Beverton-Holt	64,516	241,164	186,567
	QR Ricker	89,425	334,276	235,131

The number of spawners needed to achieve smolt capacity varied depending on the population model used (Table 11). For the Chiwawa River watershed, maximum spawners needed to achieve

population capacity for smolts ranged from 777 to 901 adults. Note that the maximum number of adults needed to achieve population capacity for smolts is less than those needed to achieve population capacity for parr. Extrapolating Chiwawa results to the entire Wenatchee River basin resulted in maximum spawner estimates of 2,904 to 3,368 adults. These estimates are considerably higher than those estimated from fitting population models to Wenatchee River basin data. The latter estimated maximum spawners ranging from 1,389 to 2,381 adults. We were able to estimate habitat capacity only with the Ricker model (Table 11). Using quantile regression to calculate the 90% RI for the Ricker model resulted in a maximum spawner abundance of 824 adults for the Chiwawa River watershed and 3,129 adults for the entire Wenatchee River basin. Extrapolating Chiwawa results to the entire Wenatchee River basin resulted in a maximum spawner estimate of 3,080, which is close to the estimate generated by fitting the model to Wenatchee River basin data.

Table 11. Comparison of the number of spawners needed to achieve smolt capacities in the Chiwawa River watershed and the Wenatchee River basin. Maximum spawners were estimated directly from the stock-recruitment functions. Maximum spawners for the entire Wenatchee River basin were also estimated as the product of the extrapolated smolt numbers times the ratio of maximum spawners to smolt capacity for Chiwawa spring Chinook. Because of the nature of the Beverton-Holt model, no maximum spawners can be calculated from that model.

Capacity type	Model	Spawners need to achieve smolt capacity		
		Chiwawa	Wenatchee	
			Chiwawa extrapolation	Wenatchee data
Population capacity	Smooth Hockey Stick	777	2,904	1,389
	Ricker	901	3,368	2,381
Habitat capacity	QR Ricker	824	3,080	3,129

As an additional exercise, we calculated smolt capacities and maximum spawners generated from fitting population models to smolt and spawner data in the Chiwawa River, Nason Creek, and White River watersheds, and compared the sum of those estimates to the Wenatchee River basin estimates. Only the Ricker model could be fit to the White River and Nason Creek data (see Hillman et al. 2017). Estimated population capacities from the Ricker model were 49,532 smolts in the Chiwawa, 4,412 smolts in Nason Creek, and 4,659 smolts in the White River, resulting in a cumulative population capacity of 58,603 smolts (1,550 spawners are needed to achieve this cumulative smolt capacity). The cumulative population capacity estimate is nearly 60% of the total population capacity calculated from fitting the Ricker model to the entire Wenatchee River basin data. If these estimates are correct, this means that about 40% of the current Wenatchee River basin smolt capacity is outside the Chiwawa River, Nason Creek, and White River watersheds. Hillman et al. (2017) report that over the period 1989 to 2016, on average, 76% of spring Chinook spawning occurs in the three watersheds. Thus, a large percentage of smolt capacity is generated outside the major spawning areas. We believe this highlights the importance of the mainstem Wenatchee River as a rearing area for juvenile spring Chinook.

Recommendations

Based on the simple analyses conducted in this report, we offer the following recommendations:

1. Where sufficient stock and recruitment data are available, and the data have sufficient contrast, then use population (stock-recruitment) modeling as the primary method to calculate population capacity and the number of spawners needed to produce the maximum number of recruits under current or average habitat conditions. Select the best fitting stock-recruitment model based upon AIC_c, unless other factors suggest otherwise, such as evidence for a biological mechanism. A biological mechanism supporting a Ricker function, for example, would be that there is a stock-dependent effect on the mortality of eggs and juveniles (i.e., mortality is proportional to the initial cohort size). When AIC_c values are not appreciably different, then select the model that is most useful (e.g., Ricker and smooth hockey stick models are easier to work with than the Beverton-Holt model).
2. Adult-to-adult data are the most relevant because they account for all life stages and delayed effects in freshwater (e.g., small size at migration), but they are also the most variable (i.e., low R^2). Therefore, adult-to-juvenile data (e.g., parr, yearling smolts, total migrants) are likely the most useful for determining freshwater population capacity. Where data are available, pre-spawn adult to spawning adult survival can also be assessed using population models to evaluate density dependence and pre-spawn adult capacity.
3. The population models used to estimate population capacity should also be used in reference streams so one can make comparisons of carrying capacities and density-corrected productivities. Unless there are good reasons for selecting a different juvenile life-stage, the default should be to use yearling smolts because they represent the capacity of the tributaries to produce yearlings and it is also a clear identification and quantification of a migrant life-stage.
4. In the absence of fish-habitat models, quantile regression can be used to estimate habitat capacity by calculating reference intervals for the population models. The percentage of the reference interval should be set using the error in the estimation of the recruits and the level of desire to exclude anomalous data. For example, if the 95% confidence interval is approximately 10% of the recruitment estimate, then the reference interval should be set at 90% (e.g., RI = 100% - C.I.%).
5. Where sufficiency conditions in (1) are not met, use habitat-based expansion of density at capacity for the most ecologically similar population. For example, use Twisp capacity estimates for habitat-based expansions in the Methow. The habitat expansion metric should be “total stream area weighted by intrinsic potential and temperature limited,” unless there are good reasons for a different expansion. The primary idea is to exclude areas that are known to not produce fish because of passage, temperature, or other limitations.
6. Capacity estimates should be described within the context of the information that was used to derive estimates. For example, spawner distribution of hatchery-origin fish could influence estimates of capacity if they are within poor habitat. However, the capacity estimates do reflect the historic and current hatchery practices. It is unknown how the capacity estimates would change if a different hatchery program that produced different spawning distributions was to be implemented. However, if those data do become available, then capacity estimates can be revised. Similarly, significant enhancements (e.g.,

improved passage) or degradations (e.g., fire) in habitat can also change capacity and can be incorporated into future estimates of capacity.

7. Regardless of the method used to estimate capacity, always describe the limitations of the data and assumptions of the models. Note where assumptions are violated and how these violations could affect the results of the analysis.

APPENDIX 2: HATCHERY REPLACEMENT RATES

Based on ideas developed by the HETT, in February 2016, the HCP Hatchery Committees and PRCC Hatchery Subcommittee agreed to the following rules and HRR targets:

1. Use the estimated 40% HRR Target during 5-year statistical evaluation periods.
2. Use varying degrees of action depending on the numbers of years that annual HRR deviates from Target.
    a. Green Light (below Target for ≤ 2 years).
    b. Red Light (below Target for > 2 years).
3. Each program will have its own HRR target with the following exceptions.
    a. Nason Creek spring Chinook will use the Chiwawa Target (there are currently no data to calculate a target for Nason Creek spring Chinook).
    b. Methow and Chewuch spring Chinook will use the greater of their two Targets (they are MetComp stock and evaluated similarly).

Table 1. Release numbers and 5-year hatchery replacement rates (HRR) targets for Upper Columbia River Hatchery Programs.

Species	Owner	Program (Hatchery)	Basin (Purpose)	Smolts released[1]	5-Year HRR[2]

[3] Harvest not included.

APPENDIX 3: PNI and pHOS Targets and Sliding Scales

Select CPUD, DPUD, and GPUD funded hatchery mitigation programs have PNI management targets, while others do not. Table 1 summarizes management strategies by species and population. Detailed information can be found in the sections that follow. Descriptions provided in the following sections are taken directly from HGMPs and/or issued and draft permits.

Table 1. Summary of management strategies by species and population.

Species	Population	Management Strategy	Comments
Spring Chinook	Wenatchee	Sliding Scale of PNI management	Details can be found in Section 2.0
	Methow	Two—population sliding scale PNI management	Details can be found in Section 3.0
	Okanogan	None Currently	Details can be found in Section 4.0
Steelhead	Wenatchee	Two-zone management.	Details can be found in 5.0
	Methow	In-development	Details forthcoming; Section 6.0
	Okanogan	None Currently	Details can be found in Section 7.0
Summer Chinook	Wenatchee	None Currently	Details can be found in Section 9.0
	Methow	None Currently	Details can be found in Section 10.0
	Okanogan	0.67; pHOS 0.30	Details can be found in Section 11.0
	Upper Columbia River	None Currently	Details can be found in Section 12.0
Fall Chinook	Hanford Reach	0.67	Details can be found in Section 13.0

2.0 Wenatchee Spring Chinook

Wenatchee spring Chinook will be managed according to the sliding scale identified in the Wenatchee Spring Chinook Management Plan (2010) and Permit Numbers 18118 and 18121. The sliding scale is based upon the estimated number of natural origin spring Chinook over Tumwater Dam. As more information becomes available the sliding scale may be adjusted as a result of gaining a better understanding of the pre-spawn mortality rate and carrying capacity.

Table 2. Sliding scale of PNI goals based on natural origin spring Chinook run size expected to the Wenatchee River basin. Percentiles are based on adult returns observed between 1999 and 2008.

Percentile	NOR Run Size				PNI
	Chiwawa	Nason Creek	White	Wenatchee River (above TWD)	
>75th	>372	>350	>87	>910	≥ 0.80
50% - 75%	278-372	259-349	68-86	631-909	≥ 0.67
25% - 50%	209-277	176-258	41-67	525-630	≥ 0.50
10%-25%	176-208	80-175	20-40	400-524	≥ 0.40
<10th	<175	<80	<20	<400	Any PNI

3.0 Methow/ Chewuch Spring Chinook

The following sliding scale (Table 3) is presented in the April 14, 2016 draft Methow Hatchery Spring Chinook Section 10-Draft. It is anticipated that no further changes will be made to the sliding scale prior to issuance of the final permits.

Table 3. PUD PNI sliding scale calculations for a range of natural run sizes.

Natural Origin Returns	PUD pHOS	WNFH pHOS	PUD pNOB	2-Pop PNI	PUD PNI (equation)
<300	Ensure minimum of 500 total spawners				
300	0.40	0.2	0.75	0.67	0.67
500	0.40	0.2	0.80	0.68	0.76
900	0.30	0.15	1.00	0.78	0.80
1500	0.25	0.1	1.00	0.8	0.80
2000	0.25	0.1	1.00	0.8	0.80
2500	0.25	0.1	1.00	0.8	0.80

4.0 Okanogan Spring Chinook

The Okanogan spring Chinook program is a re-introduction effort implemented as a non-essential experimental population under ESA Section 10j to re-introduce spring Chinook into the Okanogan River. As a non-essential experimental population targeting re-introduction and establishment of a local population of spring Chinook, the Okanogan spring Chinook program will not conduct adult management actions to reduce the proportion of 10j hatchery fish on the spawning grounds or conduct broodstocking efforts in the Okanogan for a 10-year period (2014 – 2023), as such, no PNI or pHOS objectives have been identified for this program in this 10-year period.

CJH Program segregated production released into the mainstem Columbia River are non-listed Leavenworth stock released reared/acclimated/released at CJH. Although no PNI or pHOS targets are identified for the Okanogan 10j population, minimizing strays from the CJH segregated spring Chinook program is a program objective, as such, returning segregated program fish will be subject to directed harvest and aggressive adult surplusing at CJH to minimize straying to the Okanogan River Basin as well as other extant upper Columbia River spring Chinook populations. Stray targets for the segregated program are 5% or less stray rate (i.e. spawning contribution to other upper Columbia River spring Chinook populations).

5.0 Wenatchee Steelhead

Interim escapement goal for Wenatchee River steelhead will be 1,500 spawners with an additional goal of attaining an average PNI of 0.67 for the Wenatchee River basin population as a whole. To achieve the stated goal, the Wenatchee steelhead program will use a two-zone management approach wherein the upper basin (above TWD) will be managed for recovery using an integrated recovery program, a separate spawning escapement goal, and a PNI standard to achieve the overall basin goal of an average PNI over time of 0.67 (Table 4). Areas below TWD will be managed to minimize hatchery supplementation with a pHOS goal of < 0.10.

Steelhead returning upstream of TWD will be managed as an integrated recovery program with a pNOB goal of 1.0. The above TWD escapement goal will be 1,094 spawners. Working within this framework, pNOB will be maximized above TWD while pHOS will be minimized.

Table 4. Wenatchee steelhead two-zone management and PNI targets.

Location	Run Escapement Goal	pNOB Conservation Program	pNOB Safety Net Program	pHOS	PNI
Above TWD	1,094	1.0	0.0	Varies	Varies
Below TWD	406	N/A	N/A	< 0.10	< 0.67
Basin Total	1,500	N/A	N/A	Minimal	Average = 0.67

6.0 Methow Steelhead

Methow steelhead PNI targets are currently in development.

7.0 Okanogan Steelhead

Current program has no PNI goal. CTCR submitted an Okanogan steelhead HGMP to NOAA Fisheries on February 4, 2014. Within the HGMP provisions were included to allow a greater collection of natural-origin broodstock and multiple adult management strategies to address over-escapement of hatchery-origin steelhead to the spawning grounds. The HGMP also identified a near-term (1-4 years) and a long-term PNI objectives of 0.50 and > 0.67, respectively. Once NOAA has completed the consultation and issued a new permit, providing the opportunity to increase the proportion of natural-origin fish in the broodstock and additional adult management strategies, the program will adopt the PNI objectives and this Appendix can be amended accordingly.

8.0 Wells Columbia Mainstem Safety-net Steelhead

The Safety-Net Mainstem Columbia component released below Wells Dam will be managed primarily at the Wells Hatchery volunteer channel. The objective of the adult management of the Safety-Net Mainstem Columbia component is to prevent runs of this component from moving into natural spawning areas. This will be accomplished through in-river harvest and removal of volunteers at the Wells Hatchery outfall. There are no PNI goals for this component.

9.0 Wenatchee Summer Chinook

No PNI goals are established.

10.0 Methow Summer Chinook

No PNI goals are established.

11.0 Okanogan Summer Chinook

Okanogan summer/fall Chinook will be managed to achieve a 5-year rolling average PNI of 0.67 and pHOS of 0.30. Strategies to achieve that PNI target include up to 100% pNOB, aggressive removal of hatchery-origin Chinook in selective fisheries, at the Okanogan weir, and during surplusing at CJH ladder. Reduction in the number of juveniles released in the Okanogan River Basin (integrated program) is also a management option, should adult management actions be unable to control the proportion of hatchery fish on the spawning grounds to achieve that PNI target.

CJH segregated summer/fall Chinook program rears/acclimates/releases smolts into the mainstem Columbia River at CJH. Broodstock are 100% hatchery-origin, as such no PNI target for this production component. Stray rate (i.e. contribution to upper Columbia summer/fall Chinook

populations) is 5% or less. Adult management on returning adults from the segregated program include fisheries, removal at the Okanogan weir, and removal at the CJH ladder.

12.0 Upper Columbia Summer Chinook (Chelan Falls and Wells)

No PNI goals are established. Chelan Falls and Wells FH summer Chinook programs are segregated harvest programs designed to provide opportunity for harvest. Adult returns are not intended to spawn naturally; therefore, there is no escapement goal for natural spawning areas. Adult returns will be managed to meet program objectives. Chelan Falls and Wells Hatchery summer Chinook are available for harvest in the ocean and Columbia River commercial, tribal, and recreational fisheries.

13.0 Priest Rapids Fall Chinook

The Hanford Reach fall Chinook population is intentionally supplemented by Grant PUD at the Priest Rapids Hatchery and the ACOE at the Priest Rapids and Ringold Springs hatcheries. Managers desire to achieve a population level PNI that includes all hatchery programs of $\geq$0.67. Grant PUD and the HSC do not have control over operation or expansion of the ACOE program and therefore will strive to operate the Priest Rapids Hatchery fall Chinook program in a way that does its fair share of achieving a population level PNI of 0.67.

APPENDIX 4: SPATIAL DISTRIBUTION OF SPAWNERS OR REDDS

Strategies for conservation programs typically intend that hatchery and naturally produced fish spawn together and in similar locations. However, in some cases, strategies may differ from this paradigm. In Table 1, conservation programs that have a spatial distribution management plan that deviates from similar to the natural spawning spatial distributions are presented. Otherwise, conservation programs are intended to have a spawning distribution similar to the natural origin spawning spatial distributions, as described by M&E Objective 5.3.

Table 1. Management targets for the spatial distribution of hatchery-origin redds for conservation programs that deviate from Objective 5.3.

Program	Target	Rational	Source
Carlton Summer Chinook	The observed spawning distribution of hatchery origin Methow summer Chinook from 2005-2010 represents the base-line spawner distribution for evaluating the performance of the hatchery program (i.e., M&E plan check-ins). It is acknowledged that this distribution is lower in the River than the spawning distribution of natural origin summer Chinook salmon.	Based upon an assessment of summer Chinook and ESA-listed spring Chinook abundance and spawner distribution, it was determined that an increase in summer Chinook spawning abundance in the upper most range of natural origin summer Chinook distribution or potentially above the current range may pose an unknown and potentially adverse impact to ESA listed spring Chinook. Due to the concern for spring Chinook, the HSC has endorsed an acclimation site in the Methow Basin that is lower in the basin than may be required to attain exact replication of natural and hatchery origin summer Chinook spawner distribution.	SOA 2011-02 Priest Rapids Coordinating Committee Hatchery Subcommittee Statement of Agreement on Monitoring & Evaluation (M&E) Objective for Spawning Distribution of Hatchery-Origin Summer Chinook
Dryden Summer Chinook	The observed spawning distribution of hatchery origin Wenatchee summer Chinook from 2008-2013 (previous 5 years to the current M&E check-in cycle) represents the base-line spawner distribution for evaluating the performance of the	The primary site endorsed by the HSC for Grant PUD overwinter acclimation of summer Chinook is the Dryden Pond, and is the current acclimation and release site for the existing summer Chinook supplementation program	Adapted from SOA 2011-02 Priest Rapids Coordinating Committee Hatchery Subcommittee Statement of Agreement on Monitoring & Evaluation (M&E) Objective for Spawning Distribution of Hatchery-Origin Summer Chinook

	hatchery program (i.e., M&E plan check-ins).	funded and owned by Chelan PUD. Because current data indicates that spawning distribution of hatchery summer Chinook from the existing program is lower in the Wenatchee River than natural origin spawners, expectations are that acclimation of Grant PUD's summer Chinook at Dryden Pond would continue to return hatchery origin summer Chinook that result in different spawning distributions for hatchery and natural summer Chinook.	

APPENDIX 5: WITHIN HATCHERY REARING TARGETS

Rearing Targets for Upper Columbia River Hatchery Programs. K-factor or fork length targets will be determined based on data from the pending "Five-Year Report."

Table 1. Numbers, fish per pound (fpp), coefficient of variation (CV), and condition factor (K) targets at release of Upper Columbia River Hatchery Programs.

[1] The total release includes the release of 108,249 into the Methow River at the Methow Fish Hatchery, 25,000 into the Methow River at the Goat Wall site, and 60,516 into the Chewuch River at the Chewuch Acclimation Facility.

[2] These fish come from Winthrop National Fish Hatchery (MetComp) eyed eggs.

[3] The total release includes 125,000 conservation fish and 98,670 safety net fish.

[4] The combined Okanogan and Omak steelhead release number is 100,000.

[5] The total release includes 66,771 fish into Nason Creek, 53,170 into the Chiwawa River, 102,359 into the Wenatchee River, and 25,000 into Blackbird Pond.

[6] The Wells subyearling Chinook are not reared to achieve a specific size target. The fish are released on a date to optimize survival and are grown to the largest size possible before release.

[7] The total release is divided equally among the Omak, Riverside, and Similkameen Acclimation Ponds.

[8] The total release consists of 5.6 m fall Chinook for the Grant PUD program and 1.7 M fall Chinook for the Army Corps of Engineers program.

APPENDIX 6: IDENTIFYING AND ANALYZING REFERENCE POPULATIONS

An important goal of supplementation is to increase spawning abundance and natural-origin recruitment of the supplemented population, and not reduce the productivity of the supplemented population. Indeed, a successful supplementation program must increase spawning abundance and natural-origin recruitment to levels above those that would have occurred without supplementation. There are several methods that can be used to test the effects of supplementation programs on these population metrics. One important method is to compare the performance of population metrics (e.g., spawning abundance, natural-origin recruitment, and productivity) in the supplemented population to those in un-supplemented (reference) populations. By comparing supplemented populations to reference populations, one can determine if the supplementation programs benefit, harm, or have no effect on the supplemented populations. These comparisons, however, are only valid if the performance of the reference populations is similar to the performance of the supplemented population prior to the period of supplementation. If the performance of the two populations differs significantly before any supplementation occurs, then any results from comparing the two populations after supplementation will be suspect. It is therefore important to select reference populations that are as similar as possible to the supplemented populations.

One of the goals of the Conceptual Approach to Monitoring and Evaluating the Chelan County PUD Hatchery Programs (Murdoch and Peven 2005) is to use reference populations to analyze the potential effects of hatchery supplementation programs on natural-origin salmon and steelhead spawner abundance and productivity[15]. Murdoch and Peven (2005) identified specific objectives to evaluate the performance of the program. For example, Objective 1 determines if the supplementation programs have increased the number of naturally spawning and naturally produced adults of the target population (supplemented population) relative to a reference population. Objective 7 determines if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity (e.g., number of juveniles per redd) of supplemented streams when compared to reference streams. The relevant questions tested under each objective are as follows:

Objective 1:

- Is the annual change in the number of natural-origin recruits produced from the supplemented populations greater than or equal to the annual change in natural-origin recruits in an un-supplemented population?
- Is the change in natural replacement rates within the supplemented population greater than or equal to the change in natural replacement rates in an un-supplemented population?

Objective 7:

[15] Productivity is defined as adult recruits per spawner, where recruits are the number of adults produced from a given brood year (i.e., spawners plus adults harvested).

- Is the change in numbers of juveniles (smolts, parr, or emigrants) per redd in the supplemented population greater than or equal to that in an un-supplemented population?[16]

In this paper, we describe methods used to identify suitable reference streams and statistical techniques that can be used to compare reference populations with supplemented populations. Although we apply the methods described in this paper to Chiwawa spring Chinook salmon (hereafter referred to as Chinook), the methods should also apply to steelhead and other supplemented salmon stocks in the Upper Columbia Basin.

Identification of Reference Populations

Reference populations are an important component of an effectiveness monitoring design because they provide the standard by which treatment conditions are compared (ISRP and ISAB 2005; Murdoch and Peven 2005; Galbreath et al. 2008). Selecting appropriate reference areas and maintaining them over long periods of time is needed to establish the effectiveness of supplementation programs.

We developed a three-step process for identifying suitable reference populations (Figure 1). Each step serves as a filter. That is, potential reference populations are evaluated based on specific criteria under each step. Populations that pass through each step are considered suitable reference populations for a specific supplemented population.

[16] In this paper, we only address adult recruits, not juvenile recruits. This is because we were unable to find suitable reference populations for analysis of juveniles. However, the methods described in this paper would also apply to juveniles.

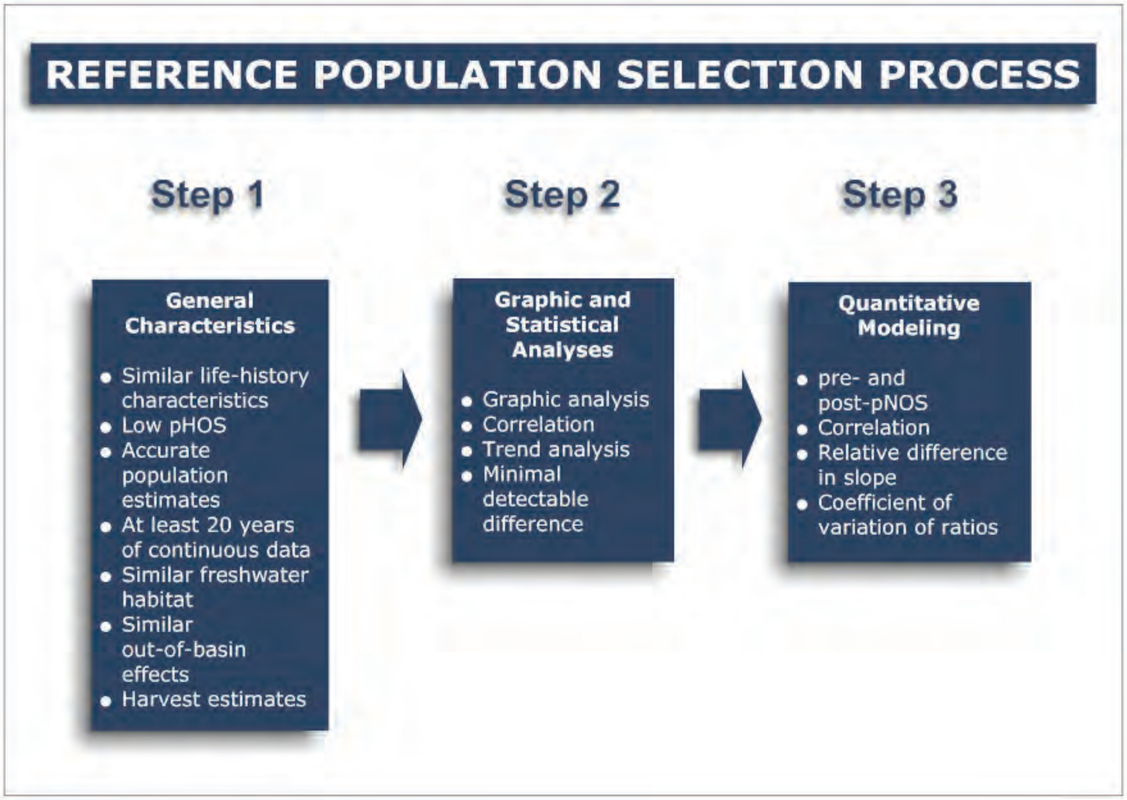

Figure 1. Criteria evaluated during each step in the process of identifying suitable reference populations.

Step 1: General Characteristics

Under step 1, potential reference populations are evaluated based on several general criteria. When compared to the supplemented population, potential reference populations should have:

- Similar life-history characteristics (e.g., run timing, migration characteristics, etc.).
- No or few hatchery fish in the reference area (pHOS < 10%).
- Accurate abundance estimates.
- Long time series of natural-origin abundance and productivity estimates (at least 20 years of continuous data).
- Similar trends in freshwater habitat.
- Similar out-of-basin effects (i.e., similar migration and ocean survivals).
- Harvest estimates for adjusting escapement estimates.

We used these criteria to begin the process of selecting suitable reference populations for the Chiwawa spring Chinook program. We began by identifying stream-type Chinook populations within the Columbia Basin. Galbreath et al. (2008; their Table 1) identified stream-type Chinook populations within the Columbia River Basin that may serve as suitable reference populations for hatchery programs. Supplementing their work with data from the NOAA Fisheries Salmon Population Summary Database, we identified 18 candidate stream-type Chinook populations that may serve as reference populations for the Chiwawa supplementation program (Table 1).

Table 1. Populations of stream-type Chinook salmon and their comparison to Chiwawa spring Chinook.

Population	Similar life-history	No or few hatchery fish	Accurate abundance estimates	Long time series (at least 20 years)	Similar freshwater habitat impairments	Similar out-of-basin effects	Comments
Deschutes River	Yes	Yes	Yes	Yes	No	No	
John Day mainstem	Yes	Yes	Yes	Yes	No	No	
Middle Fk John Day	Yes	Yes	Yes	Yes	No	No	
North Fk John Day	Yes	Yes	Yes	Yes	No	No	
Granite Creek	Yes	Yes	Yes	Yes	No	No	
Wenaha River	Yes	No	Yes	Yes	Yes	No	Hatchery strays (>10%)
Minam River	Yes	No	Yes	Yes	Yes	No	Hatchery strays (>10%)
Slate Creek	Yes	Yes	Yes	No	No	No	
Secesh River	Yes	Yes	Yes	Yes	Yes	No	
Middle Fk Salmon River	Yes	Yes	Yes	No	No	No	Fair productivity est.
Big Creek	Yes	Yes	Yes	Yes	No	No	
Camas Creek	Yes	Yes	Yes	Yes	No	No	Fair productivity est.
Loon Creek	Yes	Yes	Yes	Yes	No	No	Fair productivity est.
Sulphur Creek	Yes	Yes	Yes	Yes	No	No	
Bear Valley Creek	Yes	Yes	Yes	Yes	No	No	
Marsh Creek	Yes	Yes	Yes	Yes	Yes	No	
North Fk Salmon River	Yes	Yes	No	No	Yes	No	
Lemhi River	Yes	Yes	Yes	Yes	No	No	
East Fk Salmon River	Yes	No	Yes	Yes	No	No	Hatchery strays (>10%)
Valley Creek	Yes	No	Yes	Yes	No	No	Hatchery strays (>10%)
Chamberlain Creek	Yes	Yes	Yes	No	Yes	No	
Naches River	Yes	Yes	Yes	Yes	Yes	No	
Little Wenatchee River	Yes	No	Yes	Yes	Yes	Yes	Hatchery strays (>10%)
Entiat River	Yes	No	Yes	Yes	No	No	Hatchery release ending

We then assessed the accuracy and length of the series of abundance estimates. We assumed that abundance estimates generated from expanded redd counts or adjusted weir counts would compare well with estimates in the Chiwawa Basin, which were based on expanded redd counts. In addition, we looked for populations that had an abundance data series that extended from at least 1981 to present. Based on this analysis, we identified 18 populations with abundance estimates that could be compared to those from the Chiwawa Basin (Table 1).

Next, we determined if the potential reference populations came from watersheds with habitat conditions similar to those in the Chiwawa Basin. For this exercise, we searched recovery plans and draft recovery plans to identify tributary factors that limit Chinook abundance, productivity, and survival within the reference populations. We compared these factors with those limiting

Chinook salmon in the Chiwawa Basin. Based on this analysis, we identified eight populations with habitat impairments similar to those in the Chiwawa Basin (Table 1).

Finally, we examined the potential reference populations to see if they experienced out-of-basin effects similar to spring Chinook from the Chiwawa Basin. In this case, we compared the number of mainstem dams that each potential reference population passes during migration. Six of the potential reference populations pass less than six mainstem dams; the other populations pass eight mainstem dams (Table 1). Only the Little Wenatchee population passes seven dams, similar to the Chiwawa population.

In sum, there were no reference populations that matched the Chiwawa spring Chinook population on all the criteria identified above. Differential out-of-basin effects and freshwater habitat conditions prevented most reference populations from matching with Chiwawa spring Chinook. However, some of the potential reference populations were similar to the Chiwawa population on several criteria and warranted further investigation. We selected the following populations for further investigation: Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River.

We included the Little Wenatchee because it is within the Wenatchee River basin and experiences similar out-of-basin effects and has the same climatic and environmental conditions as the Chiwawa. A confounding effect with the Little Wenatchee is that Chiwawa hatchery fish have strayed into the Little Wenatchee. However, straying of Chiwawa hatchery fish should decrease with the change in source water to the Chiwawa acclimation ponds in 2006. We also included the Entiat River because it is an adjacent basin to the Chiwawa and experiences similar climatic and environmental conditions. The spring Chinook hatchery program that has operated in the Entiat since 1975 has been discontinued. Therefore, this population offers a unique opportunity to compare the Chiwawa population to a population in which the hatchery program has been discontinued.

Step 2: Graphic and Statistical Analysis

Graphic Analysis

Although we were unable to find potential reference populations that matched with the Chiwawa population on all criteria considered under Step 1, spawner abundance, natural-origin recruits (NORs), and productivity of some of the potential reference populations may nevertheless track closely with the Chiwawa population. If the time series of abundance, NORs, and productivity of a potential reference population tracks closely with the abundance, NORs, and productivity of the Chiwawa population, the reference population may provide a reasonable reference condition for testing the effects of supplementation on the Chiwawa population.

Under Step 2, we used graphing techniques to examine the relationship of abundance, NORs, and productivity between the Chiwawa population and the five reference populations (Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River). We compiled spawner abundance, NORs, and productivity data from local biologists and the NOAA Fisheries Salmon Population Summary Database. We then compared time series plots of spawner abundance, NORs, and productivity data of potential reference populations with the Chiwawa population (Figures 2, 3, and 4; plots on the left side of figures). The time series only included the period 1981 to 1992, which represented the period before supplementation of the Chiwawa population (pre-treatment period). We also plotted the relationship between the abundance, NORs, and productivity of each

potential reference population to the Chiwawa population (Figures 2, 3, and 4; plots on right side of figures). These plots show whether the reference populations closely tracked the Chiwawa population. As a point of reference, data points that fall along the dashed line would represent a perfect relationship between the two populations (i.e., both populations have identical abundance, NORs, and productivity estimates). While a perfect relationship between two independent populations is unrealistic, a strong linear relationship between the two populations indicates populations with similar trends.

Based on analysis of spawner abundance, the Naches River time series tracked more closely with the abundance of Chiwawa spring Chinook than did the other potential reference populations. The poor relationship with the other potential reference streams was largely because of the relatively high abundance of Chiwawa spring Chinook during the mid-1980s. As with spawner abundance, analyses of NORs indicated a close relationship between the Naches and Chiwawa populations. The other potential reference populations tracked poorly with the Chiwawa. The analyses of productivity indicated close relationships between potential reference populations and the Chiwawa population. The Naches, Sesech, and Little Wenatchee populations tracked the closest with the Chiwawa population.

When analyzing the potential effects of a supplementation program on fish performance, it is common to transform the data to meet various assumptions of statistical analysis. The most common transformation used to adjust abundance, NORs, and productivity data is the natural logarithm (LN or $\log_e$). We therefore transformed the spawner abundance, NORs, and productivity data using LN and re-plotted the relationships between the potential reference populations and the Chiwawa population (Figures 5, 6, and 7). We added 1 to each observation before taking its logarithm to avoid taking the logarithm of 0, which is undefined (note that the LN of 1 is 0).

By transforming spawner abundance, NORs, and productivity data, most of the potential reference populations tracked more closely with the Chiwawa population. The Naches, Entiat, and Little Wenatchee abundance data tracked the closest with the Chiwawa abundance data (Figure 5). For NORs, Marsh Creek and the Little Wenatchee populations tracked the closest with the Chiwawa (Figure 6). For productivity, the Naches, Sesech, and Little Wenatchee tracked the closest with the Chiwawa (Figure 7).

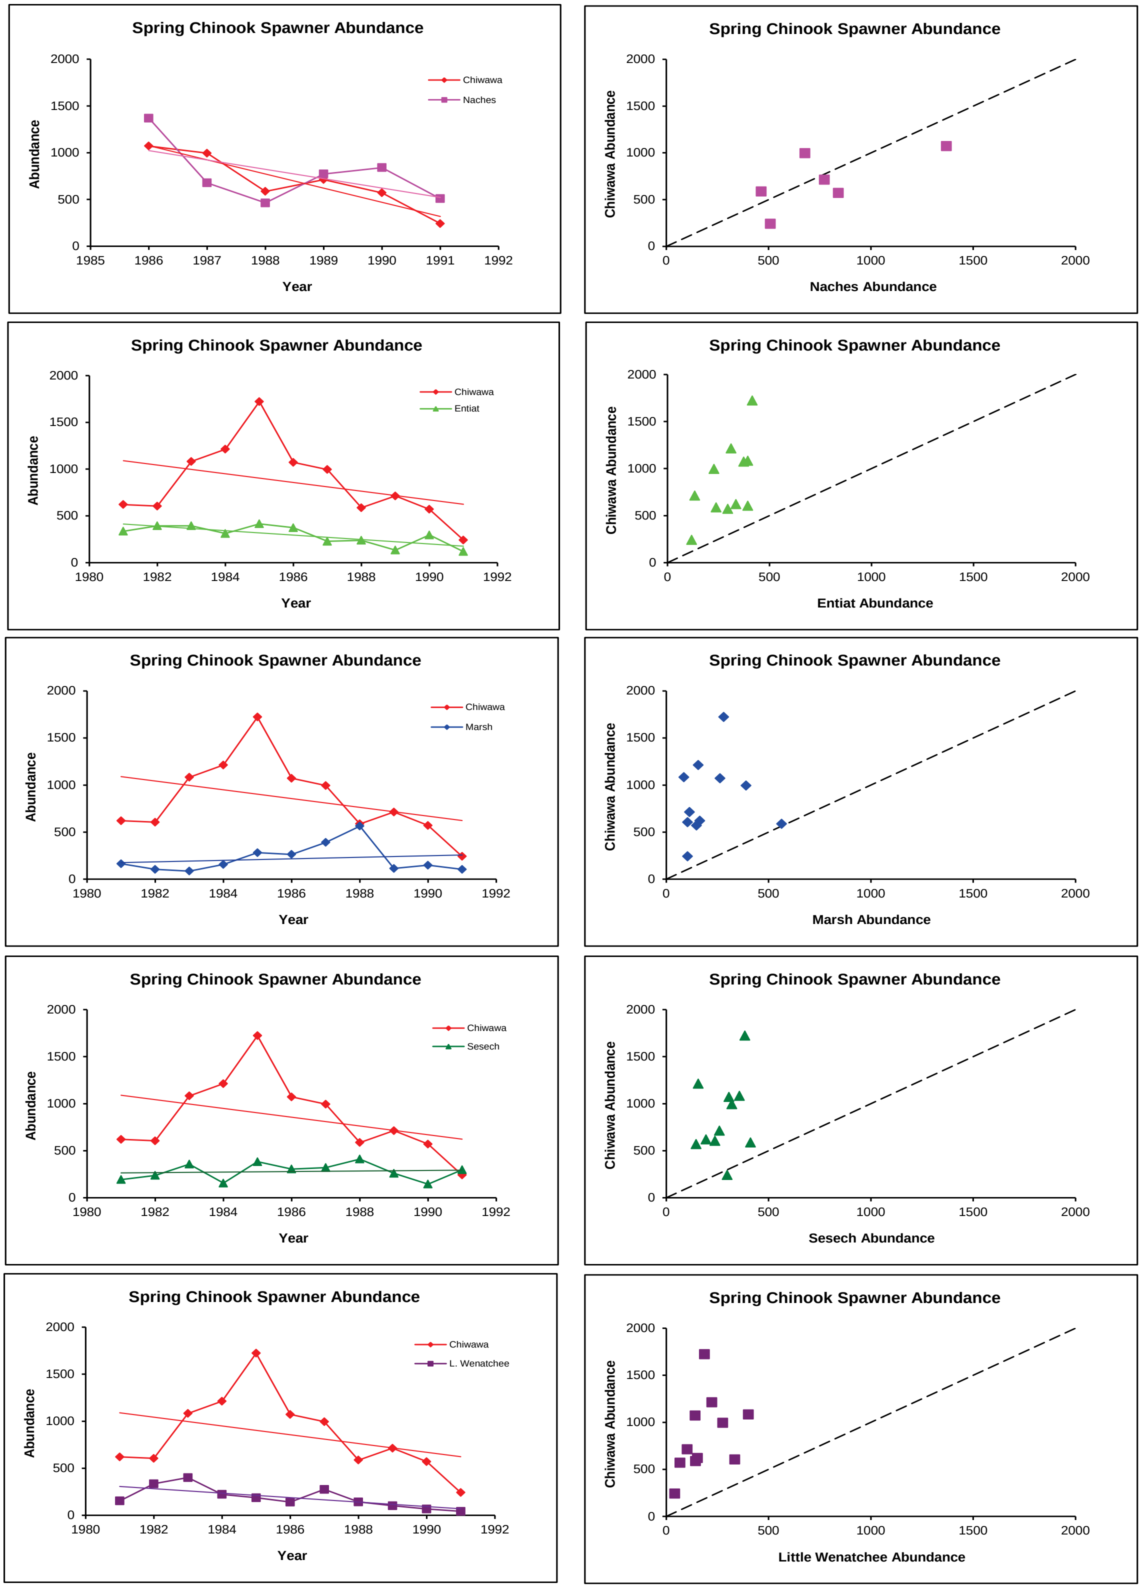

Figure 2. Time series of spawner abundance of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

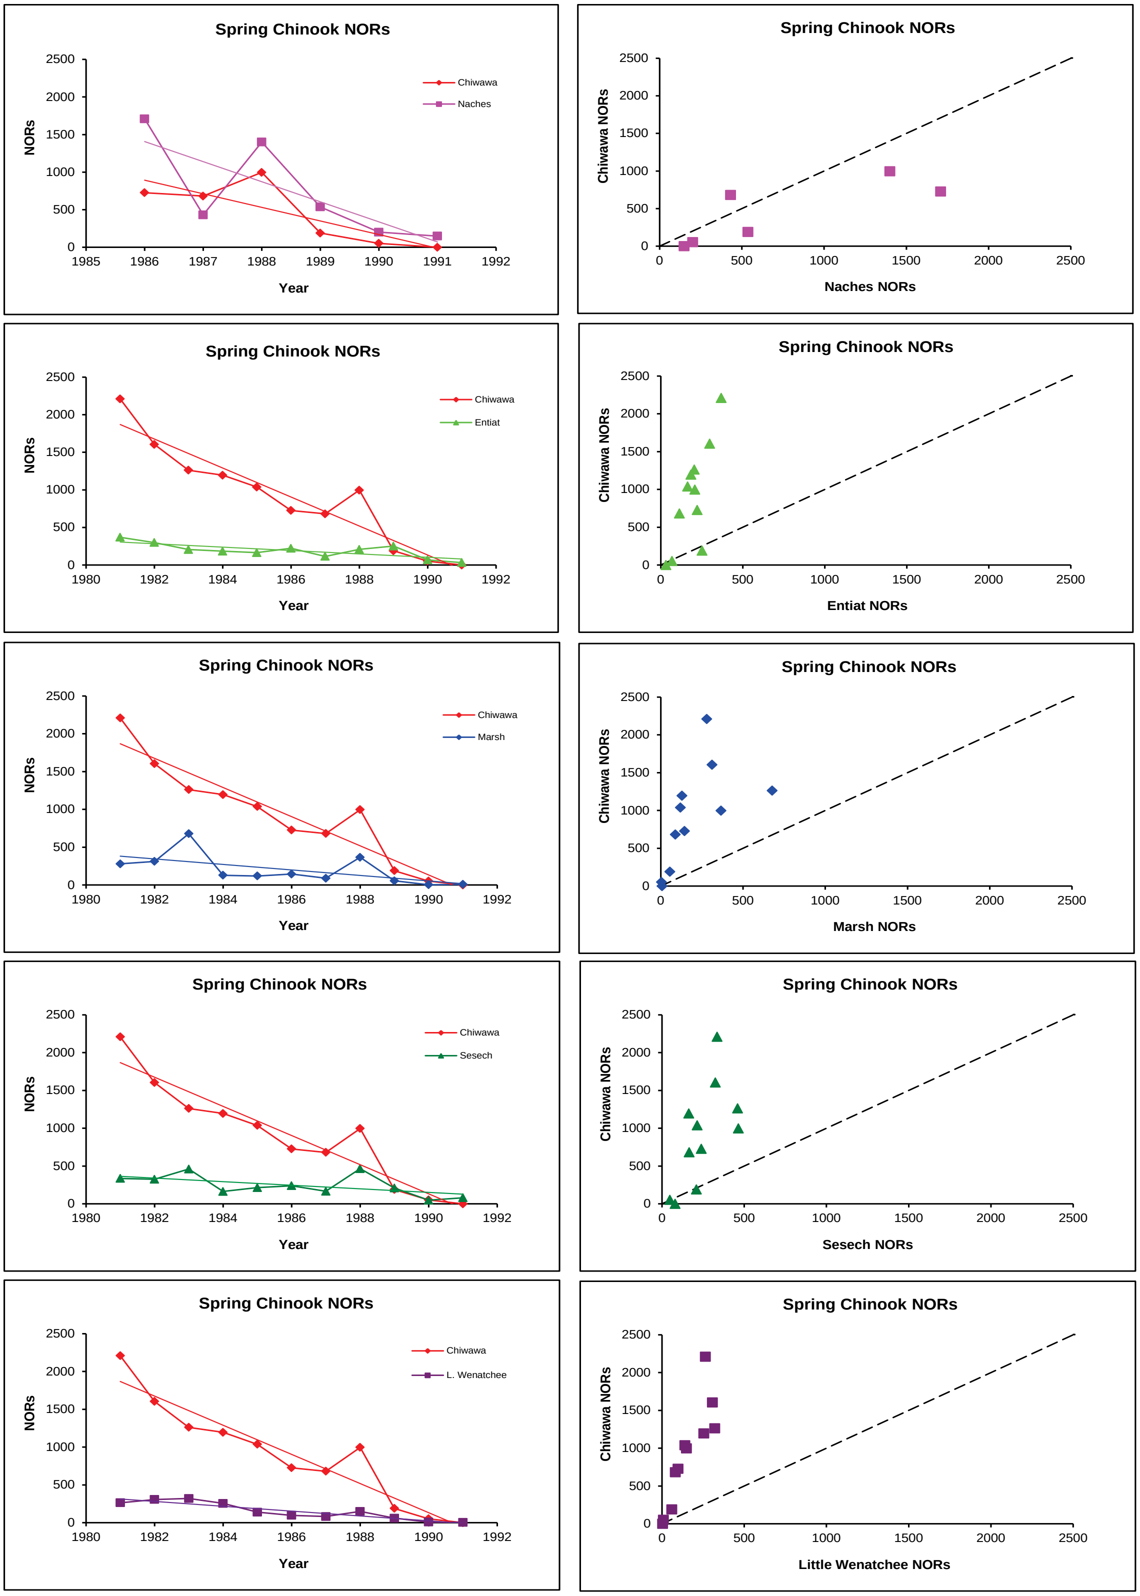

Figure 3. Time series of natural-origin recruits (NORs) of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

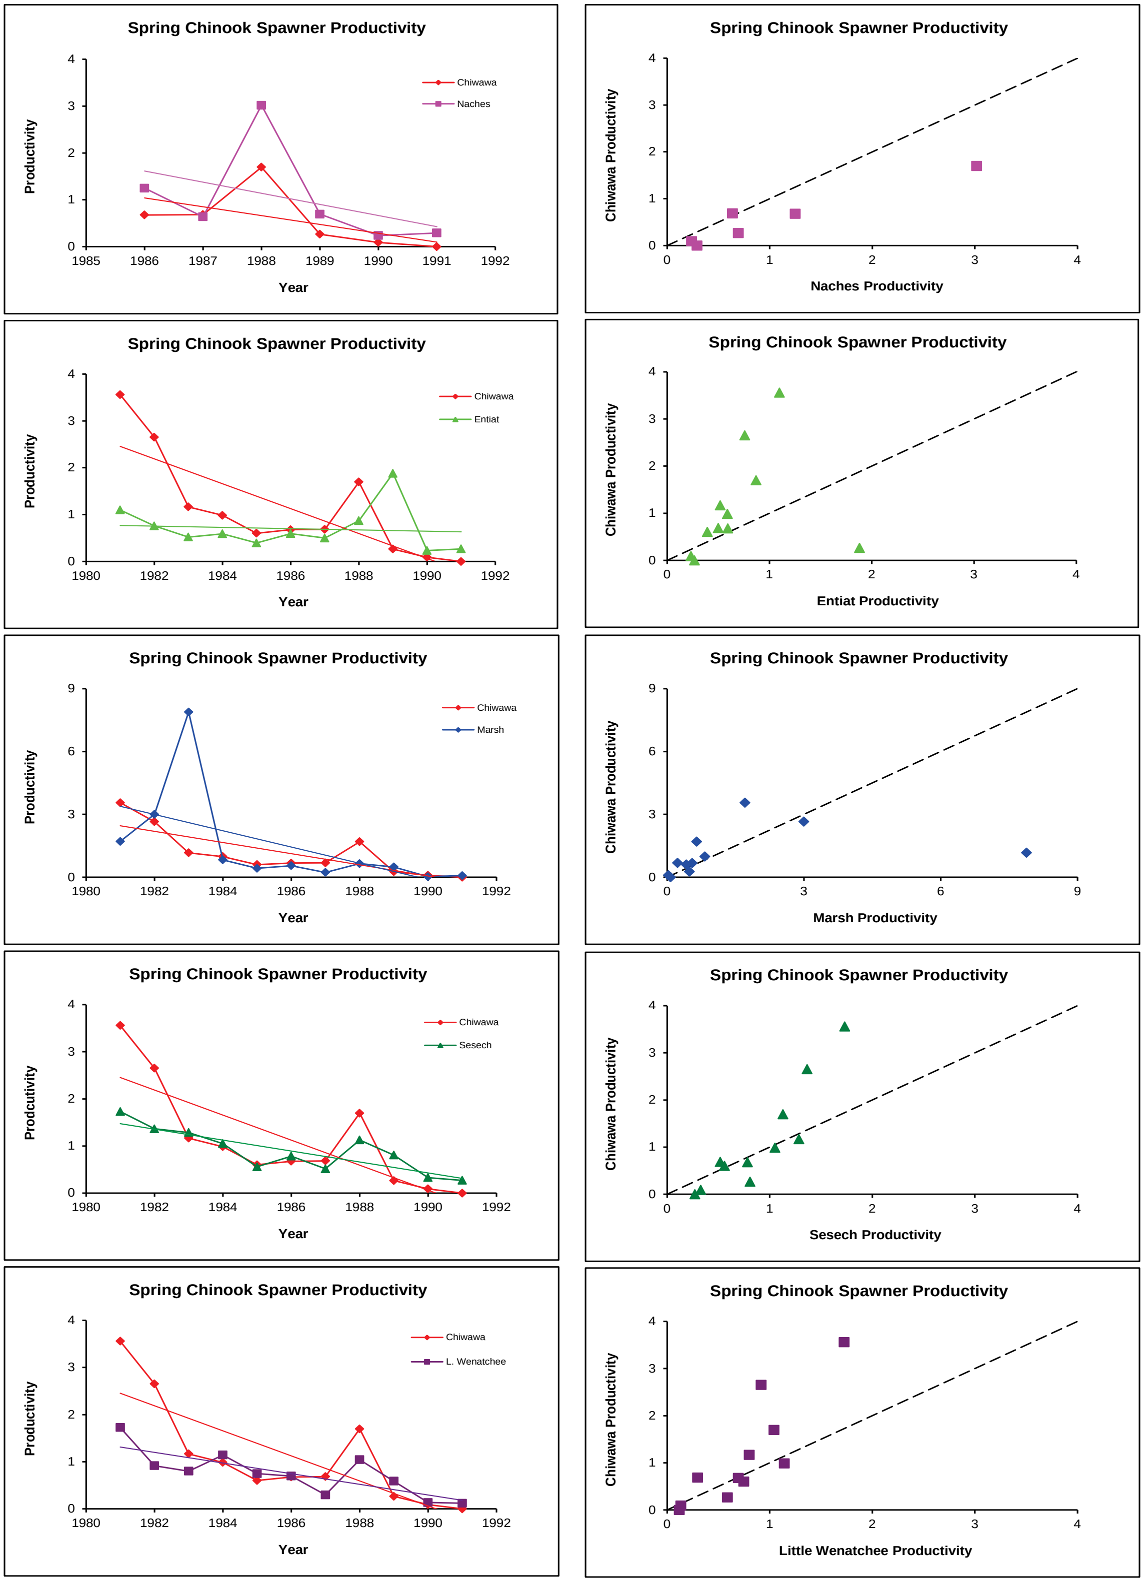

Figure 4. Time series of adult productivity of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

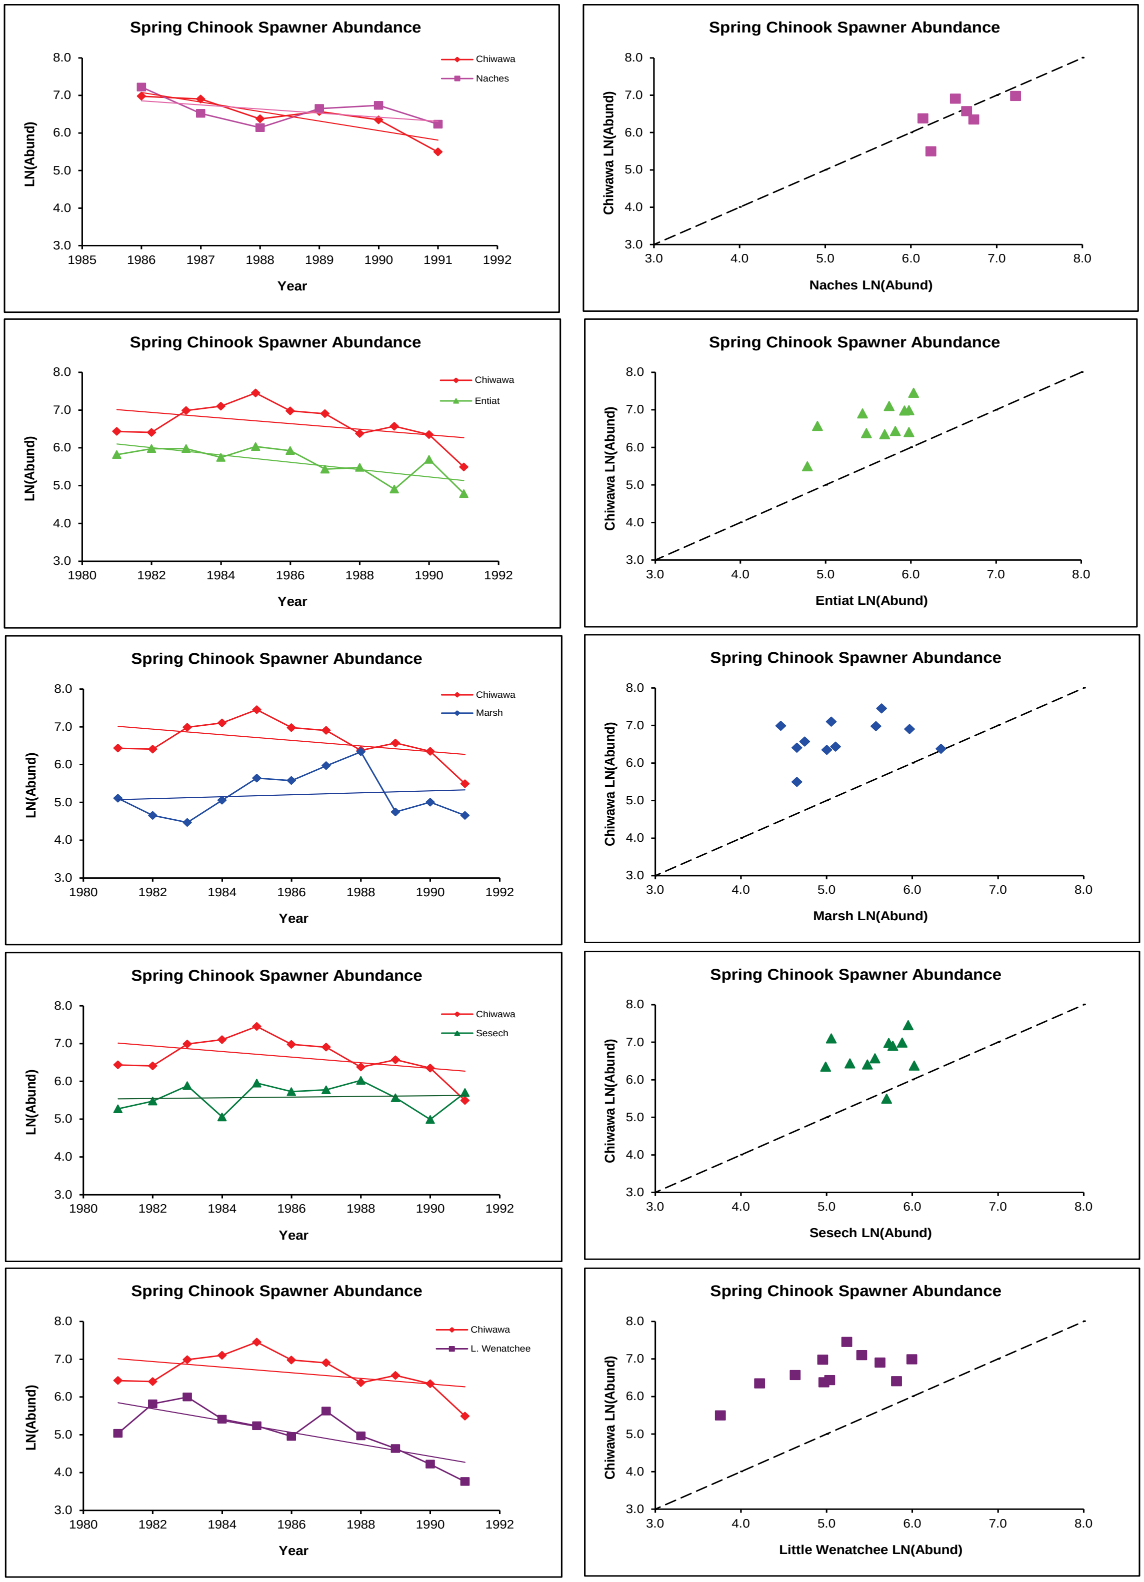

Figure 5. Time series of natural log spawner abundance of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

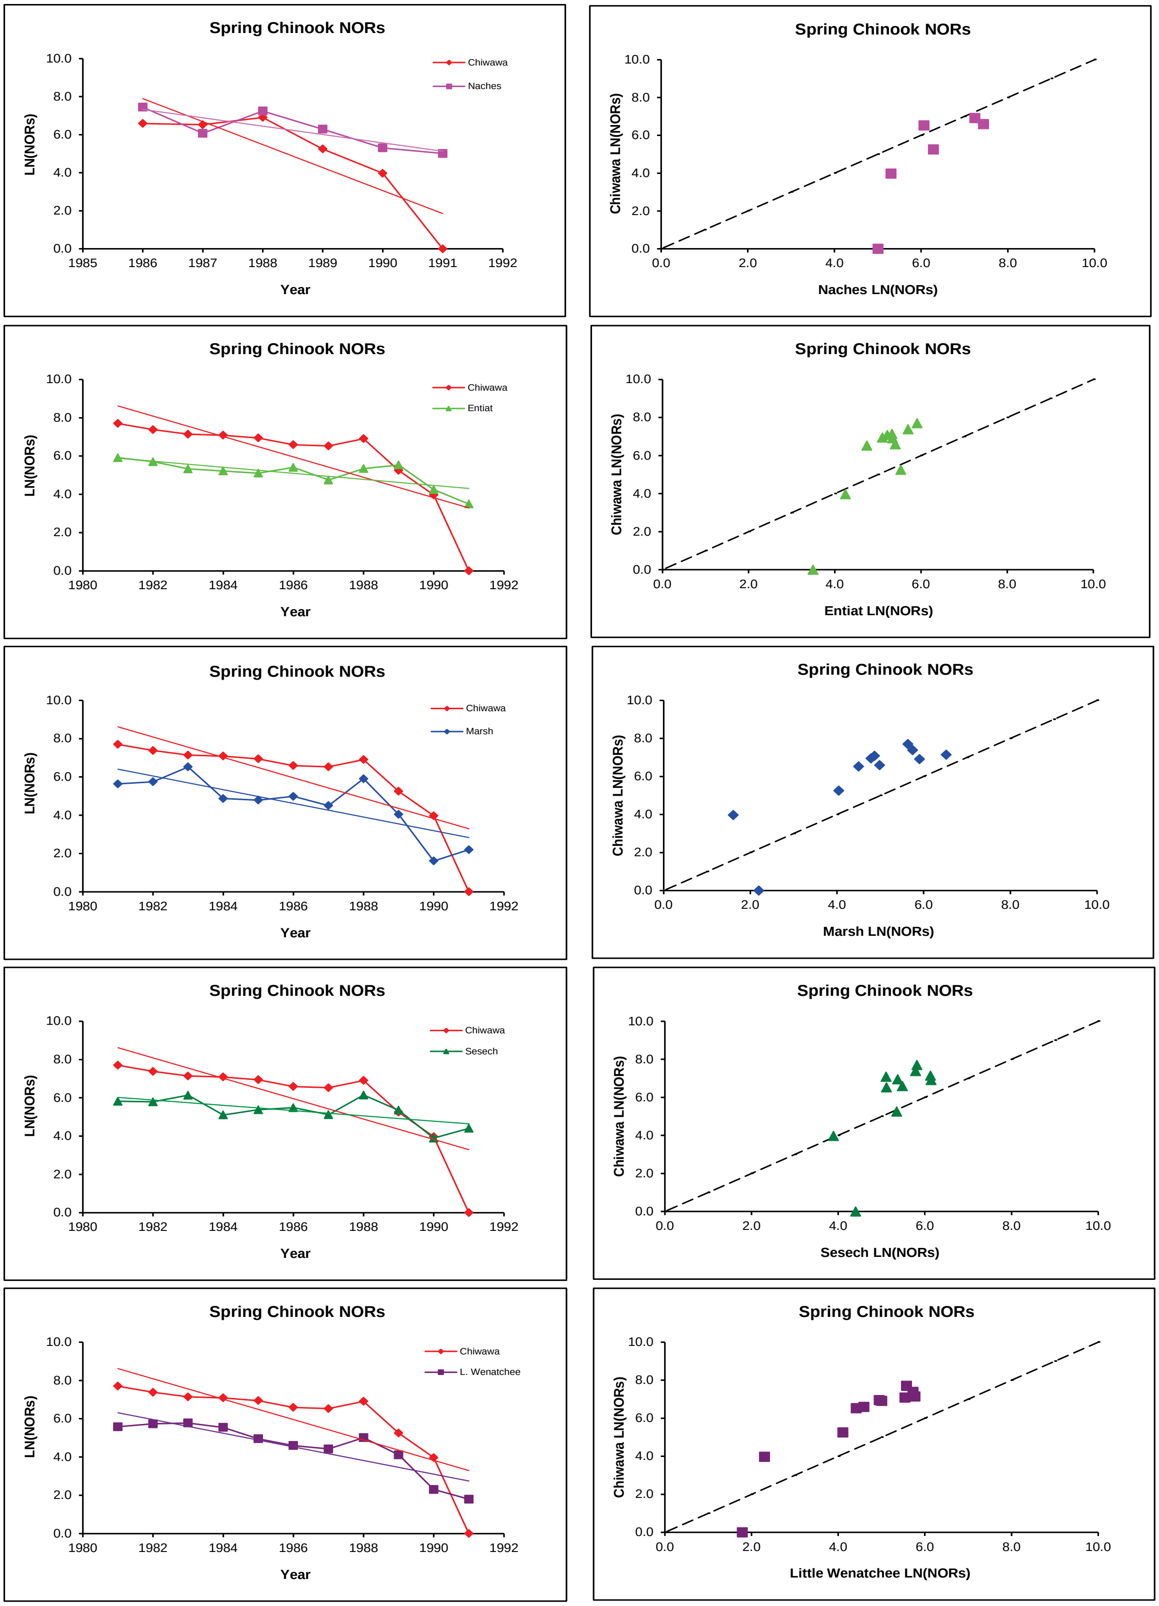

Figure 6. Time series of natural log natural-origin recruits (NORs) of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

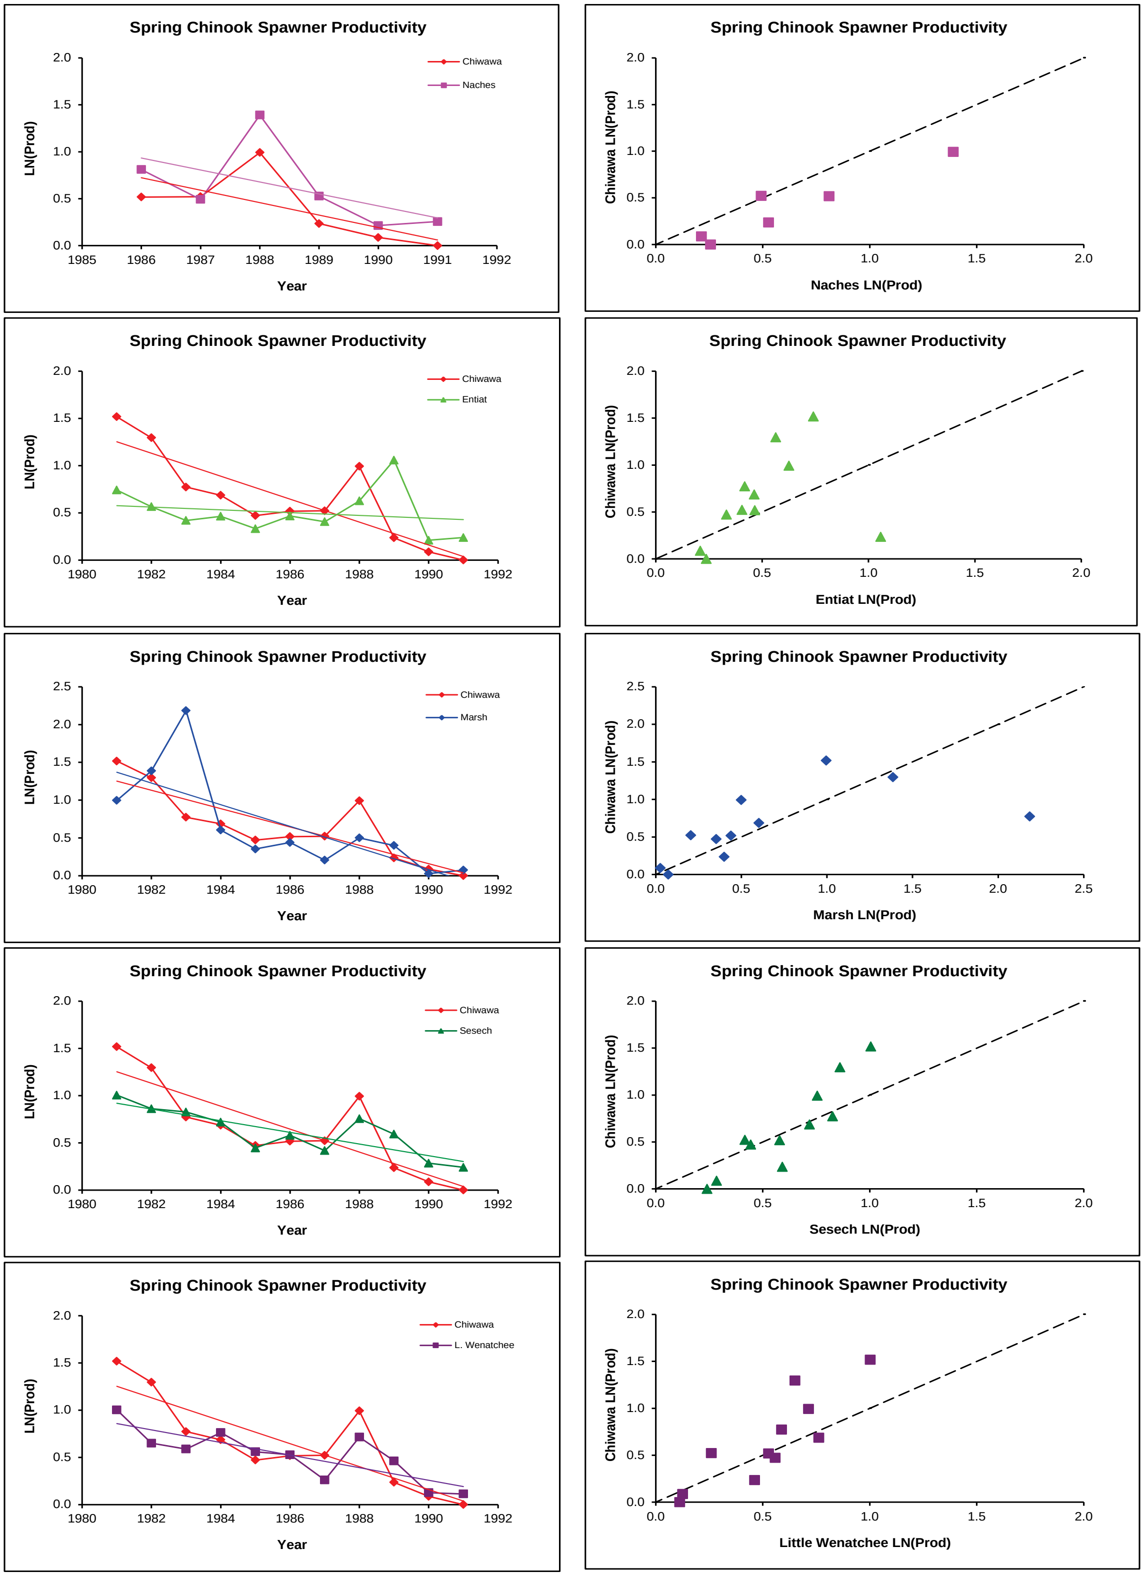

Figure 7. Time series of natural log adult productivity of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

Correlations and Trends

Other methods for evaluating the suitability of potential reference populations under Step 2 include correlation and trend analyses. For correlation analysis, we simply calculated the Pearson correlation coefficient, which is an index of the strength of the association between the potential reference populations and the Chiwawa population. The coefficient ranges from -1 to 1, where a value near 1 or -1 represents that strongest association between the populations. A value of 0 means no association. We used only spawner abundance, NORs, and productivity data during the pre-treatment period (1981-1992). We assumed that populations with coefficients greater than 0.6 represented reasonable reference conditions.

For trend analyses, we used least squares techniques to compute a straight-line trend through the spawner abundance and productivity data for the potential reference populations and the Chiwawa population. Trends were fit to the pre-treatment time series data (1981-1992). We then used t-tests to determine if the slopes of the trends between potential reference populations and the Chiwawa population differed significantly.

It is important to note that time-series trend analyses are susceptible to temporal correlations in the data. Autoregressive integrated moving average (ARIMA) models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). However, these models require a long time series (N > 40) and therefore we could not use them to model the spring Chinook data. As such, we were unable to correct for any temporal correlation that may exist within the time series.

Tests of correlation with spawner abundance data indicated that the Naches River closely correlated with the Chiwawa population (Table 2). There was no difference in abundance trends between the potential reference populations and the Chiwawa population (Table 2; Figure 2). For NORs, all potential reference populations correlated with the Chiwawa population (Table 2). However, trends in NORs of all reference populations, except Naches, differed significantly from the Chiwawa population (Table 2; Figure 3). For productivity, the Naches, Sesech, and Little Wenatchee correlated with the Chiwawa population (Table 2). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 2; Figure 4).

Table 2. Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (*) indicates significance at $P < 0.05$.

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Spawner Abundance Data				
Naches	0.684*	-0.659	8	0.528
Entiat	0.598*	-0.596	18	0.559
Marsh	0.147	-1.341	18	0.197
Sesech	0.274	-1.265	18	0.222
Little Wenatchee	0.399	-0.591	18	0.562
Natural-Origin Recruits				
Naches	0.803*	0.666	8	0.524
Entiat	0.795*	-7.495	18	0.000

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Marsh	0.605*	-5.786	18	0.000
Sesech	0.648*	-6.874	18	0.000
Little Wenatchee	0.880*	-7.206	18	0.000
Productivity Data				
Naches	0.960*	0.169	8	0.870
Entiat	0.272	-3.057	18	0.007
Marsh	0.320	0.605	18	0.553
Sesech	0.903*	-2.059	18	0.054
Little Wenatchee	0.848*	-2.065	18	0.054

We also ran correlation and trend analyses on natural-log transformed spawner abundance, NORs, and productivity data. These analyses indicated that the Naches, Entiat, and Little Wenatchee abundance data correlated with the Chiwawa population data (Table 3). None of the abundance trends of the potential reference populations differed significantly from the Chiwawa population trend (Table 3; Figure 5). For NORs, all potential reference populations correlated with the Chiwawa population (Table 3). Only trends in NORs of the Entiat and Sesech differed significantly from the Chiwawa population (Table 2; Figure 6). For productivity, the Naches, Marsh, Sesech, and Little Wenatchee correlated with the Chiwawa population data (Table 3). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 3; Figure 7).

Table 3. Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (*) indicates significance at $P < 0.05$. Analyses were conducted on natural-log transformed abundance and productivity data.

In summary, based on correlation, trend, and graphic analyses, the Naches, Entiat, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. For NORs, the Naches, Marsh, and Little Wenatchee appear to be reasonable reference populations. For productivity, the Naches, Marsh, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for the Chiwawa population.

Minimal Detectable Differences (MDD)

Given a suite of potential reference populations, it is important to conduct power analyses to determine the minimum differences that can be detected when comparing the reference populations to the supplemented population. As a final exercise under Step 2, we examined potential reference populations for the smallest minimal detectable differences. Before conducting power analyses, several decisions needed to be made, including what statistical procedures will be used to analyze the data, the desired level of statistical power (probability of rejecting a false null hypothesis), the size of the type-I error (the probability of rejecting a true null hypothesis of no difference), and the number of samples (i.e., years) included in the analysis. In this case, the number of samples represents the number of treatment (supplementation) years. The number of pre-treatment years (1981-1992) was based on the number of years of quality data available for Chiwawa spring Chinook and potential reference populations.

We designed the study as a modified BACI (Before-After, Control-Impact) design, which includes replication before and after supplementation in both the treated (T) population and the reference (R) populations. A common approach used to analyze data from BACI designs includes analysis of difference scores (Stewart-Oaten et al. 1992; Smith et al. 1993). Differences are calculated between paired treatment and reference population scores (i.e., T-R). Another approach is to calculate ratios (treatment/reference; T/R) for paired treatment and reference population scores (Skalski and Robson 1992). Finally, differences in annual changes in paired treatment and reference population scores can be calculated (i.e., ΔT-ΔR) (Murdoch and Peven 2005; Hays et al. 2006).[17] These derived difference and ratio scores are then analyzed for a before-after treatment effect with a two-sample t-test, Aspin-Welch modification of the t-test, or a randomization test. For power analyses, we calculated minimal detectable differences assuming the use of an independent two-sample t-test with a type-I error rate of 0.05, power of 0.80 (beta or type-II error rate of 0.20), and sample sizes (treatment years) of 5, 10, 15, 20, 25, and 50 years.

[17] The difference of annual difference scores was estimated by first subtracting the population parameter (e.g., spawner abundance) in year 2 from year 1. This continues for all years in the data series for both treatment ($T_{t+1} - T_t$) and reference populations ($R_{t+1} - R_t$). We then calculated differences between paired treatment and reference annual difference scores [$(T_{t+1} - T_t) - (R_{t+1} - R_t) = \Delta T - \Delta R$].

The power analysis calculated the minimal detectable difference between mean difference or ratio scores before and during supplementation. We used existing data to calculate variances for the pre-supplementation and supplementation periods. Thus, variances were known and unequal. For both spawner abundance and NORs, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was less than the mean difference during supplementation (one-tail test; Difference < 0). For productivity, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was greater than the mean difference during supplementation (one-tail test; Difference > 0).

Based on spawner abundance data, power analysis indicated that the Sesech-Chiwawa pairing consistently produced the smallest detectable differences (Table 4). However, when the abundance data were transformed using natural logs, the Entiat-Chiwawa pairing produced the smallest detectable difference (Table 5). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 334 to 394 adult spawners; transformed data ranged from 0.479 to 1.010. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

Table 4. Minimal detectable differences between mean difference and ratio scores before and during supplementation. Analyses were conducted on spawner abundance data.

Based on NORs, power analysis indicated that the Entiat-Chiwawa, Marsh-Chiwawa, and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 6). When NORs were transformed using natural logs, the Little Wenatchee-Chiwawa pairing produced the smallest detectable difference (Table 7). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 483 to 640 NORs; transformed data ranged from 0.958 to 2.262. These analyses indicate that the Entiat, Marsh, and Little Wenatchee populations appear to be reasonable reference populations for comparing NORs with Chiwawa data.

Using untransformed productivity data, power analysis indicated that the Little Wenatchee-Chiwawa pairing consistently produced the smallest detectable differences (Table 8). The Marsh-Chiwawa pairings produced the largest detectable differences. When we analyzed natural-log transformed productivity data, the Naches-Chiwawa and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 9). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 0.754 to 1.839; transformed data ranged from 0.277 to 0.477. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing productivity data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

Step 3: Quantitative Method for Ranking Selection Criteria

Not surprisingly, different selection criteria produced different results (Table 10). Determining whether a given population is or is not a suitable reference population based on selection criteria such as graphic analysis can be subjective. In addition, treating each selection criterion as equally important may not be appropriate. For example, using the information in Table 10, is it appropriate to select a reference population that has two or three “Yes” entries, or should only populations with four “Yes” entries be selected as suitable reference populations? This approach does not allow certain selection criteria to carry more weight in the overall selection process. That is, correlation may be more important than graphic analysis in the overall selection process. In order to reduce

subjectivity, we developed a method of scoring and weighting each selection criterion. This method allows a more quantitative process for selecting suitable reference populations.

Table 10. Summary of results from graphic analysis, correlations, trend analysis, and power analysis (minimal detectable differences). "Yes" indicates that the population is a suitable reference population for the Chiwawa population; "No" indicates that it may not be a suitable reference population.

Potential reference populations	Graphic analysis	Correlation	Trends	Minimal detectable differences
Spawner Abundance				
Naches	Yes	Yes	Yes	Yes
Entiat	Yes	Yes	Yes	Yes
Marsh	No	No	Yes	No
Sesech	No	No	Yes	Yes
Little Wenatchee	Yes	Yes	Yes	Yes
Natural-Origin Recruits				
Naches	Yes	Yes	Yes	No
Entiat	No	Yes	No	Yes
Marsh	Yes	Yes	Yes	Yes
Sesech	No	Yes	No	No
Little Wenatchee	Yes	Yes	Yes	Yes
Productivity				
Naches	Yes	Yes	Yes	Yes
Entiat	No	No	No	Yes
Marsh	No	Yes	Yes	No
Sesech	Yes	Yes	Yes	Yes
Little Wenatchee	Yes	Yes	Yes	Yes

We developed scoring methods for each of the following five selection criteria:

(1) The proportion of natural-origin spawners (pNOS) in the reference population for the period before supplementation (pre-pNOS);

(2) pNOS in the reference population for the period following supplementation (post-pNOS);

(3) The correlation between the reference and supplemented populations before supplementation;

(4) The relative difference in slopes between the reference and supplemented populations before supplementation; and

(5) The coefficient of variation (CV) of the ratio of supplemented to reference populations before the period of supplementation.

Each selection criteria was scored from 0 to 1, with 0 being the worst possible score and 1 being the best.

The pre- and post-pNOS values were calculated as the average pNOS values before and after supplementation, respectively. Because pNOS values range from 0-1, we did not need to rescale

these values. When using reference populations to evaluate the effects of supplementation programs, it is important that the reference populations maintain high values of pNOS throughout the life of the monitoring program. Therefore, we heavily weighted the mean pNOS scores. We assigned weights of 30 and 40 to the mean pre- and post-pNOS scores, respectively. The relatively larger weight for the post-supplementation period is to reduce the likelihood of retaining a reference population that becomes influenced by hatchery fish during the supplementation period.

We assessed the association between the reference and supplemented populations during the pre-supplementation period by calculating the Pearson correlation coefficient, which ranges from -1 to 1. To scale the coefficient between 0 and 1, we took the absolute value of the coefficient. Thus, a coefficient of -0.92 would be reported as 0.92. For our analyses, we were not concerned with the direction of the relationship, only the strength of the relationship. The correlation coefficient was given a weight of 12.5.

As noted earlier, we used least squares to fit a linear trend to each of the reference populations and the supplemented population during the pre-supplementation period. Using the slope estimates for each trend line, we calculated the relative difference in slopes as the slope of the supplemented population minus the slope of the reference population, divided by the slope of the reference population. To scale this value between 0 and 1, we used absolute values, and depending on the direction of the slopes, we subtracted the relative difference from 1. The latter was needed to make sure a larger relative difference value indicated a small difference in slopes between the supplemented and reference populations. The relative difference score was given a weight of 7.5.

Finally, as a means to score effect size, we calculated the CV of the ratio of supplemented to reference population parameters (i.e., T/R). The CV was calculated as the standard deviation of the ratios divided by the absolute value of the mean ratios. The CV was subtracted from 1. This scaled the value from 0 to 1 with larger values representing the best condition. The CV was given a weight of 10, which is greater than the weight for trend, but less than the weight for correlation.

The total score for a reference population was calculated by multiplying the estimated value, which ranged from 0 to 1, by its weight. The sum of the five weighted values provided a total score, which ranged from 0 to 100. Based on several simulations, we set the cut-off score at 81. That is, if the total score for a given reference population equaled or exceeded 81, the population was included as a suitable reference population. If the total score fell below 81, the population was not considered a suitable reference. Based on the distribution of all scores possible, a score of 81 or greater represented only 3% of the total distribution. Thus, a cut-off of 81 is quite conservative.

Under Step 3, we used this method to select the final suite of suitable reference populations. Table 11 shows results from scoring each of the reference populations using the quantitative method. Using the cut-off criterion of 81, only the Naches, Marsh, and Sesech populations would be considered suitable reference populations for the Chiwawa supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values).

Table 11. Results from scoring potential reference populations using the selection criteria (pNOS, correlation, trend, and effect size). Populations with scores less than 81 were considered unsuitable as reference populations. Populations with scores equal to or greater than 81 were considered suitable references. These results were based on natural-log transformed data.

Potential reference populations	Population metric		
	Abundance	NORs	Productivity
Naches	85	88	91
Entiat	23	21	16
Marsh	79	91	87
Sesech	84	85	88
Little Wenatchee	51	53	49

An important benefit from scoring the different selection criteria is that the total scores can be used to weight the outcome of differing statistical results. For example, analyses may show that when three suitable reference populations are compared to the supplemented population, two of the reference populations may indicate a significant treatment effect, while the third indicates no effect. Under this scenario it is not clear if the supplementation program has or has not affected the abundance or productivity of the supplemented population. If, however, the two reference populations that produced a significant result had higher total scores than the reference population that did not indicate a significant result, one can place more weight on the results from populations with higher total scores.

Conclusions

The purpose of this exercise was to develop a method for selecting suitable reference populations that could be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity. The selection process included a three-step process (Figure 8). Step 1 identified populations with similar life-history characteristics, few or no hatchery spawners, a long time series of accurate abundance and productivity estimates, and similar freshwater habitat impairments and out-of-basin effects. Populations that met these criteria were then examined for their graphical and statistical relationship with the supplemented population (Step 2). The statistical analysis under Step 2 were converted to a quantitative model (Step 3) that was used to generate a weighted score for pNOS, correlation, trends, and effect sizes for each potential reference population. Reference populations with total scores of 81 or greater were selected as suitable reference populations.

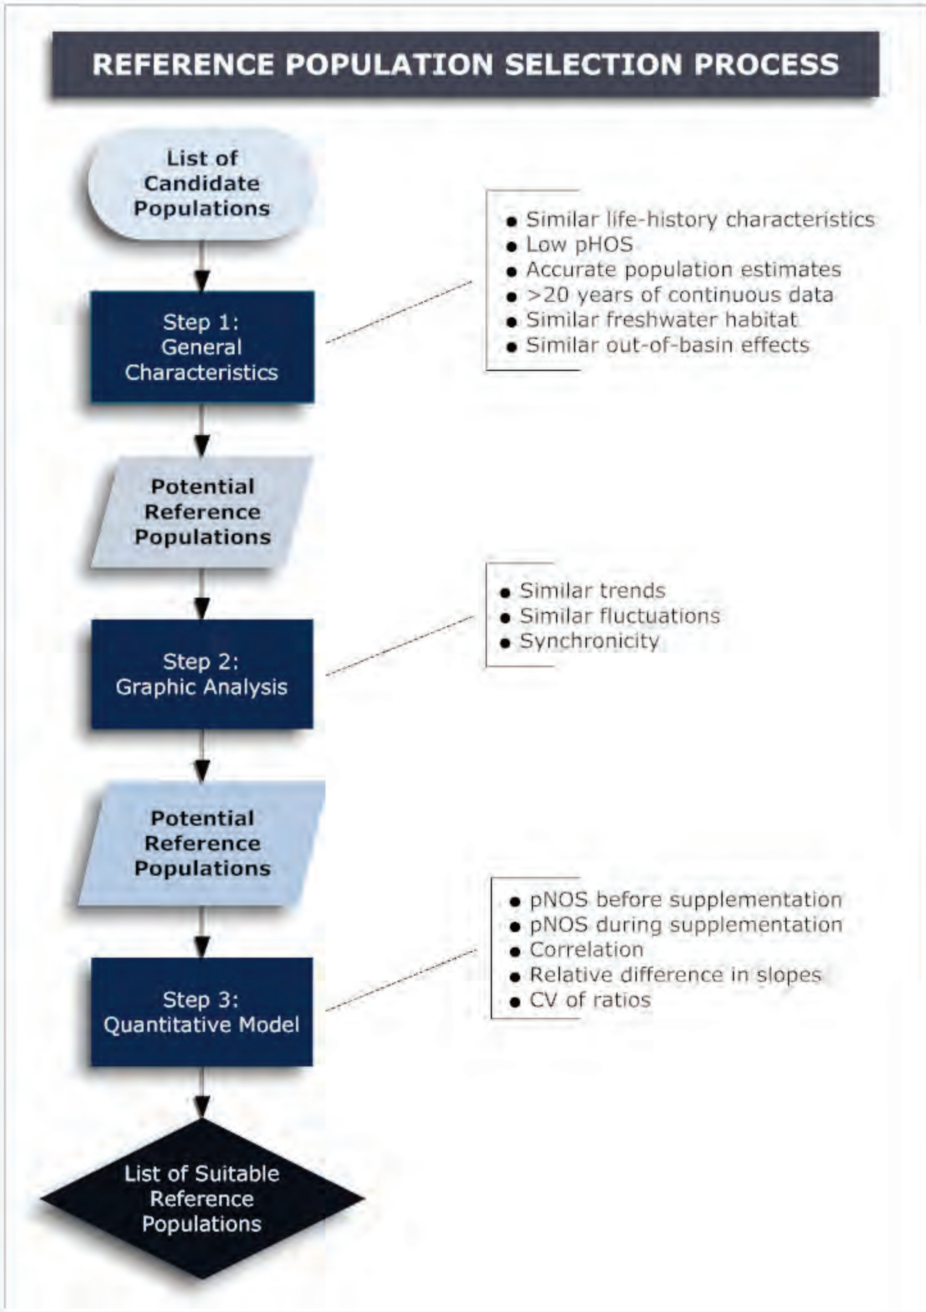

Figure 8. Three-step process for selecting suitable reference populations for supplemented populations.

We used this approach to select suitable reference populations for analyzing the effects of the Chiwawa spring Chinook supplementation program on fish abundance and productivity. The method indicated that the Naches, Marsh, and Sesech populations would serve as suitable reference populations for the Chiwawa spring Chinook supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values). However, because the presence of hatchery spring Chinook within those populations should decrease, they may serve as unique reference populations in which the comparisons change from all populations receiving

hatchery fish to only the Chiwawa population receiving hatchery fish. Therefore, we will continue to include both the Little Wenatchee and Entiat populations in future analyses.

An important assumption in the use of reference populations is that the supplemented and reference populations that tracked each other before supplementation would continue to track each other in the absence of supplementation. Given that the reference populations did not match the Chiwawa population on all criteria examined (Table 1) and some reference populations tracked the Chiwawa population more poorly than others (Figures 2-7; Tables 2-4), there may be some uncertainty as to whether differences observed between the Chiwawa and reference populations during the supplementation period are associated with the hatchery program, "nuisance" factors[18], or a combination of both. In addition, we have no ability to regulate or control activities in reference areas. Any large-scale change (man-made or natural) in reference areas could affect our ability to assess the effectiveness of the supplementation program.

Because we have no ability to maintain reference areas for long periods of time and may not be able to control all activities even within the supplemented populations, we propose the use of a "causal-comparative" approach to strengthen the certainty of our inferences (Pearsons and Temple 2010). The causal-comparative approach relies on correlative data to try and make a case for causal inference.[19] Correlation is used to rule out alternative hypotheses (note that we make our case as much if not more by disproving plausible alternatives as we do by showing that the data are consistent with a hypothesis). For example, large scale land-use activities or natural events can affect stream flows, fine sediment recruitment, and water temperatures. Changes in these factors can affect the freshwater survival and productivity of fish independently of supplementation programs. If changes in habitat, migratory, and ocean conditions do not affect reference and treatment populations similarly, inferences associated with supplementation programs may be confounded. By measuring and tracking these extraneous factors within reference and treatment areas, we can assess the effects of these state variables on population conditions independent of the supplementation programs. This allows us to more effectively assess the influence of supplementation programs on populations.

To that end, we recommend that the following state variables be measured and tracked within the Chiwawa Basin and each of the reference areas: mean annual precipitation, total and riparian forest cover, road density, impervious surface, and alluvium. These variables can be used to describe differences in water temperatures at different life stages (pre-spawning, egg incubation, and summer rearing) and substrate characteristics, including fine sediments and embeddedness (Jorgensen et al. 2009). They can be used to assess possible changes in spawner abundance, NORs, and productivity that are independent of supplementation.

---

[18] A "nuisance" factor is any factor that is outside the control of the experimenter and can affect the response variable (spawner abundance or productivity). In this case, nuisance factors may include differences in freshwater habitat trends and conditions, out-of-basin effects (e.g., migration and ocean survival), and hatchery strays that affect the Chiwawa and reference populations differently.

[19] It is important to point out that correlation does not demonstrate cause-and-effect. It only suggests a relationship between variables. Thus, inferences based on correlation lack the certainty that is associated with a design-based approach.

Analyses with Reference Populations

Once suitable reference populations are selected, methods for analyzing the supplemented and reference populations need to be identified. What follows is a description of different analyses that can be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity using reference populations. Later in this report we describe methods for assessing supplementation effects when reference populations are not available.

We used some of the reference populations selected for the Chiwawa program to illustrate the different methods for evaluating the effects of the supplementation program on spawner abundance, NORs, and productivity. For abundance, we selected the Naches, Entiat, Little Wenatchee, and Sesech populations as suitable references for the Chiwawa population. For NORs, we selected the Naches, Entiat, Marsh, and Little Wenatchee populations as suitable references. For productivity, we selected the Naches, Sesech, Little Wenatchee, and Marsh Creek as suitable references for the Chiwawa. As noted earlier, we included the Little Wenatchee and Entiat populations, even though they did not meet all the criteria for suitable reference populations.

Analysis of Trends

As a first step, we used trend analyses to assess the effects of the Chiwawa supplementation program on spring Chinook spawner abundance, NORs, and productivity. Here, we compared the slopes of the trends between each treatment/reference pair before and during supplementation using t-tests. If the hatchery program is successfully supplementing the natural spring Chinook population, trends in spawner abundance and NORs should deviate significantly (i.e., the slope of the supplemented population should be greater than the slopes of the reference populations during the supplementation period). For productivity, the slope of the supplemented population, relative to the reference population, should increase or remain the same.

Trend analysis indicated that the relationship of slopes of spawner abundance between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 9; Table 12). This was true for both transformed and untransformed abundance data. Before supplementation, spawner abundances trended down in both the Chiwawa and reference populations (Figure 9). During the period of supplementation, abundances in both the Chiwawa and reference populations trended upward. Interestingly, in nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the supplementation period than in the pre-supplementation period (Table 12). This was most evident in the transformed abundance data (Figure 9).

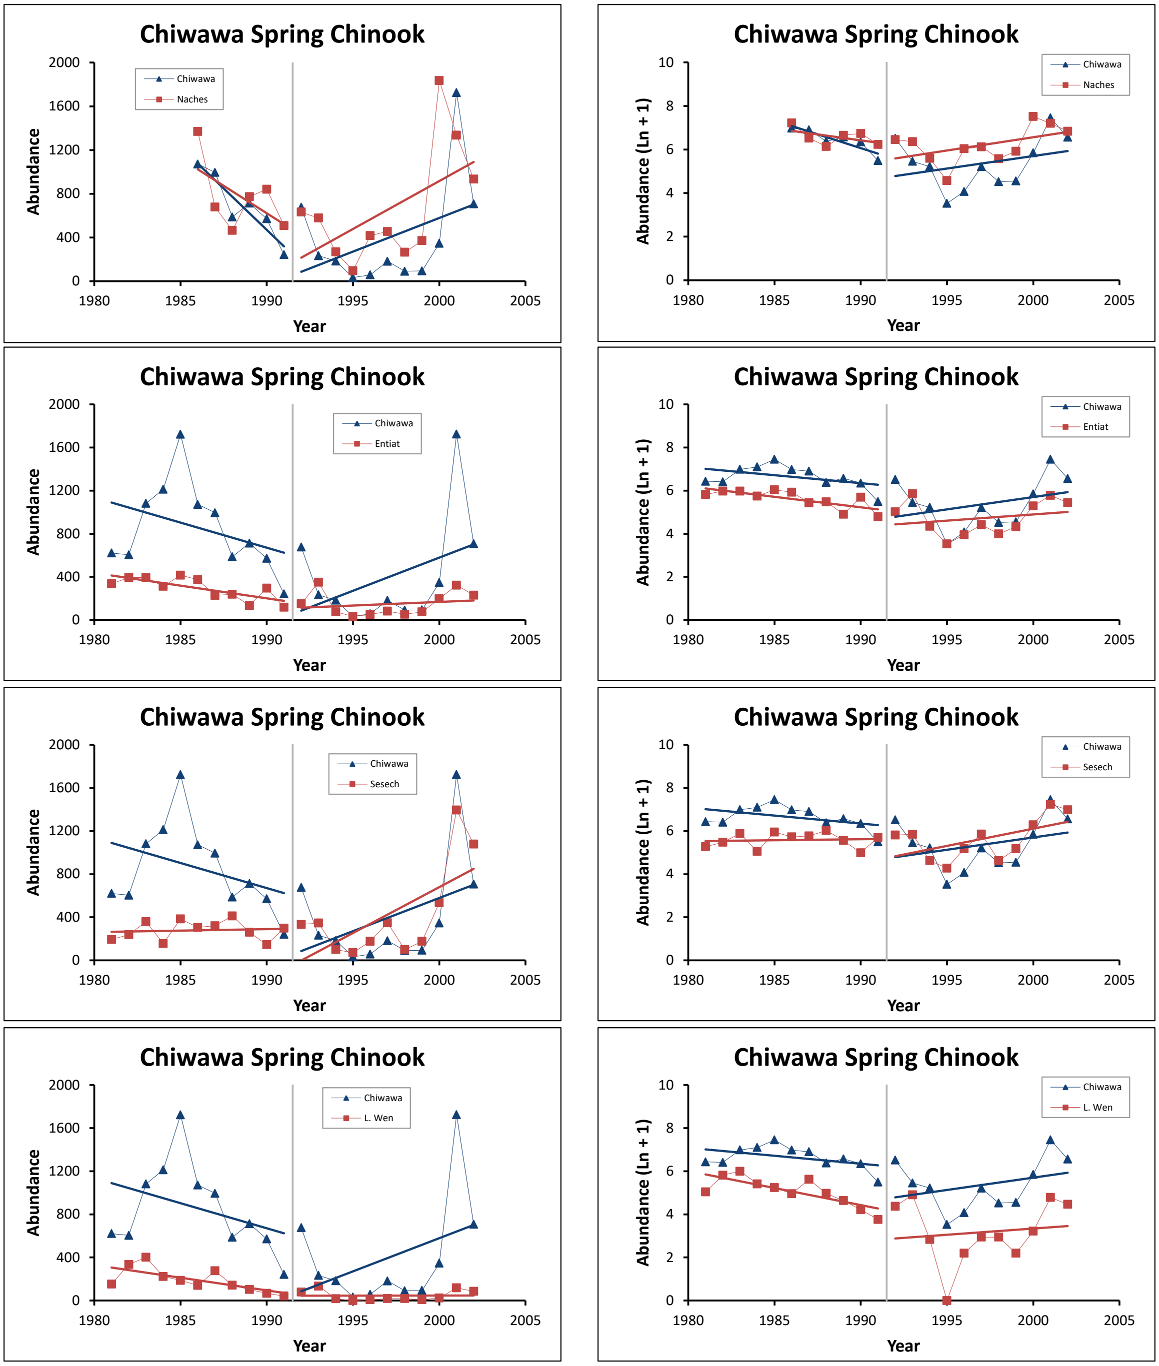

Figure 9. Trends in spring Chinook spawner abundance in the Chiwawa and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed spawner abundance data; those on the right include natural-log transformed data.

Table 12. Pearson correlation coefficients and t-test results comparing slopes of spawner abundance trends between reference populations and the Chiwawa spring Chinook population before and during the supplementation periods; for correlation coefficients, an asterisk (*) indicates significance at $P < 0.05$. Analyses include both untransformed and natural-log transformed spawner abundance data.

Trend analysis indicated that the relationship of slopes of NORs between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 10; Table 13). Before supplementation, Chiwawa NORs trended downward more strongly than the reference populations (Figure 10). However, during the supplementation period, both the Chiwawa and reference population NORs trended upward in parallel. In nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the pre-supplementation period than in the supplementation period (Table 13).

As with NORs and spawner abundance data, trend analysis indicated that the relationship of slopes of productivity (recruits/spawner) between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 11; Table 14). This was true for both transformed and untransformed productivity data. Before supplementation, productivities trended down in both the Chiwawa and reference populations (Figure 11). During the period of supplementation, productivities fluctuated widely in both the Chiwawa and reference populations. Nevertheless, during the supplementation period, productivities generally increased in both the reference and Chiwawa populations. Unlike with spawner abundance, the Pearson correlation coefficients resulting from analysis of productivity data were generally higher in the pre-supplementation period than during the supplementation period (Table 14).

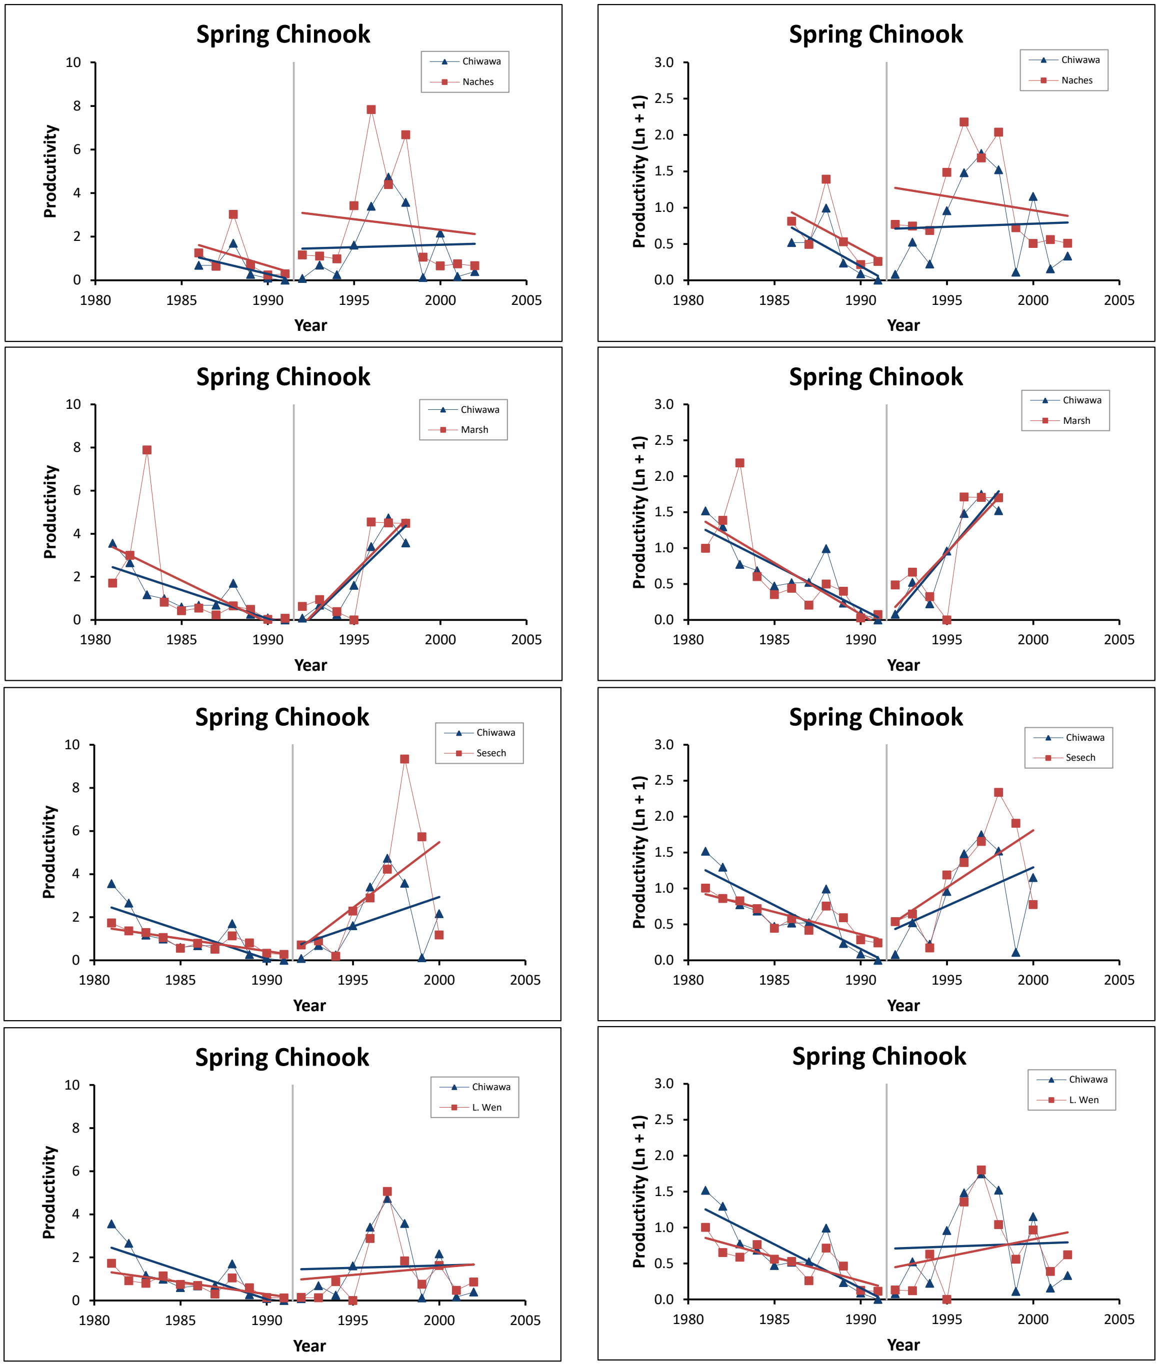

Figure 11. Trends in spring Chinook productivity (recruits/spawner) in the Chiwawa (supplemented) and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed productivity data; those on the right include natural-log transformed data.

Using trend analysis, we found no evidence that the supplementation program has significantly increased the spawner abundance and NORs of spring Chinook in the Chiwawa Basin. Even though we documented an increasing trend in spawner abundance and NORs during the supplementation period, a similar increase in spawner abundance and NORs was observed in the reference populations. In addition, we found no evidence that the supplementation program has increased the productivity of spring Chinook in the Chiwawa Basin. Importantly, the productivity of spring Chinook in the Chiwawa Basin did not trend downward during the supplementation period. Thus, based on trend analysis, it appears that the supplementation program has not increased or decreased the abundance and productivity of spring Chinook in the Chiwawa Basin.

We note that this exercise only tests the slopes of the trend lines. It does not test for differences in elevations of the trend lines. A supplementation program could increase spawner abundance, NORs, and productivity of the target population without changing the slopes of the trend lines. That is, supplementation could cause the elevation of the trend line to be greater during the supplementation period than during the pre-supplementation period. In the next section we evaluate elevation differences by testing mean differences before and after supplementation.

Analysis of Mean Differences, Ratios, and Rates

For assessing mean differences between supplemented and reference populations, we derived three different response variables using transformed and untransformed spawner abundance, NORs, and productivity data. The first included difference scores, which were calculated as the difference between paired treatment and reference data (T-R). The second included ratios, which were calculated as the ratio of paired treatment and reference data (T/R). Finally, we calculated the differences in annual changes in paired treatment and reference population data (ΔT-ΔR; see footnote #2).

If the hatchery program is successfully supplementing the natural spring Chinook population, the mean difference or ratio score of paired spawner abundance data and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean difference or ratio score during the supplementation period should be equal to or higher than the pre-supplementation period. We tested the following statistical hypotheses.

Spawner Abundance and NORs:

Ho: Mean Difference (or Ratio) before supplementation ≥ Mean Difference (or Ratio) during supplementation.

Ha: Mean Difference (or Ratio) before supplementation < Mean Difference (or Ratio) during supplementation (i.e., μ_{pre} - $\mu_{post} < 0$).

Productivity (Recruits/Spawner):

Ho: Mean Difference (or Ratio) before supplementation ≤ Mean Difference (or Ratio) during supplementation.

Ha: Mean Difference (or Ratio) before supplementation > Mean Difference (or Ratio) during supplementation (i.e., μ_{pre} - $\mu_{post} > 0$).[20]

For each set of response variables, we tested before/after supplementation effects using a one-tailed Aspin-Welch unequal-variance test. We used the Aspin-Welch unequal-variance test instead of Student's t-test, because in nearly every case, the variances of response variables in the pre-treatment and supplementation periods were unequal.[21] This was true even for natural-log transformed variables. We used the modified Levene equal-variance test to assess the equality of variance. In some cases, the distributions of response variables were not normal (based on the Omnibus Normality test and examination of histograms, normal probability plots, and box plots). Therefore, we also used a randomization test, based on 10,000 Monte Carlo simulations, to assess differences in response variables before and during supplementation. The randomization procedure only allowed the testing of two-tailed hypotheses. Therefore, we generated 95% confidence intervals on the mean difference (μ_{pre} - μ_{post}) using bootstrapping methods to determine the direction of the difference. We generated 5,000 bootstrap samples to calculate confidence intervals.

All these statistical methods assume that the samples of derived difference or ratio scores from the pre-supplementation and supplementation periods were independent. However, BACI designs, like time-series trend analysis, are repeated-measures designs and therefore are susceptible to temporal correlations in the data. This means that the two samples of difference or ratio scores may not be independent. Under this scenario, ARIMA models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). ARIMA models can be fit individually to the reference and supplemented time series data, or to a derived data series created by taking the ratio or difference of the supplemented/reference data at each time step. ARIMA models, however, require a long time series (N > 40) and therefore we could not use them to model

---

20 Because of the logic of null hypothesis testing, the rejection of the null hypothesis of no difference in productivity would mean that the supplementation program has reduced the productivity of the target population (here rejection of the null indicates "harm"). Notice that the rejection of the null hypothesis of no difference in spawner abundance means that the supplementation program has improved the spawner abundance in the target population (here rejection of the null indicates "benefit").

21 In cases in which the variances were equal, both the Aspin-Welch test and Student's t-test gave the same result.

the spring Chinook data. Thus, we acknowledge that our analyses may be confounded if the samples are not independent.

Difference Scores (T-R)

Analysis of supplementation effects on spawner abundance using difference scores indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 15; Figure 12). Only the Little Wenatchee-Chiwawa pairing using transformed abundance data indicated a significant increase in spawning abundance following supplementation. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction (i.e., CIs > 0). That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 12).

Table 15. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed spawner abundance data. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

Analysis of supplementation effects on productivity (adult recruits/spawner) using difference scores indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 17; Figure 12). All tests, regardless of treatment-reference pairs, indicated that productivity did not change significantly during the supplementation period. These tests indicate that supplementation has not negatively affected the productivity of spring Chinook salmon in the Chiwawa Basin.

Table 17. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data. Ratio Scores (T/R)

As with difference scores, analysis of supplementation effects on spawner abundance using ratios indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 18; Figure 13). Only the Little Wenatchee-Chiwawa pairing indicated a significant increase in spawning abundance following supplementation. Analysis with both transformed and untransformed Little Wenatchee-Chiwawa data indicated a significant effect. In contrast, only difference scores derived from transformed data indicated a significant effect. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction. That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 13).

Table 18. Figure 13. Mean ratios (Treatment/Reference) scores of untransformed (figures on the left) and transformed (figures on the right) spawner abundance, natural-origin recruits (NORs), and productivity data before (pre) and after (post) spring Chinook supplementation in the Chiwawa Basin. Positive effects of supplementation on spawner abundance and NORs are indicated when the post-supplementation (red) bars are greater than their corresponding pre-supplementation (blue) bars. Negative effects of supplementation on productivity are indicated when the pre-supplementation (blue) bars are greater than their corresponding post-supplementation (red) bars.

Analysis of supplementation effects on NORs using ratios indicated that supplementation did not significantly increase NORs in the Chiwawa Basin (Table 19; Figure 13). Only the Little Wenatchee-Chiwawa pairing indicated a significant increase in transformed NORs following supplementation. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction. That is, compared to the reference populations, NORs decreased in the Chiwawa Basin during the supplementation period (Figure 13).

Table 19. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed natural-origin recruits. Tests determined if the mean ratios during the supplementation period were greater than mean ratios during the pre-supplementation period.

Analysis of supplementation effects on productivity (adult recruits/spawner) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 20; Figure 13). Although the Aspin-Welch test indicated a significant effect when comparing the Chiwawa to the Marsh Creek population, both the randomization test and the bootstrap CI did not indicate a significant effect. These tests indicate that supplementation has probably not negatively affected the productivity of spring Chinook salmon in the Chiwawa Basin.

Table 20. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data. Tests determined if the mean ratios during the supplementation period were less than mean ratios during the pre-supplementation period.

Difference of Annual Difference Scores (ΔT-ΔR)

Analysis of supplementation effects on spawner abundance using difference scores of annual changes indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 21; Figure 14). None of the statistical analyses detected a significant increase in annual change in the Chiwawa Basin relative to the reference populations.

Table 21. We believe results from analysis of mean differences of annual change (ΔT-ΔR) in spawning abundance, NORs, and productivity are difficult to interpret and may be insensitive to treatment effects. A simpler analysis, which is also easier to interpret, is the use of trend analysis. Therefore, we recommend that analyses using differences of annual change be replaced with trend analysis.

Corrections for Density Dependence and Carrying Capacity

The analyses described above assume that the density of spawners or recruits does not affect the survival and productivity of fish. However, it is well known that the density of fish can affect the number of recruits as well as the productivity of the population. This occurs through the relationship between density and mortality. Mortality of fish can be generally classified as density independent and density dependent. In general, when densities are low, the mortality is density independent, but as densities increase, the amount of density-dependent mortality increases. Monitoring programs can make use of this information to derive density-corrected estimates of productivity. In this section, we describe two different methods for deriving density-corrected estimates of productivity.

The first method controlled the effects of density on productivity (adult recruits/spawner; R/S) by partitioning observed productivities into density-independent and density-dependent productivity. When abundance is below the minimum number of spawners (S) needed to produce the maximum number of recruits (K_{sp}), the observed productivity is used in statistical tests. However, when the abundance is equal to or above K_{sp}, the modeled value of productivity (R/K_{sp}) is used in statistical tests.

$$\boldsymbol{Adj\ R/S = \begin{cases} R/S, & if\ S < K_{sp} \\ R/K_{sp}, & if\ S \geq K_{sp} \end{cases}}$$

The density-independent and density-dependent productivities were then combined in a single test.

The second method was based on one of the goals of supplementation, which is to fill the capacity of the environment with fish. This method corrects for differences in carrying capacities between the supplemented and reference populations. We did this by calculating the percent saturation of NORs. That is, we calculated the fraction of the habitat (τ) that was filled with NORs by dividing the observed NOR by the modeled maximum number of NORs (K_R) that the habitat could support.

$$\boldsymbol{\tau = \frac{NOR_{obs}}{K_R}}$$

Note that 1-τ represents the unused portion of the carrying capacity and is the term that is multiplied by the exponential growth equation to derive the logistic growth equation. We included τ in the statistical analyses.

These two methods require the estimation of carrying capacity (K_R) and the spawning abundance that produces the maximum number of recruits (K_{sp}). We estimated these parameters for both reference populations and the supplemented population using Ricker, Beverton-Holt, and smooth hockey stick stock-recruitment models. We used only spawner abundance as a predictor of subsequent brood recruitment. We made the following assumptions in proceeding with the analysis:

- Density-dependent mortality—For some time period before recruitment, the brood instantaneous mortality rate is proportional to the number of parent spawners (Ricker 1954).
- Lognormal variation—At any particular spawning stock size, the variation in recruitment is log-normally distributed about its average, and acts multiplicatively (Quinn and Deriso 1999).
- Measurement error—Error in spawning stock size estimates (measurement error) is small relative to the range of spawning stock sizes observed (Hilborn and Walters 1992). Variation in realized recruitment at any particular spawning stock size (process error) dominates recruitment measurement error.
- Stationarity—The average stock-recruitment relationship is constant over time (Hilborn and Walters 1992). That is, environmental conditions randomly affect survival independent of stock size or time.

In general, the methods we used to fit the models to the data followed those outlined in Hilborn and Walters (1992) and Froese (2008). The Ricker model, which assumes that the number of recruits increases to a maximum and then declines as the number of spawners increases, takes the form:

$$\boldsymbol{E(R) = \alpha S e^{-\beta S}}$$

where E(R) is the expected recruitment, S is spawner abundance, α is the number of recruits per spawner at low spawning levels, and β describes how quickly the recruits per spawner drop as the number of spawners increases. We estimated K_R as:

$$\boldsymbol{K_R = \left(\frac{\alpha}{\beta}\right) e^{-1}}$$

and K_{sp} as:

$$\boldsymbol{K_{sp} = \frac{1}{\beta}}$$

The Beverton-Holt model assumes that the number of recruits increases constantly toward an asymptote as the number of spawners increases. After the asymptote is reached, the number of recruits neither increases nor decreases. The asymptote represents the maximum number of recruits the system can support (i.e., carrying capacity for the system; K_R). The Beverton-Holt curve takes the form:

$$\boldsymbol{E(R) = \frac{(\alpha S)}{(\beta + S)}}$$

where E(R) and S are as above, α is the maximum number of recruits produced (K_R), and β is the number of spawners needed to produce (on average) recruits equal to one-half the maximum number of recruits. Because $K_{sp} = \infty$ in the Beverton-Holt model, we estimated K_{sp} as the number of spawners needed to produce 0.99(K_R).

Like the Beverton-Holt model, the smooth hockey stick model assumes that the number of recruits increases toward an asymptote (carrying capacity; K_R) as the number of spawners increases. After the carrying capacity is reached, the number of recruits neither increases nor decreases. The carrying capacity represents the maximum number of recruits the system can support. This curve

takes the form (Froese 2008):

$$\boldsymbol{E(R) = R_\infty\left(1 - e^{-\left(\frac{\alpha}{R\infty}\right)S}\right)}$$

where E(R) and S are as above, α is the slope at the origin of the spawner-recruitment curve, and R_∞ is the carrying capacity of recruits (note that $R_\infty = K_R$). As with the Beverton-Holt model, we estimated K_{sp} as the number of spawners needed to produce $0.99(K_R)$.

We used non-linear regression to fit the three models to spawner-recruitment data. Before fitting the models, we transformed recruitment data using natural logs. We estimated bias and uncertainty measures (95% CI) for the model parameters using bootstrap procedures, which assumed that the {R, S} sample represented or approximated the population. The number of bootstrap samples was 3,000. We computed and stored the non-linear regression results for each bootstrap sample. We then calculated the bootstrap 95% CI by arranging the 3,000 bootstrap parameter values in sorted order and selected the 2.5 and 97.5 percentiles from the list.

We used Akaike's Information Criterion for small sample size (AIC_c) to determine which model(s) best explained the relationship between spawners and recruitment in the supplemented and reference populations. AIC_c was estimated as:

$$\boldsymbol{AIC_c = -2log\big(£(\theta|data)\big) + 2K + \left(\frac{2K(K+1)}{n-K-1}\right)}$$

where *log(£(θ|data))* is the maximum likelihood estimate, *K* is the number of estimable parameters (structural parameters plus the residual variance parameter), and *n* is the sample size (Burnham and Anderson 2002). We used least-squares methods to estimate *log(£(θ|data))*, which was calculated as $log(\sigma^2)$, where σ^2 = residual sum of squares divided by the sample size ($\sigma^2 = RSS/n$). AIC_c assessed model fit in relation to model complexity (number of parameters). The model with the smallest AIC_c value represented the "best approximating" model within the model set. Remaining models were ranked relative to the best model using AIC_c difference scores (ΔAIC_c), Akaike weights (w_i), and evidence ratios. Models with ΔAIC_c values less than 2 indicated that there is substantial support for these models as being the best-fitting models within the set (Burnham and Anderson 2002). Models with values greater than 2 had less support. Akaike weights are probabilities estimating the strength of the evidence supporting a particular model as being the best model within the model set. Models with small w_i values are less plausible as competing models (Burnham and Anderson 2002). If no single model could be specified as the best model, a "best subset" of competing models was identified using (1) AIC_c differences to indicate the level of empirical support each model had as being the best model, (2) evidence ratios based on Akaike weights to indicate the relative probability that any model is the best model, and (3) coefficients of determination (R^2) assessing the explanatory power of each model.

Stock-Recruitment Analysis

We successfully fit stock-recruitment models to the Chiwawa and reference population data. The span of spawner data for the Chiwawa and reference populations was greater than 14 times the minimum observed spawners, which should provide sufficient contrast for estimation of model parameters. In addition, the span of recruitment data was greater than 12 times the minimum observed recruitment, again providing sufficient contrast for estimation of parameters. The relationship between natural log R/S and spawners indicated that some of the highest productivities occurred at the lower spawner levels and the lowest productivities generally occurred at the highest spawner levels (Figure 15). This is consistent with the assumption of density-dependent mortality.

Although model fits were generally poor, explaining less than 40% of the residual variation in natural-log recruitment data, we were able to estimate average maximum recruitment levels (K_R) and the spawning levels needed to produce maximum recruitment (K_{sp}) (Table 24; Figure 15). For all populations examined, Akaike information criterion was unable to identify a best approximating model (i.e., ΔAIC_c values were less than 2, indicating support for all three models). However, evaluation of 95% CIs and the asymptotic correlation coefficients indicated that the smooth hockey stick model may be the best approximating model for each population. Therefore, we used estimates of K_R and K_{sp} derived from the smooth hockey stick model to correct for density dependence and different carrying capacities in treatment-reference comparisons.

As part of the regression diagnostics, we examined the dependence of the model residuals on time and found a significant ($P < 0.05$), positive, one-year-lag autocorrelation for the Entiat (0.562), Marsh (0.551), Sesech (0.564), and Little Wenatchee (0.629) populations. For the purposes of our work here, we did not attempt to correct for this one-year-lag correlation in the residuals. Future analyses will explore the use of autoregressive models (e.g., AR1; Noakes et al. 1987) to correct for autocorrelation.

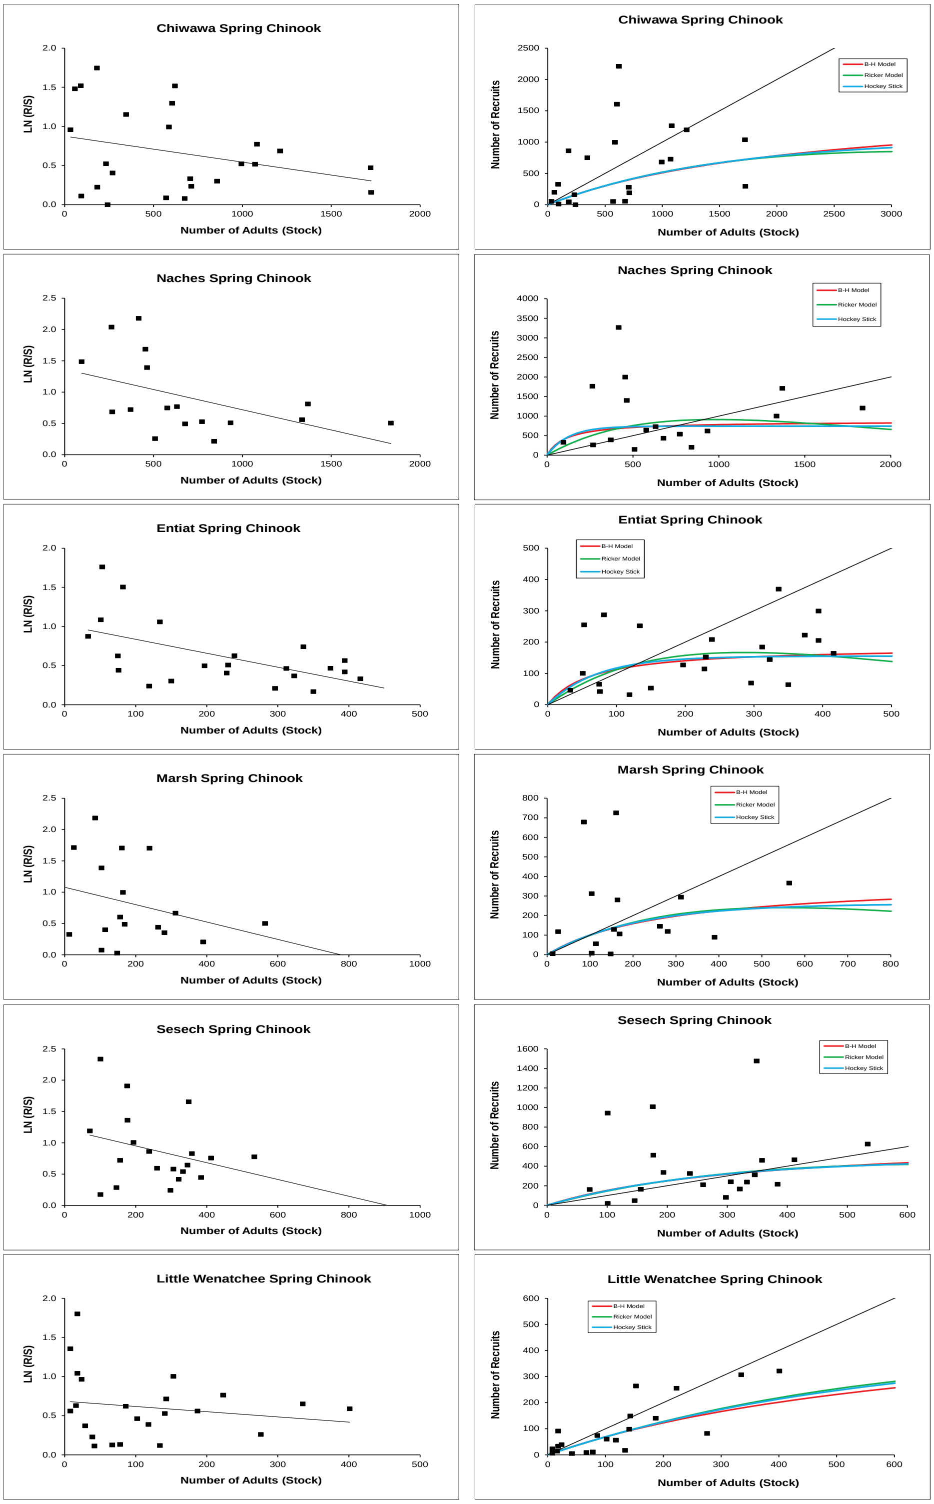

Figure 15. Relationships between natural log recruits/spawner (LN R/S) and spawners (Stock) in the Chiwawa and reference populations (figures on the left) and relationships between numbers of untransformed recruits and spawners in the Chiwawa and reference populations (figures on the right). Figures on the right also show the fit of the Ricker, Beverton-Holt, and the smooth hockey stick models to the data (black straight line represents R=S).

Table 24. Results from fitting Ricker, Beverton-Holt, and smooth hockey stick models to stock-recruitment data from the Chiwawa and reference populations. 95% CI on parameter estimates are based on 3,000 bootstrap trials; Corr coef = asymptotic correlation of the parameter estimates; K_R = maximum natural origin recruits (recruits at carrying capacity); K_{sp} = number of spawners needed to produce K_R; AICc = Akaike's Information Criterion for small sample size; Adj R^2 = coefficient of determination that is adjusted for the number of parameters in the model.

Method 1: Productivity Data Adjusted for Density Dependence

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects based on the smooth hockey stick model) using difference scores indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 25; Figure 16). All tests, regardless of treatment-reference pairs, indicated that productivity did not change significantly during the supplementation period, even though productivity did decrease during the supplementation period (Figure 16). These results are consistent with those based on unadjusted productivity data (Table 17). This is because most abundance estimates were below the level of assumed density dependence.

Table 25. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

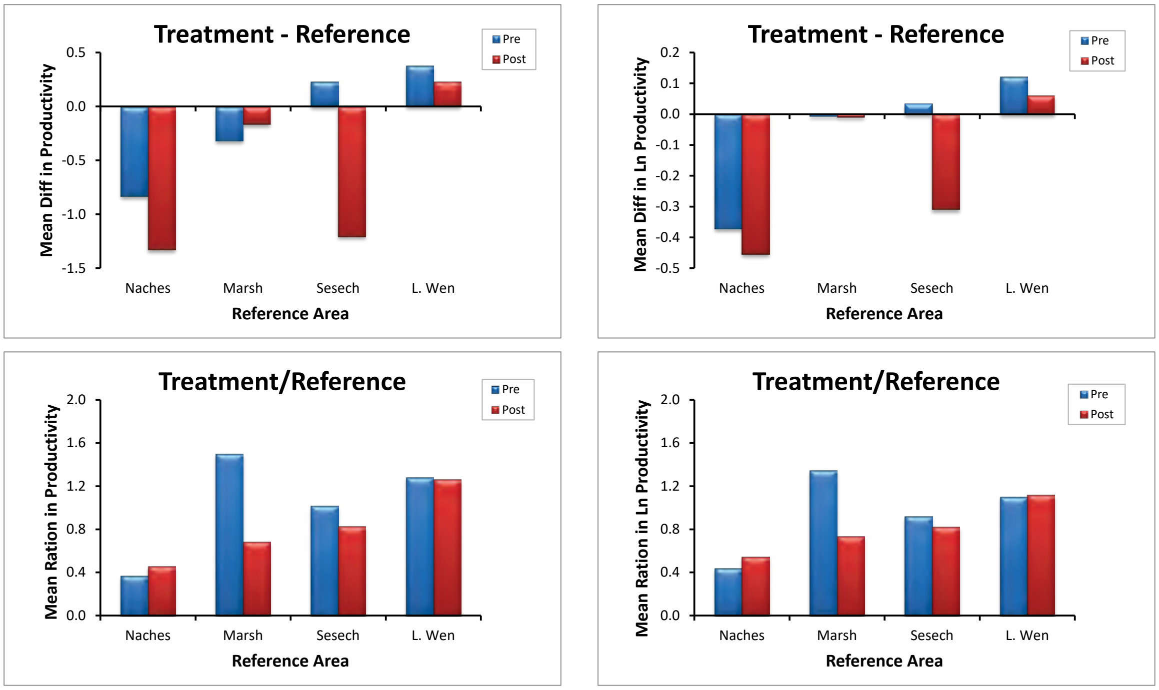

Figure 16. Mean differences (Treatment – Reference; figures on the top) and mean ratios (Treatment/Reference; figures on the bottom) of transformed and untransformed productivity data (adjusted for density dependence) before (pre) and after (post) spring Chinook supplementation in the Chiwawa Basin. Negative effects of supplementation on productivity are indicated when the pre-supplementation (blue) bars are greater than their corresponding post-supplementation (red) bars.

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 26; Figure 16). The Aspin-Welch test and the 95% CIs did indicate a significant effect when comparing the Chiwawa to the Marsh Creek population. These results are consistent with those using unadjusted productivity data (Table 20). Again, this is because most abundance estimates were below the level of assumed density dependence.

Table 26. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean ratios during the supplementation period were less than mean ratios during the pre-supplementation period.

Our analyses assume that there is a spawner abundance (K_{sp}) at which density-independent effects end and density-dependent effects begin. In reality, density-dependent effects occur at low spawning abundance and intensify as spawning abundance increases (evident in the changing slope of the three stock-recruitment curves used in our analyses). We did not account for these increasing density-dependent effects at spawner abundances less than K_{sp}. If we accounted for the increasing effects of density dependence at spawning abundances less than K_{sp}, the analysis with and without productivity adjustments may give different results.

Method 2: Fraction of Carrying Capacity Filled with NORs

We analyzed the effects of supplementation on filling the capacity of the habitat with natural-origin recruits. The smooth hockey stick model derived the carrying capacity (K_R) estimates for the Chiwawa and reference populations. The fraction of the carrying capacity filled with Chinook recruits before and during supplementation for the Chiwawa and reference populations is provided in Table 27. These data indicate that for the Chiwawa population, the mean fraction of the K_R filled with fish decreased significantly from the pre-supplementation period through the supplementation period (Table 27). Likewise, the Entiat and Little Wenatchee populations showed a significant decline in the mean fraction of K_R filled with adult recruits. In contrast, the mean fraction of K_R in the Naches and Marsh Creek populations increased during the same period (Table 27).[22] Interestingly, the fraction of K_R filled with adult recruits for all populations trended downward during the pre-supplementation period (Figure 17). During the supplementation period, however, the fraction of K_R filled with adult recruits trended upward for all populations. These results suggest that agents of mortality outside the Chiwawa and reference populations were reducing recruitment to the populations.

22 Although we do not show the results here, statistical analysis of the mean fraction of carrying capacity filled by adult recruits using natural-log transformed data produced the same result as using untransformed data. This was true for all populations.

Table 27. Fraction of the carrying capacity that was filled with Chinook salmon adult recruits in the Chiwawa and reference populations before (pre) and during (post) supplementation in Chiwawa Basin. The smooth hockey stick model estimated carrying capacity for each population. Statistical results from comparing the pre and post mean scores using the Aspin-Welch unequal-variance test are provided at the bottom of the table.

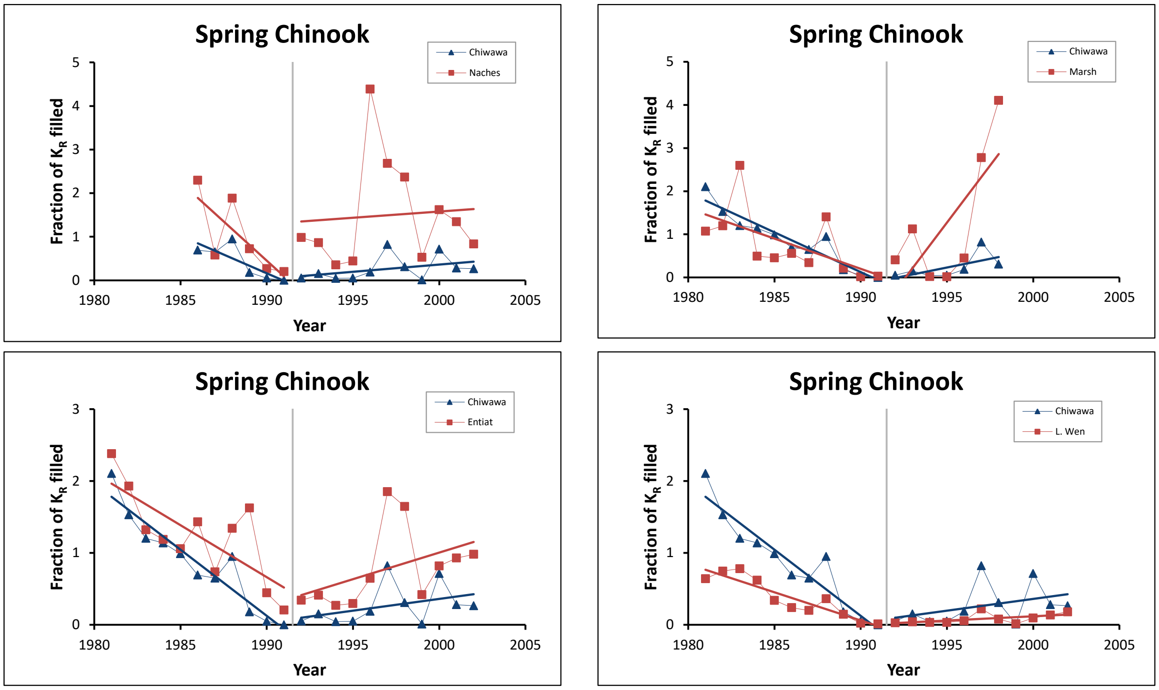

Figure 17. Trends in the fraction of the carrying capacity that was filled with Chinook salmon adult recruits in the Chiwawa and reference populations before (pre) and during (post) supplementation in Chiwawa Basin. The vertical lines in the figures separate the pre- and post-supplementation periods. The smooth hockey stick model estimated carrying capacity for each population.

We then compared the mean difference scores and ratios between the Chiwawa and reference populations before and during supplementation using data representing the fraction of K_R filled with adult recruits. In most of the Chiwawa-reference population comparisons, the absolute value of the mean difference between the fraction of K_R filled with recruits was greater in the supplementation period than during the pre-supplementation period; two of the four pairings were significant (Table 28; Figure 18). Analysis of difference scores using natural-log transformed data indicated that three of the four pairings were significant (Table 28).

Results from analyses using ratios were similar to results using difference scores. Mean ratio scores were generally smaller during the supplementation period than during the pre-supplementation period (Figure 18). This indicated that the mean fraction of K_R filled by adult recruits in most reference populations was greater during the supplementation period than during the pre-supplementation period (i.e., the denominator in the ratio increased between the pre- and post-supplementation periods). In contrast, the fraction of K_R filled by adult recruits in the Chiwawa decreased from the pre- to post-supplementation period (i.e., the numerator in the ratio decreased between the pre- and post-supplementation periods). Thus, unlike the Chiwawa population, the capacity of most reference populations was becoming more saturated during the period when the Chiwawa was being supplemented. Statistical analysis with mean ratios indicated that two of the four pairings were significant (Table 29).

Analyses comparing the Little Wenatchee with the Chiwawa indicate that adult recruits to the Little Wenatchee have been well below its carrying capacity. During the pre-supplementation period, the capacity of the Little Wenatchee was on average 37% saturated with adult recruits. During the supplementation period, the capacity of the Little Wenatchee declined to 8% saturation

with adult recruits (a 22% decline). The Chiwawa, during the pre-supplementation period, was on average 86% saturated. During the supplementation period, percent saturation in the Chiwawa decreased to 26% (a 30% decrease). During the same time periods, the capacity of the Entiat population, which until recently has been supplemented, declined from 124% to 78% saturation (a 63% decline).

Table 28. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on the fraction of the habitat capacity (K_R) that is filled with natural origin recruits. Analyses include both transformed and untransformed data. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

Comparing Stock-Recruitment Curves

As a final set of treatment and reference population comparisons, we compared the stock-recruitment curves of the Chiwawa population (using {R, S} data only from the supplementation period) to the reference populations (using all available {R, S} data). Specifically, we tested whether the regression parameters were equal between the Chiwawa population and the reference populations, and whether the fitted curves coincided between populations. Earlier in this report we described the data, methods, and results of fitting the Ricker, Beverton-Holt, and smooth hockey stick curves to the data. Because AIC_c was unable to identify a best approximating model, here we included all three models in our analyses. We tested the following hypotheses.

Parameter equivalence:

Ho: Stock-recruitment parameters (α and β) of the Chiwawa population = Stock-recruitment parameters of the reference populations.

Ha: Stock-recruitment parameters (α and β) of the Chiwawa population ≠ Stock-recruitment parameters of the reference populations.

Curve equivalence:

Ho: Modeled stock-recruitment curves of the Chiwawa population = Modeled stock-recruitment curves of the reference populations.

Ha: Modeled stock-recruitment curves of the Chiwawa population ≠ Modeled stock-recruitment curves of the reference populations.

We used two-sided randomization tests to test the null hypotheses of equal model parameters and that fitted curves coincided. Because the total number of permutations was in the millions, we used a Monte Carlo approach to randomly select 10,000 permutations. The test statistic for comparing the model parameters was formed by summing the difference between the population parameter estimates for each pair of populations. The test statistic for comparing the whole curve was formed by summing the difference between the estimated predicted values for each pair of populations at 500 equally spaced points along the curve.

Ricker Relationships

Ricker curves differed significantly between the Chiwawa and reference populations (Figure 19; Table 30). Interestingly, however, the parameters in the Ricker model did not differ significantly among most populations (Table 30). Only the β parameter differed significantly between the Chiwawa and Entiat populations.

In the Ricker model, the α parameter represents intrinsic productivity (i.e., recruits per spawner at low spawner densities). In this analysis, there was not enough evidence in the stock-recruitment data to reject the hypothesis of inequality in intrinsic productivity. Thus, this test was unable to demonstrate that supplementation, based on the Ricker curve, affected productivity in the Chiwawa population.

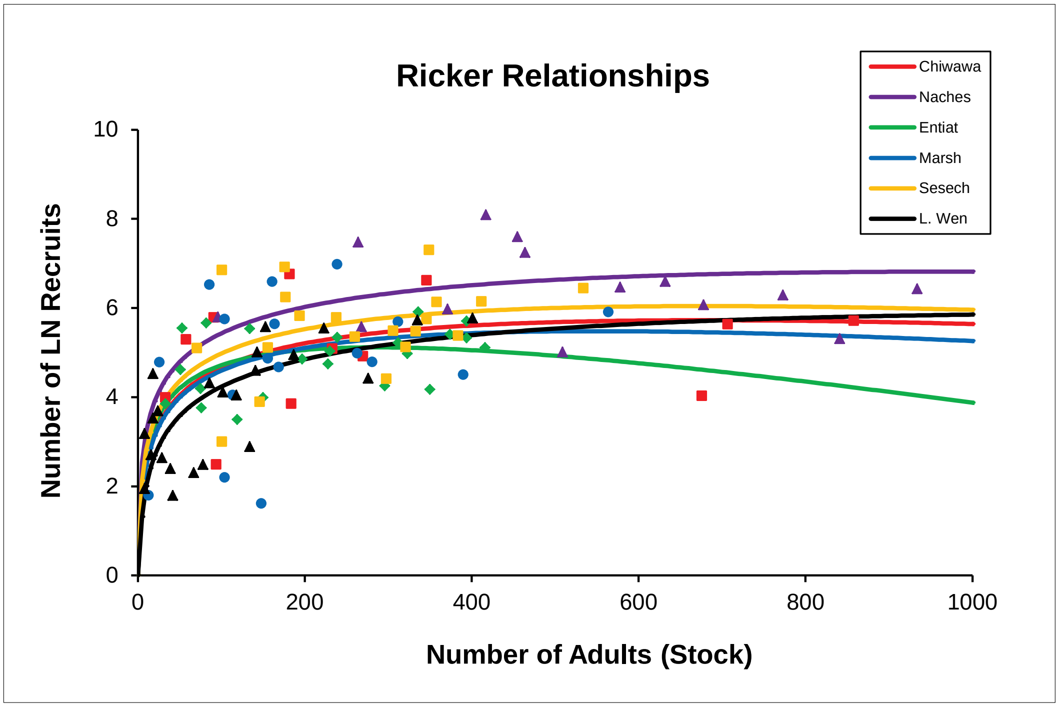

Figure 19. Scatter plot of the number of spawners and natural log adult recruits and fitted Ricker curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

Table 30. Randomization test results comparing the equality of Ricker curves and equality of parameter values (α and β). Randomization tests were based on 10,000 Monte Carlo samples. Equality or curves was based on 500 points along the x-axis (spawner abundance axis).

Curves tested	Curve inequality randomization P-value	Parameter inequality		
		Model Parameter		Randomization P-value
		Chiwawa	Reference

		β = 0.0015	β = 0.0008	0.203

Beverton-Holt Relationships

Beverton-Holt curves differed significantly only between the Chiwawa and Naches populations (Figure 20; Table 31). There was no significant difference in curves between the Chiwawa and the other reference populations. The parameters in the Beverton-Holt model did not differ significantly among any of the populations (Table 31). This was true even for the Chiwawa and Naches populations.

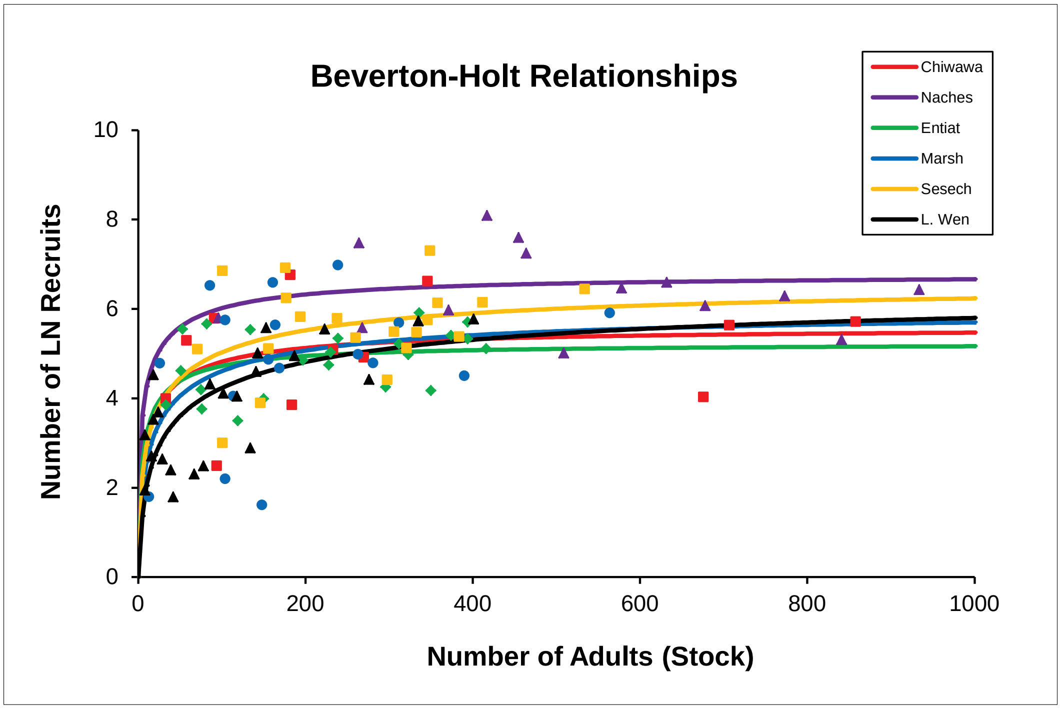

Figure 20. Scatter plot of the number of spawners and natural log adult recruits and fitted Beverton-Holt curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

Table 31. Randomization test results comparing the equality of Beverton-Holt curves and equality of parameter values (α and β). Randomization tests were based on 10,000 Monte Carlo samples. Equality or curves was based on 500 points along the x-axis (spawner abundance axis).

		β = 113.79	β = 725.87	0.751

Smooth Hockey Stick Relationships

Smooth hockey stick curves differed significantly between the Chiwawa and Naches populations and the Chiwawa and Sesech populations (Figure 21; Table 32). There was no significant difference in curves between the Chiwawa and the other reference populations. Most of the parameters in the smooth hockey stick model did not differ significantly among the populations (Table 32). However, the productivity parameter β did differ significantly between the Chiwawa and the Naches and the Chiwawa and Little Wenatchee populations. The β parameter for the Naches was significantly greater than the Chiwawa, while the β parameter for the Little Wenatchee was significantly less than the Chiwawa.

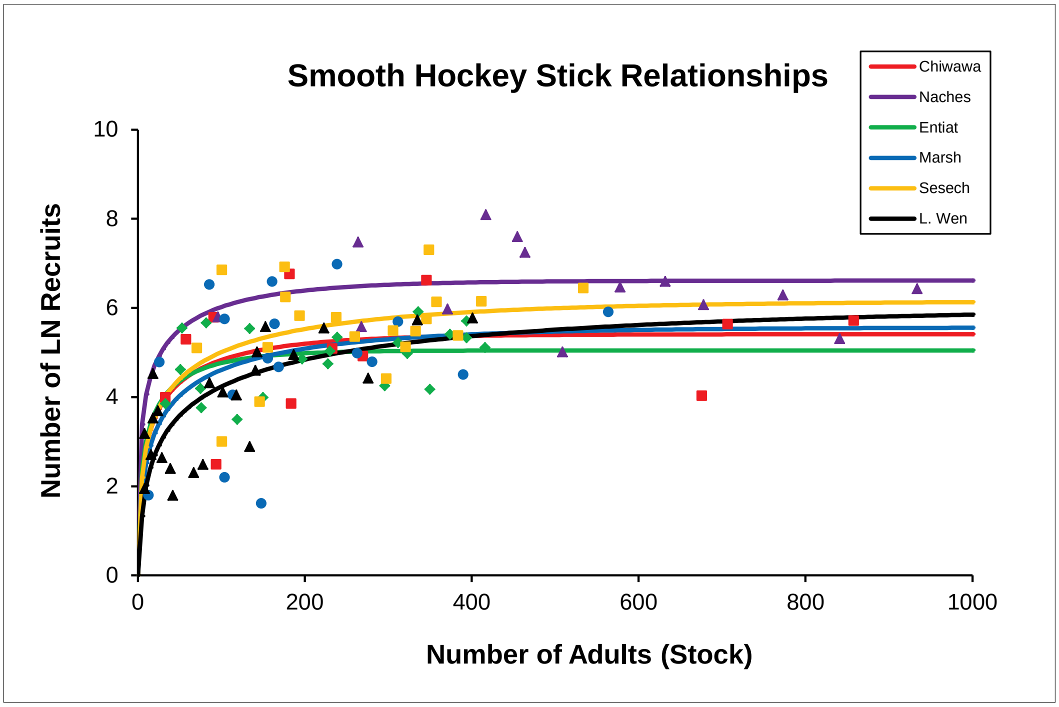

Figure 21. Scatter plot of the number of spawners and natural log adult recruits and fitted smooth hockey stick curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

Table 32. Randomization test results comparing the equality of smooth hockey stick curves and equality of parameter values (α and β). Randomization tests were based on 10,000 Monte Carlo samples. Equality or curves was based on 500 points along the x-axis (spawner abundance axis).

		β = 1.84	β = 0.75	0.000

Comparing different stock-recruitment curves and their parameters did not provide strong evidence that the supplementation program has negatively affected the productivity of the Chiwawa population.

Analysis without Reference Populations

In some cases, suitable reference populations may not exist to compare with supplemented populations. It is therefore important to have alternative analyses to assess supplementation effects. In this section, we describe methods that can be used to assess supplementation effects when suitable reference populations are not available. We discuss before-after comparisons, correlation analysis, and comparisons to standards as alternatives when reference populations are unavailable.

Before-After Comparisons

Before-after analyses compare population metrics (spawner abundance, NORs, and productivity) before supplementation to those during supplementation. In this case, data collected before supplementation represent the reference condition. The assumption is that population trajectories measured during the pre-supplementation period would continue in the absence of supplementation. We compared trends in abundance and productivity, mean abundance and productivity, and stock-recruitment relationships before and after supplementation.

Trend Analysis

Comparing trends before and after supplementation can be used to assess the effects of supplementation. Here, we compared the slopes of trends of spawner abundance, NORs, and productivity before and during supplementation using t-tests. If the hatchery program is successfully supplementing the natural spring Chinook population, the trend for spawner abundance and NORs during supplementation should be greater than the slope during the pre-supplementation period. For productivity, the slope during the supplementation period should increase or remain the same as that during the pre-supplementation period.

Visual examination of trends of Chiwawa data indicates that spawner abundance, NORs, and productivity decreased during the pre-supplementation period, but increased during the supplementation period (Figure 22). Only the changes in NOR trends were significant (Figure 22). This was true for both transformed and untransformed data.

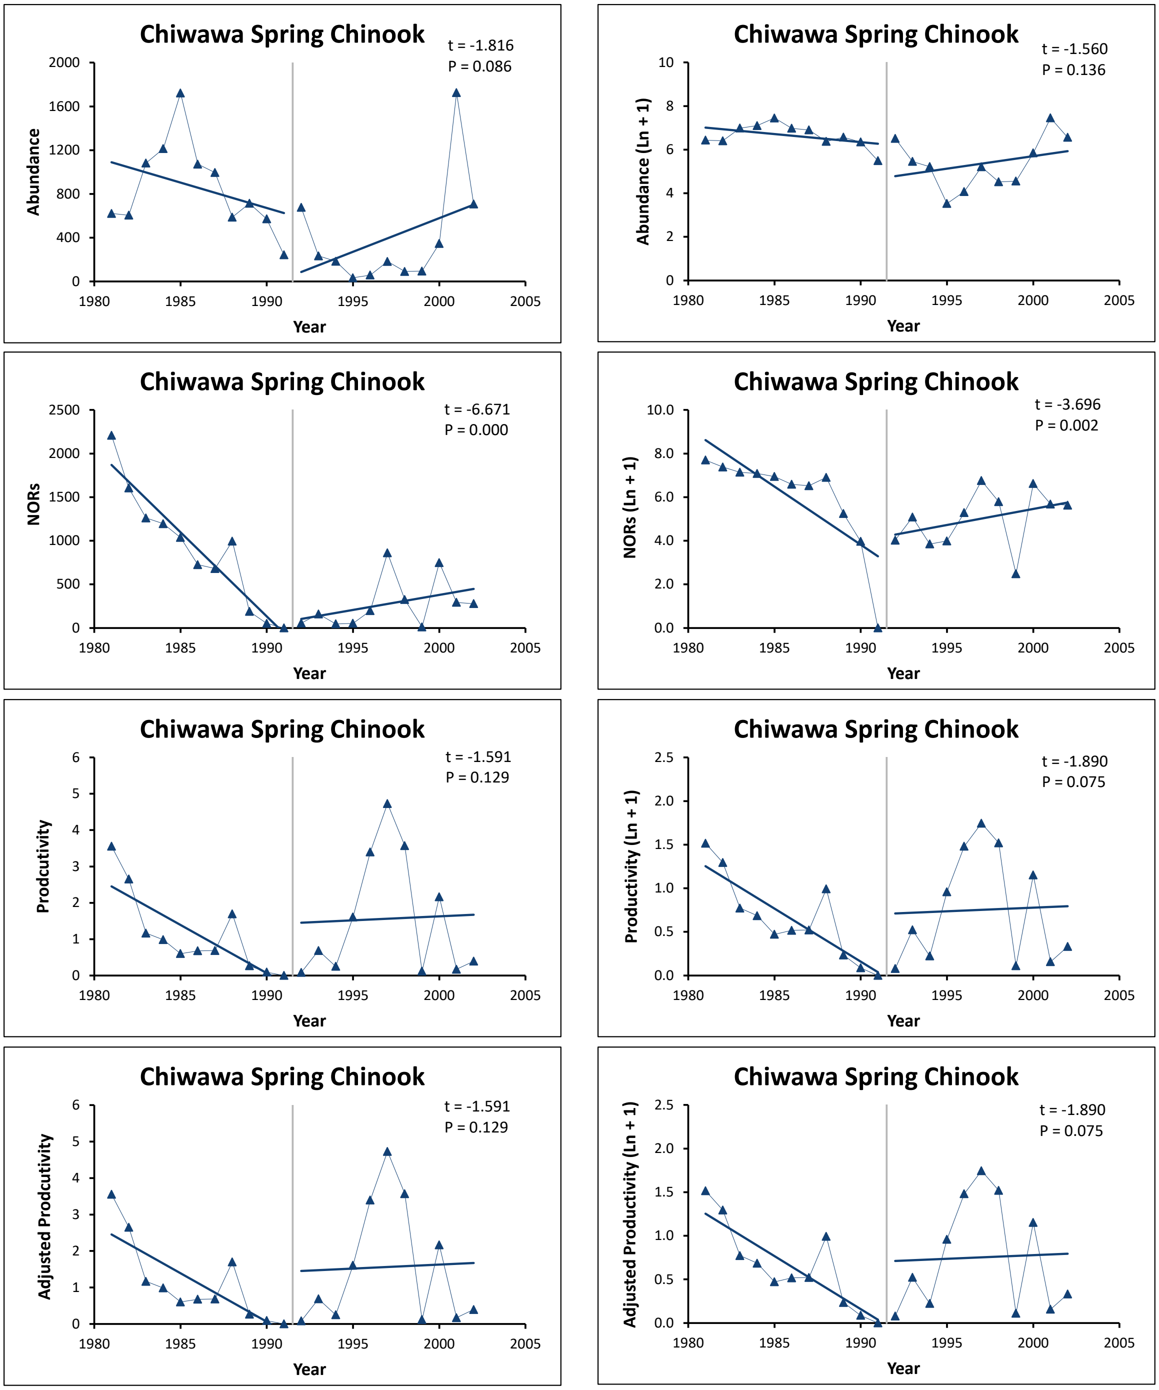

Figure 22. Trends in Chiwawa spring Chinook spawner abundance, natural-origin recruits (NORs), productivity (adults recruits per spawner), and adjusted productivity (adjusted for density dependence) before and during supplementation. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left show untransformed data; figures on the right include natural-log transformed data. Figures include results of t-tests comparing slope of trends before and during supplementation.

Analysis of Mean Scores

We also compared mean spawner abundance, NORs, and productivity data before and after supplementation. If the hatchery program is successfully supplementing the natural spring Chinook population, mean spawner abundance and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean productivity during the supplementation period should be equal to or higher than the pre-supplementation period. We tested the following statistical hypotheses.

Spawner Abundance and NORs:

Ho: Mean spawner abundance and NORs before supplementation ≥ Mean spawner abundance and NORs during supplementation.

Ha: Mean spawner abundance and NORs before supplementation < Mean spawner abundance and NORs during supplementation.

Productivity (Recruits/Spawner):

Ho: Mean productivity before supplementation ≤ Mean productivity during supplementation.

Ha: Mean productivity before supplementation > Mean productivity during supplementation.

We tested before-after supplementation effects using a one-tailed Aspin-Welch unequal-variance test. We also used a randomization test, based on 10,000 Monte Carlo simulations, to assess differences in spawner abundance and productivity before and during supplementation. The randomization procedure only allowed the testing of two-tailed hypotheses. Therefore, we generated 95% confidence intervals on the mean difference (μ_{pre} - μ_{post}) using bootstrapping methods to determine if the significant result from the randomization test was in the right direction. We generated 5,000 bootstrap samples to calculate confidence intervals.

Mean spawner abundance during the supplementation period was significantly less than the pre-supplementation spawner abundance (Table 33). Mean spawner abundance decreased 46% between the pre- and post-supplementation periods. Likewise, mean NORs decreased significantly between the two periods (Table 33). On the other hand, productivity increased slightly, but not significantly, between the pre- and post-supplementation periods (Table 33). This was true for both adjusted and transformed productivity data.

Table 33. Statistical results comparing mean scores of spawner abundance, natural-origin recruits (NORs), and productivity (using both untransformed and natural-log transformed) before and during supplementation of Chiwawa spring Chinook. Randomization tests were based on 10,000 Monte Carlo samples and 95% CI were based on 5,000 bootstrap samples.

Population metric	Mean scores		Test on means			
			Aspin-Welch test		Random test P-value	Bootstrap 95% CI
	Before	During	t-value	P-value

Adj Productivity	1.12	1.56	-0.721	0.759	0.477	-1.54 – 0.71
LN Adj Productivity	0.64	0.75	-0.450	0.671	0.652	-0.57 – 0.34

Analysis of Stock-Recruitment Curves

The third method compared stock-recruitment curves of the Chiwawa population during supplementation with those generated before supplementation. Specifically, we tested whether the regression parameters were equal between the pre- and post-supplementation periods, and whether the fitted curves coincided between the two time periods. We used the methods described earlier to fit the Ricker, Beverton-Holt, and smooth hockey stick curves to the two data sets. We tested the following hypotheses.

Parameter equivalence:

Ho: Stock-recruitment parameters (α and β) of the pre-supplementation period = Stock-recruitment parameters of the supplementation period.

Ha: Stock-recruitment parameters (α and β) of the pre-supplementation period ≠ Stock-recruitment parameters of the supplementation period.

Curve equivalence:

Ho: Modeled stock-recruitment curves from the pre-supplementation period = Modeled stock-recruitment curves from the pre-supplementation period.

Ha: Modeled stock-recruitment curves from the pre-supplementation period ≠ Modeled stock-recruitment curves from the pre-supplementation period.

We were only able to fit stock-recruitment curves to the post-supplementation data. Non-linear regression was unable to converge on a solution using only pre-supplementation data. Therefore, we were unable to use this method to test supplementation effects on the Chiwawa spring Chinook population. If we could have fit curves to both the pre- and post-supplementation periods, we would have used two-sided randomization tests to evaluate the null hypotheses of equal model parameters and that fitted curves coincided.

Before describing correlation approaches, it is important to note that comparing before-after data can sometimes be misleading. For example, the spawner abundance, NORs, and productivity data presented in Figure 22 suggest that supplementation is increasing the abundance and productivity of spring Chinook in the Chiwawa Basin. However, when we compared these trends to those from reference populations during the same time periods (Figures 9-11), it becomes clear that supplementation was not responsible for increasing the trends in spawner abundance, NORs, and productivity of the Chiwawa population. Thus, whenever possible, it is wise to compare before-after data with a reference population.

Correlation Analyses

A simple way to see if the supplementation program is increasing or decreasing productivity is to assess the association between the proportion of adult spawners that are made up of hatchery adults (pHOS) and productivity (recruits/spawner). If the supplementation program is working as planned, the increase in hatchery fish spawning naturally should increase the productivity of the population. It should not decrease the productivity of the population.

We tested the association between pHOS and adult productivity[23] using Pearson correlation. During the pre-supplementation period, productivity averaged 1.13 recruits/spawner; during the supplementation period, productivity averaged 1.39 recruits/spawner. This increase in productivity did not appear to be strongly correlated to pHOS (Figure 23). Correlation analysis showed that there was no significant association between pHOS and productivity, even though productivity increased with increasing pHOS.

23 Note that the analysis could also include juvenile productivity (e.g., smolts/spawner).

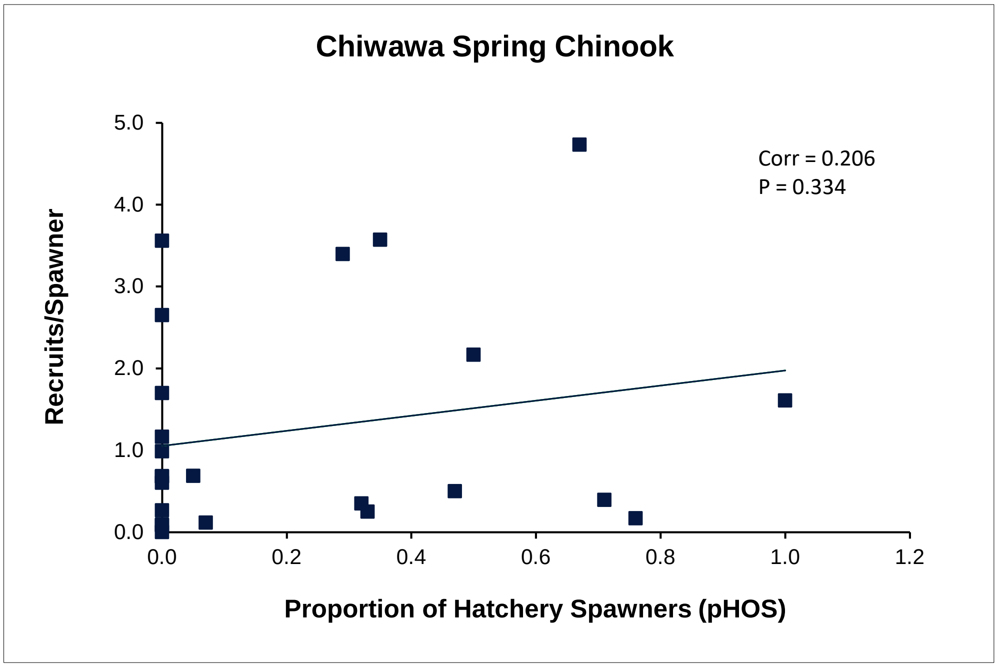

Figure 23. Association between the proportion of spawners that are made up of hatchery adults (pHOS) and the number of natural-origin recruits. The Pearson correlation coefficient (Corr) and its P-value (P) are shown in the figure.

The association between pHOS and productivity can also be assessed by testing the correlation between pHOS and the residuals from stock-recruitment curves fitted to the Chiwawa spawner and natural-origin recruitment data. This approach removes the effects of density dependence on the relationship between pHOS and productivity. A significant negative association provides evidence that hatchery-origin spawners may not be as productive as natural-origin spawners.

The Ricker, Beverton-Holt, and smooth hockey stick models were fit to the Chiwawa stock and recruitment data (including {S, R} data from both the pre- and post-supplementation period, 1981-2004) using methods described earlier. Residuals were calculated by subtracting the predicted recruitment values from the observed (modeled) values. Pearson correlation then tested the association between pHOS and the residuals from each model.

Although there was a negative trend in residuals with increasing pHOS, suggesting that hatchery-origin spawners may not be as productive as natural-origin spawners, the association was not significant (Figure 24). Thus, based on these analyses, there is no strong evidence that the supplementation program has significantly benefited or harmed the natural spring Chinook population.

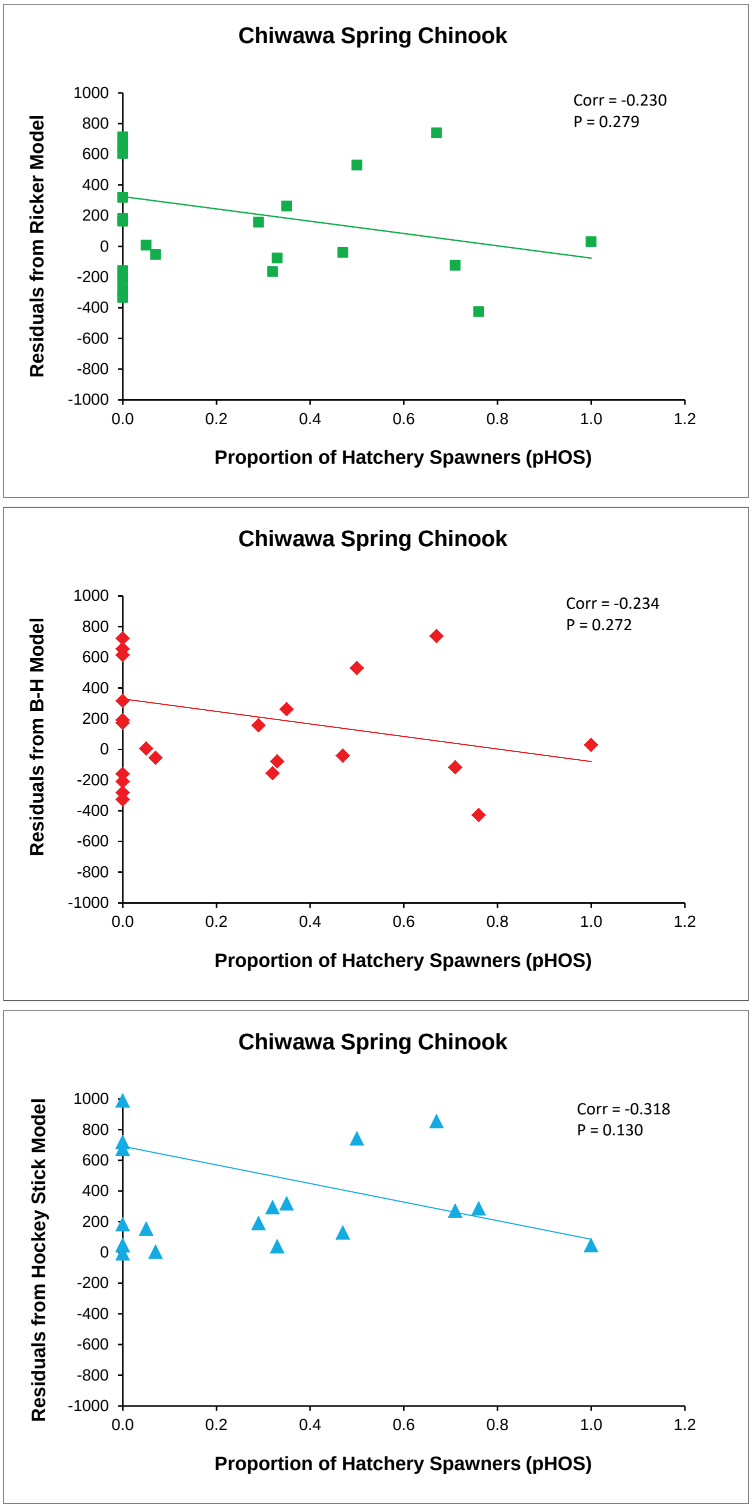

Figure 24. Association between the proportion of spawners that are made up of hatchery adults (pHOS) and the residuals from Ricker, Beverton-Holt (B-H), and smooth hockey stick stock-recruitment models. The Pearson correlation coefficient (Corr) and its P-value (P) are shown in the figures.

Comparison to Standards

In those cases in which suitable reference populations are not available and there are no pre-supplementation data, the investigator is left with comparing population parameters to relevant standards. Standards can include performance of natural-origin fish in similar environments (a type of reference condition), mitigation requirements, quantitative objectives of the program, Biological Assessment and Management Plan (BAMP) values, or other appropriate standards. An example of a statistical hypothesis would be:

Ho: Productivity (Recruits/Spawner) of the supplemented population ≥ standard productivity.

Ha: Productivity (Recruits/Spawner) of the supplemented population < standard productivity.

For these analyses to be useful, the standards must be based on biological reality.

Conclusions and Recommendations

Hatcheries are an important component of fish production within the Upper Columbia Basin. The goal of some of these programs is to supplement natural production in declining populations. The supplementation programs generally use both hatchery and natural (spawned and reared in nature from either wild or hatchery parents) adults for hatchery broodstock. These programs are designed to supplement natural populations by increasing natural reproduction while preventing the establishment of a domesticated hatchery stock. Thus, the programs should increase total spawning escapement and NORs, and not reduce the productivity of the natural population. Measuring the success of these programs is challenging and expensive.

In this paper, we described methods that can be used to determine if supplementation programs are achieving some of their goals. This paper focused on the use of reference populations to determine if the supplementation programs increase total spawning escapement, NORs, and maintain or increase productivities. In some cases, suitable reference populations may not be available (e.g., we found no suitable reference populations for Upper Columbia steelhead and sockeye). In these cases, alternative methods are needed to assess supplementation effects. We also described these alternative methods in this paper.

Identification of Reference Populations

Finding suitable reference populations that match well with supplemented populations is a difficult and time-consuming process. Our three-step selection process included identification of populations with similar life-history characteristics, few or no hatchery spawners, a long time series of accurate abundance and productivity estimates, and similar freshwater habitat impairments and out-of-basin effects. Those populations that met these criteria were then examined for their relationship with the supplemented population (in this case, the Chiwawa spring Chinook population). Several criteria were scored, including pNOS, correlation, trend, and effect size. Reference populations with total weighed scores of 81 or greater were selected as suitable reference populations.

This selection process provided a valuable framework for selecting suitable reference populations for supplemented populations. Interestingly, we found that a given reference population may match well with one parameter of the supplemented population (e.g., spawning escapement), but not for all parameters (e.g., not NORs or productivity). The reason for this may be related to errors

in the estimation of population parameters and/or differential factors limiting population parameters of supplemented and reference populations. Therefore, depending on the parameter analyzed, a different suite of reference populations may be needed.

An important assumption in the use of reference populations is that the supplemented and reference populations that tracked each other before supplementation would continue to track each other in the absence of supplementation. Given that the reference populations did not match the Chiwawa population on all criteria examined, and some reference populations tracked the Chiwawa population more poorly than others, there may be some uncertainty as to whether differences observed between the supplemented and reference populations during the supplementation period are associated with the hatchery program, or other unaccounted factors. For example, any large-scale change (man-made or natural) within the reference or supplemented population could affect our ability to assess the effectiveness of the supplementation program.

To account for some of these uncontrollable factors, we recommend the use of a "causal-comparative" approach to strengthen the certainty of our inferences. This approach relies on correlative data to try and make a case for causal inference. We recommend that the following state variables be measured and tracked within the supplemented and reference populations: mean annual precipitation, total and riparian forest cover, road density, impervious surface, and alluvium. These variables can be used to describe differences in water temperatures at different life stages (pre-spawning, egg incubation, and summer rearing) and substrate characteristics, including fine sediments and embeddedness. These state variables can be used to help explain possible changes in spawner abundance, NORs, and productivity that are independent of supplementation. In addition, the use of multiple reference streams reduces the possibility that man-made changes to a single reference stream will influence the interpretation of the results.

Analyses with Reference Populations

Using reference populations, we evaluated the effects of supplementation on natural-log transformed and untransformed total spawning escapement, NORs, and productivity by comparing trends, analyzing mean differences, ratios, and rates, and comparing stock-recruitment curves and their parameters. For trend analysis, we compared the slopes of the trends between each supplemented/reference pair before and during supplementation. If the hatchery program is successfully supplementing the natural population, trends in spawner abundance and NORs should deviate significantly during the supplementation period (i.e., the slope of the supplemented population should be greater than the slopes of the reference populations during the supplementation period), but not during the pre-supplementation period. For productivity, the slope of the supplemented population, relative to the reference population, should increase or remain the same.

Because trend analysis only tests the slopes of the trend lines, it does not test for differences in elevations of the trend lines, additional analyses were needed to determine if supplementation increased spawner abundance, NORs, and productivity of the target population without changing the slopes of the trend lines. To do this, we derived three different response variables using natural-log transformed and untransformed spawner abundance, NORs, and productivity data. The first derived variable included difference scores, which were calculated as the difference between paired treatment and reference data (T-R). The second included ratios, which were calculated as the ratio of paired treatment and reference data (T/R). Finally, we calculated the differences in annual changes in paired treatment and reference population data (ΔT-ΔR). If the hatchery

program is successfully supplementing the natural population, the mean difference or ratio score of paired spawner abundance data and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean difference or ratio score during the supplementation period should be equal to or higher than the pre-supplementation period.

As a final set of analyses, we compared the stock-recruitment curves of the supplemented population (using stock and recruitment data only from the supplementation period) to the reference populations (using all available stock and recruitment data). Specifically, we tested whether the regression parameters were equal between the supplemented population and the reference populations, and whether the fitted curves coincided between populations. Here, we were most interested in comparing the productivity parameters in the models.

Surprisingly, these different analyses yielded similar results when they were applied to the Chiwawa spring Chinook and reference population data. Trend analysis was unable to detect a significant difference in trends between the supplemented and reference populations during the supplementation period. Even though we measured an increasing trend in spawner abundance, NORs, and productivity in the supplemented population during the supplementation period, these same parameters trended upward in the reference populations. Likewise, we were unable to detect a significant supplementation effect using difference scores, ratios, and differences in annual changes. However, we found the results from analysis of mean differences of annual change difficult to interpret and they may be insensitive to treatment effects. A simpler analysis, which is also easier to interpret, is to use trend analysis. Finally, comparing stock-recruitment curves and their parameters did not provide strong evidence that supplementation has affected the productivity of the natural population.

Based on these results, we do not recommend using difference scores of annual change (ΔT-ΔR), nor do we recommend comparing stock-recruitment curves and their parameters. As noted above, difference scores of annual change are difficult to interpret and may be redundant with trend analysis. Testing stock-recruitment curves and their parameters appears redundant with testing differences in productivity using difference scores or ratios. In addition, the analyses are computer intensive and do not appear to be very sensitive to changes.

There was little difference in results using difference scores and ratios. It appears that ratios may be more sensitive to change than difference scores (e.g., we found significant differences in some comparisons using ratios but not with difference scores), but ratios can be more difficult to interpret than difference scores. Nevertheless, we recommend the use of ratios in future analyses.

Correcting for Density Dependence and Carrying Capacity

The analyses described so far assumed that the density of spawners or recruits did not affect the survival and productivity of fish. However, without controlling for density effects, productivity of the population would continue to decline with increasing abundance. This scenario could occur in supplementation programs that increase the number of spawners, and could result in lower productivities relative to reference populations. In addition, lower productivities may be caused by differential environmental carrying capacities rather than the capacity of the supplemented fish to produce offspring. Therefore, we described two different methods for deriving density-corrected estimates of productivity. The first controlled the effects of density on productivity by partitioning observed productivities into density-independent and density-dependent productivity. These productivities were then combined in a single test. The second method corrected for differences in carrying capacities between the supplemented and reference populations. This was accomplished

by calculating the percent saturation of NORs, which was estimated as the ratio of observed NORs to the maximum number of NORs that the habitat could support.

We fit Ricker, Beverton-Holt, and smooth hockey stick models to stock and recruitment data to estimate the maximum number of NORs (NORs at carrying capacity) and the maximum number of spawners needed to produce maximum NORs. We fit models to the supplemented and reference populations. Using information-theoretic criterion and evaluating the precision of estimated parameters, we found that the smooth hockey stick model provided the best estimates of maximum NORs and spawners. We used these modeled values to estimate density-independent and density-dependent productivities, and saturation of NORs.

Statistical analyses, using difference scores and ratios of adjusted Chiwawa spring Chinook productivity data, found no significant effects of supplementation on the productivity of the supplemented population. Indeed, the results from correcting for density dependence were similar to those without correcting for density dependence. This is in part because the abundance of the supplemented and reference populations has been below their respective carrying capacities in most years. This was clearly demonstrated in the analyses of NORs corrected for carrying capacity. In the supplemented population, the mean fraction of the carrying capacity filled with NORs decreased significantly during the supplementation period. In other words, the carrying capacity was filled with more NORs during the pre-supplementation period than during the supplementation period, which is contrary to the goal of supplementation. By comparison, two of the reference populations showed a similar decrease in saturation, while the other two reference populations actually increased in saturation. Analyzing the saturation scores using BACI-design analyses indicated that two of the four pairings differed significantly. That is, the percent saturation of the supplemented population decreased significantly relative to two reference populations.

Because productivity can be affected by the abundance of spawners and recruits, we recommend that future analyses comparing supplemented and reference populations adjust for density-dependent effects and differential carrying capacities. Although we detected only slight differences between adjusted and unadjusted results, as supplemented stocks recover, it will become more important to adjust productivities to account for density dependence. Importantly, the analyses using percent saturation placed NORs in the context of the carrying capacity of the environment. This will help managers determine if supplementation programs are filling or over-filling the capacity of the habitat with NORs.

As we noted earlier, analyses using productivities adjusted for density dependence assume that there is a spawner abundance at which density-independent effects end and density-dependent effects begin. In reality, density-dependent effects occur at low spawning abundance and intensify as spawning abundance increases. We did not account for these increasing density-dependent effects at lower spawner abundances. This is an area that needs additional attention.

Analyses without Reference Populations

Because of the rigorous criteria we used to select reference populations, it is likely that reference populations may not exist for making comparisons with supplemented populations. For example, we used the criteria described in this paper to identify reference populations for supplemented steelhead and sockeye populations in the Upper Columbia Basin. We were unsuccessful in identifying any suitable reference populations. Therefore, in the absence of suitable reference populations, it is important to have alternative methods for assessing supplementation effects. We described three different types of analyses one can use to assess supplementation effects in the

absence of reference populations. They include before-after comparisons, correlation analysis, and comparisons to standards.

Before-after analyses compare population metrics before supplementation with those during supplementation. In this case, data collected before supplementation represent the reference condition. The assumption is that population trajectories measured during the pre-supplementation period would continue in the absence of supplementation. We compared trends in spawner abundance, NORs, and productivity before and after supplementation. In addition, we compared mean scores in these three parameters before and after supplementation. Finally, we attempted to compare stock-recruitment parameters before and after supplementation. The hypotheses examined were that the spawner abundance and NORs would be greater during the supplementation period, and that productivities would not decline during the supplementation period.

Trend analysis indicated that the all three Chiwawa spring Chinook population parameters trended downward during the pre-supplementation period, but trended upward during supplementation. On the other hand, mean spawner abundance and NORs were lower during the supplementation period than during the pre-supplementation period. Mean productivities increased, but not significantly, during the supplementation period. We were unable to compare pre- and post-supplementation stock-recruitment curves because we were unable to fit stock-recruitment models to the pre-supplementation data.

We used correlation analyses to determine if the proportion of hatchery-origin fish that spawn naturally on the spawning grounds (pHOS) increased productivity. In addition, we used correlation to assess the association between pHOS and the residuals from stock-recruitment relationships. A significant negative association provides evidence that hatchery-origin spawners may not be as productive as natural-origin spawners. The analysis indicated that the productivity of Chiwawa spring Chinook increased with increasing pHOS, but the association was not significant. In contrast, there was a negative association between pHOS and the stock-recruitment residuals, but again the association was not significant. The latter analysis accounts for density-dependent effects.

In concert, the before-after comparisons and correlation analyses do not provide conclusive evidence that the supplementation program has increased spawner abundance and NORs, or that it has significantly reduced the productivity of the supplemented population. Although increasing the number of hatchery fish on the spawning grounds appears to reduce NORs and productivity, mean productivity actually increased during the supplementation period compared to the pre-supplementation period.

It is important to note that relying on only one set of analysis could result in drawing a wrong conclusion. For example, if we had only conducted trend analysis, we may have concluded wrongly that the Chiwawa spring Chinook supplementation program significantly increased spawner abundance, NORs, and productivity in the supplemented population. The analysis of mean scores and correlations indicates that the supplementation program has not increased spawner abundance or NORs in the supplemented population. Therefore, in the absence of suitable reference populations, we recommend that analyses include the evaluation of trends, means scores, and correlations. By conducting more than one set of analyses, one can use weight-of-evidence to assess the effects of supplementation programs.

Under the scenario that there are no reference populations or pre-supplementation data, one is left with comparing population parameters to relevant standards. These standards could come from mitigation requirements, quantitative objectives, or published or unpublished standards. One could also use correlation to evaluate the association between productivity and pHOS, but this requires a wide range in pHOS values to be most effective. A more extreme approach, which probably would not gain much traction with managers, is to shutoff the supplementation program for some time and then evaluate the effects of the program in a before-after design. The Entiat spring Chinook hatchery program provides a unique opportunity to evaluate this type of management decision.

Some Concerns and Limitations

No matter how hard we try to explain different sources of variation in population data, we are limited by the quality of the data. Teasing out the effects of supplementation requires long time series of population data. Because funding levels and methods change over time, the quality (i.e., accuracy and precision) of the data also changes over time. Importantly, the population parameters examined in this paper (spawner abundance, NORs, and productivity) are rarely measured directly in the field. That is, other population metrics, such as numbers of redds, number of fish counted at weirs or dams, scales, tags, etc., are sampled in the field. These metrics are then used to calculate spawner abundance[24], NORs, and productivity, often based on assumptions about fish/redd, pre-spawning loss, marking rates, and sampling rates. This has a tendency to increase the variability in the data independent of supplementation programs. In our studies, we can only control sampling within the supplemented populations, and even that is limited by available funding. We have no control over the sampling within reference populations. Thus, we have to assume that sampling within the reference populations will continue and that sampling effort will remain comparable to that in the supplemented populations.

In our analyses, we included both the Entiat and Little Wenatchee populations as references for the Chiwawa population. In the analyses, we treated them as equivalent to the other reference populations. That is, the statistical procedures used to compare the supplemented population to each reference population were identical. This is appropriate. However, the interpretation of the results must be different when comparing the Entiat and Little Wenatchee to the supplemented population, because they are populations that were influenced by hatchery fish. As noted earlier, the Entiat spring Chinook hatchery program has been discontinued. Therefore, it provides a unique type of reference where the comparison changes from both populations being supplemented to only one population being supplemented. For the Little Wenatchee, nearly all the strays came from the Chiwawa program. Straying should stop or be greatly reduced with the change in water supply to the Chiwawa Rearing Ponds. In sum, one must be careful in how they interpret these test-reference results.

Finally, it is important to point out that for this paper, we conducted 463 statistical tests. Because we set our Type I error rate at 0.05, by random chance alone, we may have incorrectly rejected about 23 null hypotheses. Inasmuch as this work was designed to evaluate different ways to analyze test-reference data, the number of future analyses will be greatly reduced based on the results from this work. However, if the Type I error rate is a concern to managers, researchers can

[24] The smooth hockey stick model, which we used to estimate density-dependent correction factors for productivity and NORs, is sensitive to errors in spawner escapement estimates. Therefore, it is important to use accurate and precise estimates of spawner escapement.

use a lower error rate, such as α = 0.01. Another option is to analyze test-reference data graphically. Although this is subjective, there are no statistical analyses and therefore no concerns with violating assumptions of statistical tests, including temporal correlation. We believe researchers should use the statistical procedures recommended in this report to support graphic analysis.

Wenatchee Spring Chinook Hatchery Programs
Leavenworth Hatchery first release of spring Chinook (mostly subyearlings)
From 1941-1963, average release of subyearlings was 245,000 spring Chinook
Leavenworth Hatchery releases spring Chinook annually (2.2 M release goal). Broodstock mostly from Carson, Little White Salmon, and Cowlitz hatcheries.
Leavenworth Hatchery releases spring Chinook mostly from Icicle Creek broodstock.
Leavenworth production peaks at 4.6 M (2.3 M yearlings and 2.3 M subyearlings)
Leavenworth Hatchery Release Goal reduced to 1.6 M Smolts
White River Captive Broodstock Programs began
Nason Creek Captive Broodstock Programs began
Leavenworth ad-clips 100% of production
Leavenworth release goal lowered to 1.2M yearlings
First release of F2 Chinook from the White River Captive Program
Began stray management at Tumwater
Nason Creek Supplementation Program began with a release goal of 223,670 smolts (125,000 for conservation and 98,670 for safety net)
First release of Nason Creek Chinook smolts

WHO WE ARE

The UCSRB is a non-profit corporation of WA State, recognized as a 501(c)(3). The UCSRB fosters collaboration and cooperation among participating stakeholders, or those who are simply interested in river and forest restoration activities in the Upper Columbia region. Our board consists of three county commissioners and two tribal representatives.

WHAT WE DO

Our mission is to restore viable and sustainable populations of salmon, steelhead and other at-risk species through collaborative, economically sensitive efforts, combined resources, and wise resource management of the Upper Columbia region. Since 1999, the Upper Columbia Salmon Recovery Board (UCSRB) has been the forum for local collaboration to understand and address the complexities that our communities face in the wake of three federally listed salmonids (spring Chinook salmon, steelhead and bull trout).

“It is presumed that actions within all sectors (i.e., all Hs) are necessary to achieve recovery (see Section 5.6), but because different sectors involve different parties, different decision-making processes, and different timelines, this plan respects those differences and does not attempt to prioritize actions across Hs. Actions within each sector, however, have been identified by those parties and processes and are described and categorized in this plan as short-term (those that prevent extinction or decline of populations) and long-term (those that lead to recovery) actions.”

INTEGRATED RECOVERY GOALS

1. Achieve recovery of Upper Columbia spring Chinook salmon and of Upper Columbia steelhead, which will require coordinated actions in all of the management sectors affecting salmon.

2. Engage and collaborate with sector managers in finding and implementing solutions to identified issues.

UC RECOVERY PLAN HATCHERY OBJECTIVES

Short-Term (0-15 years)

• Continue to use artificial production to maintain critically depressed populations in a manner that is consistent with recovery and avoids extinction.
• Use artificial production to seed unused, accessible habitats.
• Use artificial production to provide for tribal and non-tribal fishery obligations as consistent with recovery criteria.
• Use harvest or other methods to reduce the proportion of hatchery-produced fish in naturally spawning populations
• To the extent possible use local broodstock in hatchery programs.
• To the extent possible, integrate federal, state, and tribal-operated hatchery programs that use locally derived stocks.
• Reduce the amount of in-basin straying from current hatchery programs.

UCSRB 2007

UC RECOVERY PLAN HATCHERY OBJECTIVES

Long—Term (50-100 years)

• Phase out the use of out-of-basin stock in the federal programs at Leavenworth and Entiat National Fish Hatcheries if continued research indicates that the programs threaten recovery of listed fish and those threats cannot be minimized through operational or other changes.

• Help develop ongoing hatchery programs that are consistent with recovery.

ADULT STRAYING

In terms of its relevance to hatchery management, straying of hatchery-produced fish and the subsequent interactions between stray hatchery-origin fish and natural-origin fish on the spawning grounds has been cited as a concern in some cases (Araki et al. 2008; Kostow 2009; Brenner et al. 2012). The level of concern for stray rates is related to the degree of relatedness between the hatchery- and natural-origin fish in a watershed. Hatchery fish derived from a local population may be allowed to stray into natural production areas at higher rates than those having out-of-basin ancestry. Low stray rates can maximize hatchery benefits and minimize hatchery risks by helping maintain local adaptation and genetic variation between stocks (Hillman et al. 2012).

Spring Chinook		Brood-Years (BYs) Assessed	Hatchery Program Avg BY Stray Rate
	Chiwawa Program	BY 05-09	37%
	Methow Program	BY 05-09	3%
	Twisp Program	BY 05-09	36%
	Chewuch Program	BY 05-09	39%
	WNFH Program	BY 05-09	36.5%
	LNFH Program (non-listed harvest)	BY 05-09	4.2%

1098

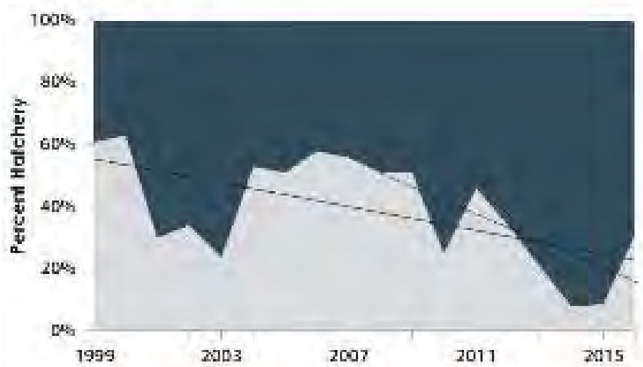
target number of natural-origin and hatchery-origin adult spring Chinook and steelhead collected for conservation program broodstock

610 SPRING CHINOOK (45% NOB)
488 STEELHEAD (45% NOB)

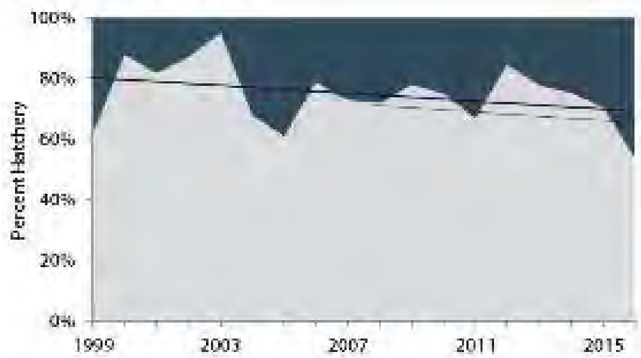
ADULT MANAGEMENT

defined as the intentional allocation of returning adult hatchery-origin adults to directly influence the number and origin composition of fish on spawning grounds. The primary goal of "adult management" is to enhance the numbers and success of naturally spawning adults. The primary objective of adult management is to attain as high a proportion of natural origin (NOR) adults on the spawning grounds as possible, while concurrently achieving an optimum spawning escapement goal and retaining appropriate numbers of broodstock (WDFW 2010).

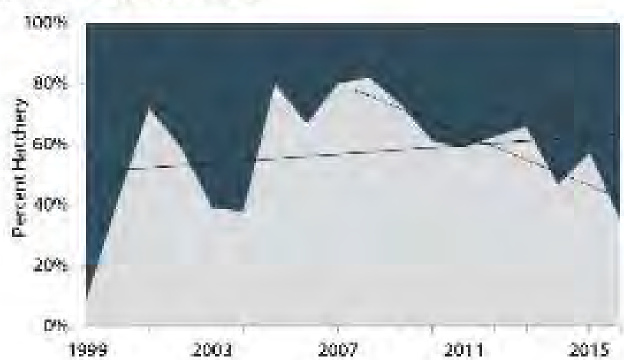
Entiat Spring Chinook



Methow Spring Chinook



Wenatchee Spring Chinook

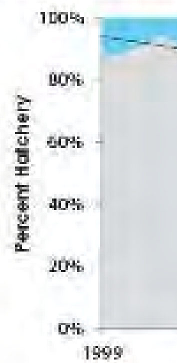


Percent Hatchery

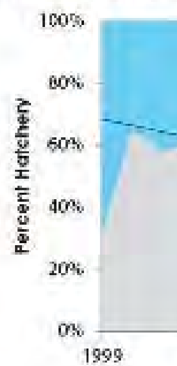
Recent pHOS Trend

Entiat Steelhead

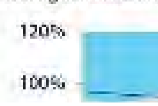
Methow Steelhea



Wenatchee Steelhe



Okanogan Steelhe

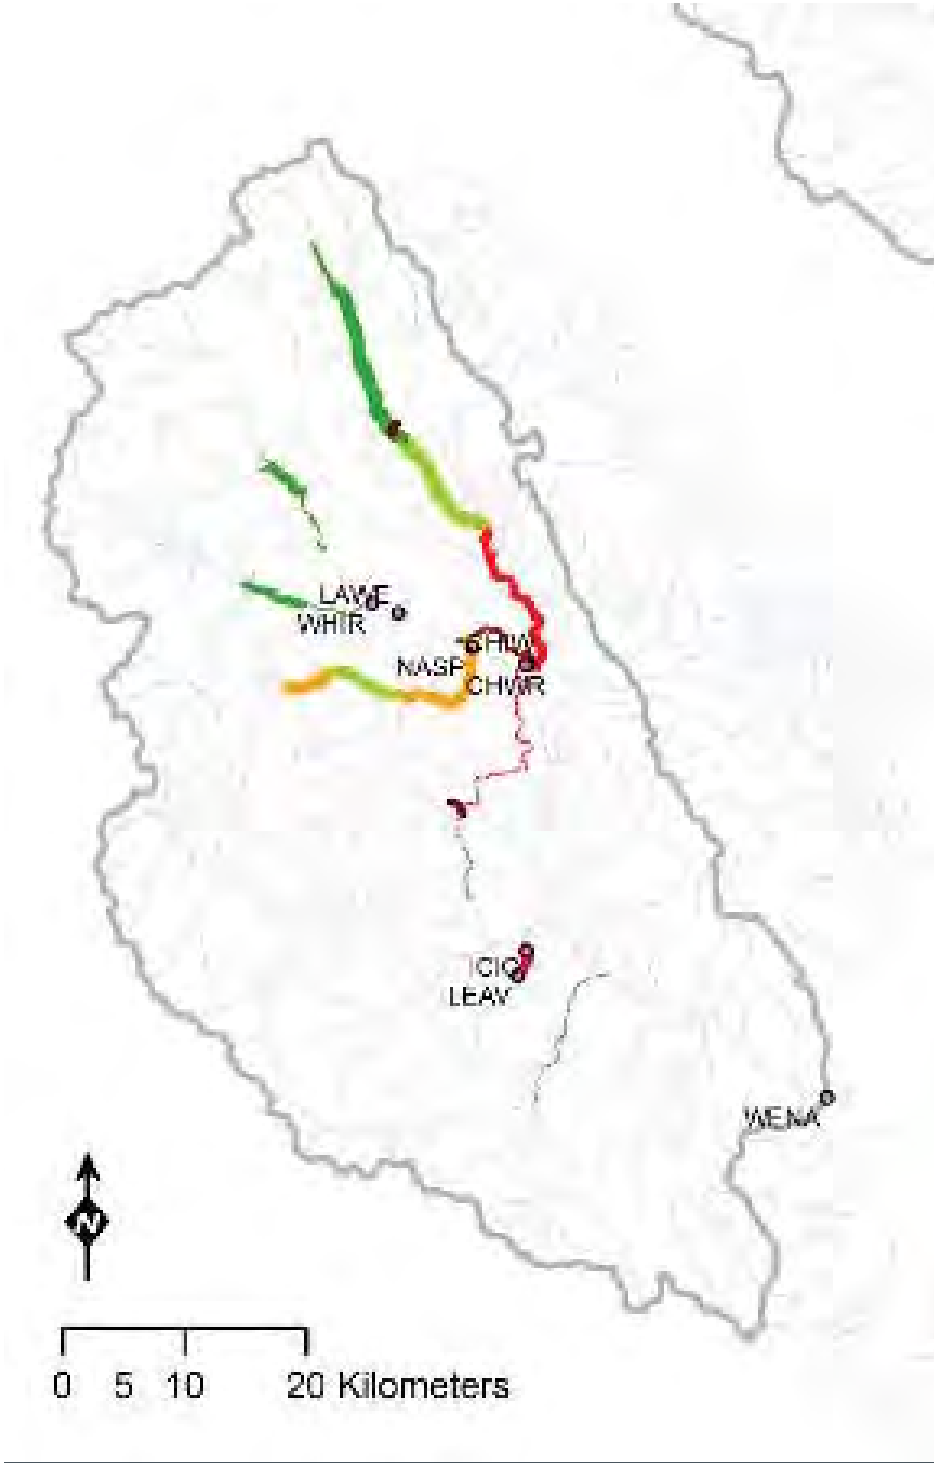


52%

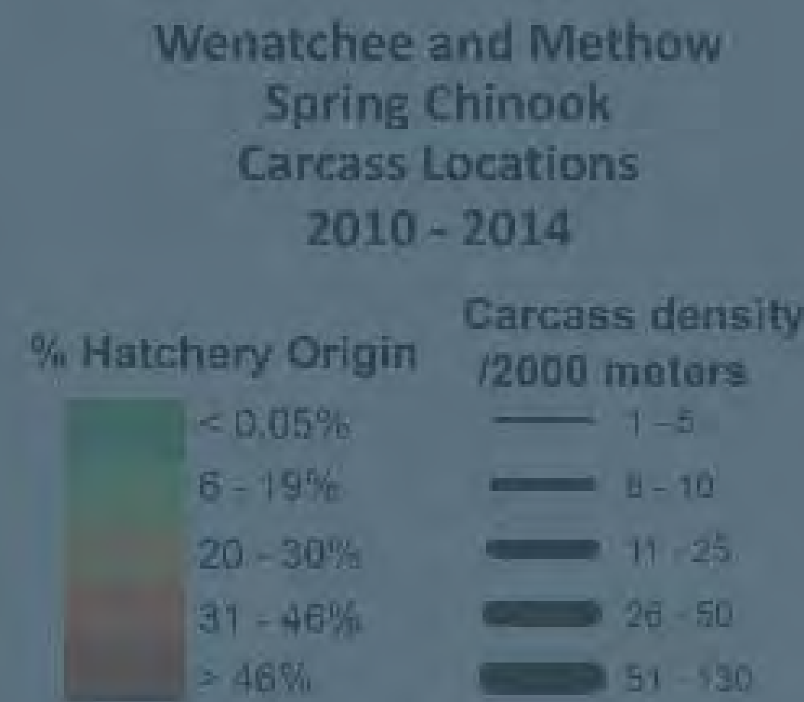
Average pHOS of spring Chinook in Upper Columbia spawning areas, ranging from 75% in the Methow to 24% in the Entiat (WDFW SaSI data 2016). Approximately 57% of steelhead spawners are hatchery-origin, ranging from 84% in the Okanogan to 30% in the Wenatchee.

57%

average pHOS of steelhead in Upper Columbia spawning areas, ranging from 84% in the Okanogan to 30% in the Wenatchee.

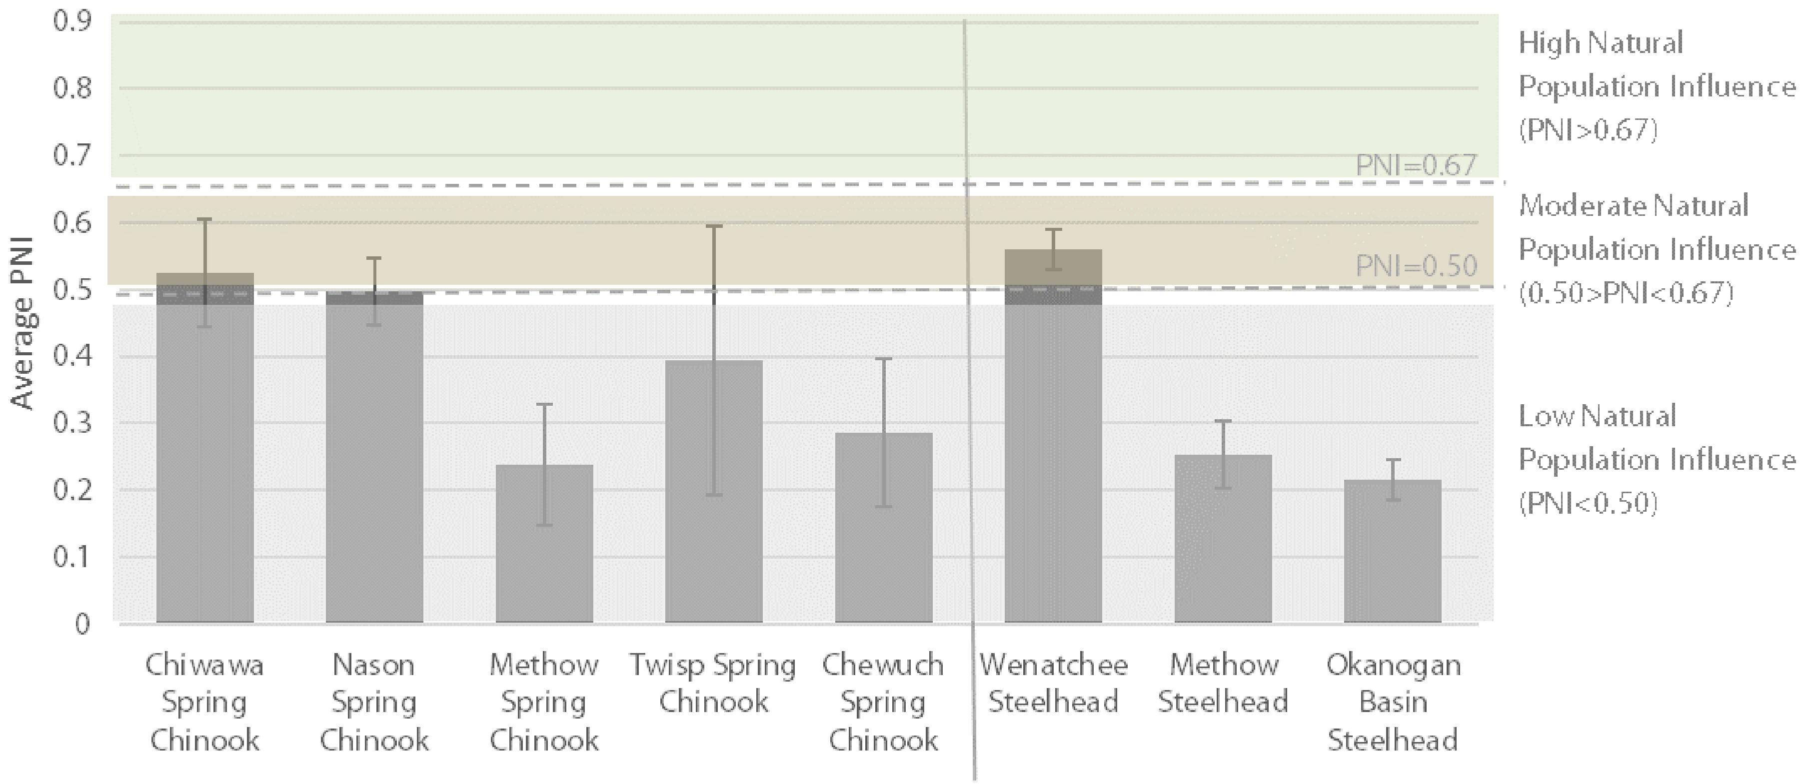


Values of pHOS vary by species, location, and year, and the scale at which it is measured is important to consider (population versus reach). Based on spawning surveys by WDFW, most hatchery-origin fish tend to spawn within a few kilometers of their release site (usually an acclimation or hatchery facility)



PNI

PNI by Supplemented Spawning Population (2011-2015)



HATCHERY PROGENY

Results from these local studies suggest that productivity of hatchery-origin fish in the natural environment, at both the smolt and adult life stages, is significantly lower than that of naturally-produced fish. These results are consistent with those reported in others RRS studies outside the Upper Columbia (e.g. Ford et al. 2015; Berntson et al. 2011; Araki et al. 2007).

UNCERTAINTIES AND DATA GAPS

- Movement and returns
- Causal mechanisms for differences
- Reference streams
- Capacity and bottlenecks
- Interactions

KEY POINTS

- Hatchery supplementation has been underway since the early 1900's.
- 21 hatchery programs in the Upper Columbia
- Conservation hatchery programs play a role in helping depressed populations avoid extinction and depensation.
- Hatchery programs are supported by extensive research and monitoring programs
- Between 2010-2015 an average of 9.6 million hatchery-origin fish were released annually.

KEY POINTS CONT...

- Thousands of hatchery-origin adults return to the Upper Columbia each year.

- Hatchery-origin adults returning to the region are managed based on permit requirements and the goals of the program from which they originate.

- There is still considerable uncertainty related to the influence of hatchery programs (both past and present).

- Total spawner abundance of salmon and steelhead in the Upper Columbia has increased over the past decade.

Appendix C
Habitat Conservation Plan Tributary Committees 2017 Meeting Minutes

Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 12 January 2017

Members Present: Lee Carlson (Yakama Nation), Jeremy Cram (WDFW), Steve Hays (Chelan PUD), Tom Kahler (Douglas PUD; on phone), Kate Terrell (USFWS), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

Members Absent: Chris Fisher (Colville Tribes)

Others Present: Becky Gallaher (Tributary Project Coordinator), Chas Kyger (Douglas PUD), and Jason Schilling (Douglas PUD). Cody Gillin (Trout Unlimited), Robes Parrish (USFWS), and Jennifer Hadersberger (Chelan County Natural Resources Department) attended the meeting for the presentations.

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Thursday, 12 January 2017 from 9:30 am to 12:45 pm.

I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda.

II. Review and Approval of Meeting Minutes

The Committees reviewed and approved the 8 December 2016 meeting notes.

III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- MVID Instream Flow Improvement Project – The project sponsor (Trout Unlimited; TU) reported that the project is almost complete. There are five wells that need to be decommissioned and one well that may need to be re-drilled. This work will be completed during the spring.
- Twisp-to-Carlton Reach Assessment Project – This project is complete. The sponsor (Cascade Columbia Fisheries Enhancement Group; CCFEG) will submit a final report soon.
- Entiat Stillwaters Gray Reach Acquisition – The sponsor (Chelan-Douglas Land Trust; CDLT) did not provide an update on this project.
- Clear Creek Fish Passage and Instream Flow Project – The sponsor (TU) has been working on administrative and permitting tasks associated with the water-right change process and the Washington Department of Health New Source Approval process. The landowner finalized easement documents for Chelan PUD, who will pull cables and install a new transformer. The sponsor plans to submit the Ecology Report of Examination at the Chelan County Water Conservancy Board meeting in January.

- Barkley Irrigation – Under Pressure Project – The sponsor (TU) reported that they met with Barkley on several occasions to discuss various pump alternatives. Each option was evaluated based on construction opinions, estimated pipe alignment and sizes, pump configuration, O&M, and replacement scheduling. They will meet again on 10 January to discuss options.
- Methow Watershed Beaver Reintroduction Project – The sponsor (Methow Salmon Recovery Foundation; MSRF) reported that there was no new activity on this project. Trapping in 2016 is complete with a total of 36 beavers captured in 2016. The final report will be submitted in March 2017.
- Similkameen RM 3.8 Project – The project sponsor (Okanogan Conservation District) reported that Cardno is refining the preferred design.
- White River Floodplain (RM 3.4) Connection Project – The sponsor (CCFEG) reported that there is no new activity on this project.
- Icicle Boulder Field Project – The sponsor (TU) reported that they have completed the design phase of the project and have started permitting discussions.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – The sponsor (WDFW) reported that the project is complete. The sponsor submitted their annual monitoring report, which was uploaded to the Extranet site.
- Permitting Nutrient Enhancement Project – The sponsor (CCFEG) reported that they are writing a summary of findings and recommendations for nutrient enhancement monitoring in the Chiwawa River and will present their findings to the Forest Service later in January.
- Burns-Garrity Design Project – The sponsor (CCFEG) reported that Rio Applied Science and Engineering (the contractor for the project) visited the site in November and performed an initial geomorphic assessment. Rio developed a document describing their initial findings and identified several alternative restoration actions. Rio will further flesh out the alternatives once they receive the hydraulic model from the Bureau of Reclamation.
- Beaver Fever Project – The sponsor (TU) reported that they have been working on landowner outreach. They are researching landownership within the Colockum drainage because there are several reaches within this drainage that show promise for beaver dam analog (BDA) implementation. The sponsor has also reached out to Weyerhaeuser hoping to implement structures on their properties.

IV. ORRI Phase II Side Channel Reconnection Project

Although Chris Fisher was unable to attend the meeting, he sent an email to the Committees asking them to consider techniques or alternatives for the ORRI Phase II project. The project, which was implemented in 2013, reconnected a side channel to the mainstem Okanagan River. The side channel was to remain connected with the mainstem at all flows. Over the past few years, monitoring has indicated that there is a blockage issue within the approach channel and flows in the side channel are too low to provide rearing habitat for native fish during low flow conditions. The information provided by Chris not only indicated a sediment blockage issue in the approach channel, but also a breach of the approach channel in 2016.

After considering the information Chris provided, the Committees agreed that measures should be implemented that maintain the side-channel reconnection at all flows. To that end, they offered the following suggestions: (1) add another riffle or expand the existing riffle in the main channel; (2) excavate to design grade; (3) widen the approach channel; and (4) add a high-flow return.

V. Beaver Fever Project Presentation

In 2016, Trout Unlimited submitted a proposal to the Committees titled, "Beaver Fever: Restoring Ecosystem Function." The purpose of the project was to reestablish beavers and install BDAs in tributaries of the Wenatchee or Entiat basins. The reintroduction of beavers and installation of BDAs should enhance salmonid habitat by increasing habitat complexity, moderating water temperatures, augmenting stream flows, trapping fine sediments, and improving riparian and off-channel connectivity. The Rock Island Tributary Committee agreed to fund the installation of BDAs in tributaries. Last month, the sponsor asked to share with the Committees some of the results from running the BRAT (Beaver Restoration Assessment Tool) model and their findings during site visits.

Cody Gillin (TU) and Robes Parrish (USFWS) provided a short presentation to the Committees on their work (see Attachement 1). So far, they have evaluated 10 drainages and found some potential areas for implementation of BDAs. In the Entiat, areas in Mud, Potato, and Roaring creeks are good candidates for BDA enhancement. They asked the Committees what should be their primary objective (e.g., water yield/storage, temperature amelioration, vegetation enhancement, habitat complexity, etc.), what is an appropriate spatial scale for implementing BDAs (e.g., focus efforts in a single watershed or disperse efforts across several watersheds), what should be monitored, and should they explore partnerships.

The Committees indicated that they would like to see enhancement work focused in one watershed. They suggested working in Mission, Peshastin, or Roaring creeks. The Committees also noted that they want TU to evaluate the effects of BDAs on water temperature, stream flows, and salmonid abundance (this is consistent with the recommendations outlined in the letter sent from the Rock Island Tributary Committee to TU in September 2016 asking the sponsor to submit a monitoring proposal to the Committees). Finally, the Committees recommended that the sponsor establish partnerships with other interested entities. They have already established a partnership with the USFWS. Establishing a partnership with WDFW and perhaps a contactor to help with monitoring would be appropriate.

VI. Nason Creek RM 4.6 Channel Reconnection Project Presentation

In 2013, the Rock Island Tributary Committee agreed to partially fund the Nason Creek RM 4.6 Side Channel Reconnection Construction Project, which was submitted by Chelan County Natural Resources Department (CCNRD). The purpose of this project was to provide high-flow refugia and rearing habitat for adult and juvenile salmonids in Nason Creek. The project would reconnect a 4.6-acre, high-flow channel to the mainstem near RM 4.6. Because the County was unable to secure a cost share (the Committee agreed to fund $88,000 of the $525,030 project), the sponsor has been unsuccessful in implementing the project. The sponsor requested a meeting with the Committee to discuss the status of the project.

Jennifer Hadersberger (CCNRD) gave a short presentation on the status of the project (see Attachment 2). She provided a brief history of the project and then described the benefits of reconnection projects in Nason Creek and elsewhere. She stated that their approach at this time is only to reconnect the downstream end of the side channel. The reason for this is because the Forest Service is unwilling to approve reconnecting the upstream end of the side Channel. The Forest Service is concerned that if the upstream end is reconnected, water will be on both sides of the road and that will increase the likelihood of the road prism being eroded during high flows. Jennifer said Washington Department of Transportation has not voiced this concern. Jennifer stated that with only a downstream connection, the project will still benefit rearing salmonids.

Jennifer asked the Rock Island Tributary Committee if they would support a downstream-only connection. The Committee indicated that this is a significant departure from the original project; therefore, the County would need to submit a new proposal. The Committee recommended that the County try to secure funding for the downstream connection through the BPA targeted solicitation process. They also recommended that the County continue to seek approval from the Forest Service to reconnect the upstream end. Once the Forest Service approves the upstream connection, funds from the Rock Island Plan Species Account can be used to reconnect the upstream end of the channel. Jennifer said the County does not want to push the Forest Service on this issue at this time.

VII. Silver Side-Channel Rehabilitation Project Presentation

Robes Parrish (USFWS) gave a presentation on the enhancement work implemented in the lower portion of the Silver Side Channel in the Methow River basin (see Attachment 3). The purpose of the project was to increase habitat quality and quantity for salmonids within the side channel and floodplain corridor. This would be accomplished by increasing sinuosity and groundwater input, improving channel geometry, adding structure and complexity appropriate to the flow regime, developing groundwater-fed alcoves, improving fish passage, adding wood cover throughout the channel, and re-vegetating the riparian zone and floodplain. The Rocky Reach Plan Species Account contributed funds for the design of the enhancement project.

Robes described the history of the project and showed aerial photos of the project site from the 1940s, 1950s, and more recently. He identified land uses and threats, and described the enhancement approach. He showed a series of photos depicting the enhancement process and panoramic views of the enhanced channel. He concluded by showing before and after pictures throughout the enhancement reach. He noted that some of the vegetation may remain dormant for a year or two. They will continue to monitor the success of the project.

VIII. Information Updates

The following information updates were provided during the meeting.

1. Approved Payment Requests in December and January:

   Rock Island Plan Species Account:

   - $136.00 to Clifton Larson Allen for Rock Island financial administration in December 2016.
   - $839.19 to Chelan County PUD for project coordination and administration during the fourth quarter of 2016.

   Rocky Reach Plan Species Account:

   - $136.00 to Clifton Larson Allen for Rocky Reach financial administration in December 2016.
   - $791.62 to Chelan County PUD for project coordination and administration during the fourth quarter of 2016.
   - $11,144.68 to Cascade Columbia Fisheries Enhancement Group for the Burns-Garrity Restoration Design Project.

   Wells Plan Species Account:

   - $446.75 to Chelan County PUD for project coordination and administration during the fourth quarter of 2016.
   - $23,444.46 to Trout Unlimited for the MVID Instream Flow Improvement Project.

2. The Committees discussed the need to add language in the Policies and Procedures document indicating that approved projects must have a signed contract within a certain time period (e.g., five years) or the Committees will cancel funding for the project. The Committees noted that there are a few projects that were approved several years ago, but the sponsors have not been able

to move the projects forward because of a lack of additional funds (cost share) and/or a lack of landowner support. As such, the sponsors have not signed contracts with the Tributary Committees. The Committees directed Tracy Hillman to include draft language in the Policies and Procedures document for review during the next meeting.

3. During the September meeting, members of the Committees identified possible funded projects they would like to visit in 2017 (see Item #2 on page 4 of the September 2016 meeting notes). Given the long list of possible projects, Tracy Hillman asked the Committees if they would like to refine the list so the tour would take no more than two days (one day for Okanogan/Methow projects and one day for Entiat/Wenatchee projects). In November, Chris Fisher recommended each member identify five projects they would like to visit. During the March meeting, members will combine their lists and identify which projects will be selected for a field visit in 2017.
4. Tracy Hillman said the Tributary Committees will continue to meet on the second Thursday of each month in 2017. Those meeting dates are as follows:
    - Jan 12
    - Feb 9
    - Mar 9
    - Apr 13
    - May 11
    - Jun 8
    - Jul 13
    - Aug 10
    - Sep 14
    - Oct 12
    - Nov 9
    - Dec 14
5. Tracy Hillman stated that John Ferguson (Chair of the HCP Coordinating Committees) sent letters to the Confederated Tribes of the Umatilla Indian Reservation and American Rivers inquiring about their interest in participating in a meeting with members of the HCP Coordination, Hatchery, and Tributary Committees. These parties were involved in negotiating the HCPs, but elected not to sign the HCPs. This is an opportunity for the Committees to provide the two parties with a progress report on implementation, as well as give them an opportunity to ask questions of the Committees members. The two entities are to provide a formal response to the invitation by 14 April 2017.

IX. Next Steps

The next meeting of the Tributary Committees will be on Thursday, 9 March 2017 at Grant PUD in Wenatchee.

Meeting notes submitted by Tracy Hillman (tracy.hillman@bioanalysts.net).

Attachment 1

Presentation by Cody Gillin on Beaver Fever Project

BDA PROJECT UPDATE

- Initial visits to about 10 drainages
- Sand, Mission, Brender, Camas, Colockum, Chiwawa, Big Meadow, Little Wenatchee, Nason area
- Some potential locations but scale and constructability would be limited due to various constraints
- Common constraints included: substrate, proximity to roads, land ownership, basin characteristics, wide channel, hydrology, uncertain sustainability

Colockum Creek

TROUT UNLIMITED

Big Meadow Creek

Colockum Creek

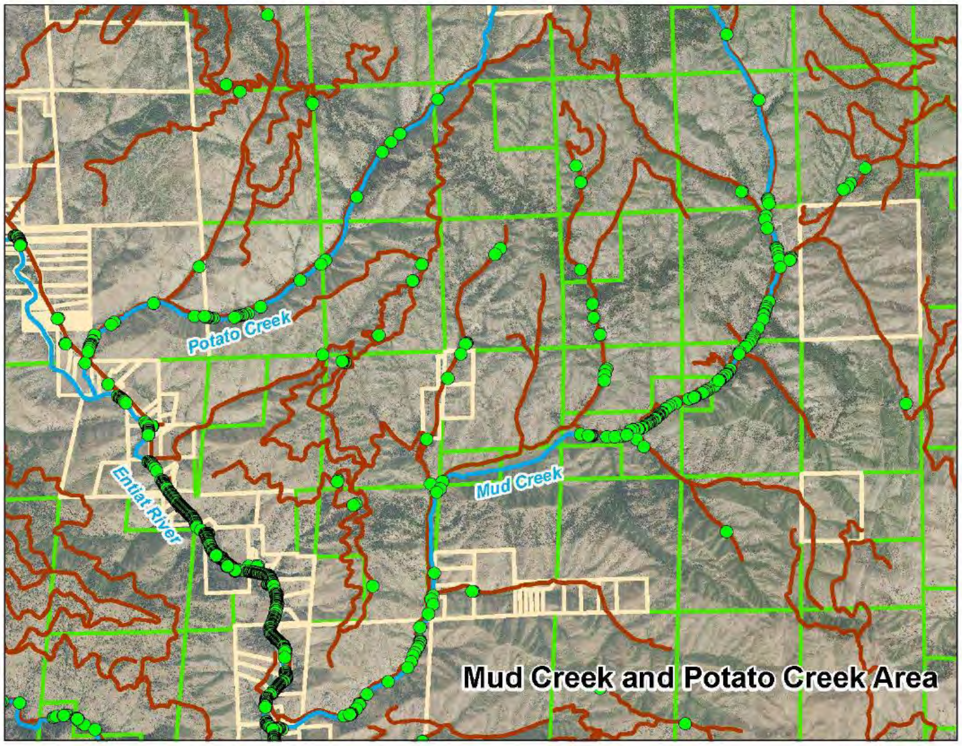
Camas Creek

OTHER LOCATIONS EXPLORED

- Kahler/Coulter Creeks: only recently secured access permission through Weyerhaeuser
- Mission/Sand Creeks: large substrate, surface bedrock, very close to roadway (Mission) or trails (Sand), confined valleys
- Chiwawa/Little Wenatchee: wide channels and large substrate
- Upper Peshastin: still need to get boots on the ground

EXPANDED SEARCH CRITERIA

- Original criteria (similar to BRAT): <9% slope, within 200 ft of roadway, suitable vegetation, Wenatchee sub-basin only
- BDA-specific criteria: <2% slope, within 200 ft of roadway, no vegetation criteria, all of Chelan County
- Mud/Potato Creeks (Entiat) were a hot spot; Roaring showed promise



Many beaver ponds

Diverse dam structures

Low gradient system

Lots of water

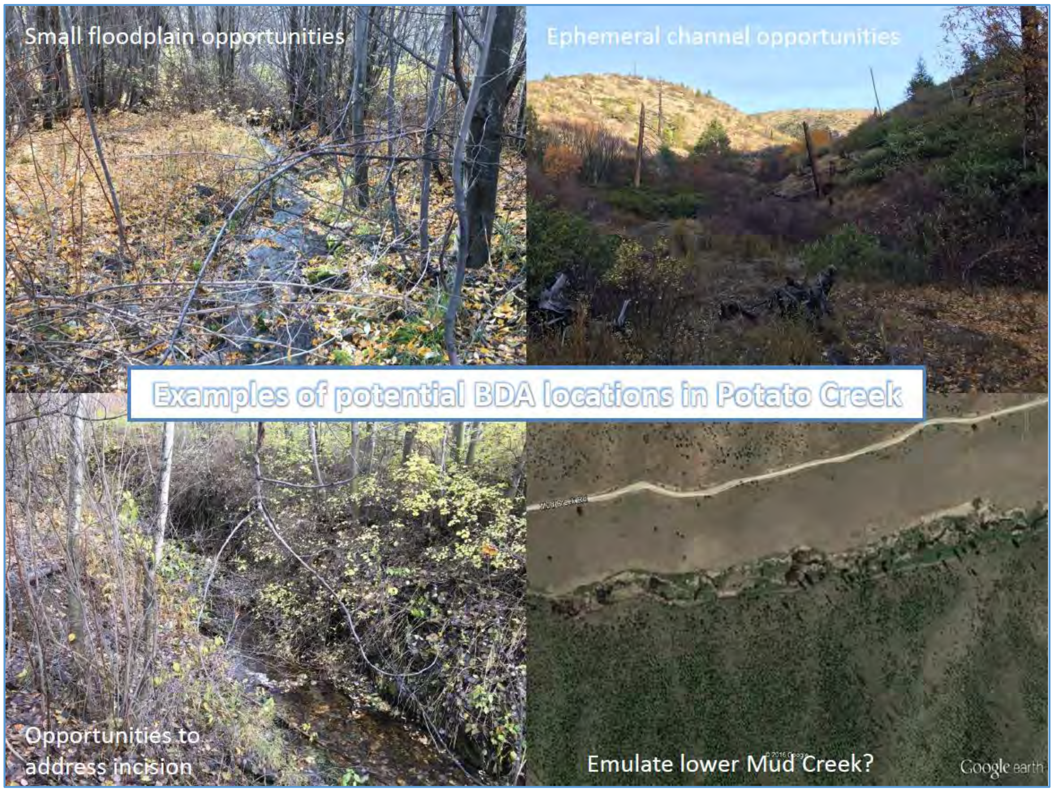
Disconnected floodplains

Mixed low and high gradient

Some channel incision

Some water

Limited active beaver sign



NEEDED GUIDANCE TO MOVE FORWARD:

- What should be our primary goals/objectives?
  - Water yield/storage?
  - Temperature amelioration?
  - Sediment reduction?
  - Vegetation expansion?
  - Direct habitat benefits?

- What is an appropriate spatial scale?
  - Single watershed (e.g., Potato Creek)? Low or high intensity?
  - Dispersed sites, multiple watersheds?

- Monitoring elements:
  - What is TRIB most interested in learning about BDAs?
  - Certain metrics are easier and less costly than others
  - Should we explore partnerships?

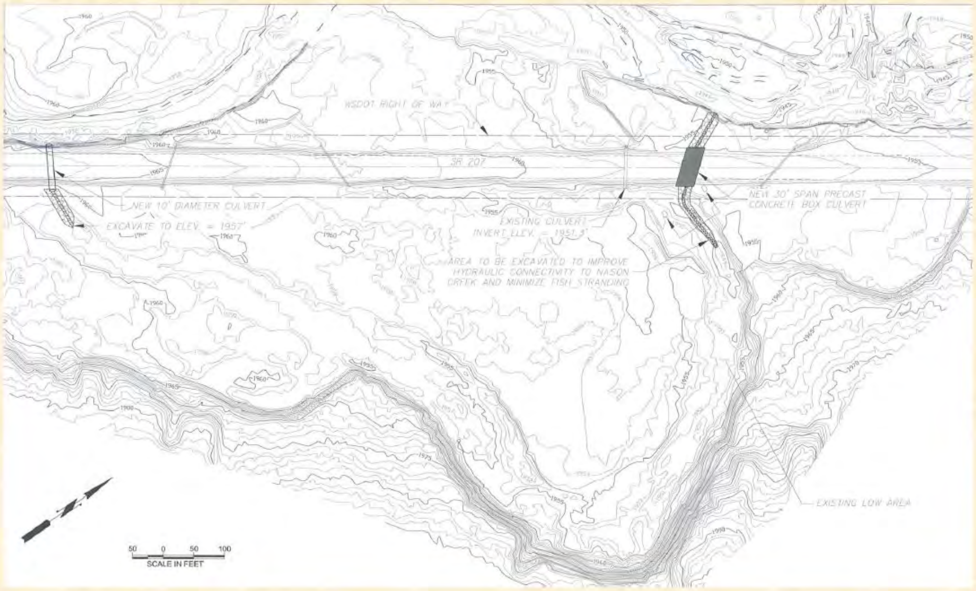
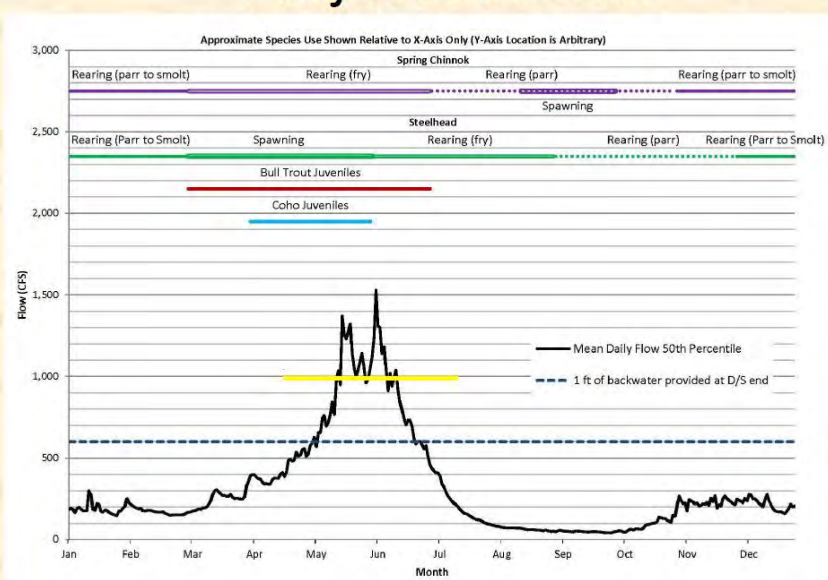
2011 Lower Nason Assessment - USBR

Plan view of proposed project

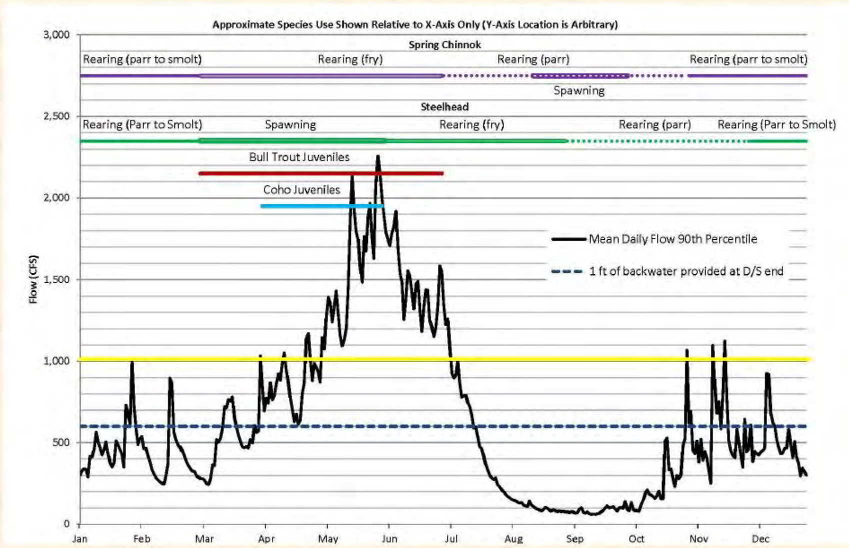


Project Benefits



Typical Flow Year (50^{th} percentile)

Project Benefits

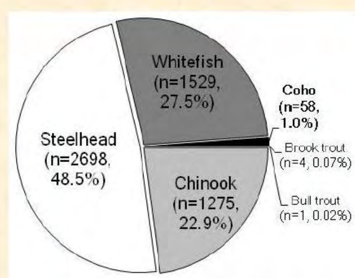


High Flow Year (90th percentile)

Do fish use side channels in Nason Creek?

- Monitoring of the nearby 2007 Oxbow has documented salmonid abundance ranging from 2-16 salmonids/100m2 (Figure 19, page 30 DOE 2011).

2010 survey data



Yakama Nation Juvenile Fish Counts in the 2007 Oxbow

Date	Nason cfs	Chinook	Steelhead
Summer 2012		165	1438
March 2013		131	426
Summer 2013		601	1040
3/20/14	404	171	301
8/27/14	66.5	421	395
3/25/15	733	28	178
8/6/15	33.7	96	372
3/8/16	542	11	83
8/9/16	69.9	30	437

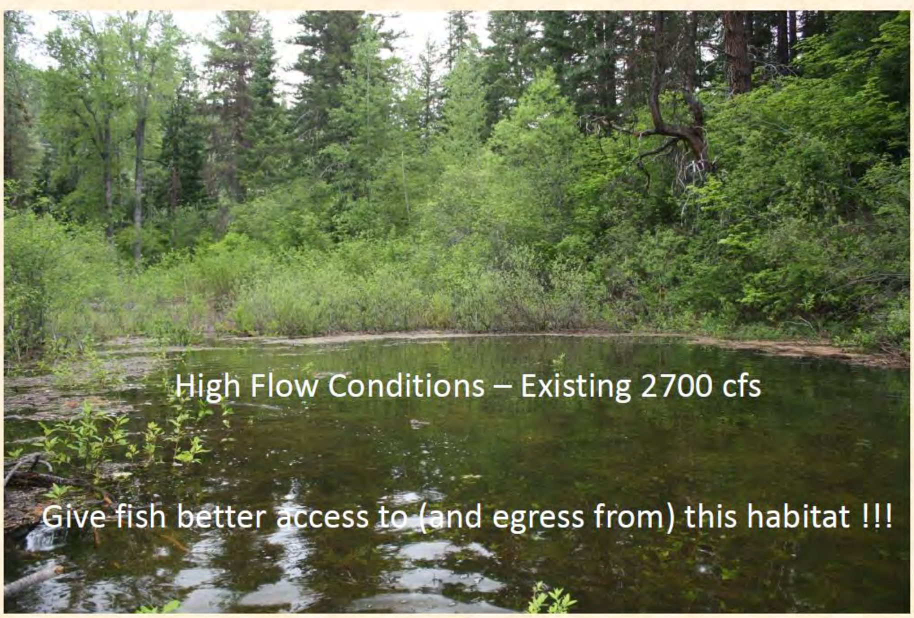
Fish counts in seasonally inundated floodplain side channels,RM 4.6.

Location	Nason discharge (cfs)	Juvenile steelhead	Juvenile Chinook
Floodplain side channel June 2014	734	0	62
Floodplain side channel April 2015	300	0	0
Newly constructed side channel April 2015	300	47	0
Newly constructed side channel March 2016 (pm)	400-750	6	0
Newly constructed side channel May 2016 (CCNRD)	869	0	2

What does the Literature Say?

- Floodplain areas provide better rearing and migration habitat for juvenile chinook salmon than adjacent river channels; salmon increase in size faster in **seasonally** inundated floodplain than in the river, suggesting better growth rates due to bioenergetics and food sources. (Sommer et al 2001)
- Floodplain side channels offer reduced competition for available prey. This study in the Methow river found that side channels are important habitat for juvenile rearing for Chinook salmon and steelhead; Chinook and steelhead rearing in side channels had lower potential exploitative competition for food with other non-target fish (sculpin and whitefish) and as a result, side channels appeared to have a greater capacity to sustain juvenile Chinook and steelhead production relative to the main channel habitat. (Bellmore 2013)

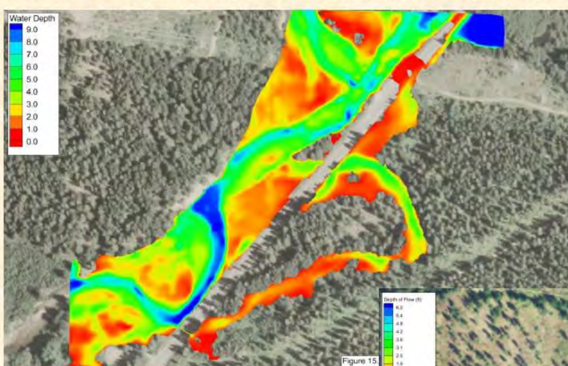
Downstream



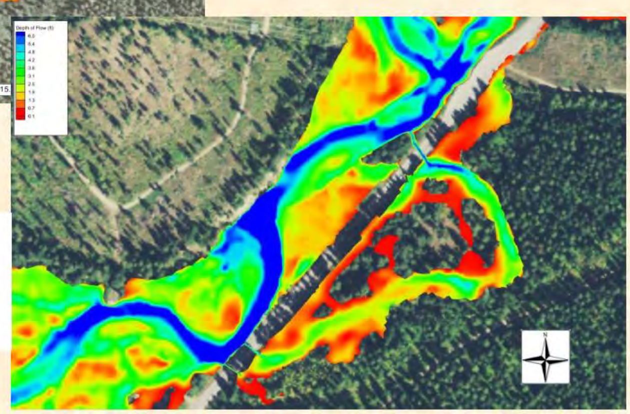
Why Downstream only connection?

1. USFS input
2. WDFW is evaluating the upstream culvert
3. Cost
4. Perhaps limited difference in biological benefit?
5. Phased

1. USFS has concerns about risk involved with upstream culvert

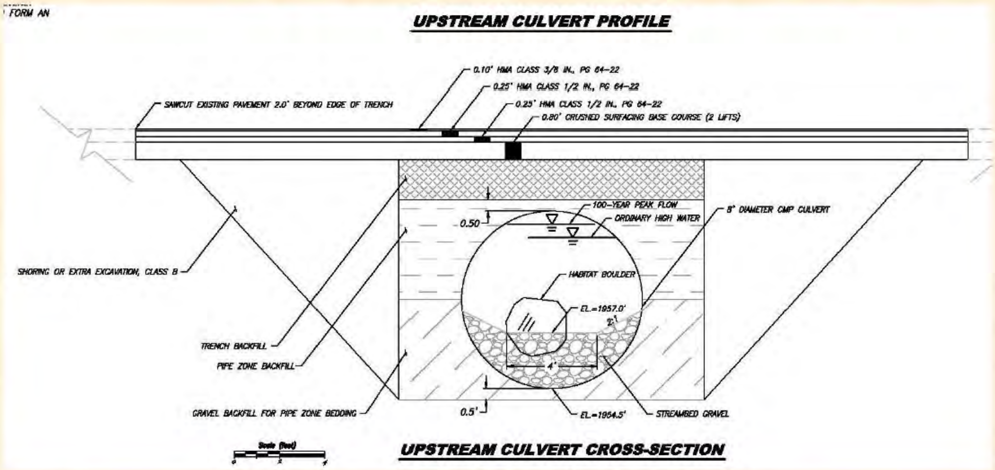


2D model existing conditions (water depth) 100 year (~6,500 cfs) event.



Proposed conditions (water depths) 100 year event.

WDFW evaluating the upstream culvert



Costs

Item	2013 Cost Est.	2016 Cost Estimate	
Construction (2 structures)	$414,530	$571,820	
Construction (1 structure)			$361,853

Project Benefits

Downstream connection = rearing habitat

Upstream connection = flushing benefit

Support for downstream only connection?

Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 9 March 2017

Members Present: Lee Carlson (Yakama Nation), Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Steve Hays (Chelan PUD), Kate Terrell (USFWS), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

Members Absent: Tom Kahler (Douglas PUD)[1]

Others Present: Becky Gallaher (Tributary Project Coordinator). Steve Kolk (Bureau of Reclamation), Deanne Pavlik-Kunkel (Grant PUD), and Denny Rohr (PRCC Habitat Subcommittee Chair) attended the meeting for the Middle Entiat Project presentation.

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Thursday, 9 March 2017 from 9:00 am to 12:00 pm.

I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda.

II. Review and Approval of Meeting Minutes

The Committees reviewed and approved the 12 January 2017 meeting notes.

III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- MVID Instream Flow Improvement Project – The project sponsor (Trout Unlimited; TU) did not provide an update on this project.
- Twisp-to-Carlton Reach Assessment Project – This project is complete. The sponsor (Cascade Columbia Fisheries Enhancement Group; CCFEG) submitted a final report, which was uploaded to the Extranet site.
- Entiat Stillwaters Gray Reach Acquisition – The sponsor (Chelan-Douglas Land Trust; CDLT) did not provide an update on this project.
- Clear Creek Fish Passage and Instream Flow Project – The sponsor (TU) did not provide an update on this project.
- Barkley Irrigation – Under Pressure Project – The sponsor (TU) did not provide an update on this project.

---

[1] Tom provided his votes on decision items following the meeting.

- Methow Watershed Beaver Reintroduction Project – The sponsor (Methow Salmon Recovery Foundation; MSRF) reported that there was no new activity on this project. The final report will be submitted in March 2017.
- Similkameen RM 3.8 Project – Chris Fisher reported that the parties held a conference call to divide the labor among the different entities. In addition, they selected a preferred design, which was approved by the Tributary Committees last year. Permit applications will be completed by the end of March.
- White River Floodplain (RM 3.4) Connection Project – The sponsor (CCFEG) reported that they are continuing discussions with WDFW to finalize the Right of Entry (ROE) permit, which is the final permit needed to begin the project. Once the ROE permit is finalized, the sponsor will schedule work with the contractor.
- Icicle Boulder Field Project – The sponsor (TU) did not provide an update on this project.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – The sponsor (WDFW) reported that the project is complete. The second-year monitoring report is due on 31 December 2017.
- Permitting Nutrient Enhancement Project – The sponsor (CCFEG) reported that they continue to work with the Forest Service to assess interest and willingness to implement the project. They are also working on the project summary and monitoring proposal that will be submitted to the Forest Service in March.
- Burns-Garrity Design Project – The sponsor (CCFEG) reported that Rio Applied Science and Engineering (the contractor on the project) received the 2-D hydraulic model from the Bureau of Reclamation. Rio is now modeling several alternative concepts and they will present those to stakeholders in April. They will then select a preferred concept.
- Beaver Fever Project – The sponsor (TU) did not provide an update on this project.

IV. Budget Amendments and Time Extensions

MVID Instream Flow Improvement Project

The Tributary Committees received a time extension request from Trout Unlimited on the *MVID Instream Flow Improvement Project*. The sponsor asked the Rock Island and Wells Committees to extend the period of their contracts from 30 September 2016 to 30 November 2017 and the Rocky Reach Committee to extend the period of their contract from 31 March 2017 to 30 November 2017. After review and discussion, ***the Committees agreed to extend their respective contracts to 30 November 2017***.

Entiat Stillwaters Gray Reach Acquisition

The Rocky Reach Tributary Committee received a time extension and amendment request from Chelan-Douglas Land Trust on the *Entiat Stillwaters Gray Reach Acquisition Project*. The sponsor asked the Committee if CDLT could use some of the remaining balance of the Entiat Stillwaters Gray Reach Acquisition Project to help cover expenses associated with lot sales and the Beutler and Scoville acquisitions, and help purchase the Coutcher and Phipps properties. To complete the transactions, the sponsor asked to extend the period of the contract from 31 March 2017 to 31 December 2018.

Because the amendment represents a significant departure in the scope of the original project, ***the Rocky Reach Tributary Committee denied the amendment and time extension***. The Committee invited the sponsor to submit a new proposal seeking funds to cover expenses associated with the Beutler and Scoville acquisitions and to help purchase the Coutcher and Phipps properties.

Similkameen RM 3.8 Rehabilitation Project

The Rocky Reach Tributary Committee received a budget amendment request from Okanogan Conservation District on the *Similkameen RM 3.8 Rehabilitation Project*. The sponsor asked the Rocky Reach Committee to add $24,851.27 to their budget in order to complete the project. The additional funds will increase "Salaries/Benefits" from $2,446.50 to $6,364.02, "Professional Services" from $64,108.00 to $84,650.00, and "Indirect/Overhead/Admin" from $815.50 to $1,207.25. The total amount of the contract will increase from $67,370.00 to $92,221.27. After careful consideration, ***the Rocky Reach Tributary Committee approved the budget amendment***.

Beaver Fever: Restoring Ecosystem Function Project

The Rock Island Tributary Committee received a budget amendment request from Trout Unlimited on the *Beaver Fever: Restoring Ecosystem Function Project*. The sponsor asked the Committee to move $1,997.00 from "Administration/Overhead" to "Salaries and Benefits," $2,294.94 from "Administration/Overhead" to "Professional Services," and $7,028.75 from "Administration/Overhead" to "Project Materials." After consideration, ***the Rock Island Tributary Committee approved the budget amendment***. The total budget amount of $108,225.94 will not change as a result of this amendment.

V. General Salmon Habitat Program Proposal

Derby Creek Fish Passage – Collins Project

Cascade Columbia Fisheries Enhancement Group is the sponsor of the *Debry Creek Fish Passage – Collins Project*. The purpose of this project is to remove the lowermost fish passage barrier culvert (RM 0.3) on Derby Creek, a tributary to the Wenatchee River. Removal of the lowermost barrier will open about 10 miles of habitat for steelhead spawning and rearing. The total cost of the project is $190,000. The sponsor requested $90,000 from HCP Tributary Funds. The Committees were unable to make a funding decision and requested additional information from the sponsor.

The Committees asked the sponsor to respond to the following questions/comments:

1. Describe the status of fish passage at the obstacles downstream from the proposed passage barrier. For example, there is one obstacle that is highlighted "unknown passability." Is this at the road or railroad crossing and is there evidence that it is passable?
2. Indicate the location of the PIT-tag array on the map prepared by Chris Dwight.
3. Does Derby Creek dewater at any time of year, and, if so, where?
4. The proposal indicates that CCFEG has removed one total barrier and received funding for removal of two additional barriers. Please show on the map prepared by Chris Dwight the location of these barriers.
5. Has NRCS confirmed that they will fund the cost share?
6. Did you consider replacing the barriers with small bridges similar to those used on Frazer Creek in the Methow River basin (e.g., see: http://methowsalmon.org/currentprojects.html)? If so, why are they not the preferred alternative?

Once the Committees receive the additional information, they will reevaluate the proposal.

VI. Review of Draft Wells HCP Tributary Committee Action Plan

Douglas PUD provided the Committees with the Draft Wells HCP Tributary Committee Action Plan for 2017. The 2017 Draft Action Plan for the Wells Tributary Committee is as follows:

Plan Species Account Annual Contribution

- $176,178 in 1998 dollars: January 2017

Annual Report – Plan Species Account Status

- Draft to Tributary Committee (TC): February 2017
- Integration into HCP Annual Report: February 2017

General Salmon Habitat Program

- Project Review and Funding Decision January – December 2017

Small Projects Program

- Project Review and Funding Decision January – December 2017

The Wells Tributary Committee approved the Tributary Section of the Wells Action Plan for 2017.

VII. Review of Draft Rock Island and Rocky Reach HCP Tributary Committees Action Plans

Chelan PUD provided the Committees with the Draft Rocky Reach and Rock Island HCP Tributary Committees Action Plans for 2017. The 2017 Action Plans for both Rocky Reach and Rock Island Tributary Committees are as follows:

- Plan Species Account Deposits: January 2017
- GSHP Project Review and Approval: Ongoing
- GSHP Project Implementation: Ongoing
- Small Project Review and Approval: Ongoing
- Small Project Implementation: Ongoing

The Rocky Reach and Rock Island Tributary Committees approved the Tributary Sections of the Rocky Reach and Rock Island Action Plans for 2017.

VIII. Review of Tributary Committees' Policies and Procedures

Policies and Procedures for Funding Projects

The Committees reviewed their Policies and Procedures document and added the following language to the beginning of Section 6.3 (Timelines and Extensions).

> *Project Sponsors must have a signed contract with the Committees within one (1) year from the date when the Committees approved the project. In the event the Project Sponsor does not have a signed contract because of a lack of additional funds (cost share), a lack of landowner support, or any other reason, the Committees may cancel funding for the project. After the one-year period, the Project Sponsor will need to resubmit a new proposal seeking funding for a canceled project.*

Following the meeting, there was discussion about the use of the word "may" in the sentence stating "…the Committees may cancel funding for the project." It was pointed out that this statement is not consistent with the first sentence of the paragraph stating that "Project Sponsors must have a signed contract…" In short, the consequence does not fit the rule. The Committees will revisit the language added to Section 6.3 during their next meeting.

The Committees also rearranged statements in Section 3.8 (Management Guidelines for Conservation Easements/Acquired Lands). They placed the statement, "Allow public access[2] except under

[2] Public access is restricted to foot access and will be provided at all times. There shall be no impediments to foot access (e.g., fences) and the access cannot devalue the habitat being protected. The Committees do not require the easement or property-title holder to provide any improvements to facilitate access or to accommodate ADA standards.

extraordinary circumstances" at the front of the list. Finally, they rearranged sub-sections under Section 3 (General Policies) to reflect a more logical order.

Tributary Committee Operating Procedures

Tracy Hillman asked if the Committees had any changes or edits to the Tributary Committee Operating Procedures document. Members had no changes to the Operating Procedures.

IX. Information Updates

The following information updates were provided during the meeting.

1. Approved Payment Requests in February and March:

   Rock Island Plan Species Account:

   - $140.00 to Clifton Larson Allen for Rock Island financial administration in January 2017.
   - $1,578.50 to Trout Unlimited for work on the MVID Instream Flow Improvement Project.
   - $767.75 to Cascade Columbia Fisheries Enhancement Group for work on the Twisp-to-Carlton Reach Assessment (final payment).
   - $102.00 to Clifton Larson Allen for Rocky Island financial administration in February 2017.
   - $2,208.14 to Cascade Columbia Fisheries Enhancement Group for work on Permitting Nutrient Enhancement in the Chiwawa River Basin.

   Rocky Reach Plan Species Account:

   - $140.00 to Clifton Larson Allen for Rocky Reach financial administration in January 2017.
   - $966.78 to Okanogan Conservation District for work in November and December on the Similkameen RM 3.8 Rehabilitation Project.
   - $380.40 to Okanogan Conservation District for work in January on the Similkameen RM 3.8 Rehabilitation Project.
   - $102.00 to Clifton Larson Allen for Rocky Reach financial administration in February 2017.
   - $939.04 to Cascade Columbia Fisheries Enhancement Group for work on the Burns-Garrity Restoration Design Project.

   Wells Plan Species Account:

   - $1,178.28 to the Methow Salmon Recovery Foundation for work on the Methow Watershed Beaver Reintroduction Project.
   - $4,319.10 to Trout Unlimited for work during January on the MVID Instream Flow Improvement Project.
   - $3,868.63 to Trout Unlimited for work during February on the MVID Instream Flow Improvement Project.

2. Becky Gallaher reported that the PUDs deposited funds into each of the Plan Species Accounts at the end of January 2017. Chelan PUD deposited $737,452 into the Rock Island Account and $349,271 into the Rocky Reach Account. Douglas PUD deposited $267,771 into the Wells Account. As of March 2017, the unallocated balances within each account were $5,559,653 in the Rock Island Account, $2,378,263 in the Rocky Reach Account, and $1,331,318 in the Wells Account. Thus, among the three accounts, there is about $8,269,234 available.
3. Becky Gallaher stated that the Methow Salmon Recovery Foundation would like to provide a personal showing of their Methow Watershed Beaver Reintroduction Project film. The film is about 25-minutes long. The Committees appreciated the offer, but declined a personal showing of the film. The Committees will view the film on their own.
4. Tracy Hillman reported that he and Becky Gallaher completed Section 2.3 (Tributary Committees and Plan Species Accounts) for the Annual Report of Activities under the Anadromous Fish Agreement and Habitat Conservation Plan for each hydroelectric project. Tracy said he sent the draft reports to Anchor QEA, who is compiling the draft annual reports. The draft reports were sent to the HCP Coordinating Committees for review. The PUDs will submit the final reports to the Federal Energy Regulatory Commission in April.
5. During the September 2016 meeting, members of the Committees identified possible funded projects they would like to visit in 2017 (see Item #2 on page 4 of the September 2016 meeting notes). Given the long list of possible projects, Tracy Hillman asked the Committees if they would like to refine the list so the tour would take no more than two days (one day for Okanogan/Methow projects and one day for Entiat/Wenatchee projects). In November 2016, Chris Fisher recommended each member identify five projects they would like to visit. During the March 2017 meeting, members agreed to wait until the April 2017 meeting to identify their top projects for a field visit.
6. Tracy Hillman reported that the Northwest Power and Conservation Council (NPCC) sent a letter (memo) asking the Independent Scientific Advisory Board (ISAB) to review Upper Columbia River Spring Chinook recovery analyses and strategies. If the ISAB accepts the request, they will likely ask for a workshop in which groups such as the HCP Tributary Committees describe their approach to selecting tributary habitat actions to protect and restore habitat conditions for spring Chinook. The ISAB has not yet accepted the request. Tracy will share the NPCC memo with the Committees.

X. Middle Entiat Project Presentation

Steve Kolk (BOR) gave a presentation on the status of the Middle Entiat Restoration Project (see Attachment 1). He described the primary objectives and scope of the project, the current landowner-project sponsor relationship, acquisition of permits, and project funding. Regarding the latter, Steve noted that BOR will be funding a large portion of the project; however, they will fall short by about $1-1.5 million to complete the project. Thus, he asked if the Tributary Committees and/or the PRCC Habitat Subcommittee would be interested in funding specific components of the restoration project.

Members of the Committees asked the following questions:

Q: When does BOR need a commitment from other funding entities?
A: Construction is scheduled to being in 2019, so a funding commitment would be needed in 2018.

Q: What is the status of the restoration design?
A: The design is at a point of delegation.

Q: How long will the restoration structures be evaluated?
A: As long as BOR is in the valley.

Q: What agreement has the County established with the landowner (CDLT)?
A: The County will take ownership of all structures on CDLT properties. DNR will own structures up to the high-water mark.

Q: Will the BOR contribute $1 million per year or $1.5 million per year?
A: If the BOR has additional money available, they will likely contribute up to $1.5 million per year.

Q: Are project sponsors planning to submit proposals through the SRFB process?
A: There are no plans to seek funding through the SRFB process this year.

Q: What is the sequence for implementing restoration actions?
A: Sections B and E will be enhanced first; F will be last.

Following questions, members urged BOR to encourage their project sponsors to submit proposals through the SRFB process. Specific projects such as levee removal and reconnecting side channels should score high in the SRFB process.

Members will further discuss the Middle Entiat Project during their April meeting.

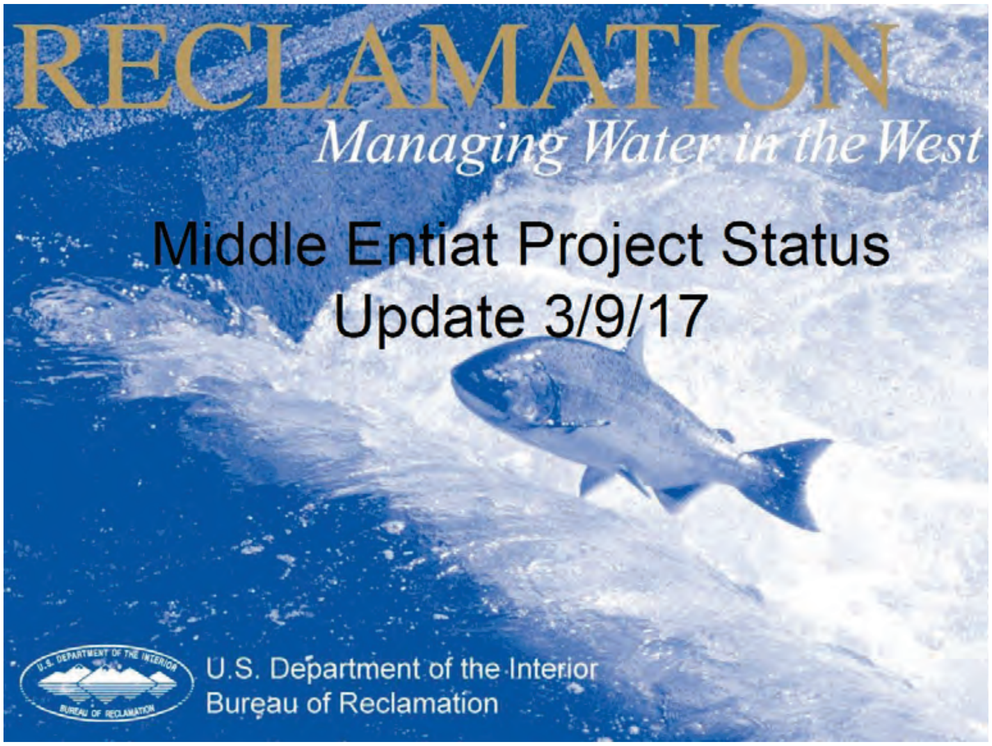
XI. Next Steps

The next meeting of the Tributary Committees will be on Thursday, 13 April 2017 at Grant PUD in Wenatchee.

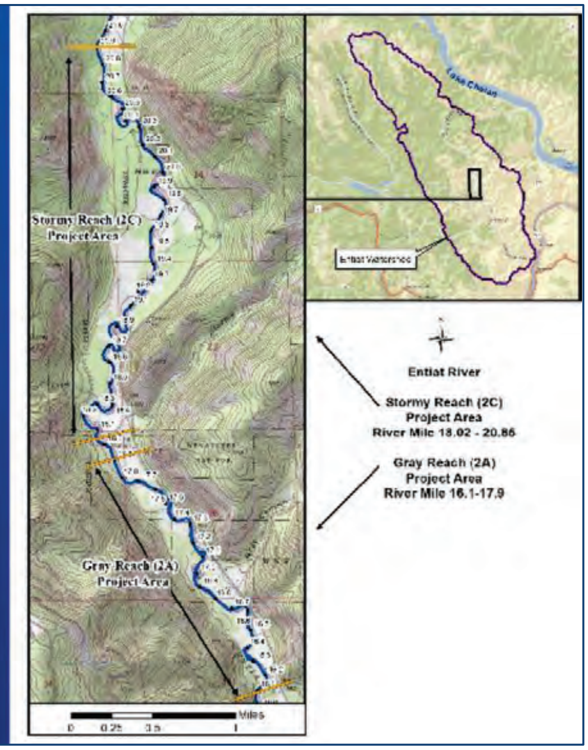
Meeting notes submitted by Tracy Hillman (tracy.hillman@bioanalysts.net).

Attachment 1

Presentation by Steve Kolk on the Status of the Middle Entiat Restoration Project



Vicinity Map

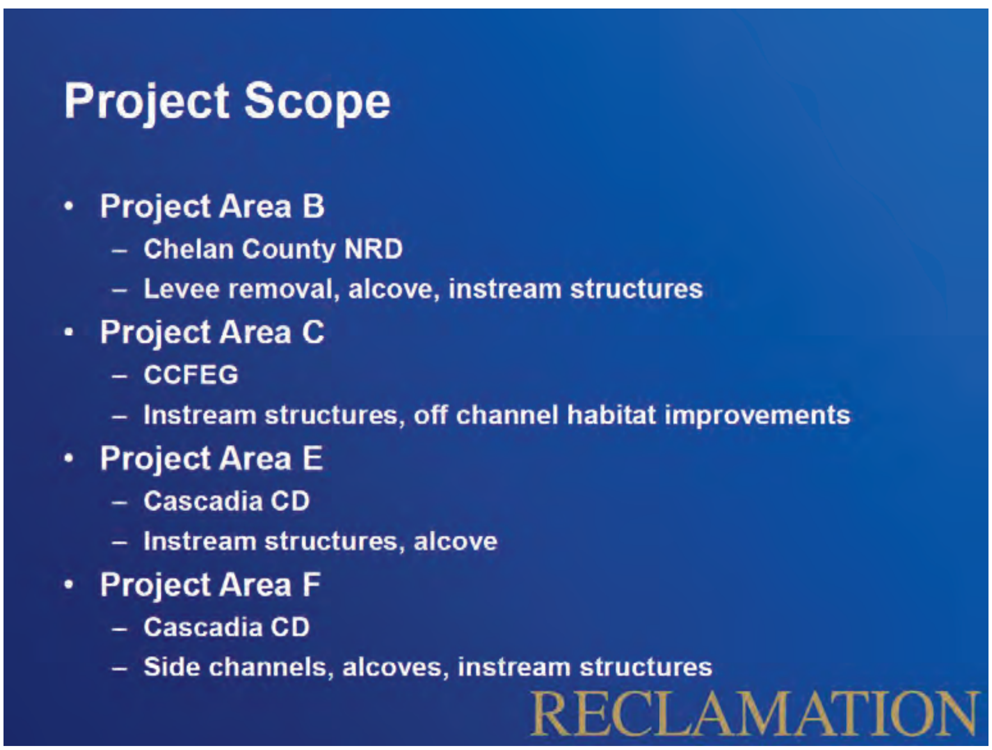


Primary Project Objectives

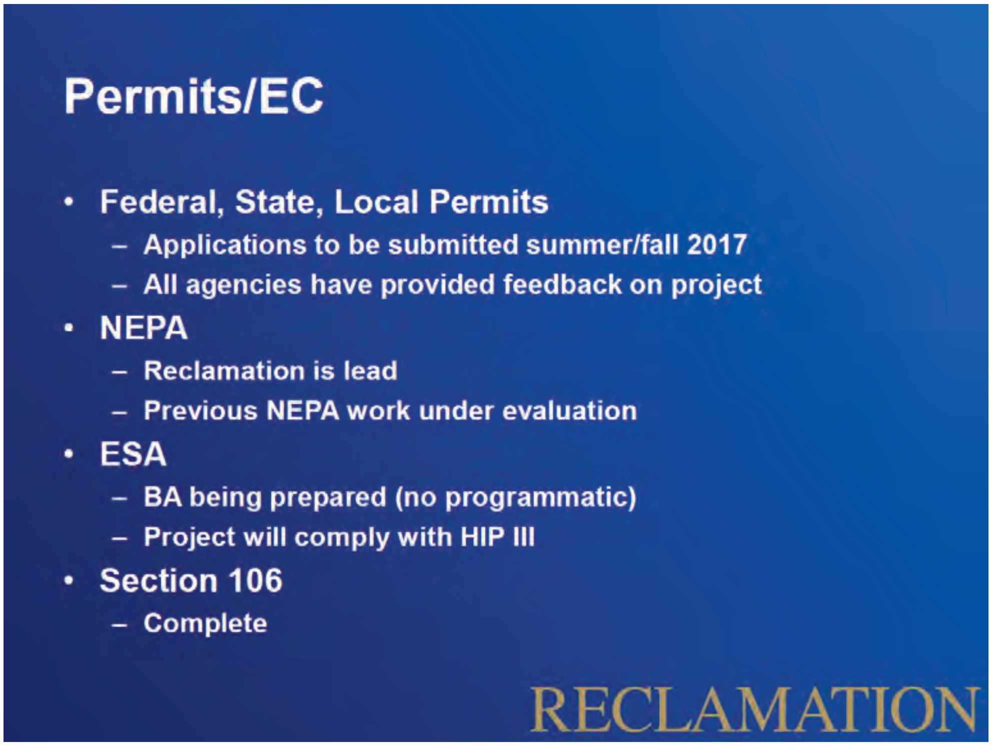
1. Improve off-channel habitat availability and quality
2. Improve habitat complexity
   a. Pool habitat frequency and quality within the main channel
   b. Edge habitat
   c. Alcove habitat
3. Re-engage channel forming processes (promote lateral channel migration)
4. Improve floodplain connectivity (reverse incision)

RECLAMATION

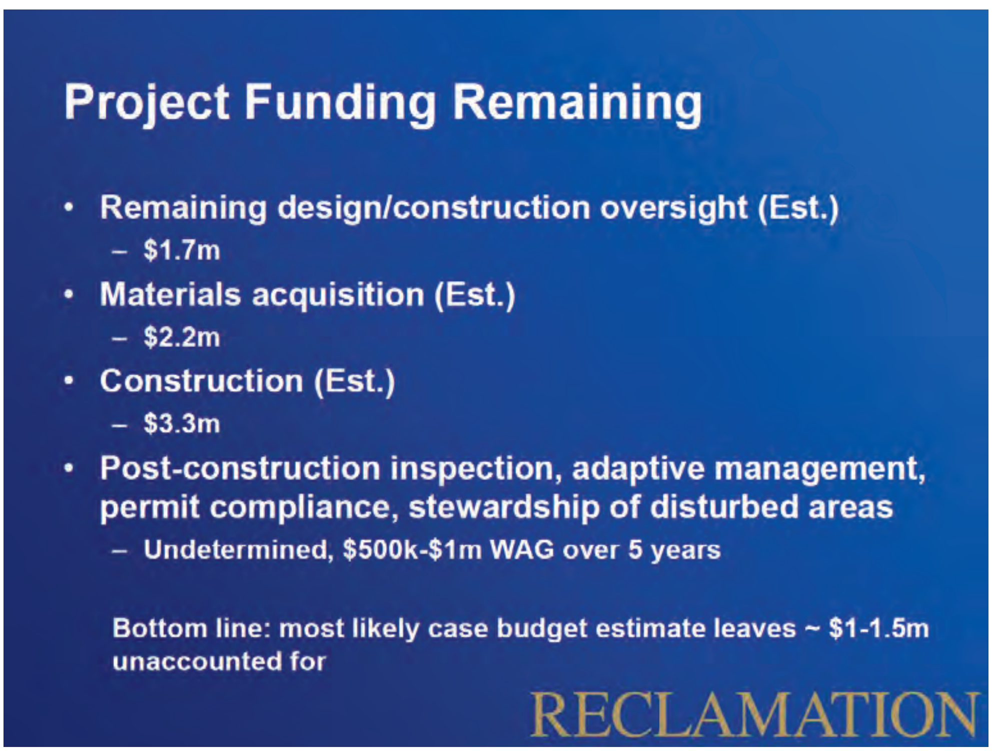
Landowner/Sponsor Considerations
1. Minimize impacts to existing habitat
a. Helicopter staging, structure assembly
2. Consider visual impacts
3. Minimize/eliminate ferrous anchoring
4. Adhere to WA HB 1194 (2013)
5. Follow BOR's Risk Based Design Guidelines
6. Rigorous inspection/adaptive management program following construction
RECLAMATION



Project Scope
• Project Area B
– Chelan County NRD
– Levee removal, alcove, instream structures
• Project Area C
– CCFEG
– Instream structures, off channel habitat improvements
• Project Area E
– Cascadia CD
– Instream structures, alcove
• Project Area F
– Cascadia CD
– Side channels, alcoves, instream structures
RECLAMATION



Permits/EC
• Federal, State, Local Permits
– Applications to be submitted summer/fall 2017
– All agencies have provided feedback on project
• NEPA
– Reclamation is lead
– Previous NEPA work under evaluation
• ESA
– BA being prepared (no programmatic)
– Project will comply with HIP III
• Section 106
– Complete
RECLAMATION



Project Funding Remaining
• Remaining design/construction oversight (Est.)
– $1.7m
• Materials acquisition (Est.)
– $2.2m
• Construction (Est.)
– $3.3m
• Post-construction inspection, adaptive management, permit compliance, stewardship of disturbed areas
– Undetermined, $500k-$1m WAG over 5 years
Bottom line: most likely case budget estimate leaves ~ $1-1.5m unaccounted for
RECLAMATION

Questions?
RECLAMATION

Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 13 April 2017

Members Present: Lee Carlson (Yakama Nation), Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Steve Hays (Chelan PUD), Tom Kahler (Douglas PUD), Kate Terrell (USFWS), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

Others Present: Becky Gallaher (Tributary Project Coordinator). Cody Gillin (Trout Unlimited) and Robes Parrish (USFWS) attended the meeting for the Beaver Fever discussion.

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Thursday, 13 April 2017 from 9:00 am to 12:30 pm.

I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda with revisions. Because of time constraints, they elected to drop discussions on the Middle Entiat Restoration Project and the Methow Beaver Project film. They will add these items on a future agenda.

II. Review and Approval of Meeting Minutes

The Committees reviewed and approved the 9 March 2017 meeting notes.

III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- MVID Instream Flow Improvement Project – The project sponsor (Trout Unlimited; TU) reported that as-builts have been completed. The remaining punch list items should be completed by 30 June 2017.
- Entiat Stillwaters Gray Reach Acquisition – The sponsor (Chelan-Douglas Land Trust; CDLT) reported that the Crone property is ready for closing.
- Clear Creek Fish Passage and Instream Flow Project – The sponsor (TU) reported that they are focused on permitting, engineering, and construction planning. They also worked on the water-right change process and completed another draft ROE, which was approved by the Chelan County Water Conservancy Board and is now being reviewed by Ecology.
- Barkley Irrigation – Under Pressure Project – The sponsor (TU) reported they have been working with Barkley Irrigation Company on pump site planning and coordination. They are evaluating three sites to determine the most affordable site for the pump station. They expect to have a site selected by late April.

- Methow Watershed Beaver Reintroduction Project – This project is complete. The final report and 2016 annual report were uploaded to the Extranet site.
- Similkameen RM 3.8 Project – The sponsor (Okanogan Conservation District; OCD) reported that Cardno has completed the design and cost estimate.
- White River Floodplain (RM 3.4) Connection Project – The sponsor (CCFEG) reported they have contracted with Dickenson Construction for the excavation phase of the project. The sponsor received an updated HPA that will allow for excavation during low flow this summer. The sponsor has submitted all materials to WDFW in order to receive the Right of Entry permit, which is the last permit needed for implementation.
- Icicle Boulder Field Project – The sponsor (TU) reported that they are procuring engineering services for the City of Leavenworth waterline. They also spent time working through project challenges, which seem to be political.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – The sponsor (WDFW) reported that the project is complete. The second-year monitoring report is due on 31 December 2017.
- Permitting Nutrient Enhancement Project – The sponsor (CCFEG) reported they will be presenting the project summary and monitoring proposal to the Forest Service in April. PACE Engineering is working on updating the QAPP to reflect Ecology's most recent concern about using analogs that may have PCBs and mercury. Last year CCFEG tested analogs from two sources and detected no toxics.
- Burns-Garrity Design Project – The sponsor (CCFEG) did not provide an update on this project.
- Beaver Fever Project – The sponsor (TU) reported that they and their restoration partners have narrowed the list of suitable sites for restoration to a few in each of the Wenatchee and Entiat basins. Additionally, they continue to consider an appropriate monitoring strategy.
- Wenatchee Sleepy Hollow Floodplain Acquisition Project – The sponsor (CDLT) did not provide an update on this project.
- Ecommunity Place Locatee Land Acquisition Project – The sponsor (Okanagan Nation Alliance; ONA) reported that the property is ready for closing. The final report has been received and will be uploaded to the Extranet site.

IV. Time Extensions

Clear Creek Fish Passage and Instream Flow Enhancement Project

The Rocky Reach Tributary Committee received a time extension request from Trout Unlimited on the *Clear Creek Fish Passage and Instream Flow Enhancement Project*. The sponsor asked the Committee to extend the period of the contract from 31 May 2017 to 30 September 2018. After review and discussion, ***the Rocky Reach Tributary Committee agreed to extend the contract to 30 September 2018***.

White River Floodplain Connection (RM 3.4) Project

The Rock Island Tributary Committee received a time extension request from CCFEG on the *White River Floodplain Connection (RM 3.4) Project*. The sponsor asked the Committee to extend the period of the contract from 30 September 2017 to 30 December 2017. After review and discussion, ***the Rock Island Tributary Committee agreed to extend the contract to 30 December 2017***.

V. General Salmon Habitat Program Proposal

Derby Creek Fish Passage – Collins Project

Last month, CCFEG submitted the *Debry Creek Fish Passage – Collins Project* proposal to the Tributary Committees. The purpose of this project is to remove the lowermost fish passage barrier culvert (RM 0.3) on Derby Creek, a tributary to the Wenatchee River. Removal of the lowermost barrier will open about 10 miles of habitat for steelhead spawning and rearing. The total cost of the project is $190,000. The sponsor requested $90,000 from HCP Tributary Funds. The Committees were unable to make a funding decision and requested additional information from the sponsor. Specifically, the Committees asked the sponsor to respond to the following questions/comments:

1. Describe the status of fish passage at the obstacles downstream from the proposed passage barrier. For example, there is one obstacle that is highlighted "unknown passability." Is this at the road or railroad crossing and is there evidence that it is passable?
2. Indicate the location of the PIT-tag array on the map prepared by Chris Dwight.
3. Does Derby Creek dewater at any time of year, and, if so, where?
4. The proposal indicates that CCFEG has removed one total barrier and received funding for removal of two additional barriers. Please show on the map prepared by Chris Dwight the location of these barriers.
5. Has NRCS confirmed that they will fund the cost share?
6. Did you consider replacing the barriers with small bridges similar to those used on Frazer Creek in the Methow River basin (e.g., see: http://methowsalmon.org/currentprojects.html)? If so, why are they not the preferred alternative?

In late March CCFEG provided responses to the Committees' questions. The sponsor also indicated that they revised the budget for the project. This is largely because they now intend to use a steel-bridge deck rather than a concrete-bridge deck. Using a steel-bridge deck reduced the estimated cost of the project by about $30,000. The revised total cost of the project is $155,000. They requested $65,000 from HCP Tributary Funds (aka Plan Species Account Funds). The Committees evaluated and discussed the responses from the sponsor and the ***Rock Island Tributary Committee elected to contribute $65,000 to the project***.

The Committee noted that if the sponsor intends to seek additional funds from the Committees to address other passage issues in Derby Creek, the sponsor will need to conduct a habitat assessment to determine the quality and quantity of habitat within the stream and also to demonstrate that steelhead and/or Chinook salmon use the stream for spawning and rearing. This will help the Committee determine if the biological benefit of enhancing fish passage justifies the cost.

VI. Review of Tributary Committees' Policies and Procedures

Policies and Procedures for Funding Projects

The Committees completed their review of the Policies and Procedures document and added the following language to the beginning of Section 6.3 (Timelines and Extensions).

> *Project Sponsors must have a signed contract with the Committees within one (1) year from the date when the Committees approved the project. In the event the Project Sponsor does not have a signed contract because of a lack of additional funds (cost share), a lack of landowner support, or any other reason, the Committees may cancel funding for the project. After the one-year period, the Project Sponsor may need to resubmit a new proposal seeking funding for a canceled project.*

Tributary Committee Operating Procedures

The Committees reviewed their Operating Procedures and elected to remove the following statement from Section IX (Plan Species Account):

> *The Committees will provide financial reports to the District no less than on a quarterly basis.*

The Committees provide annual reports and believe there is no need to provide quarterly reports.

VII. Information Updates

The following information updates were provided during the meeting.

1. Approved Payment Requests in March and April:

   Rock Island Plan Species Account:

   - $80.00 to Clifton Larson Allen for Rock Island financial administration in March 2017.
   - $44,484.53 to Okanagan Nation Alliance for the Ecommunity Place Locatee Land Acquisition.

   Rocky Reach Plan Species Account:

   - $80.00 to Clifton Larson Allen for Rocky Reach financial administration in March 2017.
   - $309.55 to Okanogan Conservation District for work in February on the Similkameen RM 3.8 Rehabilitation Project.
   - $9,000.00 to North Meridian Title for the Entiat Stillwaters Gray Reach Acquisition (Crone Property).
   - $14,500 to Chelan-Douglas Land Trust for the Entiat Stillwaters Gray Reach Acquisition (Cone Property Stewardship Plan).

   Wells Plan Species Account:

   - $833.00 to the Methow Salmon Recovery Foundation for work on the Methow Watershed Beaver Reintroduction Project (final payment).
   - $4,843.09 to Trout Unlimited for work during March on the MVID Instream Flow Improvement Project.
   - $456.64 to Chelan PUD for project coordination and administration during the first quarter of 2017.

2. Tracy Hillman shared the Salmon Recovery Funding Board (SRFB) and Tributary Committees Funding Schedule with the Committees (see Attachment 1). He said draft proposals are due on Friday, 14 April. Project tours will be on 10 May (Wenatchee), 11 May (Entiat), and 18 May (Methow). The Committees will evaluate the draft proposals on Thursday, 8 June and decide which projects should be submitted as final proposals. Final proposals are due on Friday, 30 June. The Committees will evaluate final proposals and make funding decisions on Thursday, 13 July.

3. During the September 2016 meeting, members of the Committees identified possible funded projects they would like to visit in 2017 (see Item #2 on page 4 of the September 2016 meeting notes). Given the long list of possible projects, Tracy Hillman asked the Committees if they would like to refine the list so the tour would take no more than two days (one day for Okanogan/Methow projects and one day for Entiat/Wenatchee projects). In November 2016, Chris Fisher recommended each member identify five projects they would like to visit. During

the April 2017 meeting, members agreed to wait until the May 2017 meeting to identify their top projects for a field visit.

4. Tracy Hillman reported that the Northwest Power and Conservation Council (NPCC) staff and Bonneville Power Administration (BPA) staff have scheduled a meeting with various Upper Columbia entities including tribes, state agencies, project sponsors, monitoring groups, etc. to discuss insights and experiences related to habitat actions and monitoring in the basin. Specifically, NPCC and BPA want to better understand how different entities are using data or products from the Integrated Status and Effectiveness Monitoring Program (ISEMP), Columbia Habitat Monitoring Program (CHaMP), and BPA's Action Effectiveness Monitoring (AEM) Program. The meeting will be held on Wednesday, 19 April at the Upper Columbia Salmon Recovery Board Office. Tracy said he was asked to participate in the meeting and share Regional Technical Team perspectives.

VIII. Beaver Fever Project Presentation and Discussion

Cody Gillin (TU) and Robes Parrish (USFWS) gave a presentation on the status of the Beaver Fever Project (see Attachment 2). This was the second time the project sponsors met with the Tributary Committees. The purpose of the first meeting was to get feedback from the Committees on where to focus BDA work and what metrics should be monitored to assess BDA effectiveness (see January meeting notes). During this meeting, Cody and Robes described results from their recent modeling work, which included both primary and secondary ranking criteria. Primary criteria included gradient and site accessibility. Secondary criteria included fish distribution data, temperature data, ecological concerns (limiting factors), stream flows, consideration of social-recreation-land use, and opportunities for robust monitoring. Within the Wenatchee River basin, 46 of the 78 streams ranked high according to the primary criteria, while only three streams ranked high using both the primary and secondary criteria. Those included the White River, Icicle Creek historical channel, and Icicle Leavenworth National Fish Hatchery canal. Within the Entiat River basin, five of 22 streams ranked high according to the primary criteria; two ranked high using both the primary and secondary criteria. Those were Roaring Creek and Potato Creek. Cody and Robes provided reasons why Potato and Roaring creeks are the most appropriate for BDA work. They then compared the effects of beavers and BDAs on biological, hydrologic/geomorphic, chemical parameters. They also described the potential positive and negative effects of beaver modifications on fish. They concluded their presentation by describing possible parameters to be monitored at BDA sites.

The Committees supported BDA work in both Roaring and Potato creeks and recommended that in one stream BDAs be clustered and in the other BDAs be more widely spaced. This will provide information on the effects of spatial arrangement of BDAs on fish and habitat. The Committees also recommended that the monitoring work focus on effects of BDAs on stream flows, water temperatures, other habitat conditions (metrics identified on the last slide of the presentation), and fish. The Committees had a lengthy discussion on fish monitoring. They ended by recommending the sponsor monitor abundance and distribution of different fish species seasonally before and after implementation of BDAs. They also suggested the need to monitor fish abundance and distribution in control areas (i.e., BACI monitoring design). Fish data could be collected using snorkel or electrofishing surveys. The Committees also advised the sponsor to work with WDFW on the possibility of using mark-recapture methods to estimate abundance and fish movement.

IX. Next Steps

The next meeting of the Tributary Committees will be on Thursday, 8 June 2017 at Grant PUD in Wenatchee. The Committees will tour proposed projects in May.

Meeting notes submitted by Tracy Hillman (tracy.hillman@bioanalysts.net).

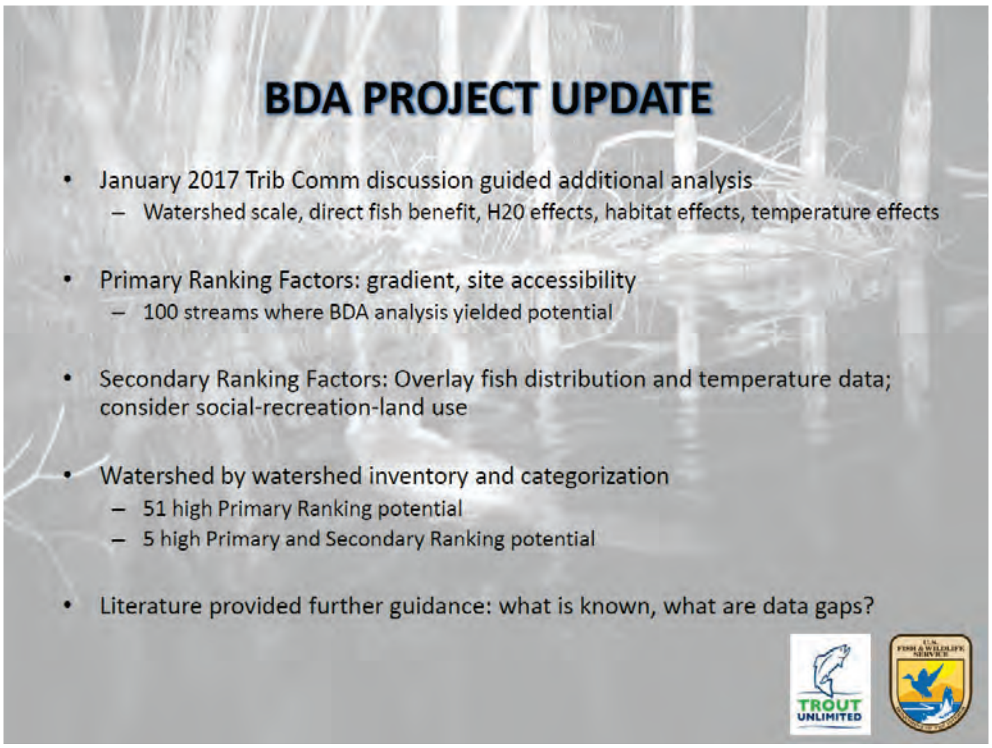
Attachment 2

Presentation by Cody Gillin and Robes Parrish on the Status of the Beaver Fever Project



CRITERIA TO ACHIEVE HIGH PRIMARY RANKING FACTOR POTENTIAL

- Many dots or dot clusters in the first run BDA suitability analysis
  - < 2% slope, within 200 feet of a road

High Primary Ranking Potential

Low Primary Ranking Potential

CRITERIA TO ACHIEVE HIGH SECONDARY RANKING POTENTIAL

- ESA and other salmonid species use (UCSRB, SWIFD)
- Addressing top Ecological Concerns in the Assessment Unit
- Perennial or near perennial flow (but not too much discharge)
- No social-recreation-land use challenges
- Watershed-scale implementation potential AND/OR opportunity for significant physical and hydrological improvements
- Validation of Primary Ranking Factors geospatial analysis
- Opportunities for robust monitoring and data gathering
- Considered historic / predicted stream temperatures
- Some objective, some based on knowledge / experience

+ access, ECs, species, flow, scale
- recreation conflict, monitoring, feasibility

+ access, ECs, species, flow, scale
monitoring, feasibility

Wenatchee River Basin Primary-Secondary Ranking Factor Results

HIGH-HIGH	HIGH-MEDIUM	HIGH-LOW
~~Icicle Historic Channel~~	Skinney Creek	Mainstem Wenatchee River
~~Icicle LNFH Canal~~	Beaver Creek	Chumstick Creek
WDFW-PUD-CDLT White River	Tronsen Creek	Mainstem Upper Icicle Creek
?	Peshastin Creek (above Ingalls)	Mainstem White River
	Lower White unnamed roadside tribs	Gill Creek
	Lower Wenatchee CDLT side channel	Fish Lake Run (outlet)
	Derby Creek	Scotty Creek
	Eagle Creek	Peshastin Creek (below Ingalls)
	Van Creek	Mainstem Mission Creek
	Sunitsch Creek	Sand Creek
	Railroad Canyon Creek	Tripp Creek
	Deep Creek	Brender Creek
	unnamed trib across from Deep Creek	Yaksum Creek

		Spromberg Canyon Creek
		Longview Canyon Creek
		Clark Canyon Creek
		Little Chumstick Creek
		Mainstem Chiwawa River
		Chikamin Creek
		Rock Creek
		Clear Creek
		Big Meadow Creek

46 of 78 Wenatchee streams with high Primary Ranking
3 with high Primary and Secondary Ranking

Entiat River Basin Primary-Secondary Ranking Factor Results

HIGH-HIGH	HIGH-MEDIUM	HIGH-LOW
Roaring Creek Potato Creek		Mud Creek Mainstem Entiat River Mainstem Mad River

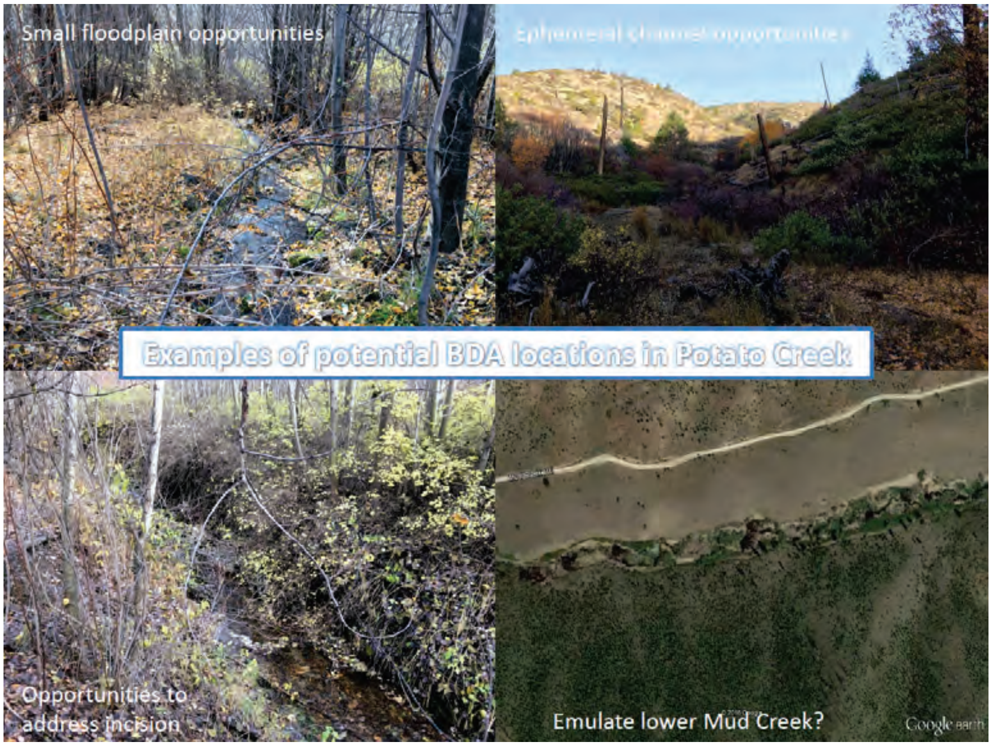
5 of 22 Entiat streams with high Primary Ranking
2 with high Primary and Secondary Ranking

THE CASE FOR ROARING AND POTATO

- ESA species
  - Roaring known Entiat STHD stronghold
  - STHD and Chinook in Potato (relative abundance unknown)

Last Antenna Group Name	Release Date MMDDYYYY	Species Code	Species Name	Run Code	Run Name	Rear Type Code	Rear Type Name	Release Site Name
DSM BYPASS SURFACE COLLECTOR	7/13/2011	3	Steelhead	2	Summer	W	Wild Fish or Natural Production	POTATC - Potato Creek, tributary to Entiat River

- Flow: Perennial / near perennial, some large substrate
- Social constraints: None to our knowledge, single to few landowners
- Scale: Multi-reach (Lower Roaring Ck.) to watershed (Potato Ck.) potential
- Validation of Primary Ranking: So far, yes, more work needed



Small floodplain opportunities
Ephemeral channel opportunities
Examples of potential BDA locations in Potato Creek
Opportunities to
address incision
Emulate lower Mud Creek?
Google earth

Side channel and floodplain
opportunities
Diversion rehabilitation opportunities
Examples of potential BDA locations in Roaring Creek
Pool development opportunities

	Beavers	BDAs	Notes
Biological Effects			
Increased fish density	●	◓	Shown for many species; higher linear and areal densities in BC
Increased fish survival	●	◓	Shown for STHD, Chinook, coho. +52% in Bridge Cr. BDA sthd.
Increased fish growth	○	○	Decreased growth in Bridge Cr. study
Fish Productivity	●	◓	+175% juv. STHD in BC after 4yrs (density, growth, survival)
Overwinter refuge	◓	(?)	-86% in Stillaguamish coho ovw capacity; freezing (eg, Wilson)?
Invertebrates	◓	(?)	>diversity but largely changes from lotic to lentic taxa
Fish barriers	○	○	Highly speculative, variable., no effect in Bridge Cr. w/236 dams for adult or juvenile upstream or downstream
Hydrologic-Geomorphic Effects			
Change Flow Regime	●	(?)	Shown under both removal and addition of dams
Aggradation/Incision	●	◓	1" to > 0.5m; more lit. on natural dams than BDAs
Groundwater storage	●	◓	Shown for small check structures and BDAs
Peak flow amelioration	●	(?)	Up to 5%. Recent paper shows not dependent on confinement
Temperature reduction	◓	◓	Positive with >depth and GW exchange. -1.5C in BC. Less flux
Channel complexity	●	◓	Most of BDA results from Bouwes 2016.
Riparian expansion	◓	(?)	Can be expansive; change in veg. types/mosaic; No lit. on BDAs
Sediment storage	●	(?)	Can be large effect: varies by age, vegetation, u/s dam failure
Heterogeneity	●	●	Incr. depths, 3x side channels, deeper pools, inundation area

	Beavers	BDAs	Notes
Chemical Effects			
Biogeochemical cycling	◓	(?)	Ponds trap WM and beaver caches store organic material
Deposition/Retention	◓	(?)	See above; Naimain 1994 constitutes much of published work
Nutrient amelioration	●	◓	Easily bound with sediment but also released upon dam failure; some European studies show retention times of 6-8 days is sufficient to remove excess nitorgen, phosphorus, and herbicides; small check dams store sediment

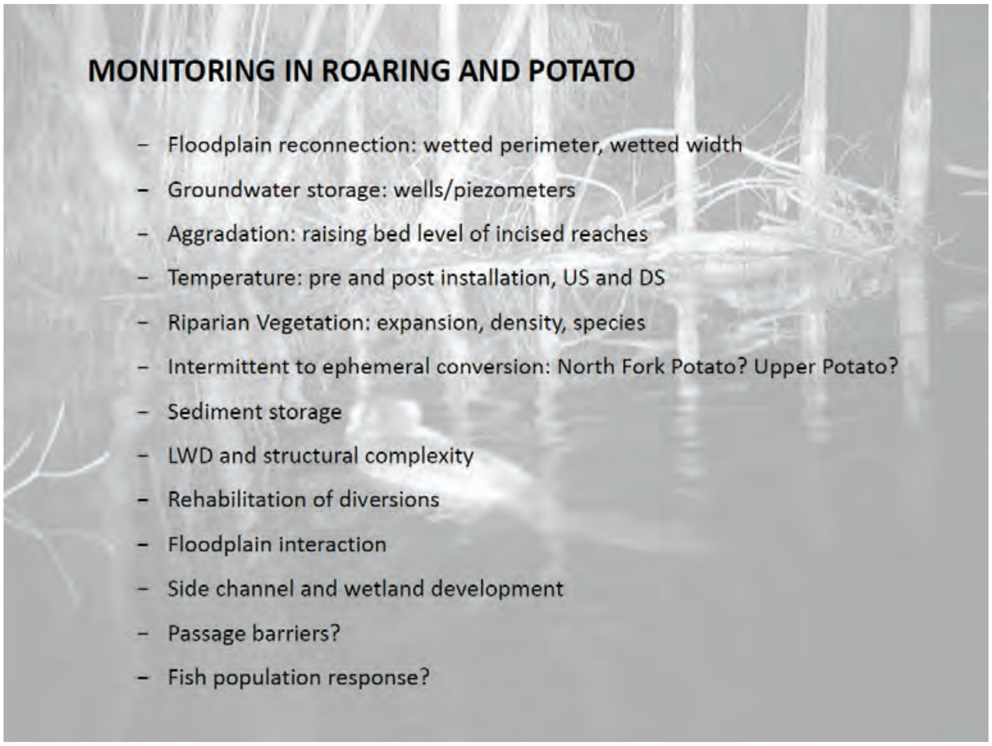
Kemp et al. (2012) meta analysis

Potential Impacts of Beaver Modifications on Fish Species

Potential Positive Impacts
- Increased fish productivity/abundance
- Increased habitat and habitat heterogeneity
- Increased rearing and overwintering habitat
- Enhanced growth rates
- Providing flow refuge
- Improved production of invertebrates

Potential Negative Impacts
- Barriers to fish movement
- Siltation of spawning habitat
- Low oxygen levels in beaver ponds
- Altered temperature regime

Kemp et al. noted that many of the positive effects cited (51.5 percent) were supported by data, while many more of the negative impacts (71.4 percent) were speculative and not supported by data collected in the field. Furthermore, the most commonly cited negative impact of beaver dams—as barriers to fish movement—was highly speculative, as 78.4 percent of the studies did not support this claim with data.



MONITORING IN ROARING AND POTATO
– Floodplain reconnection: wetted perimeter, wetted width
– Groundwater storage: wells/piezometers
– Aggradation: raising bed level of incised reaches
– Temperature: pre and post installation, US and DS
– Riparian Vegetation: expansion, density, species
– Intermittent to ephemeral conversion: North Fork Potato? Upper Potato?
– Sediment storage
– LWD and structural complexity
– Rehabilitation of diversions
– Floodplain interaction
– Side channel and wetland development
– Passage barriers?
– Fish population response?

Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 8 June 2017

Members Present: Lee Carlson (Yakama Nation), Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Steve Hays (Chelan PUD), Tom Kahler (Douglas PUD), Kate Terrell (USFWS), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

Others Present: Becky Gallaher (Tributary Project Coordinator).

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Thursday, 8 June 2017 from 9:30 am to 12:30 pm.

I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda with revisions. Two budget amendments and an update on the Beaver Creek road damage were added to the agenda.

II. Review and Approval of Meeting Minutes

The Committees reviewed and approved the 13 April 2017 meeting notes.

III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- MVID Instream Flow Improvement Project – The project sponsor (Trout Unlimited; TU) reported that they are completing the final punch list items.
- Clear Creek Fish Passage and Instream Flow Project – The sponsor (TU) reported that they completed the installation of two, 6-inch pipes that will provide a conduit for the electrical and water lines. This system will connect the new treatment plant to the water-storage cistern. Ecology recently approved the water-right change application. The Source Approval Package was compiled and submitted to the Department of Health. Finally, the sponsor initiated the bid package development process and began compiling bid and contract documents.
- Barkley Irrigation – Under Pressure Project – The sponsor (TU) reported they have been working with Barkley Irrigation Company on pump site planning and project coordination. They also spent time coordinating the Barkley and MVID ditches and continue to work through the water-right change process. They are nearing completion of the Righty of Entry.
- Similkameen RM 3.8 Project – The sponsor (Okanogan Conservation District; OCD) reported that permits, based on the updated design, have been submitted to DNR and WDFW. A paper copy will be sent to the Corps of Engineers. A Request for Proposals will be prepared and distributed in early June.

- White River Floodplain (RM 3.4) Connection Project – The sponsor (CCFEG) reported they will be coordinating with WDFW to select an appropriate time for construction. The sponsor ordered 100 cedar trees and riparian plants for revegetation work along a portion of the project.
- Icicle Boulder Field Project – The sponsor (TU) reported they have been working with their consultants to set up the scope of work for the City of Leavenworth waterline and Geotech work. Fieldwork this summer will focus on geotech work. In addition, the sponsor continues to work on permitting and they are preparing the JARPA for geotech and project implementation.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – The sponsor (WDFW) will submit the second-year monitoring report on 31 December 2017.
- Permitting Nutrient Enhancement Project – The sponsor (CCFEG) reported they have finalized the proposal for implementation and monitoring and sent it to the Forest Service and other project partners. They will hold a meeting with project partners on Friday, 9 June, to discuss project feasibility and next steps.
- Burns-Garrity Design Project – The sponsor (CCFEG) reported that selection of a restoration concept was put on hold when a landowner listed his property for sale. The sponsor continues to do landowner outreach, delineate wetlands, and discuss potential effects of restoration alternatives.
- Beaver Fever Project – The sponsor (TU) reported that they initiated site-specific research and are developing a permitting strategy. Because BDA projects have not been implemented on Okanogan-Wenatchee forest lands, the sponsor and the USFWS are reaching out to BDA implementers to learn how to permit these projects on Forest Service lands.
- Wenatchee Sleepy Hollow Floodplain Acquisition Project – The sponsor (CDLT) reported they are still waiting for funding approval from Washington Wildlife and Recreation. The legislature failed to pass a budget in the regular session or first special session. As soon as the capital budget is passed, the sponsor will prepare the boundary line adjustment to separate the house from the rest of the property. The property will then be reappraised.

IV. Budget Amendments

Clear Creek Fish Passage Project

In May, the Rocky Reach Tributary Committee received a budget amendment request from Trout Unlimited on the *Clear Creek Fish Passage Project*. The sponsor asked to move $2,000 from "Project Materials and Supplies" to Professional Services and Permitting." Via email, ***the Rocky Reach Tributary Committee approved the budget amendment***. The amendment will not change the total budget amount.

Permitting Nutrient Enhancement in the Chiwawa River Basin Project

The Rock Island Tributary Committee received a budget amendment request from CCFEG on the *Permitting Nutrient Enhancement in the Chiwawa River Basin Project*. The sponsor asked to move $1,028 from "Professional Services" and "Indirect/Admin/Overhead" to "Sponsor Salaries and Benefits." ***The budget amendment was approved.*** The amendment will not change the total budget amount.

White River Floodplain Connection (RM 3.4) Project

The Rock Island Tributary Committee received a budget amendment request from CCFEG on the *White River Floodplain Connection (RM 3.4) Project*. The sponsor asked to take all the available funds in "Excavation and Heavy Equipment" ($5,000) and "Project Materials and Equipment" ($500) and move those into "Salaries and Benefits," "Overhead and Administration," and "Permit Fees." According to the request, this amendment will leave no money for excavation and haul. The Committee questioned how the project will be completed if there is no money available to conduct excavation and heavy equipment work. As a result, ***the Rock Island Tributary Committee denied the request until the sponsor can describe how the project will be completed without excavation and haul***.

V. Time Extension

Barkley Irrigation Project

In May, the Rock Island Tributary Committee received a time extension request from Trout Unlimited on the *Barkley Irrigation Project*. Because construction on the project is unlikely to begin until this fall, the sponsor asked to extend the project from 31 May 2017 to 31 December 2018. Via email, ***the Rock Island Tributary Committee approved the time extension***.

VI. General Salmon Habitat Program Draft Proposals

The Committees received nine General Salmon Habitat Program draft proposals. The Committees reviewed each draft proposal and selected those that they believe warranted a final proposal. Projects that the Committees dismissed were either inconsistent with the intent of the Tributary Fund, did not have strong technical merit, or had low benefits per cost. The Committees assigned draft proposals to one of two categories: Fundable and Not Fundable. It is important to note that these are ratings of draft proposals and do not reflect ratings of final proposals. The Committees directed Tracy Hillman to notify sponsors with appropriate projects to submit a final proposal, with a discussion of the questions/comments identified for each draft proposal listed below. Tracy will also notify sponsors with projects that have no chance or a low likelihood of receiving funding from the Tributary Committees.

Stormy Preserve – Restore Wood Recruitment Project (Not Fundable)

The Committees recommend that this project, sponsored by Cascade Columbia Fisheries Enhancement Group, should not be submitted as a full proposal to the Tributary Committees for the following reason:

- At this time, the Committees are not interested in funding the construction of large wood structures in the Stormy Preserve. However, they would accept applications that address levee removal and floodplain reconnection projects.

Icicle RM 0.3-1.1 Habitat Design Project (Not Fundable)

The Committees recommend that this project, sponsored by Chelan County Natural Resources Department, should not be submitted as a full proposal to the Tributary Committees for the following reason:

- The Committees believe the project is too expensive for a conceptual design and they recommend that the sponsor spend time discussing the project with the landowner to find out what level of restoration the landowner will allow on their property. For example, riparian vegetation along the meander bend will need to be widened to allow for meaningful process-based restoration. It is unknown if the landowner is willing to allow widening of the riparian area at this site.

M2 WDFW Flow Connection Project (Fundable)

The Committees recommend that the project sponsor (Methow Salmon Recovery Foundation) address the following comment/suggestion as they develop the full proposal:

- The sponsor needs to describe what type of fence will be installed and who will be responsible for maintaining the fence.

M2 Mid-Sugar Acquisition Project (Fundable)

The Committees recommend that the project sponsor (Methow Salmon Recovery Foundation) address the following comment/suggestion as they develop the full proposal:

- For accounting purposes, the sponsor should include the Tributary Committees' match ($43,690) in the land purchase cost, not in the other line items.

Wenatchee LiDAR Acquisition Watershed Assessment Project (Not Fundable)

The Committees recommend that this project, sponsored by Chelan County Natural Resources Department, should not be submitted as a full proposal to the Tributary Committees for the following reasons:

- It is not clear what the project will provide in terms of restoration and protection that does not already exist. For example, roads that are likely to contribute significant amounts of fine sediments to streams have been identified or can be identified during road surveys and/or aerial photography.
- The proposal did not describe how LiDAR data combined with temperature data will be used to map the distribution of invasive species.
- A better approach would be to use Green LiDAR, at least within the floodplains.

Piscine Passage Design for Brush and Minnow Creeks Project (Fundable)

The Committees recommend that the project sponsor (Cascade Columbia Fisheries Enhancement Group) address the following comments/suggestions as they develop the full proposal:

- Because this is a design project, the sponsor needs to consider ways to reduce the cost of the project. The Committees believe the project is too expensive.
- The sponsor needs to provide information on the status of the roads. For example, will the roads, especially the one crossing Brush Creek be removed or abandoned.

Sleepy Hollow Side Channel Feasibility Study Project (Not Fundable)

The Committees recommend that this project, sponsored by Chelan County Natural Resources Department, should not be submitted as a full proposal to the Tributary Committees for the following reason:

- The Committees believe the side channel and floodplain are currently functioning to the benefit of salmonids. Indeed, the goal of the acquisition was to protect the existing habitat.

Tillicum Creek Culvert Replacement Project (Not Fundable)

The Committees recommend that this project, sponsored by Chelan County Natural Resources Department, should not be submitted as a full proposal to the Tributary Committees for the following reasons:

- The Committees believe there is limited usable habitat upstream from the culvert (there appears to be a total or partial fish passage barrier just upstream from the old road crossing).
- The channel upstream and downstream from the culvert is a confined, relatively steep channel that provides limited fish benefit. Thus, the potential benefits of the project do not justify the cost of the project.

Methow Basin Barrier and Diversion Assessment Project (Fundable)

The Committees recommend that the project sponsor (Cascade Columbia Fisheries Enhancement Group) address the following comments/suggestions as they develop the full proposal:

- Given the extensive spawning surveys conducted in the Methow River basin, the sponsor needs to describe how much more information this project will provide beyond what is currently known.
- The sponsor needs to provide a summary of what was learned from implementing a similar

project in the Wenatchee River basin.

- The sponsor should consider focusing their efforts in a few high-priority watersheds. This will reduce the need to repeat the surveys in the future.

VII. Small Projects Program Application

Poison Canyon Restoration Project

The Committees reviewed a Small Projects Program application from Chelan County Natural Resources Department titled, *Poison Canyon Restoration*. The purpose of the project is to aggrade incised reaches within Poison Canyon, a tributary to Sand Creek, which is a tributary to Mission Creek, by installing about 20 wood jams using onsite wood and hand tools. Aggrading the channel should improve instream flows and water quality in Mission Creek. The total cost of the project is $73,330. The sponsor requested $38,160 from HCP Tributary Funds. After careful consideration, ***the Committees declined the opportunity to fund the project***. The Committees believe the project is overly engineered and too expensive. Based on implementation of similar projects, the Committees believe that two or more structures can be constructed per day. In addition, they see no need for highly engineered structures in this stream. Rather, simply adding appropriately sized wood to the channel should be appropriate. This will also reduce the cost of the project. Finally, they see no need to monitor the project with game cameras or piezometers. The Committees noted that if the sponsor addresses these concerns, the sponsor is welcome to submit a revised proposal for the Committees' consideration.

VIII. Methow Beaver Project Film

Because of time constraints, the Committees were unable to watch the film, "One Stick at a Time." Members asked for the link to the film so they can watch it on their own time. Below is the link.

https://youtu.be/EQNK7W-P-_0

IX. Information Updates

The following information updates were provided during the meeting.

1. Approved Payment Requests in May and June:

   Rock Island Plan Species Account:

   - $102.50 to Clifton Larson Allen for Rock Island financial administration in April 2017.
   - $40.00 to Clifton Larson Allen for Rock Island financial administration in May 2017.
   - $2,618.83 to Cascade Columbia Fisheries Enhancement Group for the White River Floodplain Connection Project.
   - $1,665.57 to Cascade Columbia Fisheries Enhancement Group for the Permitting Nutrient Enhancement in the Chiwawa River Project.

   Rocky Reach Plan Species Account:

   - $102.50 to Clifton Larson Allen for Rocky Reach financial administration in April 2017.
   - $40.00 to Clifton Larson Allen for Rocky Reach financial administration in May 2017.

- $17,110.26 to Okanogan Conservation District for work on the Similkameen RM 3.8 Rehabilitation Project.

Wells Plan Species Account:

- $10,005.01 to Trout Unlimited for work on the MVID Instream Flow Improvement Project.

2. Tracy Hillman reported that project sponsors will give presentations to the Upper Columbia Regional Technical Team and the Tributary Committees on Wednesday, 14 June at the Sunnyslope Fire District on Easy Street. Tracy said final proposals are due on Friday, 30 June. The Committees will evaluate final proposals and make funding decisions on Thursday, 13 July.
3. Tracy Hillman said the Independent Scientific Advisory Board (ISAB) will be in Wenatchee on 19-21 July for presentations and site visits as part of their evaluation of Upper Columbia Spring Chinook. An agenda for their visit has not yet been prepared, but it is likely the ISAB will want information and maybe presentations from the Tributary Committees. Tracy said he will share more information as it becomes available.
4. Tracy Hillman and Becky Gallaher shared with the Committees possible logos for the Tributary Committees. The Committees identified one logo that with some modifications may work for the Committees. Tracy will work with the designer and present an updated version to the Committees in July.
5. Chris Fisher shared with the Committees that a rain event in early May damaged a portion of the Upper Beaver Creek road. Chris said he met on site with County Commissioners, Methow Salmon Recovery Foundation, Bonneville Power Administration, Salmon Recovery Funding Board, and others to discuss the problem. The meeting started off with Commissioners blaming fish enhancement work in Beaver Creek for causing the road damage. Chris said the engineer of the enhancement work (Tracy Drury with Anchor QEA) indicated that the road would have been damaged regardless of the habitat enhancement work. Chris said by the end of the site visit, the parties involved expressed an interest in finding common ground and moving forward in some undefined way to make the existing road safe and passable, and identify changes, repairs, and improvements that would improve both the resilience of the road and the function of the floodplain.

   Tracy Hillman noted that he received an email from Chris Johnson, Methow Salmon Recovery Foundation, asking if the Tributary Committees would support the idea of a cooperative action to help demonstrate a commitment to fish projects implemented in Beaver Creek. After a long discussion, the Committees agreed to continue to support the enhancement of fish habitat within Beaver Creek. However, they will not support the rebuilding of the road in its current location. They believe the road would have been damaged regardless of enhancement work in the stream. Thus, if the County is looking for support from the Tributary Committees to restore the existing road, the Committees are not interested. On the other hand, the Committees may support the relocation of the road, allowing Beaver Creek to use a larger portion of its floodplain. Relocating the road will make the road more resilient to future flood events and will improve the ability of Beaver Creek to sustain fish habitat. The sustainability of fish habitat is the common ground that the Committees would find compatible with a funding decision. The Committees directed Tracy to relay this information to Chris Johnson.

X. Next Steps

The next meeting of the Tributary Committees will be on Thursday, 13 July 2017 at Grant PUD in Wenatchee. At that time, the Committees will review final proposals.

Meeting notes submitted by Tracy Hillman (tracy.hillman@bioanalysts.net).

Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 13 July 2017

Members Present: Lee Carlson (Yakama Nation)[1], Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Steve Hays (Chelan PUD), Tom Kahler (Douglas PUD), Kate Terrell (USFWS), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

Others Present: Becky Gallaher (Tributary Project Coordinator).

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Thursday, 13 July 2017 from 10:00 am to 12:15 pm.

I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda.

II. Review and Approval of Meeting Minutes

The Committees reviewed and approved the 8 June 2017 meeting notes.

III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- MVID Instream Flow Improvement Project – The project sponsor (Trout Unlimited; TU) reported that they are completing the final punch list items. They are also working with MVID and the Bureau of Reclamation (BOR) on a drainage issue near Wright Road, east of Twisp. Fires upslope from the pipeline have increased surface runoff in a small canyon. The ditch that used to capture the water is now a buried pipe. BOR is working on a conceptual design and cost analysis for piping the surface-water runoff to the Methow River.
- Clear Creek Fish Passage and Instream Flow Project – The sponsor (TU) reported they are preparing bid and contract documents for the construction bid package. They are currently planning construction in late summer or early fall. They also started planning for diversion dam removal, which will occur 1-2 years after the new water system is installed.
- Barkley Irrigation – Under Pressure Project – The sponsor (TU) reported they have an executed agreement with MVID and have finalized the pump site location. With both MVID and Barkley agreements signed, they now need to secure the relationship agreement between the two parties. The sponsor started working on the headworks design and held several meetings with Barkley

[1] Lee joined via phone.

Irrigation Company and MVID to review engineer alternatives. The sponsor is still working on changing the water rights from Barkley to MVID's diversion.

- Similkameen RM 3.8 Project – The sponsor (Okanogan Conservation District; OCD) and the Colville Tribes reported that BPA reviewed the updated plan and decided not to support the project. The sponsor is working on next steps.
- White River Floodplain (RM 3.4) Connection Project – The sponsor (Cascade Columbia Fisheries Enhancement Group; CCFEG) did not provide a project update.
- Icicle Boulder Field Project – The sponsor (TU) reported they are working on the JARPA permit for geotech explorations. They intend to file permits for the project this fall in anticipation for fall 2018 construction.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – The sponsor (WDFW) will submit the second-year monitoring report on 31 December 2017.
- Permitting Nutrient Enhancement Project – The sponsor (CCFEG) did not provide a project update; however, they did provide a draft Quality Assurance Project Plan (QAPP), which is being reviewed by Ecology. The sponsor expects a permit (Administrative Order) from Ecology soon.
- Burns-Garrity Design Project – The sponsor (CCFEG) did not provide a project update.
- Beaver Fever Project – The sponsor (TU) reported they continue project planning and due diligence. The focus has been on permitting, project task sequencing, and consideration of preliminary designs.
- Wenatchee Sleepy Hollow Floodplain Acquisition Project – The sponsor (Chelan-Douglas Land Trust; CDLT) did not provide a project update.

IV. Budget Amendments

White River Floodplain Connection (RM 3.4) Project

In June, the Rock Island Tributary Committee received a budget amendment request from Cascade Columbia Fisheries Enhancement Group on the *White River Floodplain Connection (RM 3.4) Project*. The sponsor asked to take all the available funds in "Excavation and Heavy Equipment" ($5,000) and "Project Materials and Equipment" ($500) and move those into "Salaries and Benefits," "Overhead and Administration," and "Permit Fees." According to the request, this amendment would leave no money for excavation and haul. The Committee questioned how the project will be completed if there is no money available to conduct excavation and heavy equipment work. As a result, the Rock Island Tributary Committee denied the request until the sponsor can describe how the project will be completed without excavation and haul.

Following the meeting, Cascade Columbia Fisheries Enhancement Group provided additional information on the budget amendment. The sponsor noted that they have adequate funding through other sources to complete all excavation and construction work and will not need additional funds to complete the project. Given that, the ***Rock Island Tributary Committee approved the budget amendment***.

Beaver Fever: Restoring Ecosystem Function Project

The Rock Island Tributary Committee received a budget amendment request from Trout Unlimited on the *Beaver Fever: Restoring Ecosystem Function Project*. The sponsor asked if they could use $10,000 under Construction and Permitting to purchase a hydraulic post driver. The driver would be used to install BDAs. This would eliminate the need to rent the equipment and could be used on other projects. After discussion, ***the Rock Island Committee denied the budget amendment***. This is because any equipment purchased by a project sponsor with Plan Species Account funds becomes the property of the Committee.

The Committee is not set up to deal with equipment storage, maintenance, management, and liability, and they do not want to be in a position of lending expensive equipment to project sponsors. Thus, they do not want project sponsors purchasing equipment with Plan Species Account funds.

V. Time Extension

Permitting Nutrient Enhancement in the Chiwawa

The Rock Island Tributary Committee received a time extension request from Cascade Columbia Fisheries Enhancement Group on the *Permitting Nutrient Enhancement in the Chiwawa*. Because of ongoing discussions with the Forest Service, USFWS, and Ecology, the sponsor asked to extend the period of the contract from 30 June 2017 to 30 June 2018. After discussion, ***the Rock Island Committee agreed to the one-year extension***.

VI. Small Projects Program Application

Poison Canyon Restoration Project

In June, the Committees reviewed a Small Projects Program application from Chelan County Natural Resources Department titled, *Poison Canyon Restoration*. The purpose of the project was to aggrade incised reaches within Poison Canyon, a tributary to Sand Creek, which is a tributary to Mission Creek, by installing about 20 wood jams using onsite wood and hand tools. Aggrading the channel should improve instream flows and water quality in Mission Creek. The total cost of the project was $73,330. The sponsor requested $38,160 from HCP Tributary Funds. The Committees declined the opportunity to fund the project because the project was overly engineered and too expensive. The Committees also found no need for game cameras or piezometers. The Committees noted if the sponsor addresses these concerns, the sponsor is welcome to submit a revised proposal for the Committees' consideration.

Chelan County Natural Resources Department resubmitted the Small Projects Program application, which addressed the Committees' concerns. The proposed project will still construct 20 wood structures to aggrade incised reaches within Poison Canyon, but the project will use a less engineered approach and include onsite wood/brush and hand tools. The total cost of the project is $37,918. The sponsor requested $21,600 from HCP Tributary Funds. ***The Rock Island Committee approved funding for this project.*** The Committee appreciated the sponsor's responses to questions and complemented the sponsor on their diligence and desire to implement a cost-effective project.

Cottonwood Bridge Removal Project

The Committees reviewed a Small Projects Program application from Chelan-Douglas Land Trust titled, *Cottonwood Bridge Removal Project*. The purpose of the project is to remove the steel and creosoted railroad ties that make up the Cottonwood Bridge on the Entiat River. Once the bridge is removed, the sponsor can remove the associated road and begin floodplain enhancement on the Cottonwood property. The total cost of the project is $95,000. The sponsor requested $21,000 from HCP Tributary Funds. The Committees declined the opportunity to fund the project because the project did not include the removal of the bridge abutments. The Committees recommended that the sponsor resubmit a larger project the includes the removal of the abutments. The project could be a phased approach if the sponsor includes a timeline showing when each phase of the project will be completed.

Following the meeting, Chelan-Douglas Land Trust provided the following response to the Committees' comments. "*The reason the abutments are not being removed at the same time as the railroad ties and steel is due to 3 interrelated reasons: (1) due to the deterioration of the bridge, it is essential to remove it this summer, before additional high water, ice, freezing and thawing that would result in complete failure, (2) abutment removal would involve in-water work requiring additional permitting and (3) the abutments will be removed as part of a larger project, probably in 2020, to remove the fill for the bridge approaches on both sides, fill added for "streets" within the Cottonwood property, and enhancement of side channels* *through Cottonwood – all of which will involve the appropriate time, equipment and permitting. These factors all led to the conclusion that the goal for this work season should be limited to removal of the ties and steel, and "pulling back" the abutment so that it does not come apart in the river.*" After evaluating the response, ***the Rocky Reach Tributary Committee approved funding for this project***.

VII. General Salmon Habitat Program Proposals

The Committees received four General Salmon Habitat Program proposals. Before reviewing the proposals and consistent with the Committees' Operating Procedures, members of the Committees identified potential conflicts of interest. Kate Terrell recused herself from voting on the *Piscine Passage Design for Brush and Minnow Creeks Project*.

M2 WDFW Flow Connection Project

The Methow Salmon Recovery Foundation is the sponsor of the M2 WDFW Flow Connection Project. The purpose of this project is to reconnect 3.7 acres of floodplain habitat and wetlands by removing a flood levee located at RM 46.8 on the Methow River. The total cost of the project is $78,828. The sponsor requested $11,824 from HCP Tributary Funds. ***The Wells Committee approved funding for this project.***

The Committee noticed in the proposal that the sponsor expects the side channel to connect at flows above 6,000 cfs; however, Figure 1 in the proposal indicates that the channel will be connected at flows near 8,000 cfs. The Committee prefers the channel to connect at flows closer to 6,000 cfs.

M2 Mid-Sugar Acquisition Project

The Methow Salmon Recovery Foundation is the sponsor of the M2 Mid-Sugar Acquisition Project. The purpose of this project is to acquire 17.3 acres of riparian and floodplain habitat including about 1,300 feet of stream bank and 550 feet of side channel near RM 42.2 on the Methow River. The acquisition will allow for future restoration actions including side channel and floodplain reconnection and riparian enhancement. The total cost of the project is $291,268. The sponsor requested $43,690 from HCP Tributary Funds. ***The Wells Committee approved funding for this project.***

Piscine Passage Design for Brush and Minnow Creeks Project

Cascade Columbia Fisheries Enhancement Group is the sponsor of the Piscine Passage Design for Brush and Minnow Creeks Project. The purpose of this project is to produce designs and submit permits for projects that will restore fish passage and connectivity within Minnow and Brush creeks, tributaries to the Chiwawa River. The total cost of the project is $162,500. The sponsor requested $52,500 from HCP Tributary Funds. ***The Tributary Committees elected not to fund this project***.

The Committees are not interested in the Brush Creek project, because of the low biological benefit associated with it. On the other hand, the Committees see more value in restoring connectivity on Minnow Creek. Given the level of funding available from the USFWS and the possibility of receiving funding from SRFB, the Committees believe the project will receive adequate funding without the need for Plan Species Account funds. In the event the Minnow Creek project does not receive adequate funding, the sponsor can resubmit an application to the Committees. The resubmittal must include the status of the roads in Minnow Creek.

Methow Basin Barrier and Diversion Assessment Project

Cascade Columbia Fisheries Enhancement Group is the sponsor of the Methow Basin Barrier and Diversion Assessment Project. The purpose of this project is to complete a comprehensive and standardized fish barrier and diversion inventory in the Methow River basin and to prioritize barrier sites for restoration. The total cost of the project is $206,650. The sponsor requested $40,000 from HCP Tributary Funds. ***The Wells Committee approved funding for this project.***

The Committee understands that the sponsor will use a combination of prioritization methods developed by WDFW and the RTT. As a requirement of the Committee's funding contribution to this project, the Committee will need to review and approve the "final" approach used to prioritize fish passage barriers.

Summary of Review of 2017 General Salmon Habitat Program Projects.

Project Name	Sponsor[1]	Total Cost	Request from T.C.	T.C. Contribution[2]
M2 WDFW Flow Connection	MSRF	$78,828	$11,824	W: $11,824
M2 Mid-Sugar Acquisition	MSRF	$291,268	$43,690	W: $43,690
Piscine Passage Design for Brush and Minnow Creeks	CCFEG	$162,500	$52,500	$0
Methow Basin Barrier and Diversion Assessment	CCFEG	$206,650	$40,000	W: $40,000
Total:		**$739,246**	**$148,014**	**$95,514**

[1] CCFEG = Cascade Columbia Fisheries Enhancement Group; MSRF = Methow Salmon Recovery Foundation.

[2] RI = Rock Island Plan Species Account; RR = Rocky Reach Plan Species Account; W = Wells Plan Species Account.

VIII. Information Updates

The following information updates were provided during the meeting.

1. Approved Payment Requests in June and July:

   Rock Island Plan Species Account:

   - $47.50 to Clifton Larson Allen for Rock Island financial administration in June 2017.
   - $855.94 to Chelan County PUD for project coordination and administration during the first and second quarters of 2017.
   - $11,487.26 to Trout Unlimited for the MVID Instream Flow Project.

   Rocky Reach Plan Species Account:

   - $47.50 to Clifton Larson Allen for Rocky Reach financial administration in June 2017.
   - $911.16 to Chelan County PUD for project coordination and administration during the first and second quarters of 2017.
   - $3,442.78 to Trout Unlimited for work on the Clear Creek Fish Passage and Instream Flow Enhancement Project.

   Wells Plan Species Account:

   - $661.84 to Chelan County PUD for project coordination and administration during the second quarter of 2017.

2. Tracy Hillman said the Independent Scientific Advisory Board (ISAB) will be in Wenatchee on 19-21 July for presentations and site visits as part of their evaluation of Upper Columbia Spring Chinook. The Council has prepared a draft agenda for the ISAB visit.
3. Tracy Hillman and Becky Gallaher shared the updated logos for the Tributary Committees. The Committees approved the following logo:

4. Becky Gallaher reported that she received a request from Cascade Columbia Fisheries Enhancement Group asking the Wells Tributary Committee if CCFEG could use the Committee's piezometers for an assessment project in the Methow River basin. The Wells Committee approved the request, but asked that the sponsor let the Committee know how long they need the piezometers, where exactly they will use them, and for what project. Kate Terrell said she will provide Becky with a release form that is used by the USFWS when they lend equipment to project sponsors.
5. Tracy Hillman asked the Committees if they have decided on which completed project they would like to visit in 2017. Given schedules and interest, it is unlikely members will have time to visit completed projects in 2017. Chris Fisher said by August he will have information on the annual tour of projects in Canada.

IX. Next Steps

If necessary, the next meeting of the Tributary Committees will be on Thursday, 10 August 2017 at Grant PUD in Wenatchee.

Meeting notes submitted by Tracy Hillman (tracy.hillman@bioanalysts.net).

Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 9 November 2017

Members Present: Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Steve Hays (Chelan PUD), Tom Kahler (Douglas PUD), Kate Terrell (USFWS), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

Members Absent: Lee Carlson (Yakama Nation)[1]

Others Present: Becky Gallaher (Tributary Project Coordinator), Brandon Rogers (Yakama Nation), Jeff Osborn (Chelan PUD), Catherine Willard (Chelan PUD), and Scott Hopkins (Chelan PUD).

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Thursday, 9 November 2017 from 9:30 am to 12:05 pm.

I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda with additional agenda items. The Committees reviewed two Small Projects Program applications they received from the Methow Salmon Recovery Foundation.

II. Review and Approval of Meeting Minutes

The Committees reviewed and approved the 13 July 2017 meeting notes.

III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- MVID Instream Flow Improvement Project – The project sponsor (Trout Unlimited; TU) completed the remaining punch-list items and will submit their final report by the end of the month.
- Clear Creek Fish Passage and Instream Flow Project – The sponsor (TU) met with the project engineers to discuss bids and to examine the potential for cost savings through project design modifications. They found little room for cost savings by modifying structural and civil/plumbing plans. Any changes here would result in reduced functionality, quality, lifespan, or overall project value. Electrical modifications are currently being considered. For example, the current design calls for a robust, multi-function operator interface, which offers remote control capability with numerous checks and alarms. Switching to a simple control-panel interface could save several

[1] Lee provided votes on decision items following the meeting.

thousand dollars. The electrical engineer is evaluating cost savings and effort/cost. The sponsor will send the project out for bid later this year or early next.

- Barkley Irrigation – Under Pressure Project – The sponsor (TU) continues to work on the joint diversion redesign and gravity portion of the system. They have also been working on finalizing the water rights change, completing environmental compliance, securing easements, and seeking funding and general coordination with the districts.
- Similkameen RM 3.8 Project – This project is complete. The sponsor (Okanogan Conservation District; OCD) submitted the final report, which was uploaded to the extranet site.
- White River Floodplain (RM 3.4) Connection Project – This project is complete. The sponsor (Cascade Columbia Fisheries Enhancement Group; CCFEG) will submit a final report soon.
- Icicle Boulder Field Project – The sponsor (TU) dug test pits to evaluate subsurface material. The information collected is being evaluated and a report of findings should be available in November. The cultural resource survey was completed in October and that report is expected in November. Tracy Hillman stated that the Committees may receive a proposal asking for funds to install a fish screen in the Icicle Diversion. The irrigation district has stated they may not allow the Icicle Boulder Field Project to move forward unless their diversion is screened.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – The sponsor (WDFW) will submit the second-year monitoring report on 31 December 2017.
- Permitting Nutrient Enhancement Project – The sponsor (CCFEG) reported there was no new activity.
- Burns-Garrity Design Project – The sponsor (CCFEG) met recently with the "new" private landowners. The new landowners support a design for a perennial channel. The sponsor will work with WDFW and the other private landowner to select a preferred concept and then they will move forward with design. *Following the meeting, the sponsor noted that the proposed channel will be a flow-through channel connected upstream and downstream with the river.*
- Beaver Fever Project – The sponsor (TU) is communicating with private landowners and the Forest Service hoping to get interest and insight about the potential for BDA work in lower Potato Creek.
- Wenatchee Sleepy Hollow Floodplain Acquisition Project – The sponsor (Chelan-Douglas Land Trust; CDLT) reported that Larry Rees is scheduled to complete the appraisal by the end of the year.
- Poison Canyon Restoration Project – The sponsor (Chelan County Natural Resources Department; CCNRD) indicated that they awarded the construction contract to Wildfire Home Protection. All but three structures have been built. The sponsor provided photos.
- Cottonwood Bridge Removal Project – This project is complete. The sponsor (CDLT) submitted the final report, which was uploaded to the extranet site.
- M2 Mid-Sugar Acquisition Project – The sponsor (Methow Salmon Recovery Foundation; MSRF) reported that Larry Rees initiated the appraisal on 27 October. Reclamation confirmed that a project budget is being processed for prioritization of project design alternatives for 2018/2019.

IV. Small Projects Program Applications

Frazer Creek – Lazy K Property Appraisal Project

The Committees reviewed a Small Projects Program application from MSRF titled, *Frazer Creek – Lazy K Property Appraisal Project*. The purpose of the project is to appraise the value of a 20-acre parcel along Frazer Creek in the Methow River basin. Acquiring the property would allow stream restoration in a site where the 2017 flood plugged a culvert causing the stream to cut deep gullies through the property. The cost of the project is $1,421.40, which covers coordination with the landowner and appraiser, and billing and administration work. The Committees would pay for the appraiser. After careful consideration, the Committees elected not to fund the appraisal. Most of the property does not boarder the stream and restoring this site would have little biological benefit.

Upper Beaver Creek – Anderson Property Appraisal Project

The Committees reviewed a Small Projects Program application from MSRF titled, *Upper Beaver Creek – Anderson Property Appraisal Project*. The purpose of the project is to appraise the value of a 1.6-acre parcel along Beaver Creek in the Methow River basin. Acquiring the property would allow stream restoration in a site where the 2017 flood avulsed through the Anderson property and damaged the County road. The cost of the project is $1,421.40, which covers coordination with the landowner and appraiser, and billing and administration work. The Committees would pay for the appraiser. The Committees were unable to make a final decision on the project and asked for additional information. They said before they can make a final decision on the appraisal, they would like to know if the County intends to relocate the road away from the channel. They also need information on the status of the channel upstream and downstream from the property, and what measures adjacent landowners are taking, or have taken, to minimize future damage to the Anderson parcel.

Following the meeting, MSRF provided additional information on the proposed project. After carefully reviewing the proposal and the additional information, the Committees elected not to fund the appraisal. The Committees are uncomfortable acquiring the property without a comprehensive review of the vulnerability of the road from the stream.

V. Chelan River Restoration Presentation

Steve Hays gave a presentation on the Chelan River Restoration project, which was funded by Chelan PUD (see Attachment 1). He began by describing riverine conditions before hydro development in the Chelan River, and then talked about the first two Chelan Licenses. He followed that by describing the most recent relicensing process, objectives, and agreement. He then walked through the restoration process, showing the evolution of the river during the restoration process.

With the completion of the restoration work, Steve said Chelan PUD has implemented a robust monitoring program to evaluate the success of the work. He said they conduct spawning surveys for summer/fall Chinook, coho salmon, and steelhead; conduct studies to evaluate powerhouse operations on intragravel dissolved oxygen levels in redds; evaluate egg-emergence success for Chinook and steelhead; conduct snorkel surveys in designated reaches; conduct macroinvertebrate population studies; conduct water temperature monitoring and modeling; and monitor TDG, DO, pH, and turbidity. He provided results from monitoring efforts and concluded that the restoration work is providing high quality habitat for salmonids, including cutthroat trout. He added that riparian vegetation is growing rapidly, and salmonids are spawning successfully within the habitat channel and tailrace. He ended by stating, "I'm not complaining."

VI. Effectiveness of Enhancement Projects Presentation

Tracy Hillman gave a presentation on the effectiveness of tributary habitat enhancement projects (see Attachment 2). He stated that he and his coauthors (Phil Roni and Jen O'Neal) prepared a report for BPA that addressed six policy-level questions (the report was made available to the Committee members). These questions were identified by the region and answers to them will help guide the next FCRPS BiOp. In order to answer the questions, Tracy and his coauthors reviewed well over 1,000 published and unpublished papers. Of those papers, 617 met their criteria for relevance. Tracy shared the number of papers associated with different categories of enhancement actions and the countries in which the studies were conducted. He also identified the intensively monitored watersheds located throughout the Pacific Northwest.

Although the purpose of the paper was to answer the six policy-level questions, Tracy's presentation focused on what works and why. He identified six characteristics of successful projects and identified reasons why good intension fail. He referred to some of the failures as "Myths of Restoration." He concluded by providing eight recommendations.

VII. Information Updates

The following information updates were provided during the meeting.

1. Approved Payment Requests from August to November:

   Rock Island Plan Species Account:

   - $162.50 to Clifton Larson Allen for Rock Island financial administration in July 2017.
   - $2,135.41 to Cascade Columbia Fisheries Enhancement Group for the Permitting Nutrient Enhancement Project.
   - $1.891.75 to Trout Unlimited for the MVID Instream Flow Improvement Project.
   - $125.00 to Clifton Larson Allen for Rock Island financial administration in August 2017.
   - $117.50 to Clifton Larson Allen for Rock Island financial administration in September 2017.
   - $556.41 to Chelan County PUD for project coordination and administration during the third quarter of 2017.
   - $2,190.97 to Trout Unlimited for the Beaver Fever – Restoring Ecosystem Function Project.
   - $1,827.95 to Trout Unlimited for the MVID Instream Flow Improvement Project.
   - $162.50 to Clifton Larson Allen for Rock Island financial administration in October 2017.
   - $6,828.79 to Cascade Columbia Fisheries Enhancement Group for the White River Floodplain Connection Project.
   - $1,000.00 to the Upper Columbia Salmon Recovery Board for the Upper Columbia Science Conference.

   Rocky Reach Plan Species Account:

   - $162.50 to Clifton Larson Allen for Rocky Reach financial administration in July 2017.
   - $4,080.73 to Okanogan Conservation District for the Similkameen RM 3.8 Rehabilitation Project.

- $1,191.16 to Okanogan Conservation District for the Similkameen RM 3.8 Rehabilitation Project.
- $125.00 to Clifton Larson Allen for Rocky Reach financial administration in August 2017.
- $117.50 to Clifton Larson Allen for Rocky Reach financial administration in September 2017.
- $417.05 to Chelan County PUD for project coordination and administration during the third quarter of 2017.
- $11,000.00 to Chelan-Douglas Land Trust for the Cottonwood Bridge Removal Project.
- $2,614.51 to Okanogan Conservation District for the Similkameen RM 3.8 Rehabilitation Project (withholding 10% until final report is received).
- $162.50 to Clifton Larson Allen for Rocky Reach financial administration in October 2017.
- $10,000.00 to Chelan-Douglas Land Trust for the Cottonwood Bridge Removal Project.
- $290.50 to Okanogan Conservation District for the Similkameen RM 3.8 Rehabilitation Project (this was the 10% that was withheld from the final invoice).
- $1,000.00 to the Upper Columbia Salmon Recovery Board for the Upper Columbia Science Conference.

Wells Plan Species Account:

- $195.03 to Chelan County PUD for project coordination and administration during the third quarter of 2017.
- $376.94 to Trout Unlimited for the MVID Instream Flow Improvement Project.
- $2,192.00 to Douglas County PUD for Wells Administration.
- $1,000.00 to the Upper Columbia Salmon Recovery Board for the Upper Columbia Science Conference.

2. Tracy Hillman reminded the Committees of the email that Steve Kolk (BOR) sent the Committees in late September providing an update on the Middle Entiat Restoration Project. In his email, Steve asked if the Committees would like him to attend a future meeting and provide additional updates. The Committees indicated that at this time there is no need for Steve to provide an update in person. Email updates will suffice.
3. Tracy Hillman reminded the Committees that the Upper Columbia Science Conference, which is hosted by the Upper Columbia Salmon Recovery Board, will be on 24 and 25 January 2018 in Wenatchee. In October, each Committee agreed to donate $1,000.00 to the Conference. Funding will come from administrative expenses (not to exceed $80,000 per year per account) under the Plan Species Accounts. This level of sponsorship identifies the Committees as "Gold Sponsors."
4. Tracy Hillman said the Rocky Reach Tributary Committee approved a budget amendment and scope change for the Clear Creek Fish Passage and Instream Flow Enhancement Project in August. In early August, the sponsor (Trout Unlimited) asked to add activities related to water/electrical lines and treatment building to the deliverables. Specific activities included clearing/grubbing, trenching, piping, electrical, plumbing/mechanical, building construction,

moving chlorine injection and backup power equipment to a new location, inspections, and final approvals. In addition, the sponsor asked for an additional $77,174.40 to complete the project. Although the Rocky Reach Tributary Committee approved the scope change and budget amendment, which increased the total contribution from the Committee to $146,674.40, the Committee let the sponsor know they are growing increasingly concerned with the planning, management, and implementation of this project. This was the fifth amendment to this project. The Committee trusts that the sponsor will do a better job of planning and managing similar future projects.

5. Chris Fisher asked if the Committees would be interested in reviewing a proposal to fund the monitoring of discharge in select tributaries in the Methow River basin. Chis said the tributaries include Early Winters, Eight-Mile, Gold, Little Bridge, and Libby creeks. In the past, the Rocky Reach Tributary Committee approved funding for a similar monitoring effort in the Okanogan Basin. Members indicated they would review a proposal to monitor discharge, but they would need to know how the work will lead to habitat enhancement projects.
6. Chris Fisher said the Okanagan Nation Alliance is planning wetland construction in the parcel recently acquired with the help of Rock Island Plan Species Account funds. They are also doing floodplain construction near the Town of Oliver.

VIII. Next Steps

The next meeting of the Tributary Committees will be on Thursday, 11 January 2018 at Grant PUD in Wenatchee.

Meeting notes submitted by Tracy Hillman (tracy.hillman@bioanalysts.net).

31	495	......	500	465	......	2,070	......	5,340	......	5,340	1,820	......

NOTE.—Gage not read Sundays (except June 18) and a few other days; discharge interpolated. Discharge October 17-22, when gage was not read, estimated at 360 second-feet. Low discharge March 10 due to backing of water in lake while bridge was being repaired. Decrease in discharge August 26 due to inserting flashboards to raise the lake surface for navigation.

Looking downstream on site of proposed tail race, 12/15/26

PRE-CHELAN HYDRO CONDITION

Columbia River at flood, Beebe Bridge and Camp #4, 5/30/28

Confluence of Chelan and Columbia rivers, 6/21/27

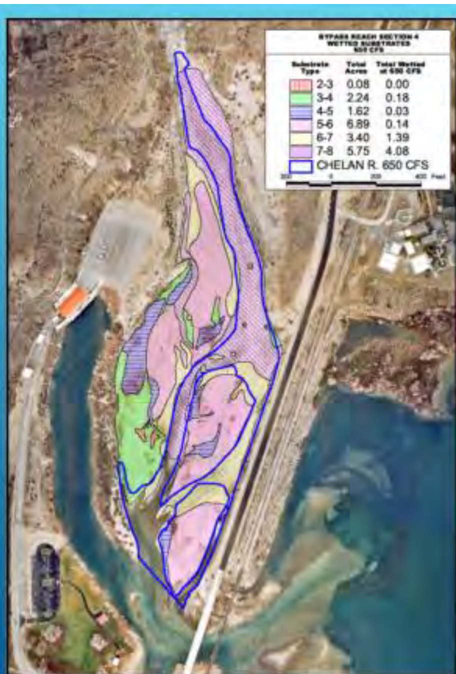
FIRST TWO CHELAN LICENSES

- Lake Chelan Hydroelectric Project Had No Provision for Minimum Flows – River Dry from Lake Chelan Dam to Chelan Falls 9 Months of the Year 1926 – 2009
- Lake Storage Managed Only For Recreation, Power Generation and Flood Control
- 1980s Relicense Focused On Parks, Lake Fisheries and Wildlife
- Restoration of Chelan River Flows and Habitat Not In Terms and Conditions in 1980s

RELICENSING OBJECTIVES

- FERC Relicense Negotiations Included Minimum Flow Regime and Fish Habitat Enhancements for Anadromous Fish Spawning and Rearing
- Habitat Modeling Estimated Possible 2.8 Acres of Chinook and 2.2 Acres of Steelhead Spawning Habitat in Scattered Pockets at 650 cfs Flow
- Existing Tailrace/Columbia River Spawning Habitat 2.8 Acres for Chinook and 2.2 Acres for Steelhead
- Summer Chinook Salmon Had Established Spawning Population on Alluvial Fan at Chelan Falls Beginning in 1980s – Demonstrating Feasibility of Adding Habitat
- Upper Three Reaches Managed for Resident Fish – Goal for Population of 200 Cutthroat Trout, the Native Salmonid
- Habitat Modeling Estimated Flows of 80 cfs – 160 cfs Yielded Most Acres of Habitat
- Main Limiting Factor Summer Water Temperatures > 24 Degrees C

REACH 4 - 2004



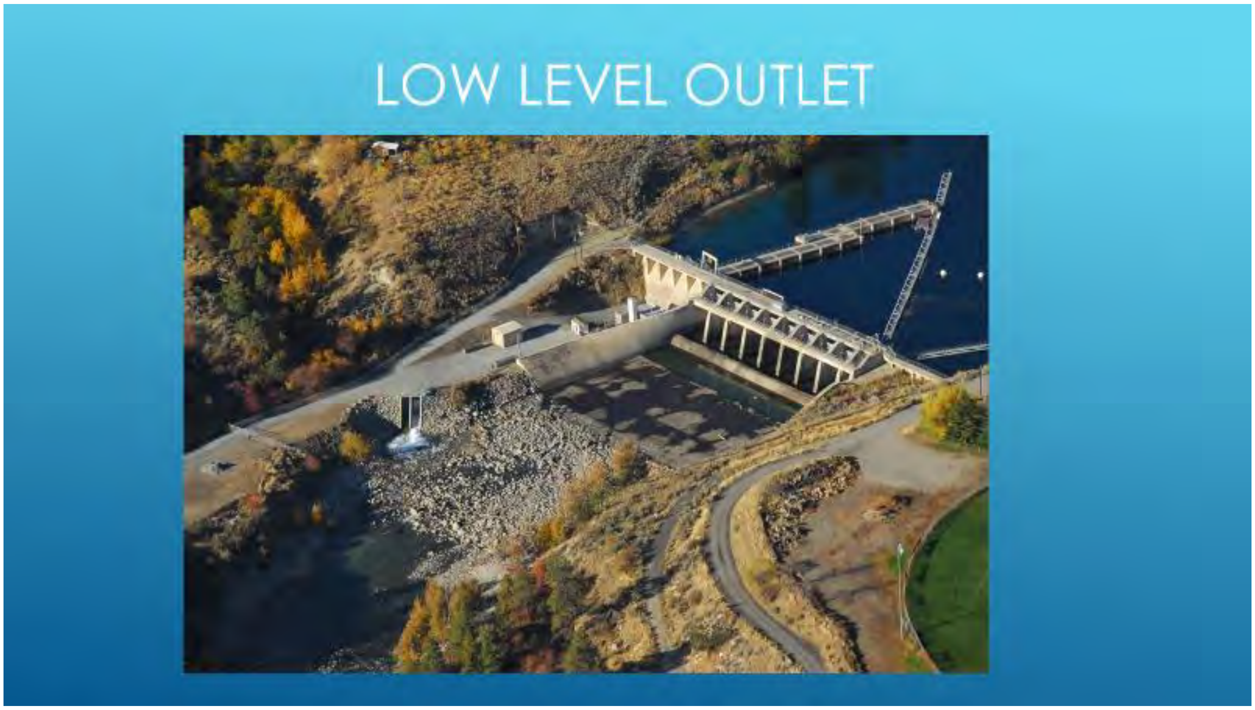
RELICENSING AGREEMENT

- Minimum Flow of 80 cfs Released from Dam, with May 15 – July 15 Minimum of 200 cfs in Average Runoff Years and 320 cfs in High Runoff Years
- Create Approximately 2 Acres of New Spawning and Rearing Habitat in Reach 4
- Fill Portion of Tailrace To Increase Chinook Spawning Habitat and Improve Existing Tailrace Spawning Habitat
- Create Sinuous Habitat Channel with Five Pool/Riffle Components – Boulder and Wood Structure Features for Rearing and Steelhead Spawning Cover
- Use Pumped Flows to Provide Habitat Channel Spawning Depths Velocities: March 15 – May 15 for Steelhead, October 15 – November 30 for Chinook
- Operate Powerhouse As Necessary to Maintain Favorable Spawning and Incubation Conditions, Including Intra-gravel DO in Tailrace
- Investigate Water Temperature Dynamics, Model Studies to Evaluate Potential Temperature Reduction Measures, and Riparian Feasibility Study in Reach 1 for Cutthroat Population

LET'S BUILD IT

Chelan River, Reach 4 and Tailrace
New Stream Channel Construction
Aerial Showing Redds
November 5, 2008

COMPLETED PROJECT



LOW LEVEL OUTLET

REACH 1 – THEN AND NOW

Chelan River before construction, 10/22/25

RESULTS

M&E INCLUDES

- Spawning Surveys for Summer Chinook and Coho in Fall, Steelhead in Spring
- Studies to Determine Powerhouse Operations Necessary to Maintain Intra-Gravel DO ≥ 6.0 mg/l in Tailrace Redds
- Snorkel Surveys Reach 4 and Reach 1
- Egg – Emergence Survival Studies for Chinook and Steelhead
- Macroinvertebrate Population Studies
- Water Temperature Monitoring and Model Study
- Water Quality Assessment for TDG, DO, pH, Turbidity

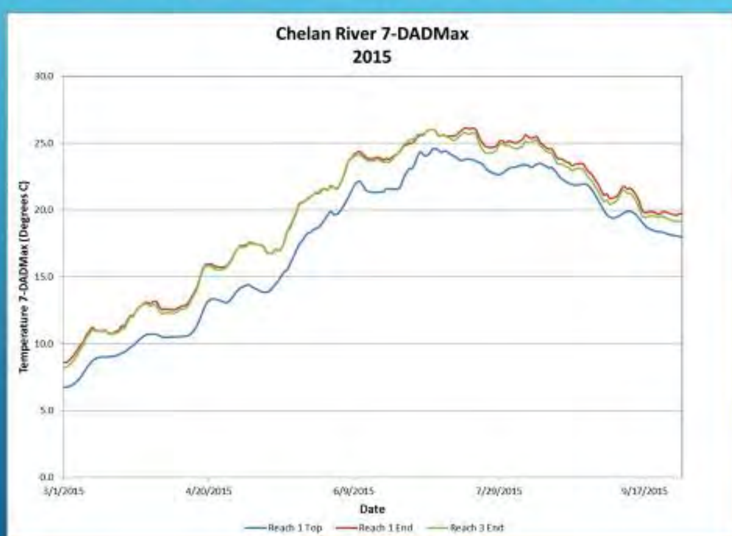
CHELAN RIVER IS WARM

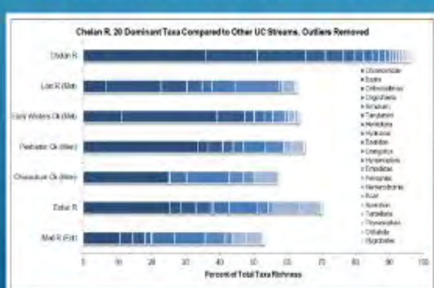


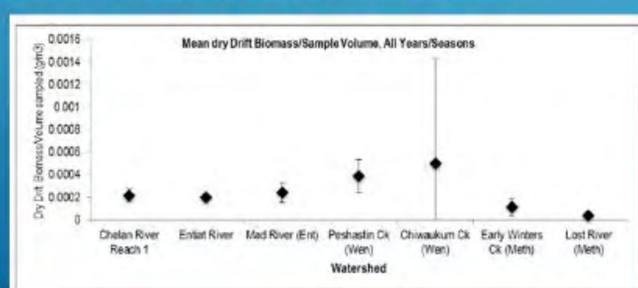
TEMPERATURE MODEL FINDINGS

- Hyporheic Zone Parameters Had Most Influence on Model Calibration
- High Degree of Hyporheic Exchange – 30% of Flow Fraction
- Daily Maximum Temperature Could Be Reduced by Up to 2 Degrees C if Flow Increased from 80 cfs to 500 cfs
- However, Daily Minimum Temperature Would Increase by the Same Amount and Hyporheic Influence Could be Reduced
- Mature Riparian Vegetation Only Reduce Maximum Temperature by 0.1 Degrees C

MACROINVERTEBRATE STUDIES

- Benthic and Drift Samples had Limited Species Richness – Similar to Upstream Above Dam Samples
- Some Drift Samples in Tailrace and Habitat Channel Had High Abundance of Lake Species – Cladocerans and Copepods
- Dominant Taxa Were Chironomidae, Baetis and Orthocladinae
- Drift Abundance in Reach 1 Similar to CHaMP Data for Local Streams





CUTTHROAT DON'T LOOK STARVED

Cutthroat Trout stocked in Reach 1 on 3/24/15 and recaptured 6/24/15 (photo by Graham Simon, WDFW)

I'M NOT COMPLAINING

QUESTIONS?

Attachment 2

Presentation by Tracy Hillman on Effectiveness of Tributary Habitat Enhancement Projects

Purpose

Respond to six, policy-level questions:

- What are the effects of habitat actions on habitat conditions?
- Which actions are most effective in producing desired habitat conditions for salmonids?
- How do salmonids respond to changes in habitat conditions?
- What are the effects of individual actions on fish at the site, reach, and watershed scales?
- Are benefits sustained over time?
- Which actions provide the greatest benefit to fish?

2

Approach

Conducted a comprehensive review of published and unpublished literature (reviewed 617 papers).

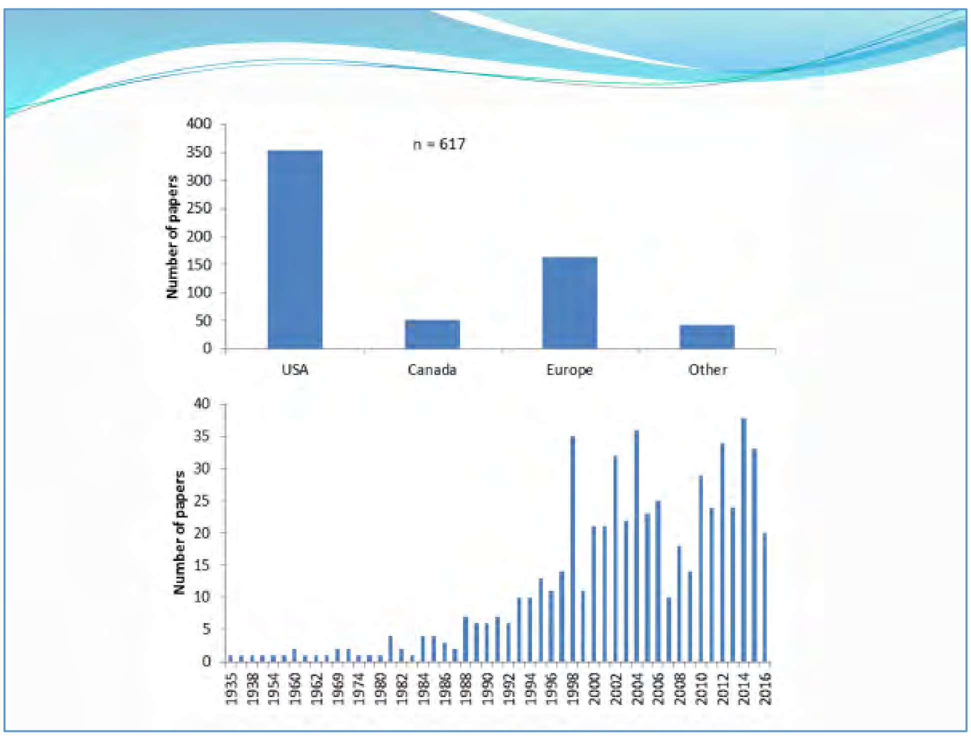
Criteria for relevance:

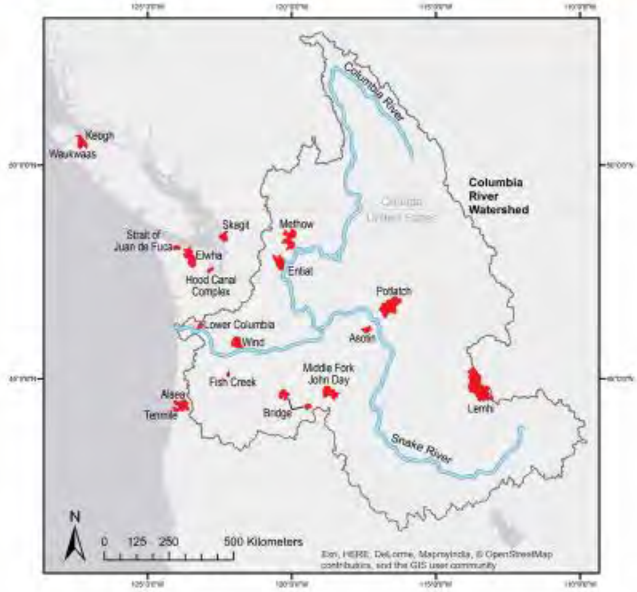
- Paper must describe results from monitoring and evaluation of enhancement actions.
- Paper must provide quantitative information on physical and biological response to enhancement.

Compiled an annotated bibliography of all papers reviewed and summarized results for eight categories of enhancement.

3

PROJECT CATEGORY	SUBCATEGORY	NUMBER OF STUDIES
Fish Passage	Barrier Removal Entrainment	56
Instream Structures	Large wood and boulder placement Engineered Logjams Gravel addition Beaver enhancement structures	254
Off-Channel/Floodplain Habitat	Reconnection Levee Removal/Setback Side Channel and Pond Construction/Creation Channel Enhancement/Re-meandering	133
Riparian Improvement	Riparian Plantings and Silviculture Treatment Riparian Fencing and Grazing Invasive Species Control	77
Sediment Reduction	Road Agricultural practices	33
Flow Augmentation	Water release or improvement Irrigation improvement	24
Nutrient Enhancement	Salmon carcasses or carcass analogs Organic or inorganic nutrient addition	38
Acquisition and Protection	Land acquisition, lease, or easement	1





6

What Works and Why?

Implementing the *right action* in the *right place* at the *right time*!

Right Action:

- Actions that remove or minimize threats causing limiting factors.
- Actions that address the factors affecting the limiting life stage.

Right Place:

- Actions that improve or are not affected by degraded upstream process.
- Actions that treat a large percentage of the degraded habitat (20%).

Right Time:

- Actions that are sequenced appropriately.

7

Characteristics of Successful Enhancement Work:

- Understanding the habitat requirements of the target species and their life-history characteristics.
- Assessments that identify enhancement opportunities and provide a clear understanding of the problems and limiting life-stage and habitats.
- Implementation plans that prioritize locations for enhancement and prioritize actions (sequencing).

8

Characteristics of Successful Enhancement Work:

- Extensive coordination among stakeholders, landowners, funding and monitoring entities, and implementers.
- Success is directly related to the size or magnitude of the treatment.
- Incorporation of effectiveness monitoring within an adaptive management framework.

9

Why Do Good Intensions Fail?

- **Pristine Fantasy** – Assuming we can achieve some pre-development condition or single endpoint.
- **Field of Dreams** – Focus solely on the physico-chemical conditions.
- **Copy-Cat Approach** – Over use of a method that is not sufficiently validated.
- **Fast Forward** – Belief we can accelerate ecosystem structure and function.

10

Why Do Good Intensions Fail?

- **Command and Control** – Illusion that we can control nature (focus on treating symptoms).
- **Cornucopian Belief** – Technology will solve the problem.
- **Ecological Trap** – When good animals love bad habitat.
- **Perceptual Trap** – When good animals avoid good habitat.

11

Recommendations

- Protect high-quality habitat.
- Focus on removing or reducing the threats or key limiting factors that degrade habitat conditions.
- Address and work within natural watershed processes.
- Screen water-withdrawal structures to reduce entrainment.

12

Recommendations

- Reconnect spawning and rearing areas.
- Instream structures should be used in concert with actions that improve watershed processes.
- Nutrient enrichment projects should be considered experimental.
- Extensive coordination among all parties.

13

Appendix E
Statements of Agreement for Habitat Conservation Plan Coordinating Committees

Final
Rock Island Habitat Conservation Plan
Coordinating Committee

Statement of Agreement
February 3, 2017

Acknowledgement of Rock Island
Powerhouse 1 Units B1-B4 Consultation

Agreement Statement
The Rock Island HCP Coordinating Committee (CC) have reviewed the draft letter to the Federal Energy Regulatory Commission (FERC) regarding the upcoming maintenance activities at units B1-B4 in Powerhouse 1 at Rock Island Dam, and agree the proposed work will not adversely affect aquatic resources or Chelan PUD's obligations under the HCP.

Background

Beginning in April 2016, the CC was made aware of the maintenance activities proposed to occur to rehabilitate units B1-B4 in Powerhouse 1 at Rock Island Dam. During the October 25, 2016 CC meeting, Brett Bickford, Chelan PUD Engineering and Project Management Director, formally presented the activities to occur from 2017 to 2020, complete with a description of turbine components to be replaced and those components to remain the same.

A new modern turbine design with tighter operating tolerances and fixed blade angle positioned for optimum flow conditions supporting efficient power generation are expected to benefit fish passage survival. Additionally, laminar flow conditions associated with peak generating capability equate to providing fish the best possible flow conditions for turbine route passage. In 2013, the HCP Coordinating Committee approved Chelan PUD's 2013 Comprehensive Progress Report that concluded Chelan PUD had reached no net impact at Rock Island with respect to all planned species.[1] Chelan PUD's achievement of no net impact in 2013 was successfully achieved while operating the vintage 1933 units. The proposed rehabilitation work will not alter the HCP Coordinating Committee's 2013 finding of no net impact and in fact, Chelan PUD anticipates that the new modern design of present day turbines will offer additional survival benefit of fish passing through the rehabbed B1-B4 units. A project survival standard check-in study is scheduled for 2020 (post B1-B4 rehab) to verify continued achievement of the juvenile survival standard. The schedule has all PH1 units in operation by April 2020 providing the best chance for success during the 2020 HCP check-in.

On November 15, 2016, Chelan PUD provided to the CC a draft letter addressed to FERC for agency and committee comments. After completion of a 30 day review on December 15, 2016, and receiving no comments, Chelan PUD filed the letter with FERC.

[1] Statement of Agreement, Approval of Rock Island and Rocky Reach HCPs 2013 Comprehensive Progress Report (Approved February 26, 2013).

FINAL

Rocky Reach and Rock Island Habitat Conservation Plans Coordinating Committees

Statement of Agreement

Designation of Juvenile Coho in Phase III (Standard Achieved) at the Rock Island and Rocky Reach Projects

(March 30, 2017)

Agreement Statement

The Rock Island and Rocky Reach HCP Coordinating Committees (CC) have reviewed PIT-tag based estimates of juvenile coho passage survival compared with PIT-tag based yearling Chinook passage survival in the Columbia River hydropower system, prepared by J. Skalski and R. Townsend (2017). The CC agrees that comparison of PIT-tag based juvenile coho survival and yearling Chinook survival using juveniles released in the Methow sub-basin upstream of the Rocky Reach Project over seven consecutive migration years (2010-2016) demonstrates that juvenile coho survive hydropower system passage similar to yearling Chinook. Because juvenile coho and yearling Chinook passage survival is comparably similar, and because Chelan PUD has measured direct passage survival of yearling Chinook through Rocky Reach ($\hat{S}$ = 92.72) and Rock Island ($\hat{S}$ = 93.75) Projects in HCP acoustic tag survival studies, the CC also agrees that juvenile coho survival can be estimated using Chelan PUD's yearling Chinook acoustic tag survival estimates and coho PIT-tag based survival estimates. Yearling Chinook are in Phase III (Standard Achieved) at both Rock Island and Rocky Reach Projects. The CC acknowledges that based on the estimated juvenile coho Project survivals of 93.98% at Rock Island and 92.94% at Rocky Reach (Skalski and Townsend 2017), the CC agrees to move juvenile coho at both Projects from Phase III Standard Achieved Interim-Value to designation of Phase III Standard Achieved, with 93% survival at both Projects.

Background

The Rocky Reach and Rock Island HCP Coordinating Committees reviewed and approved an SOA on June 26, 2007 and agreed that (1) an interim coho juvenile survival value of 93% would be assumed and (2) juvenile coho survival studies would not be performed unless there was compelling information that demonstrated hydro project operations were having an impact greater than seven percent mortality on coho. As approved, juvenile coho were designated as Phase III (Standard Achieved – Interim Value) for the Rocky Reach and Rock Island projects.

Comparison of Juvenile Coho and Yearling Chinook PIT-tag Survival Estimates Through the Mid-Columbia

PIT-tag based estimates of survival for hatchery released juvenile coho and hatchery released yearling Chinook through the Mid-Columbia can be used to evaluate how juvenile coho survive relative to yearling Chinook. Skalski and Townsend (2017) analyzed PIT-tagged juvenile coho and PIT-tagged yearling Chinook released from Winthrop National Fish Hatchery, Methow Hatchery and all Methow Sub-basin acclimation sites to estimate juvenile passage survival from Rocky Reach tailrace to McNary tailrace, and survival from McNary to John Day tailrace, 2010 through 2016 (Table 1) .

Table 1. Cormack-Jolly-Seber PIT tag survival estimates of juvenile coho salmon and yearling Chinook salmon from Rocky Reach (RRH) to McNary (MCN) and McNary to John Day (JD) for pooled releases from the Winthrop National Fish Hatchery, Methow Hatchery, and Methow sub-basin final acclimation sites.

Year	Release Sizes Coho/Chinook	PIT Survival Coho/Chinook RRH to MCN	$\hat{S}$ SE Coho/Chinook	PIT Survival Coho/Chinook MCN to JD	$\hat{S}$ SE Coho/Chinook
2010	11,859 / 25,806	88.15% / 76.17%	(0.0915)/ (0.0421)	96.73%/ 100.1%	(0.1570)/ (0.1228)
2011	20,873 / 28,117	66.55% / 62.65%	(0.0411)/ (0.0314)	120.3%/ 97.11%	(0.1778)/ (0.1022)
2012	17,891 / 29,569	67.78% / 72.07%	(0.0362)/ (0.0336)	84.39%/ 78.38%	(0.0742)/ (0.0549)
2013	23,851 / 35,498	83.34%/ 82.15%	(0.0547)/ (0.0423)	83.26%/ 91.25%	(0.0931)/ (0.0916)
2014	23,489 / 22,475	72.60%/ 75.39%	(0.0436)/ (0.0565)	87.25%/ 93.0%	(0.0822)/ (0.1255)
2015	24,233 / 31,913	75.18%/ 71.08%	(0.0863)/ (0.0422)	91.69%/ 80.44%	(0.2036)/ (0.0837)
2016	17,885 / 31,884	67.73% / 76.09%	(0.0223)/ (0.0252)	98.66%/79.70%	(0.0828)/ (0.0502)

(Source: Skalski and Townsend 2017)

The PIT-tag survival estimates for juvenile coho and yearling Chinook were generated for fish migrating in the same river reaches in the same years, Rocky Reach to McNary and McNary to John Day, 2010 to 2016 (Skalski and Townsend 2017). Comparison of Rocky Reach to McNary reach survival estimates suggest juvenile coho salmon and yearling Chinook have the most comparable survivals with a survival ratio near 1.0000. In six of seven years of comparison, reach survival ratios for juvenile coho to yearling Chinook were not significantly different between the two species and the seven year weighted mean reach survival ratio was not significantly different (weighted mean=0.9549; SE=0.0307; P=0.1921) (Table 2).

Table 2. Ratios of multiple-project (hydro system) reach survivals for the above Rocky Reach release groups of juvenile coho and yearling Chinook salmon, (2010–2016). Numbers in bold indicate survival ratios that are significantly different from 1 ($P < 0.05$).

Species Ratio	Year	Rocky Reach to McNary	P (≠ 1)	McNary to John Day	P (≠ 1)
Coho/Yrl Chinook	2010	1.1573 (0.1361)	0.2478	0.9602 (0.1949)	0.8382
	2011	1.0623 (0.0845)	0.4612	1.2392 (0.2248)	0.2873
	2012	0.9405 (0.0667)	0.3720	1.0767 (0.1210)	0.5264
	2013	1.0145 (0.0846)	0.8641	0.9124 (0.1371)	0.5231
	2014	0.9630 (0.0925)	0.6890	0.9382 (0.1544)	0.6888
	2015	1.0577 (0.1367)	0.6730	1.1399 (0.2795)	0.6168
	2016	0.8901 (0.0416)	**0.0082**	1.2379 (0.1299)	0.0670

Projection of Coho Salmon Project Survival Using Acoustic Tag/PIT Tag Survival Estimates

A ratio estimator was used to project coho salmon acoustic-tag passage survival based on PIT-tag data on juvenile coho salmon, and PIT-tag and acoustic-tag data on yearling Chinook salmon. Using PIT-tag releases, reach survivals from Rocky Reach tailrace (detections in the Rocky Reach bypass) to McNary tailrace were estimated for coho and yearling Chinook salmon for the years 2010–2016 (Table 1). In addition, acoustic-tag investigations were performed on yearling Chinook salmon at Rocky Reach (i.e., 2010, 2011) and Rock Island (i.e., 2007, 2008, and 2010) as part of the HCPs' survival compliance testing. Assuming the PIT-tag studies and acoustic-tag studies are each reliably estimating the same quantities, ratios of reach survivals for juvenile coho and yearling Chinook salmon should be the same whether they were estimated using acoustic or PIT tags.

Table 3: PIT-tag reach survival estimates from Rocky Reach tailrace to McNary tailrace $\left(\hat{S}^{\mathrm{PIT}}_{\mathrm{RR-MCN}}\right)$, ¼-root survival $\left(\hat{S}^{1/4}\right)$, and coho-to-Chinook-salmon survival ratios through the four Mid-Columbia projects $\left(\hat{R}\right)$. Standard error in parentheses.

	$\hat{S}^{\mathrm{PIT}}_{\mathrm{RR-MCN}}$		$\hat{S}^{1/4}$		
Year	Coho	Chinook	Coho	Chinook	$\hat{\bar{R}}^{\mathrm{PIT}}_{\mathrm{Coho/Chin}}$
2010	0.8815	0.7615	0.9690	0.9342	1.037
2011	0.6655	0.6265	0.9032	0.8897	1.015
2012	0.6778	0.7207	0.9074	0.9214	0.985
2013	0.8334	0.8215	0.9554	0.9520	1.004
2014	0.7260	0.7539	0.9231	0.9318	0.991
2015	0.7518	0.7108	0.9312	0.9182	1.014
2016	0.6773	0.7609	0.9072	0.9340	0.971
				Average	**1.0024** (0.0084)

(Source: Skalski and Townsend 2017)

The value of $\hat{\hat{R}}$ = **1.0024** in Table 3 above was used to project average direct-measured yearling Chinook salmon acoustic tag passage survival at the Rocky Reach Project of $\hat{S}_{\mathrm{Chin}_{\mathrm{ACO}}}$ = 0.9272 into a coho salmon project passage survival estimate, where

$$\begin{aligned}\hat{S}_{\mathrm{Coho}_{\mathrm{ACO}}} &= \hat{\hat{R}}^{\mathrm{PIT}}_{\mathrm{Coho/Chin}} \cdot \hat{\hat{S}}_{\mathrm{Chin}_{\mathrm{ACO}}} \\ &= 1.0024(0.9272) \\ &= \mathbf{0.9294}\ \left(\widehat{\mathrm{SE}} = 0.0081\right).\end{aligned}$$

The same coho-to-Chinook-salmon survival ratio of $\hat{\hat{R}}$ = **1.0024** was used to project average direct-measured yearling acoustic tag passage survival at the Rock Island Project of $\hat{S}_{\mathrm{Chin}_{\mathrm{ACO}}}$ = 0.9375 into a coho salmon project passage survival estimate, where

$$\begin{aligned}\hat{S}_{\mathrm{Coho}_{\mathrm{ACO}}} &= \hat{\hat{R}}^{\mathrm{PIT}}_{\mathrm{Coho/Chin}} \cdot \hat{\hat{S}}_{\mathrm{Chin}_{\mathrm{ACO}}} \\ &= 1.0024(0.9375) \\ &= \mathbf{0.9398}\ \left(\widehat{\mathrm{SE}} = 0.0233\right).\end{aligned}$$

Skalski, J.R. and R. L. Townsend, 2017. Comparison of Juvenile Survival of Chinook Salmon, Sockeye Salmon, Steelhead, and Coho Salmon through the Chelan PUD Projects, 2010-2016. Columbia Basin Research, School of Aquatic and Fishery Science, University of Washington. January 26, 2017.

Appendix F
Statements of Agreement for Habitat Conservation Plan Hatchery Committees

Rocky Reach and Rock Island HCP Hatchery Committees
Statement of Agreement

Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 13, 2017
(Chelan PUD, NMFS, USFWS, WDFW, YN, and CCT approved on March 13, 2017)

Statement

The Rocky Reach and Rock Island Habitat Conservation Plans (HCP) Hatchery Committees (HC) approve the Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 13, 2017. Any future alterations of the schedule will require HCP Hatchery Committees approval.

Background

Chelan PUD's HCPs specify the need to update the hatchery monitoring and evaluation (M&E) plan every five years and to comprehensively review the hatchery program every 10 years utilizing new information from the M&E program. The National Marine Fisheries Service Section 10(A)(1)(a) and 10(A)(1)(b) Endangered Species Act permits for Chelan PUD's hatchery programs and the *Monitoring and Evaluation Plan for PUD Hatchery Programs* also contain reporting requirements for hatchery M&E information. To date, these reporting requirements have not aligned, which has resulted in a disjointed review and input cycle to inform updates to M&E plans, recalculation of hatchery production, evaluation of M&E objectives, status of meeting permit requirements, and adaptive management actions. The document, Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 13, 2017, optimizes the sequence of hatchery M&E reporting and is the new reporting schedule for hatchery M&E information.

Rocky Reach and Rock Island HCP Hatchery Committees
FINAL Statement of Agreement
Regarding District's Coho Obligation
November 15th, 2017

Approved as follows: CCT approved via email on November 14, 2017, and Chelan PUD, WDFW, USFWS, NMFS, and YN approved on November 15, 2017.

Statement

The Rocky Reach and Rock Island HCP Hatchery Committees (hereafter "Committees") agree that Chelan PUD shall provide coho compensation for the Methow River and Wenatchee River sub-basins at a rate equivalent to 7.0% at each project to meet Chelan PUD's No Net Impact hatchery obligations for brood years 2017 to 2021 (release years 2019 to 2023); therefore, 7.0% will be used as the coho hatchery compensation rate until the next scheduled hatchery compensation recalculation (2023). Methodology described in the SOA Regarding the 2013 No Net Impact Recalculation Methodology (dated July 20th, 2011) will be used to calculate hatchery compensation levels for coho.

Background

On June 20, 2007, the Committees agreed to implement coho hatchery compensation as detailed in Section 8.4.3.a of the Rocky Reach and Rock Island HCPs and agreed that the District shall begin providing hatchery compensation no later than October 1, 2007. On March 28, 2017, the Rocky Reach and Rock Island Coordinating Committees agreed to use Chelan PUD's yearling Chinook acoustic tag survival estimates and coho PIT-tag based survival estimates to estimate juvenile coho survival of 93.98% at Rock Island and 92.94% at Rocky Reach (Skalski and Townsend 2017) which culminated in a 93% survival value at both projects.

Calculations for the Methow Sub-basin Coho Reintroduction Project

Compensation for **hatchery-origin smolts** will be determined by multiplying the Program's annual release targets from the Methow sub-basin coho reintroduction project by the unavoidable project mortality (1-(0.93 x 0.93)) for Rocky Reach and Rock Island.

Compensation for **natural-origin smolts** produced is determined by:

- Mean NOR[1] to Rocky Reach (return years 2008 to 2011 and 2013 to 2015) = 43
- Mean NOR in absence of project mortality: 43/0.9300 = 46
- Adult equivalents to meet NNI: 46-43=3
- Mean 8-year SAR (release years 2008-2015 Methow sub-basin hatchery program) = 0.59%
- Compensation for natural-origin smolts: 3/0.0059 = 508 smolts

Calculations for the Wenatchee Sub-basin Coho Reintroduction Project

Compensation for **hatchery-origin smolts** will be determined by multiplying the Program's annual release targets from the Wenatchee sub-basin coho reintroduction project by the unavoidable project mortality (1-0.93) for Rock Island.

Compensation for **natural-origin smolts** is determined by:

- Mean NOR to Rock Island (return years 2007-2016) = 529
- Mean NOR in absence of project mortality: 529/0.9300 = 569
- Adult equivalents to meet NNI: 569-529 = 40
- Mean 10 year SAR[2] (release years 2006-2015 Wenatchee sub-basin hatchery program) = 0.75%
- Compensation for natural-origin smolts: 40/0.0075 = 5,333 smolts

[1]Natural-origin return=NOR
[2]SAR=releases from the Wenatchee hatchery programs and returns to Priest Rapids Dam (versus Rock Island Dam due to historic variable PIT tag detection efficiency at the adult ladders).

SUMMARY

Outmigrating juvenile Chinook *Oncorhynchus tshawytscha,* Sockeye *O. nerka*, Coho *O. kisutch* salmon and steelhead *O. mykiss* were enumerated, examined for PIT tags, and evaluated for descaling, injury and mortality at the Rock Island Dam Juvenile Sampling Facility. This facility is operated by Chelan County Public Utility District # 1 (CCPUD) personnel daily April 1 to August 31. Yearling and subyearling Chinook Salmon as well as steelhead were examined for gas bubble trauma between April 12 and July 19. This was the thirty-second consecutive year that the juvenile salmonid spring and summer outmigration was monitored at Rock Island Dam. Species composition and condition data were transmitted daily to the Fish Passage Center (FPC), which manages the Smolt Monitoring Program (SMP) throughout the Columbia River Basin. Data collected by the SMP provides information for in-season management decisions regarding juvenile anadromous fish passage. Total river flow and Rock Island Powerhouse 2 flow during bypass trap operations averaged 131.25 kcfs and 91.29 kcfs, respectively. Spill for fish passage began on April 11 and continued through August 12.

In 2016, the Rock Island Dam Juvenile Sampling Facility (RIJSF) collected 126,705 juvenile salmonids. The middle 80% of the combined juvenile salmonid outmigration (all species) passed Rock Island Dam during a 32 day period from late April to late May. Duration of the middle 80% passage was 18 days for yearling Chinook Salmon, 53 days for subyearling Chinook Salmon, 23 days for steelhead, 20 days for Sockeye Salmon and 17 days for Coho Salmon. Of the 126,705 fish examined for condition, 0.72% were descaled (>20%), 0.43% injured and 0.71% mortalities. A total of 2,200 yearling Chinook Salmon, subyearling Chinook Salmon, and steelhead were examined for gas bubble trauma, with 0.59% showing some external signs. A total of 19,511 Chinook Salmon, Sockeye Salmon and steelhead were tagged with passive integrated transponder (PIT) tags between April 5 and August 13. Incidental catch totaled 842 fish comprised of adult steelhead, adult Chinook Salmon, adult Sockeye Salmon, jack Chinook Salmon, Rainbow Trout, Bull Trout, Kokanee, Mountain Whitefish, adult Lamprey, juvenile Lamprey, and Northern Pikeminnow.

INTRODUCTION

In 1982, the Northwest Power Planning Council developed a fish and wildlife program to protect, mitigate, and enhance fish and wildlife resources impacted by the construction and operation of the Columbia River Basin hydroelectric facilities. This program established a water budget that allocates upstream water storage for in-stream flow supplementation, which is intended to improve passage conditions for downstream migrating salmon and steelhead. The program also called for studies to monitor juvenile fish migration timing and survival (McDonald and Keesee 1997). The fisheries agencies and tribes formed the Fish Passage Center (FPC) to interact with hydro system operators and regulators in managing anadromous fish passage. Technical advice regarding flow, spill, and fish facility operations is provided to fisheries managers. The FPC developed the Smolt Monitoring Program (SMP) to assess daily information for in-season management decisions. Several sites were selected on the Columbia and Snake rivers as smolt monitoring stations. Rock Island Dam was selected as one of these stations (1985) because it is the first dam downstream from all major salmon and steelhead production tributaries on the mid-Columbia River (Figure 1; McDonald and Keesee 1997).

The SMP at Rock Island Dam was designed to index the daily number of outmigrating juvenile salmonids (i.e., target species) to include Chinook Salmon *Oncorhynchus tshawytscha, S*ockeye Salmon *O. nerka, C*oho Salmon *O. kisutch,* and steelhead *O. mykiss.* Observations were reported as wild or hatchery based on an excised fin(s) or external marks or tags including anchor tags, visual implant elastomer (VIE) tags, and previously passive integrated transponder (PIT) tagged fish. The PIT tagging program was implemented with a goal of tagging a random sample from the middle 80% of the outmigration of yearling and subyearling Chinook Salmon, Sockeye Salmon, and both hatchery and wild steelhead. Data collected under the SMP and PIT tagging programs allows for the comparison and evaluation of year to year migration timing, magnitude, and travel time of juvenile salmonids, both naturally and hatchery produced.

Chelan County Public Utility District # 1 (CCPUD) began spilling water for fish passage at Rock Island Dam to meet fish survival goals of the Rock Island Habitat Conversation Plan (HCP) that CCPUD entered into with state and federal resource agencies and Native American tribes. Studies have reported the level of total dissolved gas (TDG) at hydropower facilities can be affected as a result of spill (Ebel et al. 1975; Weitkamp and Katz 1975). High levels of TDG and the resulting supersaturated water can cause gas bubble trauma (GBT) in aquatic species. The presence of GBT can manifest as bubbles or blisters under the skin in juvenile salmonids (Weitkamp and Katz 1980). In 1996, the SMP implemented GBT monitoring at Rock Island Dam juvenile bypass sampling facility to focus on detecting external signs of GBT.

METHODS

Bypass Trap Operation

The Rock Island Dam Juvenile Sampling Facility operated from April 1 through August 31. Operations were conducted by CCPUD Fish and Wildlife personnel 7 days a week with 24 hour sampling periods from 09:00 am to 09:00 am. Fish were collected from Powerhouse # 2 turbine intake gatewells and the fishway attraction water intake. Fish entering the gatewells and attraction water intakes pass into a bypass channel through a series of submerged orifices. Incline dewatering screens separate fish from the bypass flow and deposit them into a sampling raceway (Figure 2). Fish were held in the raceway (4.4 cubic meters) for up to 24 hours. Each day at 0900 fish were crowded from the raceway into an elevator hopper and hoisted to the upper deck of the trap. Fish were transferred from the hopper via water to water using a 4 inch flex hose into an aluminum holding tank (4.0 cubic meters) in the fish sampling building. After examination, fish were transferred to a recovery tank (1.35 cubic meters) before release into the tailrace area. Two 5 hp submersible pumps installed in the right bank fish ladder provided a continuous supply of river water to the holding, sampling and recovery tanks.

Sampling

All fish collected were enumerated and examined. Groups of between 30 and 50 fish were netted using sanctuary nets into a sampling tank where they were anesthetized with a solution of tricaine methanosulfonate (MS-222: 1ml/2.11 liters) before being sampled and PIT tagged. An ionic salt solution (i.e. Pro Poly Aqua) was added to all sampling tanks within the fish sampling building to reduce handling stress and to promote healing after PIT tagging. All salmonids were enumerated by species, scanned for PIT tags, visually inspected for anchor tags, VIE tags, clipped fins, eroded fins and assessed for descale, injury and mortality.

After sampling, all fish were transferred to a recovery tank. When all fish had fully recovered from the anesthetic (1 hour minimum), they were released via a 10 cm aluminum pipe from the recovery tank to the tailrace of Rock Island Dam. The release area of the tailrace was protected from avian predation with parallel strands of stainless steel wire mounted above the pipe outlet and across the tailrace of the dam. The U.S. Department of Agriculture, Wildlife Services (USDA) suppressed predation by various piscivorous birds and northern pikeminnow in the tailrace using non-lethal and lethal means.

The physical condition of target salmonids was determined by estimating the degree of descaling on each live salmonid. Salmonids with descale greater than 20% on any one side were counted as decaled. Any fish with descale greater than 20% on any one side, except Sockeye Salmon (> 5%), or which had any visible injury, were not used for PIT tagging. Injury and mortality were enumerated for each species. In 2000, the FPC changed the identification criteria for smolt monitoring purposes to better quantify Endangered Species Act (ESA) listed versus non-listed populations (Table 1). Juvenile salmonids were classified as clipped or unclipped based on the presence of absence of the adipose fin. This change was due to recovery efforts of stocks listed under the ESA in the Columbia River Basin.

Unclipped steelhead were examined for visual implant elastomer (VIE) tags, eroded fins, or any combination of marks. Steelhead that were unclipped, but possessed frayed or eroded fins were classified as an “eroded fin” and enumerated as an unclipped hatchery fish with no distinguishing marks or tags. Only unclipped steelhead that possessed none of these distinguishing marks or tags were classified as wild steelhead. Yearling Chinook, subyearling Chinook, Coho, and Sockeye Salmon were classified as clipped or unclipped.

Table 1. FPC fish identification criteria.

Species	Fork length (mm)	Classification
Chinook yearling*	80 – 180	Clipped/ Unclipped
Chinook subyearling*	61 – 160	Clipped/ Unclipped
Chinook fry	< 61	Clipped/ Unclipped
Coho	61 – 180	Clipped/ Unclipped
Coho fry	< 61	Unclipped
Sockeye	< 211	Clipped/ Unclipped
	> 211	Kokanee
Steelhead	< 301	Clipped/ Unclipped
	> 301	Rainbow Trout
Steelhead fry	< 61	Unclipped

*Determined by emigration timing and fork length.

PIT Tagging

Sub-samples of yearling Chinook, subyearling Chinook, and Sockeye Salmon as well as steelhead were PIT tagged each week using quotas established by the FPC (Table 2). If any week’s quota was not met, the remainder was not added to the following week’s quota. The criteria used to determine fish origin remained the same as in previous years (i.e., hatchery or unknown). The complex marking schemes of hatchery fish precluded the presence of an adipose fin as an accurate indicator of wild fish, therefore fish with an adipose fin present are classified as fish of unknown origin per SMP guidelines. In 2016, the tagging of yearling Chinook and steelhead was conducted by Real Time Research and Oregon State University (RTR/OSU), with funding from the U.S. Army Corps of Engineers (USACE) to evaluate avian predation in the hydro system, and utilized species origin classification of hatchery, wild, and unknown origin.

Taggers for CCPUD injected tags by hand using a 10cc medical syringe with a push-rod mechanism and a 12-gauge hypodermic needle. Syringes and needles were sterilized for a minimum of 15 minutes in 91% isopropyl alcohol before each use. Fish used for PIT tagging must fall within length and condition limits established to help minimize mortality of fish placed under additional stresses (Table 3). Tagging data was electronically transferred to the Passive Integrated Transponder Information System (PTAGIS) daily. The FPC will report the results of the 2016 Rock Island Dam PIT tag program in the 2016 annual report.

Table 2. Weekly quotas for PIT tagging Rock Island Dam Juvenile Sampling Facility, 2016.

Sockeye	70	200	< 5%

*Determined by emigration timing and fork length.

Gas Bubble Trauma

Yearling and sub-yearling Chinook Salmon and steelhead were examined for evidence of GBT between 12 April and 19 July 2016. Each week a random sample of up to 100 target species fish were examined twice per week. Target species were considered Yearling Chinook Salmon and steelhead in the spring and subyearling Chinook Salmon in the summer. Examinations followed FPC standardized procedure as outlined by FPC (2016).

RESULTS AND DISCUSSION

Species Composition and Passage Timing

Yearling Chinook

A total of 30,042 yearling Chinook Salmon (26,468 clipped and 3,574 unclipped) were collected during the sampling season. Yearling Chinook Salmon were collected beginning on 1 April and collected daily from 1 April until 4 June. The last clipped and unclipped yearling Chinook Salmon was collected on 13 August and 7 June, respectively. Duration of the middle 80% yearling emigration was 18 days (Table 4).

Subyearling Chinook

A total of 14,821 subyearling Chinook Salmon (423 clipped, 8,068 unclipped, and 6,330 classified as fry) were collected during the sampling season. Subyearling Chinook Salmon were first collected on 1 April and daily through 25 August. The last collection of clipped subyearling Chinook Salmon was 23 July. Unclipped subyearling Chinook Salmon and unclipped Chinook Salmon fry were last collected on 31 August and 1 August, respectively. Duration of the middle 80% sub-yearling emigration was 53 days (Table 4).

Steelhead

A total of 12,080 steelhead (7,226 clipped and 4,854 unclipped) were collected during the sampling season. Steelhead were first collected on 2 April and daily between 2 April and 28 June. The last unclipped and clipped steelhead was collected on 28 August and 12 July, respectively. The duration of the middle 80% steelhead emigration was 23 days (Table 4).

Sockeye

A total of 38,450 Sockeye Salmon (3 clipped, 38,444 unclipped, and 3 fry) were collected during the sampling season. Sockeye Salmon were first collected 1 April, and collected daily between 1 April and 29 May. The last clipped and unclipped Sockeye Salmon were collected on 27 June and 26 August, respectively. The duration of the middle 80% sockeye salmon emigration was 20 days (Table 4).

Coho

A total of 31,312 Coho Salmon (126 clipped, 31,183 unclipped, and 3 fry) were collected during the sampling season. Coho Salmon were first collected on 1 April and were collected daily between 8 April and 18 June. The last clipped and unclipped Coho Salmon were collected on 7 June and 19 July, respectively. The duration of the middle 80% Coho Salmon emigration was 17 days (Table 4).

Total Salmonid Run

The Rock Island Dam Juvenile Bypass Trap Facility collected a total of 126,705 juvenile salmonids in 2016. Sockeye salmon comprised 30.3% of the season total followed by Coho (24.7%), yearling Chinook (23.7%), subyearling Chinook (11.7%) and steelhead (9.5%) (Figure 3). Species composition of smolts in daily samples is presented in Appendix A. Peak passage occurred on 3 May with predominately Sockeye salmon. Adipose clipped juveniles accounted for 27.3% of the season total. The duration of the middle 80% salmonid emigration was 32 days (Table 4).

Table 4. Juvenile salmonid collection counts and run timing (middle 80%) for the Rock Island Dam Juvenile Sampling Facility, 2016.

Number				Dates

Run-of-River Fish Condition Evaluations

All juvenile salmonids that were collected at the Rock Island Dam Juvenile Sampling Facility (RIJSF) were routinely inspected for descale, injury and mortality. A total of 126,705 fish were examined for condition during the 2016 sampling season (Table 5). Proportions of descale, injury and mortality of target salmonids sampled at RIJSF are shown in Figures 4 & 5. The results from daily samples are reported in Appendix B.

Descale

Fish were examined for descaling on all live target salmon and steelhead during the 2016 sampling season, with the exception of salmonid fry due to their small size. A fish with more than 20% descale on one side was classified as descaled. Of the fish examined, the percent classified as descaled was 0.72% (n=911).

Injury

Injury is characterized as lacerations or bruises occurring to any part of the head or body. These types of injuries can lead to mortality. In 2016, the percent injury was 0.43% (n=542, all species).

Mortality

Mortalities collected during the sampling season were categorized as *facility*, *sample*, or *tagging* caused mortalities. A *facility* mortality is any fish recently dead or near death on arrival to the raceway which exhibit fresh descale or injury. A *sample* mortality is any fish killed as a result of the sampling activity. A *tagging* mortality is any fish that dies as a result of injury or stress during the PIT tagging process. In 2016, the total percent mortality was 0.71% (n=906) for all target species.

During the first day of operation on April 1, 2017, a higher than normal mortality rate of 52.74% (n=77) was observed. All of the mortalities observed were subyearling Chinook fry determined to be caused by increased velocities across the traveling screens due to a regulating gate set too far open. The regulating gate was adjusted accordingly, and a decrease in mortality was observed over the following days. The overall observed mortality for all species during the month of April 2017 was 1.19%, with the recorded mortality on April 1, 2017 accounting for 20.3% of that rate.

Table 5. Summary of Descale, Injury, and Mortality for All Species, 2016, RIJSF.

2016	Number Examined	Number OK	Number Descaled	Percent Descale	Number Injured	Percent Injured	Mortality			Percent Mortality
							Facility	Sample	Tagging	
Yearlings	30,042	29,773	119	**0.40%**	87	**0.29%**	53	8	0	**0.20%**

PIT Tagging

A total of 19,511 juvenile salmonids were PIT tagged between 5 April and 13 August (Table 6). Tagging of yearling Chinook Salmon, Sockeye Salmon and steelhead occurred from 5 April to 14 June. Tagging of wild, hatchery, and unknown steelhead, as well as wild, hatchery, and unknown yearling Chinook Salmon, was performed by RTR/OSU, with funding from the USACE. This tagging was part of a USACE and OSU study to evaluate the impacts of avian predation on salmonid smolts from the mid-Columbia and Snake Rivers. Tags for the predation study were provided by USACE. Tagging of unknown Sockeye Salmon and unknown subyearling Chinook Salmon was performed by CCPUD personnel using origin criteria and PIT tags provided by the FPC. Tagging of subyearling Chinook Salmon occurred between 13 June and 13 August.

Table 6. Number of salmonids PIT tagged during the 2016 RIJSF monitoring season.

Yearling Chinook[1]				Unclipped Chinook Subyearling	Unclipped Sockeye	Steelhead[1]			
Hatchery	Wild	Unknown	Total			Hatchery	Wild	Unknown	Total
4,478	579	3	5,060	4,069	4,109	4,392	1,762	119	6,273

1 Fish were tagged by RTR/OSU

Mark and Tag Recaptures

All target salmonids and steelhead were visual and electronically examined for external and internal marks or tags.

PIT Tags

A total of 2,709 previously PIT tagged juvenile salmon and steelhead from upriver sources were detected at the RIJSF in 2016.

Incidental species

A total of 842 non-target fish representing multiple species were collected and enumerated(Table 7). Among the non-target species collected, there were 150 Pacific lamprey, 111 adult steelhead, 2 adult chinook and 35 adult sockeye. There were also 50 mini-jack chinook, 1 bull trout, 196 rainbow trout, 94 kokanee, 189 pikeminnow, and 8 whitefish. In addition, there were 6 fish that crews recorded as “others” but are not part of the SMP reporting protocol (FPC 2016). All non-target fish were either returned to the fish ladder or directly to the river.

Gas Bubble Trauma Monitoring

Unpaired fins and eyes were examined for signs of GBT from 12 April thru 19 July. Examinations were performed a total of 22 days (Appendix D). The sampling goal of 100 fish was reached on all of the 22 sample days (100%). Yearling Chinook Salmon and steelhead were sampled 12 days and 13 days respectively. Subyearling Chinook Salmon were sampled 10 days. A total of 2,200 juvenile salmonids and steelhead were examined for external signs of GBT (Table 8). A total of 13 fish showed signs of GBT (0.59%). A rank was assigned to fish examined for GBT based on the area percent of fins or eyes covered with bubbles (0 = no bubbles, 1 =1-5%, 2 = 6-25%, 3 = 26-50%, 4 = 50-100%). All 13 recorded signs of GBT were in the fins of examined juvenile salmon and steelhead. Of the 13 fish that showed signs of GBT, 12 were recorded with a rank of “1” and 1 was recorded with a rank of “2”.

Table 8. Number of juvenile salmon and steelhead examined for external signs of GBT, 2016.

River Flows

River flows were recorded daily from 1 April through 31 August (daily mean flows were calculated for the 24 hour period from 09:00 a.m. to 09:00 a.m.). Daily mean river flows ranged from a low on 28 August of 73.20 kcfs to a high on 22 April of 217.00 kcfs (Table 9). Spill for fish passage at Rock Island Dam began on 11 April and ran continuously through 12 August (Table 10). Powerhouse # 1 flows ranged from 2.40 kcfs on 10 August to 32.20 kcfs on 19 April. Powerhouse # 2 (PH-2) flows ranged from 60.50 kcfs on 26 August to 122.80 kcfs on 16 April. Daily mean total river flow for the sampling season was 131.25 kcfs.

Table 9. Rock Island Dam total river flow and powerhouse operations by month, 2016.

Mean Flow (kcfs)					
	April	**May**	**June**	**July**	**August**

Fish Spill

Table 10. Rock Island Fish Spill Program Results, 2016.

Rock Island Spring Fish Spill

Species:	Juvenile steelhead, yearling Chinook, Sockeye (smolts)
Fish Spill target percentage:	10% of day average flow
Spill Start, Stop dates:	Start April 10, 0001 hours; Stop May 28, 2400 hours
End Spring Spill percentage:	15.59% (9.95% fish spill + 5.64% forced spill)
Number of spill days:	49 (1,176 hours)
Average daily plant discharge:	160,343 cfs (4/10-5/28)
Average daily total spill rate:	25,005 cfs
Average daily fish spill rate:	15,961 cfs
Hours forced spill > 10% fish spill:	511 of 1,176 total hours

Rock Island Summer Fish Spill

Target species:	Subyearling Chinook (smolts)
Spill Start, Stop dates:	Start May 29, 0001 hours; Stop August 11, 2400 hours
Total spill days:	75 (1,800 hours)
Spill target percentage:	20% of day average flow at RI
End season spill percentage**:**	19.90% (19.87% fish spill + 0.03% forced spill)
Average daily plant discharge:	120,671 cfs (5/29-8/11)
Average daily total spill rate:	24,012 cfs
Average daily fish spill rate:	23,977 cfs
Hours forced spill > 20% fish spill:	5 of 1,800 total hours

ACKNOWLEDGMENTS

The Rock Island Dam juvenile fish bypass monitoring program was funded by the Bonneville Power Administration, U.S. Department of Energy, as part of the Northwest Power Planning Council's Fish and Wildlife Program. We wish to thank Michele DeHart, Brandon Chockley, and Chris McCarty of the FPC, and Pacific States Marine Fisheries Commission who provided continued support for the Smolt Monitoring Program throughout the monitoring season. Chelan County PUD provided the facility, equipment and personnel to conduct the monitoring. We would also like to thank the following Chelan County PUD Natural Resource Division Fish and Wildlife personnel for their valuable work contributions to the Smolt Monitoring and PIT tagging programs at the Rock Island Dam Smolt Monitoring Facility: Todd West, Steve Hemstrom, Dave Beardsley, Todd Jackson, and Nathan Clark.

Wenatchee, Washington 98801

December 30, 2016

Abstract

This report provides information on Chelan PUD's Northern Pikeminnow (*Ptychocheilus oregonensis*) control programs for 2016. This program entails the use of deck and boat fishermen (USDA), long liners (Columbia Research), the East Wenatchee Rotary Club Pikeminnow Derby, as well as several miscellaneous efforts throughout the year.

Northern Pikeminnow are one of the most abundant predators of juvenile steelhead and salmonids (*Oncorhynchus spp.*) in the Columbia River. In 1998, the American Fisheries Society (AFS) formally changed the common name of this fish from Northern Squawfish to Northern Pikeminnow. Pikeminnow may concentrate in hydroelectric project tailraces during the late spring and summer months, concurrent with the juvenile salmonid migrations. The Public Utility District No. 1 of Chelan County (District) initiated a pikeminnow removal program in 1994 at Rocky Reach dam and extended the program to include Rock Island in 1995. Since 1996, the District has contracted annually with the United States Department of Agriculture Wildlife Services (USDA) to carry out this program. In addition to the USDA program, Chelan PUD conducted a pilot study using set-lines in 2005 under contract with Columbia Research. The objective of the set-line program was to remove pikeminnow from over-wintering habitats before the start of out-migration of salmonid smolts. The District also provides funding for the annual Pikeminnow Derby sponsored by the East Wenatchee Rotary Club. This year marked the 24th consecutive year for the annual derby and the 21st consecutive year that the District has provided funding for the event.

In 2016, a total of 91,522 pikeminnow were removed from Rocky Reach and Rock Island reservoirs (60,327 by USDA, 27,472 by Columbia Research, 2,347 during the Pikeminnow Derby, and 1,376 by miscellaneous projects).

Introduction

Northern Pikeminnow (*Ptychocheilus oregonensis*) are native to the Columbia River. Burley and Poe (1994) identified pikeminnow as the most abundant predator on out-migrating juvenile steelhead and salmonids (*Oncoryhynchus spp*.) in the mid-Columbia River between Priest Rapids and Chief Joseph dams. They also concluded that the highest abundance of pikeminnow concentrate in the tailrace areas. Loch et al (1994) reported that the highest consumption of juvenile salmonids takes place within the tailraces of dams and those pikeminnow densities in these areas increase during the late spring and summer. Pikeminnow are believed to become highly piscivorous on juvenile salmonids at approximately 280 mm (11 inches) and their predation rate on juvenile salmonids increase significantly as their size and age increases (Peterson, 2001).

In an effort to reduce predation on juvenile salmonids, the District implemented a pikeminnow removal program (Program) in 1994 in the Rocky Reach project area and in1995 the program was expanded to include the Rock Island project area. From 1996 to present time, the District has contracted with the United States Department of Agriculture, Wildlife Services (USDA) to employ anglers to fish for pikeminnow during the summer months from the District's dams and reservoirs. The program has continued to focus on increasing fishing effort, increasing pikeminnow catch totals, and evaluating catch data to characterize attributes of the pikeminnow populations in the reservoirs. As a result, the USDA fish for a longer duration and with multiple boats. From 2005 to current, the District has contracted Columbia Research to fish for pikeminnow within the District's reservoirs with set-lines in an effort to remove pikeminnow from deeper over-wintering areas. Chelan PUD has also provided funding for the annual Pikeminnow Derby sponsored by the East Wenatchee Rotary Club. This year marked the 21st consecutive year that the District has partnered with the Rotary Club.

Program Objectives

The objectives for the 2016 pikeminnow removal program were three-fold:

1) Reduce the number of pikeminnow in the Rocky Reach and Rock Island tailraces and reservoirs in order to reduce predation on juvenile anadromous salmon and steelhead smolts.

2) Continue to evaluate the efficiency of angling methods and the timing of seasonal fish movement to improve the efficiency and harvest.

3) Continue to evaluate current and historic catch statistics characterize effects of the removal program on pikeminnow populations in Rocky Reach and Rock Island reservoirs.

Methods and Materials

USDA

Since 1996, the District has contracted the USDA to conduct pikeminnow fishing from Rocky Reach and Rock Island projects. The USDA employs approximately 17 anglers to fish during the summer months. Crews consist of four 3-person boat crews, one 3-person crew at Rocky Reach dam, and one 2-person crew at Rock Island dam. Boat crews fished for 23 weeks from 25 April to 28 September. Deck crews fished for 16 weeks from 25 April to 12 August.

Each angler is outfitted with two fishing rods and reels, assorted tackle, tackle box, small ice chest (for keeping bait cool), fillet knife (for cutting bait), pliers, line clippers, personal floatation device, hard hat, 5 gallon bucket, and data sheets to record weekly catch. Each crew also carries a District radio or cell phone for communication. For more detail description of equipment used by anglers, please refer to West (2001).

Anglers fish a variety of locations within the tailraces and reservoirs in search of the most productive fish locations. Early in the fishing season when catch rates are low, anglers move in search of "hot spots". Later in the season when flows reside, water temperatures increase, and when anglers become more familiar with pikeminnow holding areas and feeding activity, the anglers are able to concentrate their efforts in established locations.

Each crew leader is in charge of recording specific information. Data is collected weekly from each crew including; total number of pikeminnow caught, total number of hours fished, fishing locations, number of non-target fish captured, and the dates that were fished. Twice a week anglers are required to measure fork length on all pikeminnow in order to evaluate the size distribution. Upon capture, pikeminnow are measured, euthanized, and their carcasses are returned to the river. All non-target species are released immediately back into the reservoir.

Columbia Research

Set-lines are the primary fishing technique used by Columbia Research to capture and remove pikeminnow. Set-lines are long weighted nylon lines with buoys attached at each end. The weighted rope allows the set-line to sink and remain on the bottom of the reservoir where pikeminnow tend to congregate during the winter months. Approximately 120 small hooks are attached to each line. Each hook is tied to a leader that contains a small float, which allows the hook to float slightly off the bottom substrate. An 8-pound test leader allows non-target species to break free from the set-line upon capture.

Each day, between 15 and 20 set-lines are deployed and allowed to fish for 24 hours. Deployment of set-lines occurs in the Rocky Reach and Rock Island reservoirs and varies in depth between 10 feet to 150 feet. Once set-lines are retrieved and non-target species are released, pikeminnow are measured (fork length) and turned into the District for rendering. Columbia Research provides the District with specific information including; the number of pikeminnow caught on each set-line, fork length (mm), depth and location of each set-line, and set-line time. They also provide the District with any incidental species encountered during set-line retrieval.

East Wenatchee Rotary Club
The East Wenatchee Rotary Club takes place during the last week in June. During this two-day event, sportsmen fish Rocky Reach and Rock Island reservoirs for pikeminnow. After each day, the anglers submit their fish for count and total weight. Prizes are awarded to individuals who catch the most pikeminnow by weight. Daily prizes are awarded for the largest fish and the most fish as well.

Chelan County PUD #1
In past years, the District has either contracted or operated a pikeminnow trapping project using modified lamprey traps. Traps were very effective during peak pikeminnow migration season. However, trap efficiency is significantly decreased during seasons of above average adult Sockeye Salmon runs. The last year traps were used was in 2010. For an overview on trap configurations, please refer to Mallas and Stevenson, 2008. For past catch data, please refer to Keller et. al., 2010.

Program Contracts and Compensation

USDA
The USDA receives compensation on an hourly basis for labor through an annual contract. The contract is typically less than 7 months in duration, from May through mid-October. In 2016, the contract payout was $402,710.00. USDA rod and reel fishing activities for the tailrace and boat crews takes place 5 days a week for 8 hours each day.

Columbia Research
In 2016, Columbia Research received $3.00 for each fish between 127 mm and 227 mm and $7.25 for each fish great than 227 mm in fork length. Columbia Research received no compensation for fish measuring less than 127 mm. Columbia Research anglers fish 7 days a week, for up to 15 hours a day during the contract period. In 2016, Columbia Research conducted set-line fishing in the Rocky Reach and Rock Island reservoirs in two distinct seasons. In the spring Columbia fished from April into July, and in the fall from October into November. The total contract payout was $179,906.75.

East Wenatchee Rotary Club
The District contracts with the East Wenatchee Rotary Club to hold the annual Pikeminnow Derby. In 2016, this contract was $20,000 with specific requirements for anglers to fish in Rocky Reach and Rock Island reservoirs only.

Results

USDA
Since 2003, the USDA has removed 607,514 pikeminnow from the Rocky Reach and Rock Island projects. In 2016, USDA crews removed 60,327 pikeminnow from May through mid-October. (Table 1).

Pikeminnow Size Distribution

The USDA submitted length measurements to the District weekly. Fish lengths are recorded into size categories 10 mm in length. A total of 25,000 pikeminnow were measured in 2016. Of the pikeminnow measured, 21,431 were less than or equal to 250 mm, and 3,569 were greater than 250 mm (Table 2).

The overall mean fork length of pikeminnow removed from both Rocky Reach and Rock Island in 2016 was 183 mm. The mean length for Rocky Reach and Rocky Island were 177 mm and 233 mm respectively. Overall mean lengths have been generally decreasing over time and mean lengths in 2016 were the lowest since measurements began in 2003 (Table 3).

Pikeminnow Catch Rates

In 2003, 2004, and 2005 the angler hours were reported as fishing day (8 hours). From 2006 through 2016, anglers fishing from the dam reported their time as "angling hours" while boat anglers reported fishing time as boat hours". Angling hours were just that – defined as the number of hours the tailrace crews spent fishing. Boat hours are defined as the number of hours the boat was in the water. It does not include the time required to launch or load the boat, refuel, or purchasing equipment. The catch per angler hour (CPAH) increased every year through 2008. The CPAH then began to decrease through 2012 before it began to generally increase again to 5.8 in 2016 (Table 4).

Table 4. The overall rod and reel CPAH for USDA pikeminnow anglers from May to October, 2003 to 2016.

Year	Angler Hours	Fish Captured	CPAH
2003	6,857.00	19,754	2.9
2004	11,676.00	36,145	3.1
2005	10,849.00	39,818	3.7
2006	9,159.50	40,747	4.4
2007	9,513.50	46,240	4.9
2008	8,317.50	42,158	5.1
2009	10,004.50	50,333	5.0
2010	10,187.50	47,354	4.6
2011	10,300.75	36,401	3.5
2012	10,261.05	36,118	3.5

2013	10,387.75	47,563	4.6
2014	10,333.60	44,826	4.3
2015	10,251.00	59,730	5.8
2016	10,438.50	60,327	5.8

Cost Benefit Analysis

Expenditures for the USDA portion of the pikeminnow predator program have fluctuated since the initial start of the contract in 1996. Since 2013, the cost per fish has been near or below $7.00 with the exceptions of years 2011 through 2014 when prices reached a peak in 2012 at $9.85 per fish (Table 5).

Table 5. Cost of USDA pikeminnow program and the cost per fish breakdown from 2003 to 2016.

Year	Cost of Program	Fish Captured	Cost per fish
2003	$135,709.98	19,754	$6.87
2004	$237,834.10	36,145	$6.58
2005	$255,233.38	39,818	$6.41
2006	$263,225.62	40,747	$6.46
2007	$253,395.20	46,240	$5.48
2008	$264,752.24	42,158	$6.28
2009	$327,164.50	50,333	$6.50
2010	$332,425.08	47,354	$7.02
2011	$342,533.41	36,401	$9.41
2012	$355,685.00	36,118	$9.85
2013	$360,780.96	47,563	$7.59
2014	$373,112.00	44,826	$8.32
2015	$397,619.00	59,730	$6.66
2016	$402,710.00	60,327	$6.68

Non-Target Fish Species

Rod and reel angling is one preferred pikeminnow removal method because baits can be tailored to exploit primarily pikeminnow and is the least harmful to non-target species. Non target species caught in 2016 included; chiselmouth (*Acrocheilus alutaceus*), peamouth (*Mylocheilus caurinus*), large scale and bridgelip suckers (*Catostomus spp*.), mottled sculpin (*Cottus bairdii*), bass (*Micropterus dolomieu*), mountain whitefish (*Prosopium williamsoni*), walleye (*Sander vitreum*), yellow perch (*Perca flavescens*), white sturgeon (*Acipenser transmontanus*), carp (*Cyprinus carpio*), adult and juvenile salmon, and adult steelhead and resident rainbow trout (*Oncorhynchus mykiss*). In 2016, all non-target fish were released unharmed back to the river.

Columbia Research

Columbia Research has removed 320,865 pikeminnow from Rocky Reach and Rock Island reservoirs from 2005-2016. In 2016, set-lines run by Columbia Research produced 27,472 pikeminnow (Table 6).

Table 6. Total pikeminnow removed from Rocky Reach and Rock Island projects by Columbia Research from 2005 to 2016.

Year	Columbia Research
2005	19,337
2006	22,418
2007	21,301
2008	21,472

2015	26,790
2016	27,472
Total	320,865

Pikeminnow Size Distribution

Columbia Research submitted length measurements to the District for all pikeminnow captured. Fish lengths are recorded into size categories 10 mm in length. Of the pikeminnow measured, 11,780 were less than or equal to 250 mm, and 15,692 were greater than 250 mm (Table 7).

Table 7. Size and number of pikeminnow captured by Columbia Research in Rocky Reach and Rock Island reservoirs in 2016.

Size (mm)	Columbia Research

521-530	1
531-540	20
541-550	0

Because the set-line program is an incentive based contract and that the main objective is to target deep over wintering habitats, Columbia Research is required to measure every pikeminnow captured. Both of these factors contribute to Columbia Research producing larger mean lengths compared to other District pikeminnow capture projects. In 2016, the average mean fork lengths in the Rocky Reach reservoir and Rock Island reservoir were 260 mm and 252 mm respectively. The overall 2016 mean fork length was 258 mm. The overall mean fork length for Columbia Research has been trending downwards with the largest mean fork length (282 mm) in 2005 and the smallest mean fork length in 2016 (Table 8).

Table 8. The mean fork length of pikeminnow removed by Columbia Research set-line fishing at Rocky Reach and Rock Island projects, 2005 to 2016.

Year	Rocky Reach Mean Length (mm)	Rock Island Mean Length (mm)	Overall Mean Length (mm)
2005	N/A	N/A	282
2006	N/A	N/A	281
2007	269	294	281
2008	269	268	269
2009	274	272	274
2010	267	256	261
2011	258	270	261
2012	293	288	275
2013	268	273	270
2014	262	274	268
2015	268	276	270
2016	260	252	258

Pikeminnow Catch Rates

In 2016, Columbia Research removed 27,472 pikeminnow during 61,920 hours of set-line effort. This equates to 7,430,400 hook hours as each set line has 120 hooks. The overall catch per unit effort (CPUE) was 0.37 for 2016. The District calculates CPUE as the number of pikeminnow captured per 100 hook hours. In general, the CPUE for Columbia Research has remained pretty constant. The last two years have produced the highest CPUE's at 0.42 and 0.37 (Table 9).

Table 9. Annual catch per unit effort (CPUE) for Columbia Research in Rocky Reach and Rock Island reservoirs, 2008 to 2016.

Year	Total Hook Hours	Fish Captured	CPUE*
2008	6,624,000	21,472	0.32
2009	10,980,000	31,683	0.29
2010	8,517,600	31,620	0.37
2011	10,332,000	32,846	0.32
2012	9,388,800	29,526	0.31
2013	9,129,600	29,310	0.32
2014	8,643,600	27,090	0.31
2015	6,402,240	26,790	0.42
2016	7,430,400	27,472	0.37

*CPUE is calculated as the number of pikeminnow per 100 hook hours.

Cost Benefit Analysis
Columbia Research is compensated on a per-fish basis. Fish captured between 127 mm and 227 mm were compensated at a lower rate than fish captured that measured greater than 227 mm in length. These two size categories are considered "Under" and "Over" the 227 mm delineation. In 2005, Columbia Research received $2.75 or $5.50 per fish depending on size. In 2006, compensation rate increased to $3.00 and $6.00 respectively. In 2007, the compensation rate increased to $3.00 and $6.25 depending on fish size. From 2008 to 2011, Columbia Research received $3.00 or $6.50 per fish. For years 2012 and 2013 the compensation rate increased to $3.00 and $6.75 respectively. From 2014 to 2016 the compensation rate has been $3.00 for fish 127 mm to 227 mm and $7.25 for fish greater than 227 mm in length. No compensation was awarded for any fish measuring less than 127 mm. For the District's total annual compensation to Columbia Research for their pikeminnow efforts and the equivalent annual cost per fish refer to Table 10.

Table 10. Cost of Columbia Research set-line program in Rocky Reach and Rock Island and the cost per fish breakdown from 2005 to 2016.

Year	Cost of Program	Fish Captured	Cost per fish
2005	$99,726.00	19,337	$5.16
2006	$125,000.00	22,418	$5.58
2007	$124,998.75	21,301	$5.87
2008	$124,997.50	21,472	$5.82
2009	$174,999.50	31,683	$5.52
2010	$174,999.50	31,620	$5.53
2011	$180,250.50	32,846	$5.49
2012	$180,000.00	29,526	$6.10
2013	$179,988.75	29,310	$6.14
2014	$179,742.50	27,090	$6.64
2015	$179,998.50	26,790	$6.72
2016	$179,906.75	27,472	$6.55

*CPUE is calculated as the number of pikeminnow per 100 hook hours.

Non-Target Fish Species
The non-target fish species caught by Columbia Research included chiselmouth, peamouth, large scale and bridgelip suckers, mottled sculpin, mountain whitefish, white sturgeon, and burbot (*Lota lota*). In 2016, no adult or juvenile salmon or steelhead were captured. All non-target fish were released unharmed back into the river.

East Wenatchee Rotary Club
The East Wenatchee Rotary Club Annual Pikeminnow Derby has captured 60,415 pikeminnow in 42 days of total fishing since 1996. In 2016, the annual derby produced 2,347 pikeminnow over the 2-day event. There were 98 tickets sold (82 adults and 16 youth). Of the participants, 76 people turned in fish (68 adults and 8 youths). Participation and total number of pikeminnow captured were both down in 2016 (Table 11).

Table 11. Total pikeminnow removed from Rocky Reach and Rock Island reservoirs during the annual Pikeminnow Derby from 1996 to 2016.

Year	Pikeminnow Captured
1996	1,800
1997	2,240
1998	1,847
1999	2,294
2000	1,370
2001	1,601
2002	2,783
2003	2,568
2004	2,943
2005	3,950
2006	3,445
2007	3,812
2008	4,474
2009	3,812
2010	5,027
2011	3,274
2012	2,894
2013	2,944
2014	2,563
2015	2,427
2016	2,347
Total	60,415

Discussion

USDA

The continued success of the USDA program is likely a result from a variety of factors. A key efficiency is credited to a core group of veteran anglers who return to work in the program each year, resulting in better catch rates overall. Experienced anglers are more productive, relying on their knowledge of pikeminnow holding areas in the reservoirs, effective baits, and presentation methods. While the USDA continues to catch similar numbers of pikeminnow each year, the overall average size has dropped considerably over the course of the program. This resulted in the lowest average size observed ever for the program in 2016. The start and duration of the USDA pikeminnow program is designed to coincide with the outmigration period of juvenile salmonids. Smolts arrive at Rocky Reach and Rock Island Dams in early April, and continue passing the dams through the end of August. Pikeminnow primarily ascend the adult fish ladders during mid-May through September. Peak ladder passage occurs in August at Rocky Reach and in mid-July at Rock Island. The highest catch rates for pikeminnow usually occur in July and August for Rocky Reach and Rock Island.

Columbia Research

The objective for the Columbia Research set-line program was to remove large pikeminnow that congregate in deep over-wintering areas. Columbia Research has become very efficient at using set-lines. Because set-line angling is designed to capture fish that hold on or near the river bottom, targeting deep areas within the reservoir where pikeminnow congregate in colder months is effective. Pikeminnow likely move into deep pools where the daily water temperature remains more constant. A fish's metabolic rate decreases over winter periods, and hence it needs less food to survive (Sauter et. al, 1994). By presenting pikeminnow with food that they do not have to chase, they likely expend very little effort and energy to obtain the bait. The boat crew deployed 20 set-lines nearly every day at various depths. In 2016, all fish were caught at depths between the surface and 120 feet with most fish being caught between the surface and 90 feet.

Fishing with set-lines and at deeper depths has resulted in Columbia Research having a larger mean length than USDA over the years. From year to year there is some overlap but it can be seen that the two programs are targeting pikeminnow from different size classes (Figure 1). Also seen in Figure 1 is that the trend for both programs is a reduction in mean length over time. If capture rates can outpace the recruitment rate then this would result in a reduction in mean length over time. Columbia Research's mean length has steadily declined despite the fact they are targeting larger fish for a higher payout. It is predicted that the programs will reach a point where capture rates will off-set the recruitment rates and mean lengths will start to level off.

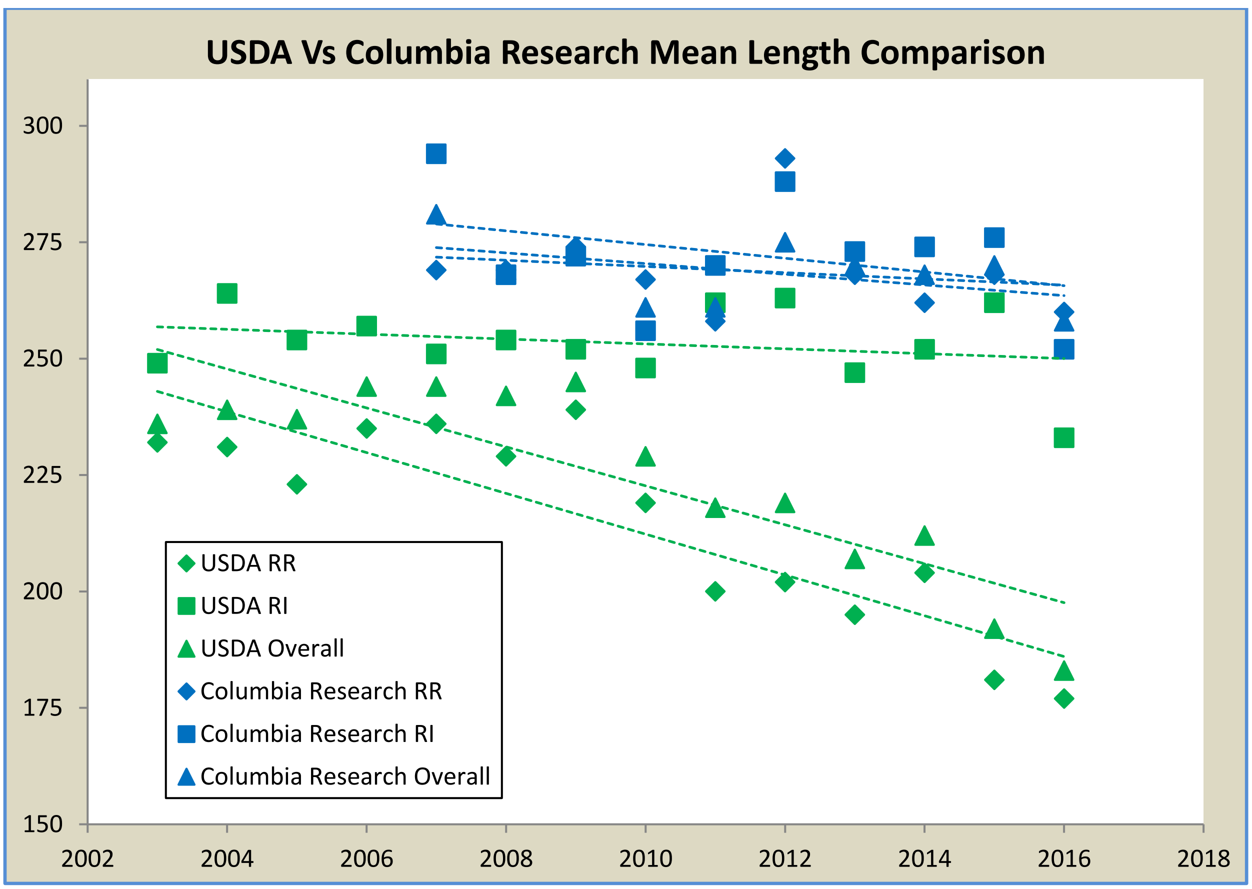

Figure 1. Mean fork lengths (mm) for pikeminnow captured by Columbia Research and the USDA from 2003 to 2016.

East Wenatchee Rotary Derby

The Pikeminnow Derby is nearing its 25th annual event in a few years and marks the District's longest effort toward reduction in pikeminnow numbers. While numbers in the past have been higher, this year's effort was impacted by poor weather on the second fishing day. The derby is only a two-day event and can be influenced heavily by weather. Since the limiting factor is the number of anglers on the river, additional efforts should be put into increasing the number of anglers participating. This was addressed in 2015 by doubling the prize contribution by the District from $10,000 to $20,000.

Chelan County PUD (miscellaneous)

In past years the District has conducted pikeminnow ladder trapping efforts in both Rocky Reach and Rock Island fish ladders. These efforts were abandoned in the 2011 season due to the increased bycatch of adult Sockeye Salmon. With the increased run sizes of Sockeye Salmon and the overall success of the District's other pikeminnow programs, the District abandoned the ladder trapping completely in 2012.

In 2016, there were 1,376 pikeminnow caught in miscellaneous instances. Some of these miscellaneous captures included bycatch at facilities, fish ladder outage rescues, bycatch during miscellaneous studies, and a few targeted angling efforts by District employees. These various events accounted for 1.5% of the total pikeminnow catch in 2016. An overall visual of the District's different pikeminnow programs can be seen in Figure 2.

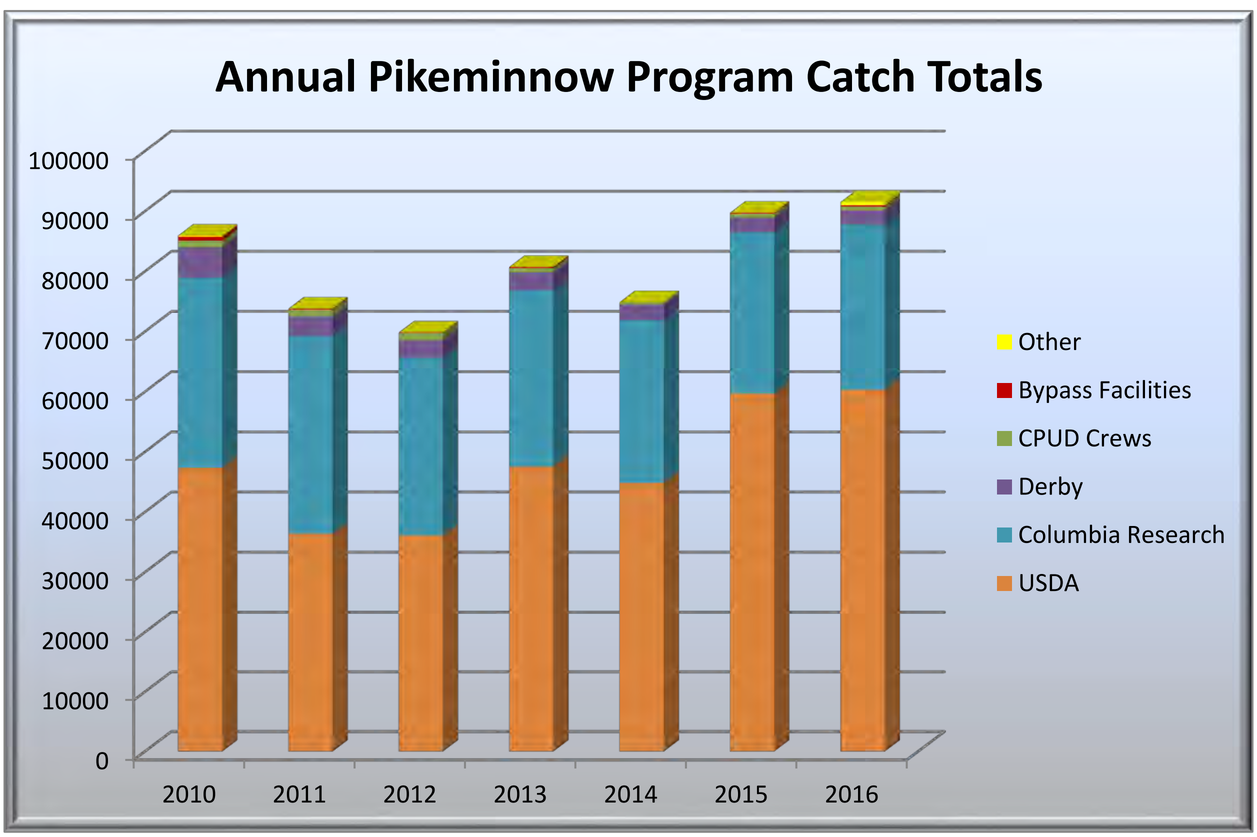

Figure 2. Breakdown of pikeminnow contributions from Chelan County PUD's different pikeminnow programs from 2010 to 2016.

Project Recommendations

USDA

Several factors, including USDA angler skills, reservoir knowledge, increased efforts, and overall program duration combined to make the 2016 the most successful pikeminnow effort to date for the USDA. The USDA anglers continue to maintain excellent pikeminnow catch rates by documenting fish movements and holding locations. We expect that overall catch may increase as anglers continue to learn where pikeminnow reside during the summer and fall months. However, if the program has started to outpace the recruitment efforts, then we may start to see a decrease in total capture numbers. If possible, the District should continue to utilize USDA anglers with experience and knowledge of the reservoirs and who are familiar and adept at the angling techniques used in the program.

Columbia Research

We recommend continuing the set-line program at the 2016 funding and effort level. This program is productive because it compensates on a per fish basis, with no equipment, fuel, or administrative costs. The current recommendation is to continue to start the program in February and continue through November to take advantage of favorable CPUE documented during past fishing efforts in November.

East Wenatchee Rotary Derby

The District should continue to fund the East Wenatchee Rotary Club Pikeminnow Derby at its current funding level. The derby removes a large number of fish in a short time frame of two days. This likely provides an immediate within-year benefit to juvenile survival in the reservoirs. Since 1996 the derby has removed 60,415 pikeminnow in just 42 days of effort. In order to increase overall angler turn out the District should increase efforts to advertise the derby. The increased advertising along with the contribution increase from $10,000 to $20,000 in 2015 should help encourage higher participation. The Rotary Club should continue to host the event concurrent with the peak smolt migrations through Rocky Reach and Rock Island Reservoirs.

Final Plan

Prepared By:

Lance Keller
&
Scott Hopkins

January 2017

Introduction:

The primary objective of the Rock Island Smolt Monitoring Project (RISMP) is to provide information on Mid-Columbia juvenile salmonid out-migration timing to the Fish Passage Center (FPC). Another objective of this project is to provide information to the Columbia River basin-wide database for passive integrated transponder (PIT) tagged fish in coordination with Pacific States Marine Fish Commission (PSMFC). This data will improve the fish managers understanding of smolt out-migration timing and survival in the Columbia River System. A further objective of the project is to monitor downstream migrating juvenile salmonids for signs of gas bubble trauma (GBT).

This program is designed to measure the migration characteristics of emigrating salmonids. It also provides a comparison and evaluation of year-to-year migration information such as travel time and peak abundance. Monitoring at Rock Island Dam is ideal for indexing juvenile salmonid emigration and travel time because the trap site is located down river from four major tributaries and several hatcheries that release fish to the mid-Columbia Basin. Daily collections will be used to compute the 10%, 50%, and 90% dates of passage at the collection site.

Bypass Monitoring Requirements:

Sampling will begin on 1 April 2017 and will be completed on 31 August 2017. Data summary, analysis and report writing will occur throughout the sampling period and be completed by 31 January 2018.

A. Tasks

Public Utility District #1 of Chelan County, hereafter referred to as the District, will monitor the gatewell orifice bypass trap from 1 April to through 31 August 2017. Personnel monitoring the bypass trap at Rock Island Dam will consist of District employees. A District Fish and Wildlife Specialist will supervise the onsite crew at the bypass trap. A permanent District Biologist will oversee the monitoring program.

Fish will be collected continuously during the monitoring period. Fish will be examined during regular work hours (0700–1530 hrs), unless large numbers of fish are entering the flume of the bypass trap, in which case fish would be removed and recorded as the appropriate sample days catch. Fish will be delivered via the bypass elevator to a 12' x 4' x 3.5' aluminum holding tank in the sampling facility, which is plumbed for continuous flow of river water. Small samples (40-60) of fish will be pre-anesthetized using a pre-mixed solution of MS-222 (1.8 ml per gal. of water) before being moved by net into the sorting holding tank with a solution of MS-222 (3.6 ml per gal of water). *** See MS-222 stock solution mixing rates below.** Fish will be identified by species, interrogated for a PIT tag, and examined for marks indicating hatchery origin and descaling. Anesthetized fish will recover in a separate holding tank and be released after they have recovered from anesthesia.

Sub-samples of up to 100 Chinook and steelhead will be examined for signs of GBT twice weekly. The unpaired fins and eyes will be examined for the presence of bubbles. Absence or presence of GBT symptoms as well as the location and severity of symptoms will be reported to the FPC daily throughout the sampling season.

Insertion of PIT tags will begin when an increase in the number of juvenile salmon being captured in the bypass trap is observed, usually around mid-April, and will continue throughout the monitoring season as appropriate for each species. The target of the PIT tagging operation will be the middle 80%, of both the Wenatchee, Methow and Okanogan runs that pass the dam during April and May respectively. Beginning in June, subyearling Chinook will be marked until 4,800 fish have been tagged.

Fish will be injected with PIT tags by hand using a medical syringe/push rod mechanism with a sterile 12-gauge veterinary needle. Tagged fish will be placed on a plastic covered measuring board where the information and length measurements will be recorded by touching the stylus directly on the digitizing board. Data for PIT tagged fish and the number of tagged fish will be recorded directly into a computer via a digitizing board.

Standard PIT tagging procedures will be followed and PIT tags, equipment, and other miscellaneous tagging supplies will be purchased under the RISMP contract. Data will be entered into a computer and supplied to a District Biologist and the FPC daily by modem.

B. RIJSF Sampling

Run-of-river fish collected at the Rock Island Juvenile Sampling Facility (RIJSF) to evaluate fish for the following:

1. Run timing of target species:
    a. Provide standardized juvenile capture rate data to supplement Program RealTime (UW) run-timing predictions
    b. Guide decisions about initiating spring and summer fish spill
        i. Currently spring and summer fish spill occurs at Rock Island Dam

2. Fish species composition:
    a. Guide decisions about starting or stopping spill
        i. Currently spring (10%) and summer (20%) fish spill occurs at Rock Island Dam.
        ii. Report counts and condition of all salmonid species to the FPC daily.

3. Fish condition:
    a. Evaluate run-of-river fish condition for migrating juvenile salmon and steelhead.
        i. Descale: 20% or more scale loss on either side
        ii. Injury: Scratches, bruises, or hemorrhages
        iii. Mortality: Any fish dead on arrival to sampling facility
        iv. Examine juvenile salmonid emigrants for symptoms of GBT twice weekly. Report GBT examination results to FPC when collected.

4. Origin of fish stocks and identification of marked individuals:
    a. PIT tags
    b. Fin clips
    c. Acoustic tags
    d. Other external marks or tags

5. PIT tagging:
    a. Insert PIT tags into between 200 and 600 unclipped Chinook yearlings, unclipped sockeye, hatchery steelhead and wild steelhead weekly (Table 1). Refer to FPC to determine if tagging should start/stop outside the criterion set in Table 1.
    b. Insert PIT tags into as many unclipped subyearling Chinook daily as necessary to reach 600 fish per week over an 8-week period between mid-June and mid-August (seasonal total of 4,800 fish).
    c. Transfer PIT tag generated data to PSMFC PITAGIS system daily.

6. Daily reporting:
    a. Report counts and condition of all salmonid species to the FPC daily.
    b. Report the average river flow, average flow through Powerhouse No.1, average flow through Powerhouse No. 2, and average spill daily.
    c. Report GBT examination results to FPC when collected.

Table 1. Weekly PIT tagging quotas at Rock Island Dam during the 2017 smolt monitoring season. Refer to FPC to determine if tagging should occur outside these time periods.

	Weekly Quotas				
Week Starting	Unclipped Chinook Yearling	Unclipped Chinook Subyearling	Unclipped Sockeye	Hatchery Steelhead	Wild Steelhead

Season Totals	**3,800**	**4,800**	**3,600**	**2,800**	**1,200**

Daily Protocol for Fish Collection:

Standard Operations:

1. Fish will be collected continuously during the monitoring period 0900-0900 (24 hours).
2. Fish will be examined during regular work hours (0700–1530 hrs), unless large numbers of fish are entering the flume of the bypass trap, in which case fish would be removed and recorded as the appropriate sample days catch.
3. Dewatering screens are raised and fish crowded into the transport elevator.
    a. If large numbers of fish are present in the sampling raceway, use more than one elevator trip. If excessive numbers of fish are present see the Special Operations section.
4. Fish will be delivered via the bypass elevator to a 12' x 4' x 3.5' aluminum holding tank in the sampling facility.
    a. Ensure continuous flow of river water to holding tank.
5. Small samples of fish will be moved into the sorting holding tank with a solution of MS-222 (3.6 ml per gal of water). *** See MS-222 stock solution mixing rates below.**
6. Fish will be identified by species and condition.
    a. Evaluate all steelhead and salmonids for injuries and descaling.
7. Scan each fish for PIT tags, fin clips, external tags and acoustic tags.
8. If needed, collect and hold fish for PIT tagging, acoustic tagging and/or marked releases (Special Operations).
9. Allow anesthetized fish (examined for species composition and fish condition) to recover in the facility's holding tank for at least 1.0 hours.
    a. Release fish after they have recovered from anesthesia.

2017 - MS-222 Recommended Knockdown & Maintenance Dosage

(CCPUD) Stock Solution Mix Ratio MS-222:

1000 grams per 5 gals. of water	*(18.925 liters per 5 gals.)*
200 grams per 1 gal. of water	*(3.785 liters per 1 gal.)*
53 grams per 1 liter of water	

(CCPUD) Stock Solution Used for Fish Examination:

Pre-anesthetized Dose:

Use 1.8 ml of stock solution per gal of water for pre-anesthetized dose

Use 9 ml of stock solution per 5 gals. of water

(CCPUD) Stock Solution Used for Fish Examination:

Knockdown Dose:

Use 3.6 ml of stock solution per 1 gal. of water in knockdown tank ***OR***

Use 18 ml of stock solution per 5 gals. of water

* **The amount of MS-222® used, however, varies throughout the season depending upon**

temperature, the number of fish in each chamber and the species of fish being sedated.

Special Operations:

1) PIT tagging:
   a) Insert PIT tags into between 200 and 600 unclipped Chinook yearlings, unclipped sockeye, hatchery steelhead and wild steelhead weekly (Table 1).
   b) Insert PIT tags into as many unclipped subyearling Chinook daily as necessary to reach 600 fish per week over an 8-week period between mid-June and mid-August (seasonal total of 4,800 fish).
   c) Transfer PIT tag generated data to PSMFC PITAGIS system daily.
   d) Return to step 8 under Standard Operations

2) Excessive Fish:
   a) Upon estimation by the Bypass Crew that the trap contains too many fish (~5,000 fish) to work up in the allotted time period, the Bypass Foreman will **immediately** contact the Fishway Attendant whose name appears on the **Lock-out Tag** (currently Brad Whitehall ext. 4538) on the main RI Bypass trap gate. The designated Fishway Attendant must be present to operate the gate to let fish pass when additional processing time is needed.
   b) When the number of smolts captured in the RI Bypass trap exceeds the capacity of the holding tank up above (5,000 fish depending on species composition), the Bypass Crew will use extra time to work through ***all of the fish in that sample***. When enough fish have been processed the remaining fish down below can be brought up via hopper elevator. If all fish cannot be removed from trap, then at 9:00 a.m. the main RI bypass gate will be opened to allow the following day's fish to return directly to the river. This will allow more time to work up the current day's fish. Additional water may be added using the new upwelling valve that was added in December 2015.
   c) Following completion of that sample (i.e. empty trap), the main bypass gate will be closed and fish will be counted/evaluated according to normal protocol. The **crew will document the actual trap re-deployment time**, and enter the reduced sample-time into the FPC data link so the following days sample can be properly expanded into 24 hours (for example 21 or 22 hour sample time instead of 24) for the next day's sample. The FPC's SMP site is set up to receive reduced sample times, and provide an expanded estimate for a full 24 hour sample. This is important to maintain index sample consistency and the RI smolt numbers used in UW's Program RealTime run forecaster to predict smolt passage percentiles at RI Dam.
   d) This protocol will allow for minimal error (estimating a full count with only 2-3 hours of missing sample time rather than 12 hours) in achieving an expanded 24-hour trap count.

Bull Trout:

1) Columbia River bull trout are a **federally threatened species** and have federal protection under the **Endangered Species Act (ESA).** The US Fish and Wildlife Service (USFWS) issued a Biological Opinion on the effects to bull trout for incorporating Chelan's HCPs into the Rock Island Project license. The USFWS issued an annual incidental take (injure or kill) level of no more than 2% of the bull

trout passing through the juvenile fish bypass per year. In 2017, if a bull trout is incidentally captured during daily sampling at the Rock Island juvenile sampling facility, please follow these protocols:

2) ***Healthy bull trout:*** If you capture a bull trout during sampling, take a fork length measurement, document condition, scan for any PIT-tags; note the collection time and water temperature. In the event that a tag is detected it should be included in the appropriate days P4 file. After a bull trout is incidentally subjected to anesthesia and identified in the sorting trough, allow for normal recovery time in fresh water and then release the fish back to the pipe.
3) ***Sick or injured bull trout:*** If you capture a sick or injured bull trout during sampling operations, do not retain it unless you are *absolutely positive* that it is destined to die if released (for example, the fish is unable to right itself, is upside down and barely gilling, pupil is non-responsive). If the fish has a possible chance to survive, then follow directions in step 2 above.
4) ***Bull trout mortalities:*** If you encounter a bull trout mortality, please save, identify, and preserve (bag, identify and freeze) the fish, and ***inform Steve Hemstrom ext. 4281 following completion of the Index sampling that day***. Please document and communicate the circumstances in which the fish was found, and any apparent physical injury (including descale) you observe. Scan the fish for any possible PIT-tags and document any tags into that days P4 file. Make arrangements to deliver the specimen to the Fish and Wildlife building at headquarters.
5) ***Sub-adult bull trout PIT Tagging:*** No PIT tagging will occur in 2017.
6) ***Sub-adult bull trout tissue sample:*** No tissue samples will be taken in 2017.

Adult Lamprey:

1) ***Healthy adult lamprey:*** If you capture an adult lamprey in the bypass trap, take an overall measurement, an inner dorsal distance measurement (if possible), document condition, scan for any tags (1/2 and full duplex), and note the time and water temperature. After data is collected, transfer the lamprey and release in a calm spot on the Douglas county side of the forebay. In the event that a tag is detected it should be included in the appropriate days P4 file.
2) ***Sick or injured adult lamprey:*** If you capture a sick or injured adult lamprey during sampling operations, do not retain it unless you are absolutely positive that it is destined to die if released. If the fish has a possible chance to survive, then follow directions in step 1 above.
3) ***Adult lamprey mortalitites:*** If you encounter an adult lamprey mortality, please save, identify, and preserve. Please follow the same procedures as you would for bull trout mortalities.

Adult Steelhead:

1) ***Adult Steelhead:*** If you capture an adult steelhead in the bypass trap, try to determine if it is a kelt or an adult that is yet to spawn. If it is a kelt, record for daily catch info and release back into the fish ladder. If it is a healthy adult that has fallen back, then you may transfer and release it into the forebay in a calm spot upstream of the traveling screens.

White Sturgeon:

1) ***Healthy sturgeon:*** If you capture a sturgeon at R.I. bypass, take a fork length, weigh it if possible, scan for any tags, record condition and any applicable information about scutes (# and side of removed scutes). In the event that a tag is detected it should be included in the appropriate days P4 file. After data is collected, transfer the sturgeon and release in a calm spot on the Douglas county side of the forebay.
2) ***Sick or injured sturgeon:*** If you capture a sick or injured sturgeon during sampling operations, do not retain it unless you are absolutely positive that it is destined to die if released. If the fish has a possible chance to survive, then follow directions in step 1 above.
3) ***Sturgeon mortalities:*** If you encounter a sturgeon mortality, please save, identify, and preserve (if small enough), and **inform Lance Keller ext. 4299**. Please document and communicate the circumstances in which the fish was found, and any apparent physical injury you observe. If the specimen is small enough, take a fork length, weight, and scan for any tags. In the event that a tag is detected it should be included in the appropriate days P4 file. Also record any information regarding scutes (# and side of removed scutes). Arrange to deliver the specimen to the Fish and Wildlife building at headquarters when applicable.

Contingencies:

If, after start-up of the bypass system, we encounter any unforeseen problem(s) with fish collection, we will immediately work to correct the problem(s) and consult with the HCP Coordinating Committee.

C. Statement of BPA's involvement in the Project

The RISMP is a cooperative study between The District, Bonneville Power Administration (BPA), and the FPC. The District will provide supervisory costs for the project as it relates to District personnel, while BPA will pay for the remaining costs of the project. These costs include (but are not limited to) labor, benefits, transportation, miscellaneous materials and administrative overhead.

D. Time Schedule

Sampling will begin on 1 April 2017 and will be completed on 31 August 2017. Samples will be collected from 0900 hrs to 0900 hrs the following day throughout the sampling period.

E. Reporting Tasks

Fieldwork for this project occurs in the 6-month period between April and September. A final report on the 2017 Smolt Monitoring Program will be issued by 31 January 2018.

Place of Operations:

All sampling will take place at the Rock Island Dam Powerhouse No. 2, which is located 15 miles southeast of the city of Wenatchee, at Columbia River mile 453.

Personnel Involved:

The Senior Fisheries Biologist for Chelan County P.U.D. is Lance Keller. He can be reached at (509) 661-4299, fax (509) 661-8108, Email lance.keller@chelanpud.org or mail P.O. Box 1231, Wenatchee WA, 98807.

The Fisheries Biologist for Chelan County P.U.D. is Scott Hopkins. He can be reached at (509) 661-4763, fax (509) 661-8108, Email scott.hopkins@chelanpud.org or mail P.O. Box 1231, Wenatchee WA, 98807.

Fish &Wildlife Operations Superintendant for Chelan County P.U.D. is Todd West. He can be reached during normal working hours at (509) 661-4559, Email todd.west@chelanpud.org or mail P.O. Box 1231, Wenatchee WA, 98807.

The District crew working at Rock Island Dam will be supervised by a Fish & Wildlife Specialist/Foreman.

Fish and Wildlife Helpers who will be working on the project will be hired in the spring of 2017.

Appendix J
2017 Wenatchee Steelhead Release Plan
(Brood Year 2016)

Memorandum

Date: March 3, 2017

To: Rock Island and Rocky Reach HCP Hatchery Committees

From: Catherine Willard (CPUD), Scott Hopkins (CPUD), Chris Moran (WDFW), and Mclain Johnson (WDFW)

Re: 2017 Wenatchee Steelhead Release Plan (Brood Year 2016)

<u>Background</u>

Chelan PUD is required to produce 247,300 steelhead smolts for release into the Wenatchee River Basin in 2017 as part of the Rock Island and Rocky Reach HCP requirements. As of February approximately 267,035 Wenatchee summer steelhead (142,224 HxH and 124,811 WxW) are on station at the Facility. Beginning in winter 2011 the Chelan PUD Wenatchee River steelhead program was relocated to the Chiwawa Acclimation Facility ("Facility") (Figure 1) following significant upgrades to accommodate tributary based overwinter acclimation for the Wenatchee steelhead program. Steelhead are transferred from Eastbank Hatchery to the Facility in November and released in April through May. The Facility consists of three, in line circular, dual-drain tanks within an enclosed building and are operated on a partial water reuse system (RAS). The two outer tanks hold steelhead during rearing and the center tank is used solely for receiving fish that are allowed to move from the outer tanks to the center tank during release. Fish are not provided the opportunity to move to the center tank until gates are removed (typically April 20th). When the center tank contains a pre-determined number of fish for a release, fish are loaded into a hatchery truck and truck-planted at one of five release locations. This "screening" method has been used to differentiate between apparent active migrants (fish that move from the outer tanks to the center tank) from apparent non-active migrants (fish that do not move from the outer tank to the center tank).

In addition to the circular vessels, there are three traditional flow-through raceways (RCY) located outside. The smaller of the three, Raceway Three (RCY3), is used to rear steelhead when it is not needed for rearing "high ELISA" spring Chinook juveniles. Raceways One (RCY1) and Two (RCY2) are located adjacent to each other. The wall between the two raceways contains a gated opening that when removed, allows fish to move between the raceways. In addition to removing the gate, the water is lowered in the receiving pond (typically April 20th) to establish a directional flow that apparent active migrant fish may cue to. Similar to the RAS vessels, this set-up allows for a screening method that attempts to differentiate between apparent active- and apparent non-active migrants. When RCY1 contains the pre-determined number of fish suitable for release, fish are loaded into a transport truck and truck-planted at one of five release locations. Historically, this screening method has been termed a volitional release but is currently termed a screening method as this more accurately describes the end result of the action.

2017 Release Strategy Objectives

- Evaluate best hatchery management practices for hatchery releases to optimize homing fidelity, minimize residualism, maximize out-migration survival, and minimize negative ecological interactions (Draft NMFS Wenatchee River Steelhead Section 10 Permit).
- Assess hatchery release practices to inform development of a residualism baseline for the Wenatchee steelhead program consistent with the Draft NMFS Wenatchee River Steelhead Section 10 Permit DRAFT Steelhead Residual Management Plan.
- Utilize data collected from the 2017 Wenatchee River Steelhead release to assess applicable monitoring and evaluation objectives (i.e., Objectives 4 and 6) for the Wenatchee River summer steelhead hatchery program (Hillman et al. 2013).

Methods

The 2017 release strategy will evaluate the effectiveness of the screening method, and the role of rearing vessel (RAS versus RCY) and brood origin on fish performance (e.g., juvenile survival and adult returns). The 2017 release plan methodology will consist only of screened releases; release years 2015 and 2016 evaluated screened and non-screened releases. Additionally, 2,500 PIT tags will be applied to non-movers remaining in RCY2 at the end of the screened release period to increase the PIT sample size of non-movers to better understand their post release performance. As with previous years, the release numbers and locations identified in Table 1 are proportionally based on the spawning distributions in the respective streams.

- Cormack-Jolly–Seber survival probabilities to MCN will be calculated for each release group using recaptures of PIT-tagged fish.
- The percentage of PIT-tagged fish detected in the Wenatchee sub-basin after July 1 of the year of release will be calculated to estimate potential residualism for each release group.

Release Timing

In an effort to more closely align hatchery steelhead releases with the peak outmigration period for wild steelhead and potentially increase smolt to smolt survival, all fish located at the Facility will be released by May 8th; fish acclimated at Blackbird Island Pond will be allowed to volitionally move out of the pond through the end of June (after which time the pond outlet will be closed as in years past).

Release Location

Release locations in 2017 will be the same as the previous two years.

Pre-release Monitoring and Evaluation

Throughout acclimation and release, established sampling, transfer and release protocols will be followed (Hillman et al. 2013). Additionally, to gain an additional year of data for the RAS reared steelhead that are screened, assessment of smolt index and precocial maturation will be conducted via non-lethal sampling from the two screened RAS vessels (n=200 movers; n= 200 non-movers).

Table 1. Steelhead release numbers and locations, 2017.

Vessel	Origin[1]	Estimated Number Released[2]	Estimated # PIT-tagged	Destination	rkm	Movers or Non-movers
RAS3	WxW	11,971[3]	2,375	Nason	7.0	Movers
RCY1	Mixed	38,210	2,181	Nason	7.0	Movers
RAS1	WxW	11,720[3]	2,375	Nason	7.0	Movers
		61,901		**Total**		
RCY1	Mixed	78,299	4,469	U. Wenatchee	79.2	Movers
		78,299		**Total**		
RCY1	Mixed	73,379	4,188	Chiwawa	11.4	Movers
		73,379		**Total**		
RCY1	Mixed	Unknown	Unknown	L. Wenatchee	40.2	Non-movers
RAS1	WxW	Unknown	Unknown	L. Wenatchee	40.2	Non-movers
RAS3	WxW	Unknown	Unknown	L. Wenatchee	40.2	Non-movers
ELISA	HxH	24,952	2,500	Blackbird	40.5	Movers

[1]Mixed = HxH and WxW.
[2]Releases will occur April 20 - May 8; any remaining non-movers will be released by May 8th.
[3]Maximum estimated number of fish to be released; non-movers have not been subtracted from these totals.

2017 Fish Spill Plan

Rock Island and Rocky Reach Dams

Public Utility District No. 1 of Chelan County

Prepared By:

Thad Mosey
Fisheries Biologist

Public Utility District No. 1 of Chelan County
Wenatchee, Washington

Final
March 28, 2017

Introduction and Summary

In 2017, Public Utility No. 1 of Chelan County (Chelan PUD) will implement spill operations for fish passage at the Rock Island and Rocky Reach and projects. Spill timing and spill percentages are specified by the anadromous Habitat Conservation Plans (HCP) for each respective project. Chelan PUD conducted juvenile project survival studies from 2002 through 2011 at Rocky Reach and Rock Island under varying spill levels in order to achieve HCP survival standards. The Rock Island Project completed multiple survival studies over a nine year period (17 total studies) for spring migrating Plan Species (yearling Chinook, steelhead, sockeye), first using a 20 percent spill level, then a 10 percent spill level. Rock Island will continue to spill 10 percent of day average flow during the spring outmigration period through at least year 2020. Rocky Reach completed its suite of HCP survival studies for spring migrating Plan Species in 2011 (14 studies), under spill and no-spill operation at the dam. HCP juvenile survival standards were achieved for species tested with a no spill operation (yearling Chinook, steelhead, sockeye). Project spill levels are summarized in Tables 2 and 4 of this plan. Chelan PUD holds valid Incidental Take Statements (ITS) from National Oceanic and Atmospheric Administration Fisheries (NOAA) and the United States Fish and Wildlife Service (USFWS) for HCP fish spill operations at Rocky Reach and Rock Island dams.

For the 2017 juvenile outmigration, Chelan PUD will operate the Rocky Reach juvenile fish bypass system (JFBS) starting 1 April for the spring juvenile outmigration of yearling Chinook, steelhead, and sockeye. Spring spill at Rocky Reach Dam will consist of hydraulic spill for reservoir control only. HCP Project survival standards were achieved with bypass-only operations. During the subyearling Chinook outmigration in 2017, Rocky Reach will spill 9 percent of day average river flow for a duration covering 95 percent of subyearling outmigration past the dam.

At Rock Island Dam in 2017, Chelan PUD will operate the Project with a 10 percent day-average spill level for the spring outmigration period. Rock Island has also completed HCP spring Plan Species survival testing for all Plan Species with a 10 percent spill level at the dam and has achieved juvenile survival standards for yearling Chinook, steelhead and sockeye and combined adult-juvenile survival for all three species.

During the summer period in 2017, Rock Island Dam will spill 20 percent of the day-average river flow for the outmigration of subyearling (summer) Chinook. Spill is the primary means of juvenile salmon and steelhead passage at Rock Island per Section 5.4.1(a) of the Rock Island HCP. Spring and summer spill will cover 95 percent of the juvenile fish outmigration for yearling/subyearling Chinook, steelhead, and sockeye in 2017.

Rocky Reach Juvenile Fish Bypass Operations

Rocky Reach will operate its JFBS continuously through the spring outmigration period, beginning 1 April 2017. Daily index sampling (for steelhead, yearling Chinook, and sockeye) will be performed at the bypass sampling facility to estimate the outmigration percentiles for each species through the spring period. During "index sampling" each day, a total of four 30-minute samples (Table 1) will be taken beginning at the top of each hour, 0800 to 1100 hours. Spring spill for fish passage is not required at Rocky Reach in addition to the JFBS operation, but periods of forced spill may occur under high river flows. Some level of forced spill (river flow above 201 kcfs turbine capacity) normally occurs at Rocky Reach in the spring. Over the past 20 years, forced spill has occurred approximately 28 percent of all hours, April through June.

Sampling protocols at the Rocky Reach bypass system in 2017 will remain consistent with those used in 2004-2016. Daily sampling in spring and summer periods (Monday through Sunday) will use four 30-minute "index periods" at 0800, 0900, 1000, and 1100 hours (Table 1). The sample target for each 30-minute sample will be 350 smolts during the spring period (yearling Chinook, steelhead, and sockeye combined), and 125 smolts for summer period (subyearling Chinook). If the number of fish collected in the bypass sampling raceway is estimated to reach the maximum number prior to completion of the 30-minute sample, the sampling screen will be retracted from the bypass conduit, and the number of fish collected in the shortened sample period will be proportionately expanded to the entire 30-minute period.

Table 1. Index sampling times at the Rocky Reach juvenile fish bypass and the number of smolts per sample. Sample times and sample targets have remained consistent since 2004.

Time	Sample Duration	Number of Smolts	Day of Week
08:00-08:30	30 minutes*	350 (spring) 125 (summer)	Monday-Sunday
09:00-09:30	30 minutes*	350 (spring) 125 (summer)	Monday-Sunday
10:00-10:30	30 minutes*	350 (spring) 125 (summer)	Monday-Sunday
11:00-11:30	30 minutes*	350 (spring) 125 (summer)	Monday-Sunday

*Sample duration may be less than 30 minutes if smolt numbers are met prior to full 30 minute sample time

Rocky Reach 2017 Summer Spill Operations

Rocky Reach Dam will spill 9 percent of the estimated day average river flow for the subyearling Chinook outmigration (Table 2). Spill will commence in late May to early June upon arrival of subyearling Chinook smolts in the Rocky Reach bypass samples. Juvenile run-timing information at Rocky Reach will be used to estimate subyearling Chinook passage percentiles (from the University of Washington's Program RealTime run forecaster) and guide spill operations to cover 95 percent of the summer outmigration. Actual subyearling counts in combination with juvenile passage estimates from the University of Washington's Program RealTime run forecaster will determine start and stop dates for the summer spill program.

The HCP guidelines for starting and ending summer spill at Rocky Reach are as follows:

1. Summer spill will start at midnight no later than the day on which the estimated 1-percentile passage point is reached, as indicated by Program RealTime run-forecast model. Subyearling Chinook will be defined as any Chinook having a fork length from 76 to 150 mm.

2. Summer spill season will generally end no later than 15 August, but not until subyearling index counts from the juvenile bypass sampling facility are 0.3 percent or less of the cumulative run for three out of any five consecutive days (same protocol used 2004-2016) and Program RealTime is estimating that the 95th percentile passage point has been reached. In addition, spill operations must cover at least 95% of the subyearling outmigration

Diel Spill Shaping at Rocky Reach and Rock Island Dams

Daily spill volumes will be shaped within each 24-hour period at Rocky Reach Dam during the summer spill period, and at Rock Island Dam during both spring and summer spill periods (Tables 2 and 4).

Spill-shaping attempts to optimize spill water volume to maximize spill passage effectiveness for smolts. The diel spill shape functions to provide either higher or lower spill volume during periods of either higher or lower fish passage. Spill-shaping is based on the observed diel (24-hour) passage distributions of smolts at each project during spring and summer (Steig et al. 2009, Steig et al. 2010, Skalski et al. 2008, Skalski et al. 2010, Skalski et al. 2011, Skalski et al. 2012). The different spill percentages and time blocks are shaped such that the summation of water volume from all time blocks within the day equals the volume of water that would have been spilled under a constant, unshaped spill level (i.e. spill at 9 percent day-average river flow at Rocky Reach with no shaping). The hourly spill shape in 2017 will remain consistent with previous years, 2004-2016. Spill gates 2 through 8 will be used to meet daily spill percentage targets.

Table 2. Fish spill percentages and spill shape for the Rocky Reach spill program, 2017.

Project	Season	Daily Spill Average	Within-Day Spill Levels	Duration (# of hours each day)	Hourly Blocks of Spill	Spill Shape %
Rocky Reach	Spring	none	--	--	--	--
Rocky Reach	Summer*	9%	Med	1	0000-0100	9.0
			Low	6	0100-0700	6.0
			Med	2	0700-0900	9.0
			High	6	0900-1500	12.0
			Med	9	1500-2400	9.0

*Spill for subyearling Chinook

2017 Run-Timing Predictions

Chelan PUD contracts with the University of Washington (UW) to provide run-timing predictions and year-end observed values for spring and summer out-migrating percentiles for salmon and steelhead. UW's Program RealTime run-time forecasting model is used for this purpose. Program Real-Time provides daily forecasts and cumulative passage percentiles for steelhead, yearling/subyearling Chinook and sockeye at both Rocky Reach and Rock Island dams. This program enables Chelan PUD to better predict the time when a selected percentage of these species will arrive, and when a given percentage of any stock has passed. The program utilizes daily fish counts from the Rocky Reach bypass sampling facility and the juvenile fish bypass trap at Rock Island Dam. Estimates of passage percentiles are generated with the model's forecast error and are displayed with the daily predictions at:

http://www.cbr.washington.edu/crisprt/

Historic Run Timing

Estimated mean passage dates (first percentile to the 95th percentile) for each species at Rocky Reach and Rock Island dams are summarized in Table 3. Run-timing dates are estimated from daily index sample counts at the Rocky Reach JFBS (2004-2016), and from the Rock Island bypass trap, (2002-2016). At Rocky Reach Dam, the subyearling Chinook run generally begins the first week of June, with the one-percentile passage date on 31 May (mean date for years 2004-2016). Rocky Reach subyearling passage reaches the 95th percentile, on average, around 7 August (2004-2016, range: 21 July to 24 August).

Rock Island Dam juvenile salmon and steelhead sampling from the Smolt Monitoring Program (SMP; 2002-2016) indicates that the first percentile (one-percent passage) mean passage date for combined spring migrants (yearling Chinook, steelhead, and sockeye) occurs around 18 April (Table 3). The latest spring spill start date for Rock Island Dam per the HCP is 17 April. The summer outmigration of subyearling Chinook smolts at Rock Island Dam generally begins in early June (although fry are encountered earlier), and on average, reaches the 95th percentile passage point around 7 August (range: 22 July to 19 August, 2002-2016).

Table 3. Spill percentages, bypass operation dates, and mean passage percentile dates (2002-2016) for the 1st and 95th percentile passage points for HCP spring and summer outmigrants at Rocky Reach and Rock Island dams.

Rocky Reach	**steelhead**	**yearling Chinook**	**sockeye**	**subyearling Chinook**
Percent Spill	0% Spring	0% Spring	0% Spring	9% Summer
1st, 95th percentile Passage Dates	4/16, 5/30	4/15, 5/28	5/5, 5/24	5/31, 8/7
RR Bypass System Operation	4/1 – 8/31	4/1 – 8/31	4/1 – 8/31	4/1 – 8/31
Rock Island	**steelhead**	**yearling Chinook**	**sockeye**	**subyearling Chinook**
Percent Spill	10% Spring	10% Spring	10% Spring	20% Summer

Rock Island 2017 Spring Spill Operations

In 2017, Rock Island Dam will spill 10 percent of the estimated day average river flow starting no later than 17 April and will end spill after 95 percent of spring outmigrants have passed the dam (usually the first week of June), with spill being provided for at least 95% of the spring species outmigration. Spill volume will be shaped to maximize spill efficiency (Table 4). Chelan PUD personnel will operate the Rock Island bypass trap, an upper Columbia SMP site, continuously from 1 April through 31 August (seven days per week) to provide daily smolt counts. Index counts will provide the basis to determine the start and end of the spring and summer outmigration periods. The HCP guidelines to start and end the spring spill program at Rock Island Dam are as follows:

1. The Rock Island spring spill program will begin when the daily smolt passage index count exceeds 400 fish for more than 3 days (this corresponds to the approximately 5 percent passage date), or no later than 17-April, as outlined in Section 5.4.1. (a) of the Rock Island HCP.

2. Rock Island spring spill will end 1) following completion of the spring outmigration (95 percent passage point), and 2) when subyearling (summer) Chinook have arrived at the Project.

Operators will utilize the following spill gate sequence to meet daily spill percentage targets: 32, 31, 30, 1, 26, 16, 18, 24, 29, 17, 19, 20, 22, 25, 7, and 8.

Rock Island 2017 Summer Spill Operations

Rock Island will spill 20 percent of the estimated daily average river flow for a duration covering 95 percent of the summer outmigration of subyearling Chinook. Daily smolt counts from the Rock Island bypass trap will inform decisions on when to start and stop spill. The HCP guidelines to start and stop summer spill at Rock Island Dam are outlined as follows:

1. Rock Island summer spill in 2017 will begin immediately after completion of the spring spill. The summer spill level will be 20 percent of day average flow, shaped to increase spill efficiency. Spill will continue for a duration covering 95 percent of the subyearling Chinook outmigration.

2. Summer spill will generally end no later than 15 August, or when subyearling Chinook counts from the Rock Island trap are 0.3 percent or less of the cumulative run total for

three out of any five consecutive days, and UW's Program RealTime is estimating 95 percent run completion (same protocol used in 2004-2016).

Operators will utilize the following spill gate sequence to meet daily spill percentage targets: 32, 31, 30, 1, 26, 16, 18, 24, 29, 17, 19, 20, 22, 25, 7, and 8.

Table 4. Spill percentages and hourly spill shape for the Rock Island spring and summer fish spill program, 2017.

Project/Season	Daily Spill Average	With-in Day Spill Levels	Duration (# of hours each day)	Hourly Blocks of Spill	Spill Shape %
Rock Island Spring*	10%	High	4	0000-0400	12.5

*Spring spill for yearling Chinook, steelhead, and sockeye; **summer spill for subyearling Chinook.

Spill Program Communication

Chelan PUD's HCP representative will notify the HCPCC not less than once per week when fish passage numbers indicate that specific triggers for starting or stopping spill are likely to occur in the immediate future. Chelan PUD will notify the HCPCC regarding any unforeseen issues that pertain to the spill program as the season progresses. Communications with the HCPCC on spill information will generally be made by email, pre-scheduled conference calls, and HCPCC monthly meetings.

Subject: **DRAFT UPPER COLUMBIA RIVER 2017 BY SALMON AND 2018 BY STEELHEAD HATCHERY PROGRAM MANAGEMENT PLAN AND ASSOCIATED PROTOCOLS FOR BROODSTOCK COLLECTION, REARING/RELEASE, AND MANAGEMENT OF ADULT RETURNS**

The attached protocol was developed for hatchery programs rearing spring Chinook salmon, summer Chinook salmon and summer steelhead associated with the mid-Columbia HCPs; spring Chinook salmon, summer Chinook salmon and steelhead programs associated with the 2008 Biological Opinion for the Priest Rapids Hydroelectric Project (FERC No. 2114); and fall Chinook salmon consistent with Grant County Public Utility District and Federal mitigation obligations associated with Priest Rapids and John Day dams (ACOE funded), respectively. These programs are funded by Chelan, Douglas, Grant County Public Utility Districts (PUDs), and ACOE and are operated by the Washington Department of Fish and Wildlife (WDFW), with the exception of the Omak Creek/Okanogan Basin steelhead broodstock collection, and acclimation/release of Omak Creek steelhead which is implemented by the Confederated Tribes of the Colville Reservation (CTCR).

This protocol is intended to be a guide for 2017 collection of salmon (2017BY) and steelhead (2018BY) broodstocks in the Methow, Okanogan, Wenatchee, and Columbia River basins. It is consistent with previously defined program objectives such as program operational intent (i.e., conservation and/or harvest augmentation), mitigation production levels (e.g., HCPs and Priest Rapids Salmon and Steelhead Settlement Agreement), changes to programs as approved by the HCP-HC and PRCC-HSC, and to comply with ESA permit provisions, USFWS consultation requirements.

Notable in this year's protocols are:

- Continuing for 2017, no age-2 or 3 males will be incorporated into spring or summer Chinook programs unless necessary to maintain effective population size (minimum female to male ratio of 1:0.75; conservation programs only).

- Use of ultrasonography to determine the sex of each fish retained for brood to ensure achieving the appropriate number of females for program production (does not include Priest Rapids Hatchery).

- Utilization of genetic sampling/assessment to differentiate Twisp River and Methow River Basin natural-origin spring Chinook adults collected at Wells Dam, and CWT interrogation during spawning of hatchery spring Chinook collected at the Twisp Weir and Methow FH to differentiate Twisp and Methow Composite hatchery fish for discrete management of Twisp and Methow Composite production components for the GPUD, CPUD and DPUD programs.

- Collection of only hatchery adult steelhead at Wells Dam/Hatchery for the Lower Methow safety-net (WFH/MFH), and Wells Hatchery Okanogan and mainstem Columbia safety-net programs.

- Collection of spring Chinook for the Nason Creek and Chiwawa programs using combination of Tumwater Dam and the Chiwawa Weir.

- Targeted collection of 100% of the Wenatchee summer Chinook and Wenatchee hatchery origin steelhead broodstock at Dryden Dam to reduce the number of activities that may contribute to delays in fish passage at Tumwater Dam (some adult collections at Tumwater may be necessary if sufficient adults cannot be acquired at Dryden Dam).

- Targeted collection of 100% of the natural origin steelhead broodstock at Tumwater Dam.

- Collection of summer Chinook broodstock from the Chelan Falls Canal Trap (CFCT), sufficient to meet the entire Chelan Falls yearling program of 576K. Summer Chinook collections at Entiat Hatchery may be used to support the Chelan Falls program if broodstock collection efforts at the CFCT fall short.

- Collection of surplus hatchery origin steelhead from the Twisp Weir (up to 25% of the required broodstock) to produce the 100K Methow safety-net on-station-released smolts (up to 17 adults). The remainder of the broodstock (51) will be WNFH returns collected at WNFH (or by angling/trapping for WNFH program) and/or Methow Hatchery and surplus to the WNFH program needs. Collection of Wells stock may be used if WNFH and Twisp returns are insufficient. The collection of adults will occur in spring of 2018.

- Summer Chinook collections at Wells Dam to support the CJH program may occur if CCT broodstock collection efforts fail to achieve broodstock collection objectives.

- Collection of ad-clipped only (no wire) spring Chinook adults (or possibly eggs identified through CWTs from ad-clipped +CWT CJH segregated returns)may occur from facilities in the Methow basin and/or Wells Dam. These alternative collection locations will only be used if CCT and USFWS broodstock collection efforts fail to achieve broodstock collection objectives for the CJH segregated program, or if conditions (e.g., spill at CJD, ladder/trap efficiency) appear unconducive to efficient collection of broodstock.

Collection will run concurrent with spring Chinook broodstock collection for Methow Hatchery.

- Collection from the Wells Hatchery volunteer channel of Wells summer Chinook to support the YN, Yakima River summer Chinook program.

- Targeted collection of 1,000 adipose present, non-coded wire tagged fall Chinook from the PRD OLAFT.

- Targeted collection of about 400 adipose present, non-coded wire tagged fall Chinook using hook and line efforts in the Hanford Reach.

These protocols may be adjusted in-season, based on actual run monitoring at mainstem dams and/or other sampling locations. Additional adaptive management actions as they relate to broodstock objectives may be implemented as determined by the HCP-HC or PRCC-HSC and within the boundaries of applicable permits.

Also included in the 2017 Broodstock Collection Protocols are:

Appendix A: 2017 BY Biological Assumptions for UCR Spring, Summer, and Fall Chinook and 2018 BY Summer Steelhead Hatchery Programs
Appendix B: Current Brood Year Juvenile Production Targets, Marking Methods, Release Locations
Appendix C: Return Year Adult Management Plans
Appendix D: Site Specific Trapping Operation Plans
Appendix E: Columbia River TAC Forecast
Appendix F: Annual Chelan, Douglas, and Grant County PUD RM&E Implementation Plans
Appendix G: DRAFT Hatchery Production Management Plan

Methow River Basin

Spring Chinook

Inclusion of natural-origin fish in the broodstock will be prioritized for the aggregate conservation program in the Methow Basin. Collections of natural-origin fish will not exceed 33% of the Methow Composite (i.e., non-Twisp) and Twisp natural-origin run escapement consistent with take provisions in Section 10 (a)(1)(A) Permits 18925 and 20533.

Hatchery-origin spring Chinook, if needed, will be collected in numbers excess to program production requirements to facilitate BKD management, comply with ESA Section 10 permit take provisions, and to meet programmed production shortfalls with natural origin fish. Based on historical Methow FH spring Chinook ELISA levels above 0.12, any hatchery origin spring Chinook broodstock collection will include hatchery origin spring Chinook in excess to broodstock requirements by approximately 33.3% (based upon the most recent 5-year mean

ELISA results for the Methow/Chewuch program; 11.8% for the Twisp program). For purposes of BKD management and to comply with maximum production levels and other take provisions specified in ESA Section 10 permits 18925 and 20533, culling will include the destruction of eggs from hatchery-origin females with ELISA levels greater than 0.12 and/or that number of hatchery origin eggs required to maintain production at 223,765 yearling smolts. Culling of eggs from natural-origin females will not occur unless their ELISA levels are determined by WDFW Fish Health to be a substantial risk to the program. Progeny of natural-origin females, with ELISA levels greater than 0.12, may be differentially tagged for evaluation purposes. Annual monitoring and evaluation of the prevalence and level of BKD and the efficacy of culling returning hatchery- and natural-origin spring Chinook will continue and will be reported in the annual monitoring and evaluation report for this program.

WDFW genetic assessment of natural-origin Methow spring Chinook (Small et al. 2007) indicated that Twisp natural-origin spring Chinook can be distinguished, via genetic analysis, from non-Twisp spring Chinook with a high degree of certainty. The Wells HCP Hatchery Committee accepted that Twisp-origin fish could be genetically assigned with sufficient confidence and that natural origin collections can occur at Wells Dam. Scale samples and non-lethal tissue samples (fin clips) for genetic/stock analysis will be obtained from adipose-present, non-CWT, non-ventral-clipped spring Chinook (suspected natural-origin spring Chinook) collected at Wells Dam, and origins assigned based on genetic analysis. Natural-origin fish retained for broodstock will be PIT tagged (pelvic girdle) for cross-referencing tissue samples/genetic analyses. Tissue samples will be preserved and sent to the WDFW genetics lab in Olympia Washington for genetic/stock analysis. Spring Chinook collected from Wells will be held until genetic analysis results are received (unless adult holding is not yet available due to the Wells modernization project, in which case fish will be held at Methow FH pending results), then transferred to and retained at Methow Hatchery and spawned for each program depending on results of DNA analysis. Brood collection of NORs at Wells will be based upon assignment of Twisp NORs to the Twisp program and non-Twisp NORs being used to support Methow and Chewuch River releases. Spring Chinook collected at Methow Hatchery will be held at MFH until genetic analysis results are received and then handled accordingly.

The number of natural-origin Twisp and Methow Composite (non-Twisp) spring Chinook retained will be dependent upon the number of natural-origin adults returning and the collection objective limiting extraction to no greater than 33% of the natural-origin spring Chinook return to the Methow Basin. Natural origin fish not assigning to the Twisp or Methow Composite will be released back into the Columbia River.

Weekly estimates of the passage of Wells Dam by natural-origin spring Chinook will be provided through stock-assessment and broodstock-collection activities. This information will facilitate in-season adjustments to collection composition so that extraction of natural-origin spring Chinook remains no more than 33%. Trapping at the Winthrop NFH will be included, if needed, in the event of broodstock shortfalls.

Pre-season run-escapement of Methow-origin spring Chinook to Wells Dam during 2017 is estimated at 3,265 spring Chinook, including 2,292 hatchery and 973 natural origin spring Chinook (Table 1 and Table 2). In-season estimates of natural-origin spring Chinook will be adjusted proportional to the estimated returns to Wells Dam at weekly intervals and may result in adjustments to the broodstock collection targets presented in this document.

The following broodstock collection protocol was developed based on BKD management strategies, projected return for BY 2017 Methow Basin spring Chinook at Wells Dam (Table 1 and Table 2), and assumptions listed in Appendix A.

The 2017 aggregate Methow spring Chinook broodstock collection will target up to 122 adult spring Chinook (18 Twisp, 104 Methow; Table 3). Based on the pre-season run forecast, Twisp fish are expected to represent about 5% of the CWT tagged hatchery adults and 18% of the natural origin spring Chinook passing above Wells Dam (Tables 1 and 2). Based on this proportional contribution and a collection objective to limit extraction to no greater than 33% of the age-4 and age-5 natural-origin spawning escapement to the Twisp, the 2017 Twisp origin broodstock collection will total 18 wild fish, representing 100% of the broodstock necessary to meet Twisp program production of 30,000 smolts. Methow Composite fish are expected to represent about 42% of the CWT tagged hatchery adults and 82% of the natural origin spring Chinook passing above Wells Dam (Tables 1 and 2). Based on this proportional contribution and a collection objective to limit extraction to no greater than 33% of the age-4 and age-5 natural-origin recruits, the 2017 aggregate Methow broodstock collection will total 104 natural origin spring Chinook. Broodstock collected for the aggregate Methow programs represents 100% of the broodstock necessary to meet the Methow programs production of 223,765 smolts. The Twisp River releases will be limited to releasing progeny of broodstock identified as wild Twisp and or known Twisp hatchery origin fish, per ESA Permit 18925. The MetComp releases will include progeny of broodstock identified as wild non-Twisp origin (or known Methow Composite hatchery origin if needed to meet shortfalls in the production goal) fish. Age-3 males ("jacks") will not be collected for broodstock.

Table 1. Brood year 2012-2014 age class-at-return projection for wild spring Chinook above Wells Dam, 2017.

Total	**223,765**		**61F/61M**	**122**		

Trapping at Wells Dam will occur at the East and West ladder traps beginning on May 1, or at such time as the first spring Chinook are observed passing Wells Dam, and continue through June 30, 2017 (collection quotas will be prioritized for the May 1-June 20 time frame). Spring Chinook broodstock collection and stock assessment sampling activities authorized through the 2017 Douglas PUD Hatchery M&E Implementation Plan will utilize a combination of trapping on the East and West ladders as per the detailed descriptions of the modified trapping operations for spring Chinook collection in Appendix D (pages 38 and 39). Natural origin spring Chinook will be retained from the run, consistent with spring Chinook run timing at Wells Dam (weekly collection quota). Collection goals will be developed by Wells M&E staff to identify the most appropriate spatial and temporal approach to achieving the overall brood target. All natural origin spring Chinook collected at Wells Dam for broodstock will initially be held at Wells FH (or immediately transferred to Methow FH taking into account the status of adult holding during the modernization project) pending genetic results and then transferred to Methow FH. Fish collected at MFH will remain at MFH or be transferred to WNFH.

Collection of ad-clipped only (no wire) spring Chinook adults (or possibly eggs identified through CWTs from ad-clipped +CWT CJH segregated returns) may occur from facilities in the Methow basin and/or Wells Dam. These alternative collection locations will only be used if CCT and USFWS broodstock collection efforts fail to achieve broodstock collection objectives for the CJH segregated program, or if conditions (e.g., spill at CJD, ladder/trap efficiency) appear unconducive to efficient collection of broodstock. Collection will run concurrent with spring Chinook broodstock collection for Methow Hatchery.

Trapping at the Twisp Weir for spring Chinook may begin May 1 or at such time as spring Chinook are observed passing Wells Dam and may continue through August 23. The trap may be operated up to seven days per week/16 hours per day (provided it is manned during active trapping).

However, trapping at the Methow Outfall trap may continue beyond the Twisp Weir operations as needed to meet basin wide PNI/pHOS objectives. Pending development of an adult management plan for spring Chinook in the Methow basin, hatchery-origin adults captured at the Methow Outfall (surplus to the Methow Hatchery program) will be: 1) used for adult out-planting to increase natural production (see Appendix for approved plan) and secondarily 2) transferred to the WNFH for incorporation into WNFH brood, or removed as surplus as supported by the HGMP's of both facilities.

Steelhead

Douglas PUD and Grant PUD steelhead mitigation programs above Wells Dam utilize adult broodstock collections from multiple sources and locations such as at Wells Dam, Twisp Weir, Methow Hatchery volunteer trap, WNFH volunteer traps, Omak Weir, Wild horse Creek box trap and angling in the Methow River and Okanagan River (Table 5). Generally incubation/rearing occur for the Methow safety net, Okanogan, and Columbia River release at Wells Fish Hatchery (FH) with incubation/early rearing at Methow Hatchery for the DPUD conservation program. Broodstock for the conservation programs (USFWS and DPUD) is achieved via hook-and-line in the Methow Basin and the Twisp Weir (as needed), respectively (these programs are under program design review and may composite the broodstock). Broodstock for the Methow safety net program is achieved primarily through returns to WNFH (including hook and line-caught HOR steelhead) and surplus fish removed at Methow Hatchery and the Twisp Weir.

Specific program brood sources are structured as follows:

Twisp River – Conservation Releases

Due to the recent increased concern for inbreeding depression risk (Ryman-Laikre) for the Twisp program as a result of low Ne and other confounding issues, the design of Twisp program is currently under review.

The HC and JFP are working to redefine the scope and nature of the 2017 brood and future Twisp program. Parties will complete this task no later than October 1 (or sooner) of the current year such that an approved plan can be implemented and in a manner that does not unnecessarily delay consultation on the Methow steelhead HGMPs.

Wells Hatchery – Methow River Release

The Wells Hatchery Methow River release (Methow safety net program) uses locally collected hatchery origin broodstock representative of the Twisp and WNFH conservation programs and as needed, the Methow safety-net program. Adults are collected in concert with adult management activities at the Twisp Weir, Methow Hatchery, WNFH, and through hatchery fish intercepted during natural-origin brood hook-and-line collection for the USWFS Winthrop conservation program. As a backup to potential collection shortfalls in the Methow safety-net program and as a result of uncertainties in spring collection efficiencies, a portion of the Methow program will be augmented with collection of hatchery origin adults (30) occurring in the fall at Wells Dam. These fall-collected fish will be considered surplus to any spring-collected Methow, and eggs and/or fry from these surplus broodstock may be utilized for other programs in the upper Columbia. At least through the 2017 releases, fish are released from the Methow Hatchery, but may be released at other locations in the lower Methow once the HC approves a plan for such releases.

Wells Hatchery-Columbia River Release

The Wells Hatchery Columbia River releases will use returns to Wells Hatchery and may be augmented with adult returns to the Methow Hatchery and Winthrop NFH if needed to fulfill the program. To ensure the safety-net programs (Methow and Okanogan) have broodstock, a portion of the broodstock requirement (60 adults) will be collected at Wells Dam in the fall of 2017, and held at Wells Hatchery (Table 5). These fall-collected fish will be considered surplus to the spring-collected Methow and Okanogan broodstock, and eggs and/or fry from these surplus broodstock may be utilized for other programs in the upper Columbia. Fish are released to the Columbia River, immediately downstream of Wells Dam.

Winthrop NFH – Methow River Release

The USFWS Methow River release will primarily use natural-origin fish collected through hook-and-line collection efforts in the Methow River each spring. In the event NO collection falls short of the target, WNFH hatchery-origin returns will be prioritized, followed by safety-net hatchery returns. Transfer of adult and/or gametes/eggs between program will be carefully choreographed to ensure fish are being utilized in the most efficient and effective manner. Fish may be released throughout the Methow basin.

Okanogan River releases

The Okanogan River uses a combination of natural and hatchery-origin adults collected in Omak Creek and elsewhere in the Okanogan Basin through CCT collection efforts. As a backup to potential collection shortfalls in the Okanogan, a portion of the Okanogan program may be augmented with Okanogan locally-adapted hatchery-origin adults identified at spawning from 30 back up adults collected in the fall at Wells Dam. If needed to supplement spring collections, only fish with positive CWT for Okanogan origin will be used for this safety net aspect of the program. These fall-collected fish will be considered surplus to any spring-collected Okanogan broodstock, and eggs and/or fry from these surplus broodstock will be utilized for other programs in the upper Columbia. Surplus fish will be surplussed at the earliest time when overages are apparent.

Steelhead programs located upstream of Wells Dam and at Wells Hatchery are presented in Table 4.

Table 4. 2018 brood year Steelhead Programs at Wells Hatchery and Upstream of Wells Dam

Program	Hatchery	Owner	Release Location	Release Target	Broodstock Collection Locations
DPUD Conservation[2]	TBD	Douglas PUD	TBD	48,000 (S_1)	TBD
Methow Safety-Net	Wells Hatchery	Douglas PUD	Methow Hatchery	100,000	HxH: Twisp Weir (up to 25%) + WNFH Hatchery (75%) or WNFH 1st, MFH 2nd to make up balance
Mainstem Columbia Safety-Net	Wells Hatchery	Douglas PUD	Wells Hatchery	160,000	HxH: Wells FH/Dam returns (1st option); Methow FH/WNFH (2nd option)
WNFH Conservation Program	WNFH	USFWS	WNFH or other locations as determined by the JFP	Up to 200,000 (S_2)	Maximize use of NOR, up to 55 pair captured by hook and line in the Methow River and Spring Creek Weir.
Okanogan[1]	Wells Hatchery/ St. Mary's Pond	Grant PUD/CCT	Okanogan tributaries	100,000[1]	Okanogan Basin, Wells Dam

[1] CCT received approval for the Okanogan steelhead HGMP as part of their Tribal Resource Management Plan in February, 2017. Omak Creek and Wells Fish Hatchery are no longer separate hatchery programs. Up to 58 broodstock (NOB or HOB) may be collected from throughout the Okanogan basin (or Wells Dam if necessary) to meet the 100k program.

2 The DPUD Twisp conservation program is currently under re-development after detection of inbreeding depression risk. The HC and JFP have committed to developing an approved plan in sufficient time for implementation and such that is doesn't negatively affect the consultations for Methow steelhead HGMPs.

The following broodstock collection protocol was developed based on mitigation program production objectives (Table 6), biological assumptions (Appendix A), and the probability that sufficient adult steelhead will return in 2017/2018 to meet production objectives absent a preseason forecast at the present time.

For the 2018 brood steelhead programs operating above Wells Dam, a total of 350 adults (152 natural origin and 198 hatchery origin adults) are estimated to be needed to fulfill the respective mitigation obligations (Table 6). To support these obligations and to ensure sufficient backup adults are on hand in the event tributary based collection efforts fall short of targets, trapping at Wells Dam and/or Wells FH will selectively retain up to 257 hatchery origin steelhead (west [and east, as necessary] ladder and volunteer trap collection; Table 5). As a note, all potential broodstock will be scanned for PIT tags at collection and PIT tagged fish will be returned to the river to meet their monitoring objective. Any adult determined to have been part of the Yakama Nations kelt reconditioning program will be released in the vicinity it was collected.

Twisp Conservation Program (DPUD)

Due to the increased concern for inbreeding depression risk (Ryman-Laikre) for the Twisp program as a result of low Ne and other confounding issues, the design of the Twisp program is currently under review.

The HC and JFP are working to redefine the scope and nature of the 2017 brood and future Twisp program. Parties will complete this task no later than October 1 (or sooner) of the current year such that an approved plan can be implemented and in a manner that does not unnecessarily delay consultation on the Methow steelhead HGMPs.

Methow Safety Net Program

Up to 14 surplus hatchery-origin Twisp-stock steelhead (to meet up to 25% of the 100K Methow Safety-Net release) will be targeted at the Twisp Weir and moved to Wells Hatchery for spawning. No less than 46 hatchery adults will be targeted at WNFH and through angling efforts, and if needed/available, Methow Hatchery volunteer traps to meet the balance of the program needs (Table 6). Up to 30 hatchery origin Wells stock collected and held at the Wells Hatchery will be used as a final option if broodstock collection at the Twisp Weir, and WNFH and MH traps/collection efforts are unsuccessful (Table 5). If needed, WNFH HO fish identified through PIT tag detections, collected at the MFH outfall may be transferred to WNFH for use in the Spawning Channel Evaluation Project rather than retained for broodstock. Coordination between USFWS and WDFW hatchery staff will occur during the season to determine prioritization.

Methow Conservation Program (USFWS)

Approximately 110 natural origin adults (55 pair) will be targeted for retention through hook–and-line collection efforts in the Methow River (Table 6). In the event of a shortage, excess hatchery steelhead from the Twisp Weir and volunteer returns to the WNFH (including angle-caught fish) will be utilized as needed to augment WNFH broodstock. Should there be inadequate surplus steelhead from these sources, excess hatchery steelhead (presumed Methow Safety-Net origin) captured at the Methow Hatchery volunteer trap will be used to fulfill the program. Natural-Origin females will be live-spawned and reconditioned.

Okanogan Hatchery/Endemic Program

Up to 58 adult steelhead will be targeted in the Okanogan Basin, including up to 100% natural-origin adults (dependent on run size and within the 33% natural origin extraction rate) (Table 5). Additionally, up to 30 hatchery adult steelhead will be targeted at Wells Dam/Hatchery as a back-up collection contingency due to unknown broodstock collection efficiencies in the Okanogan River Basin (Table 5).

Table 5. Broodstock collection locations, number, and origin by program.

Program	Number of Adults[1]		Primary collection location	Number of backup adults[2]	Backup collection location(s)	Total adult collection[1]	
	Hatchery	Wild				Hatchery	Wild
DPUD Columbia R.	108		Wells FH/Dam Wells Dam		Methow FH	108	
DPUD Methow R.	68		Twisp weir (14) Methow FH (46)	Up to 30	WNFH[3] Wells Dam	98	
DPUD Met. Conservation		24	Twisp weir	NA	NA		24
GPUD Okanogan R.	0-58[6]	0-58[7]	Omak Cr., Okanogan R. and tributaries.	Up to 30	Wells Dam, Wells FH[5]	0-88	0-58
USFWS Methow R.		110	Methow R. WNFH[4]	NA	Methow FH		110
Total **(PUD programs)**	**176-234**	**24-82**		**Up to 60**		**206-294**	**24-82**
Total **(All programs)**	**176-234**	**134-192**		**Up to 60**		**206-294**	**134-192**

[1] Assumes a 1:1 sex ratio (see table 6). Natural origin females will be live spawned and reconditioned.
[2] All backup broodstock are hatchery origin adults.
[3] May include hatchery origin adults collected via the USFWS hook and line efforts for natural origin fish in the Methow River and adult returns to WNFH.
[4] May also include excess hatchery origin adults collected via angling and at Methow FH and the Twisp Weir.
[5] Spring collection of hatchery origin steelhead as needed to meet program shortfall for the Okanogan Program.
[6] Dependent upon number of NOR broodstock collected in the Okanogan Basin, age structure and fecundity to achieve sufficient brood for a100k smolt program for the Okanogan.
[7] Depending upon NOR abundance and trapping efficiency

Table 6. Number of broodstock needed to produce approximately 608,000 smolts for the above Wells Dam 2018 brood summer steelhead programs. Includes primary collection location(s) and mating strategy. *Broodstock totals do not include additional fish that may be collected at other locations as a backup for shortfalls from primary collection sources*.

Program	Production target/request	Number of Adults		Total	Collection location	Mating protocol
		Hatchery	Wild			
DPUD[1] Columbia R.	160,000	54F/54M		**108**	Wells Dam/Twisp Weir/	1:1
DPUD[2] Methow R.	100,000	34F/34M		**68**[4]	Twisp Weir, MFH, WNFH, Wells Dam	1:1
DPUD Methow Conservation	48,000		12F/12M	**24**	TBD	2x2 Factorial
GPUD Okanogan R.[3]	100,000	14F/14M	15F/15M	**58**[5]	Okanogan R./Omak Creek	1:1/2x2[7]
USFWS	200,000		55F/55M	**110**[6]		2X2 Factorial
Total[4]	**608,000**	**109F/109M**	**75F/75M**	**368**		

[1] Mainstem Columbia releases at Wells Dam. Target HxH parental adults as the hatchery component.
[2] Methow hatchery release of HxH fish produced from either adults returning from the Winthrop conservation program, adults trapped at MFH, and/or surplus hatchery adults from the Twisp weir.
[3]CCT intends to achieve greater than 0.5 pNOB in both 2017 and 2018, but the actual number will be dependent upon run size and trap efficiency, per the HGMP. Numbers of hatchery and wild males and females in this table should not be taken as the goal or limit for any collection effort, as it could be up to 100% pNOB or pHOB.
[4] Up to an additional 30 hatchery adults will be collected at Wells FH as a fall back to shortfalls in collections for the Methow safety net.
[5] Up to an additional 30 hatchery origin adults will be collected at Wells Dam as backup to potential shortfalls in Okanogan Basin collection efforts.
[6] Collection priority: 1) hook and line, 2) adult returns to WNFH, 3) excess adult returns to Methow Hatchery.
[7] A 1:1 mating protocol will be used for all HxH/HxW crosses within the Okanogan. The Okanogan locally-adapted natural stock (WxW) will utilize a minimum 2x2 factorial mating to minimize potential negative effects associated with a small effective population size.

Overall collection for the PUD programs will be 294 fish (a combination of program specific and back-up adults; Table 5) and limited to no more than 33% of the entire run and/or 33% of the natural origin return. Hatchery and natural origin collections will be consistent with run-timing of hatchery and natural origin steelhead at Wells Dam and the Twisp Weir. Trapping at the Wells Dam ladders will occur between 01 August and 31 October, up to three days per week, and up to 16 hours per day, as required to meet broodstock objectives. Trapping will be concurrent with summer Chinook broodstocking efforts through 15 September on the west ladder (Appendix D). Operational criteria and dates for the Twisp Weir are still under construction.

Adult return composition including number, origin, age structure, and sex ratio will be assessed in-season at Priest Rapids and Wells dams. Broodstock collection adjustments may be made based on in-season monitoring and evaluation. If collection of adults from the east ladder trap is necessary, access will be coordinated with staff at Wells Dam due to the rotor rewind project.

Surplus UCR Juvenile Steelhead Management

In the event excess juvenile are produced from the over-collection efforts to support the Methow safety net and /or Okanogan programs which rely on spring adult collections, the parties agree that distribution of juveniles will follow the following priority matrix:

1. Used to support shortfalls in the WNFH production obligation provided fish health and/or marking requirements for the program can be met.

2. Used to support any shortfalls in the Wells Columbia River release provided fish health and/or marking requirements for the program can be met.

3. Used to support shortfalls in the Ringold SHD program provided fish health and/or marking requirements for the program can be met.

4. Out-planted to landlocked lakes within Okanogan County and/or Colville Reservation provided fish health requirements can be met or provided stocking allotments are not exceeded (as determined by WDFW, YN and CCT fishery managers, as applicable).

In addition, surplus fish, including broodstock, will be distributed at the earliest possible life-stage (e.g., prespawn adults, eyed-egg, fry) per WDFW policy.

Summer/fall Chinook

The summer/fall Chinook mitigation program in the Methow River utilizes adult broodstock collections at Wells Dam and incubation/rearing at Eastbank Fish Hatchery. The total production level target is 200,000 summer/fall Chinook smolts for acclimation and release from the Carlton Acclimation Facility.

The TAC 2017 Columbia River UCR summer Chinook return projection to the Columbia River (Appendix D) and BY 2012, 2013, and 2014 spawn escapement to tributaries above Wells Dam indicate sufficient summer Chinook will return past Wells Dam to achieve full broodstock collection for supplementation programs above Wells Dam. The following broodstock collection protocol for the Methow summer Chinook program was developed based on initial run expectations of summer Chinook to the Columbia River, program objectives, and program assumptions (Appendix A).

For 2017, up to 118 natural-origin summer Chinook at Wells Dam west (and east, if necessary) ladder(s), including 59 females for the Methow summer Chinook program (Table 7). Collection will be proportional to return timing between 01 July and 15 September. Summer Chinook stock assessment will run concurrent with summer Chinook broodstock collection at the west ladder trap. Trapping may occur up to 3-days/week, 16 hours/day (48 cumulative hours per week). Age-3 males ("jacks") will not be collected for broodstock.

Should use of Wells Dam be needed to meet any shortfalls in broodstock for summer/fall

Chinook programs occurring in the Okanogan Basin, the CCT will notify the HCP-HC and Wells HCP Coordinating Committee/PRCC-HSC and coordinate with Douglas PUD, Grant PUD, and WDFW to facilitate additional broodstock collection effort. Summer Chinook broodstock collection efforts at Wells Dam, should they be required to meet CJH program objectives, will be conducted concurrent with broodstock collection efforts for the Methow summer Chinook program and or steelhead collection efforts for steelhead programs above Wells Dam.
If the probability of achieving the broodstock goal is reduced based on passage at the west ladder or actual natural-origin escapement levels, broodstock collections may be expanded to the east ladder trap and/or origin composition will be adjusted to meet the broodstock collection objective. If collection of adults from the east ladder trap is necessary, access will be coordinated with staff at Wells Dam due to the rotor rewind project.

Table 7. Number of broodstock needed for Grant PUDs Methow summer Chinook production obligation of 200,000 smolts, collection location, and mating strategy.

Program	Production target	Number of Adults		**Total**	Collection location	Mating protocol
		Hatchery	Wild			
Methow	200,000		59F/59M	**118**	Wells Dam	1:1
Total	**200,000**		**118**	**118**		

Rearing – Early rearing growth will be modulated for a targeted size at release of approximately 18 fpp. Beginning on or about February 1, fish will be fed to satiation to maximize spring growth regardless of end size.

Release - The summer Chinook salmon acclimated at the Carlton Acclimation Facility will be forced released using the following criteria.

- all fish will be released during darkness (e.g., 9:00 PM or later),
- all fish will be released when Columbia River and Methow River flows are predicted to be satisfactory,
- all fish will be released no later than May 7 regardless of flow conditions,
- attempts will be made to have a steady release of fish to reduce collisions on the PIT antenna array.

Satisfactory flows in the Columbia occur when spilling flows are started and flows in the Methow River are satisfactory when flows are high and turbid. Releases will not occur until satisfactory flows in the Columbia occur, but could occur if Methow River flows are not satisfactory due to insufficient snow pack.

Columbia River Mainstem below Wells Dam

Summer/fall Chinook

Collection at the Wells FH volunteer channel will be used to collect the broodstock necessary for the Wells FH yearling (320,000) and sub-yearling (484,000) programs.
Because of CCT concerns about sufficient natural origin fish reaching spawning grounds and to ensure sufficient NOR's being available to meet the CCT summer Chinook program, incorporation of natural origin fish for the Wells program or programs with broodstock originating from the Wells volunteer channel, will be limited to fish collected in the Wells volunteer channel. The following broodstock collection protocol was developed based on mitigation objectives and program assumptions (Appendix A).

WDFW will target 494 run-at-large summer Chinook from the volunteer ladder trap at Wells Fish Hatchery outfall for the Wells sub-yearling and yearling programs, and up to 178 for the YN 275K-350K green egg request for the Yakima summer Chinook program (Table 8). Due to fish health concerns associated with the volunteer collection site (warming Columbia River water during late August), the volunteer collection will begin July 1 and terminate by August 31.

For 2017, broodstock collection for the Chelan Falls summer Chinook program will be prioritized at the Chelan Falls Canal Trap (CFCT) which was successfully piloted in 2016, beginning July 1 through September 15. Collection efforts in the EBO in 2015 and 2016 were insufficient to meet the adult requirements for the Chelan Falls program necessitating development of alternate collection locations/strategies. If shortfalls in adult needs are expected and the number of females needed to meet program has not been reached by August 15th, the HCP HC will discuss whether broodstock collection may default to surplus summer Chinook from the Entiat NFH or other HCP approved location to make up the difference. The 2017 broodstock target for the Chelan Falls program is 358 adults (Table 8). The total production level supported by this collection is up to 576,000 yearlings for the Chelan Falls program.

Table 8. Number of broodstock needed for the combined Chelan and Douglas PUD Columbia River below Wells summer Chinook production obligations of 1,380,000 smolts, collection location, and mating strategy. Also includes broodstock necessary for outside programs that rely on adult collection at Well Hatchery in 2017.

Program	Production target	Number of Adults[2]		Total	Collection location	Mating protocol
		Hatchery	Wild			
Wells 1+	320,000	94F/94M		**188**	Wells VC[3]	1:1
Wells 0+	484,000	153F/153M		**306**	Wells VC[3]	1:1
Chelan Falls 1+	576,000	179F/179M		**358**	CFCT[4]	1:1
Yakama Nation	350,000[1]	89F/89M		**178**	Wells VC[3]	NA
Total	**1,730,000**	**515F/515M**		**1,030**		

[1] The YN request is for between 275K and 350K green eggs to support the Yakima River summer Chinook program.
[2] The number of adults collected for these programs may indirectly incorporate natural origin fish; however, because they are volunteers, the

number is likely to be less than 10% of the total.
[3] Wells Hatchery volunteer channel trap.
[4] Chelan Falls Canal Trap

Wenatchee River Basin

In 2017 the Eastbank Fish Hatchery (FH) is expecting to rear spring Chinook salmon for the Chiwawa River and Nason Creek acclimation facilities located on the Chiwawa River and Nason Creek. The program production level target for the Chiwawa program (Chelan PUD obligation) in 2017 is 144,026 smolts, and based upon the biological assumptions (Appendix A) will require a total broodstock collection of about 74 natural origin spring Chinook (Table 10). The spring Chinook production obligation for Grant PUD in the Wenatchee Basin is 223,670 smolts (125,000 conservation and 98,670 safety net) and based upon the biological assumptions (Appendix A) will require a total broodstock collection of 142 adults (70 natural origin and 72 hatchery origin; Table 10).

Pre-season run-escapement of Wenatchee spring Chinook to Tumwater Dam during 2017 is estimated at 5,410 spring Chinook, including 4,637 hatchery and 773 natural origin spring Chinook (does not include age-3 males; Table 9). In-season estimates of natural-origin spring Chinook to Tumwater Dam will be provided through stock-assessment and broodstock-collection activities. This information will facilitate in-season adjustments to collection composition so that extraction of natural-origin spring Chinook remains no more than 33%.

Table 9. Age-4 and age-5 class return projection for wild and hatchery spring Chinook to Tumwater Dam during 2017.

	Chiwawa Basin			Nason Cr. Basin			Wenatchee Basin to Tumwater Dam		
	Age-4	Age-5	Total	Age-4	Age-5	Total	Age-4	Age-5	Total
Estimated wild return	418	108	**526**	123	32	**155**	614	159	**773**
Estimated hatchery return	3,238	63	**3,301**	1,336	0	**1,336**	4,574	63	**4,637**
Total	3,656	171	**3,827**	1,459	32	**1,491**	**5,188**	**222**	**5,410**

Table 10. Number of broodstock needed for the combined Wenatchee spring Chinook production obligation of 367,969 smolts, collection location, and mating strategy.

Program	Production target	Number of Adults		**Total**	Collection location	Mating protocol
		Hatchery	Wild			
Chiwawa Conservation	144,026	18F/18M	37F/37M	**74**[1]	Chiwawa Weir and Tumwater Dam[4]	2x2 factorial
Nason Conservation	125,000	0	35F/35M	**77**[2]	Tumwater Dam[4]	2x2 factorial

Nason Safety net	98,670	34F/34M[3]	0	**68**	Tumwater Dam	1:1
Total	**367,969**	**104**	**144**	**255**[2]		

[1] Includes 36 hatchery origin adults (represents ~50% of the adult target) to ensure the Chiwawa production goal is met if insufficient NO adults are collected).
[2] Includes ~10% additional NO fish for the Nason program to account for fish that may assign back to the White River spawning aggregate. No more than 70 NO fish will be retained for spawning.
[3] Chiwawa hatchery fish will only be collected to satisfy the Nason Cr. safety net program if in-season estimates of returning Nason conservation fish fall short of expectations.
[4] Collection of NO fish at Tumwater for the Chiwawa program will include previously PIT tagged adults (NO juveniles PIT tagged at the Chiwawa smolt trap).

Chiwawa River Conservation Program Broodstocking:

- Based upon estimates of returning previously PIT tagged NO fish to Tumwater Dam (Table 11), approximately 30 previously PIT-tagged NO spring Chinook from the Chiwawa River could be collected at TWD between June 1 and July 15, concurrent with Nason Creek brood stocking, adult management, RM&E, and the RRS Study.
- The balance of adults needed to meet the Chiwawa Conservation program (up to ~74 total or ~37 females) would be collected at the Chiwawa Weir.
    - Weir operations would be on a 24 hour up/24 hour down schedule from about June 1 through August 15 (not to exceed 15 cumulative trapping days). Timing of trap operation would be based on NO fish passage at TWD and would use estimated travel times (derived from PIT tags) to the lower Chiwawa PIT tag antenna array.
    - In the absence of adequate redd count data (i.e. until 2018) to calculate the 10% threshold, if after 15-days of weir operation, 67 bull trout encounters, or 15 August, the NO broodstock target is not reached, the balance of the mitigation obligation will be met through hatchery fish already retained for the Chiwawa program at TWD.
    - Over five years, the average number of bull trout captured during weir operation shall not exceed 70 individuals per year. Additionally, no more than 10 percent of the estimated mean number of adult bull trout in the Chiwawa Basin (using up to a rolling five year average derived from expanded redd counts) may be encountered during broodstock collection without concurrence from the USFWS. Sufficient redd data to calculate a full five year average is expected to be available as early as 2018.
    - To ensure the production target is met for the Chiwawa program, in the event that insufficient NO adults are collected for the conservation program, HO adults (presently estimated at 50% of the total broodstock requirement, however may be adjusted up or down depending on the run) would be collected at TWD to make up the shortfall (see Table 10) between June 1 and July 15.
    - Historic and in-season data for NO spring Chinook timing to the lower Chiwawa array from TWD will be used to determine optimal dates for collection.

- o Any bull trout that are caught at the Chiwawa trap will be immediately removed and released at a site ~10KM upstream of the weir to prevent fallback/impingement and to mitigate for potential delay. Handling and transport will be conducted by WDFW hatchery staff.
- o If a bull trout is killed during trapping, despite implementing conservation measures, trapping activities will cease and not continue until additional measures to minimize risks to bull trout can be discussed with the USFWS.

Table 11. PIT tagged natural origin adults to Tumwater Dam for the most recent 5-years (2012-2016) with conversion rates from Bonneville Dam.

	Detections at Bonneville Dam		Detections at Tumwater Dam			
Return year	Nason	Chiwawa	Nason	Conversion rate	Chiwawa	Conversion rate
2012	7	60	5	0.714	52	0.867
2013	2	29	2	1.000	22	0.759
2014	6	66	1	0.167	29	0.439
2015	9	42	6	0.667	28	0.667
2016	8	34	8	1.000	24	0.706
Mean	6.4	46.2	4.4	0.710	31.0	0.688
Geomean	5.7	44.0	3.4	0.603	29.5	0.671

Nason Creek Conservation Program Broodstocking:

- Up to ~77 NO spring Chinook (to allow for up to 10 percent of White River NO fish estimated to be encountered at Tumwater Dam MSA; Table 10) would be collected at TWD between June 1 and July 15.
  - o Only 70 NO adults (35 females) will be retained to produce the 125K Nason Conservation program.
  - o Collection of additional HO fish may occur in the event NO collection/retention falls short of expectation.
  - o Brood stock collection would run concurrent with adult management, RM&E, and the Spring Chinook Relative Reproductive Success Study. The GAPS microsatellite panel and existing GAPS plus WDFW spring Chinook Wenatchee baseline will be used for genotyping and GSI analyses similar to methods used in 2013.

- Decision Rules:
  - o Any fish that assigns to the White River with greater than 90% surety will be released in the White River.

  - Unassigned fish (individuals that can't be assigned to the Wenatchee Population or Leavenworth NFH), will be released upstream of Tumwater Dam.
  - In the event more fish assign to Nason or Chiwawa than are needed to meet the conservation program, the excess with the lowest assignment probabilities will be returned to the river upstream of Tumwater Dam.

Nason Creek Safety Net Program Broodstocking:

- Up to ~68 HO spring Chinook adults (from safety net program – identified by snout wire + body wire) would be targeted at TWD (Table 10) between June 1 and July 15, concurrent with NO brood stock collection, adult management, RM&E, and the Spring Chinook Relative Reproductive Success (RRS) Study.

Nason Creek spring Chinook Rearing/Release Strategy:

Rearing – Early rearing growth will be modulated for a targeted size at release of approximately 18 fpp. Beginning on or about February 1, fish will be fed to satiation to maximize spring growth regardless of end size.

Release - Spring Chinook salmon acclimated at the Nason Creek Acclimation Facility will be forced released using the following criteria.

- all fish will be released during darkness (e.g., 9:00 PM or later),

- all fish will be released when Columbia River and Nason Creek flows/conditions are predicted to be satisfactory,

- all fish will be released no later than May 7 regardless of flow conditions,

- attempts will be made to have a steady release of fish to reduce collisions on the PIT antenna array.

Satisfactory flows in the Columbia occur when spilling flows are started and flows in Nason Creek are satisfactory when flows are high and turbid. Releases will not occur until satisfactory flows in the Columbia occur, but could occur if Nason Creek flows are not satisfactory due to insufficient snow pack.

<u>*Steelhead*</u>

The steelhead mitigation program in the Wenatchee Basin uses broodstock collected at Dryden and Tumwater dams located on the Wenatchee River. Per ESA section 10 Permit 1395 provisions, broodstock collection will target adults necessary to meet a natural origin – conservation (WxW) oriented program, not to exceed 33% of the natural origin steelhead return to the Wenatchee Basin and a hatchery origin (HxH) – safety net program. The conservation and safety net programs each make up approximately half of the 247,300 production obligation. Based on these limitations and the assumptions listed in Appendix A, the following broodstock collection protocol was developed:

WDFW will retain a total of 140 mixed origin steelhead for broodstock for a smolt release objective of 247,300 smolts (Table 12). The 70 hatchery origin adults will be targeted at Dryden Dam and if necessary Tumwater dam. The 70 natural origin adults will be targeted for collection at Tumwater Dam. Collection will be proportional to return timing between 01 July and 14 November. Collection may also occur between 15 November and 5 December at both traps, concurrent with the Yakama Nation coho broodstock collection activities. Only adipose present coded wire tagged hatchery fish (or previously PIT tagged WxW hatchery progeny) will be retained for the safety net program. Adult return composition including number, origin, age structure, and sex ratio will be assessed in-season at Priest Rapids and at Dryden Dam. In-season broodstock collection adjustments may be made based on this monitoring and evaluation. To better ensure achieving the appropriate females equivalents for program production, the collection will include the use of ultrasonography to determine the sex of each fish retained for broodstock.

In the event steelhead collections fall substantially behind schedule, WDFW may initiate/coordinate adult steelhead collection in the mainstem Wenatchee River by hook and line. In addition to trapping and hook and line collection efforts, Tumwater and Dryden dams may be operated between February and early April the subsequent spring to supplement broodstock numbers if the fall trapping effort provides fewer than the required number of adults.

Table 12. Number of broodstock needed for the combined 2018 BY Wenatchee summer steelhead production obligation of 247,300 smolts, collection location, and mating strategy.

Program	Production target	Number of Adults		**Total**	Collection location	Mating protocol
		Hatchery	Wild			
Wenatchee Conservation[1]	123,650	0	35F/35M	**70**	TWD[3]/Dryden LBT-RBT[4]	2x2 factorial
Wenatchee Safety net[2]	123,650	35F/35M	0	**70**	Dryden LBT-RBT[4] /TWD[4]	1:1
Total	**247,300**	**70**	**70**	**140**		

[1] Broodstock collection for the conservation program will occur primarily at Tumwater Dam and will only fall back to Dryden Dam trapping facilities if a shortfall is expected.
[2] Broodstock collection for the safety net program will occur primarily at the Dryden Dam trapping facilities to minimize activities at TWD that could increase unintended delays on non-target fish. Collection at Tumwater Dam will only occur if shortfalls in broodstock are expected at Dryden Dam.
[3] TWD=Tumwater Dam.
[4] Dryden LBT-RBT= Dryden Dam left and right bank trapping facilities.

Summer/fall Chinook

Summer/fall Chinook mitigation programs in the Wenatchee River Basin utilize adult broodstock collections at Dryden and Tumwater dams, incubation/rearing at Eastbank Fish Hatchery (FH) and acclimation/release from the Dryden Acclimation Pond. The total production level target for BY 2017 is 500,001 smolts (181,816 GCPUD mitigation and 318,185 CCPUD mitigation).

The TAC 2017 Columbia River UCR summer Chinook return projection to the Columbia River (Appendix D) and BY 2012, 2013 and 2014 spawner escapement to the Wenatchee River indicate sufficient summer Chinook will return to the Wenatchee River to achieve full broodstock collection for the Wenatchee River summer Chinook supplementation program. Review of recent summer/fall Chinook run-timing past Dryden and Tumwater dam indicates that previous broodstock collection activities have omitted the early returning summer/fall Chinook, primarily due to limitations imposed by ESA Section 10 Permit 1347 to minimize impacts to listed spring Chinook. In an effort to incorporate broodstock that better represent the summer/fall Chinook run timing in the Wenatchee Basin, the broodstock collection will front-load the collection to account for the disproportionate collection timing. Approximately 43% of the summer/fall Chinook destined for the upper Basin (above Tumwater Dam) occurs prior to the end of the first week of July; therefore, the collection will provide 43% of the objective by the end of the first week of July. Weekly collection after the first week of July will be consistent with run timing of summer/fall Chinook during the remainder of the trapping period. With concurrence from NMFS, summer Chinook collections at Dryden Dam may begin up to one week earlier. Based on these limitations and the assumptions listed in Appendix A, the following broodstock collection protocol was developed:

WDFW will retain up to 262 natural-origin, summer Chinook at Dryden and/or Tumwater dams, including 131 females (Table 13). To better ensure achieving the appropriate females for program production, the collection will implement the draft Production Management Plan, including ultrasonography to determine the sex of each fish retained for broodstock. Trapping at Dryden Dam may begin 27 June and terminate no later than 15 September and operate up to 7-days/week, 24-hours/day. Trapping at Tumwater Dam if needed may begin 15 July and terminate no later than 15 September and operate up to 48 hours per week for broodstock related activities.

Table 13. Number of broodstock needed for the combined 2017 BY Chelan and Grant PUD Wenatchee summer Chinook production obligations of 500,001 smolts, collection location, and mating strategy.

Program	Production target	Number of Adults		Total	Collection location	Mating protocol
		Hatchery	Wild			
Chelan PUD	318,185		83F/83M	**172**		
Grant PUD	181,816		48F/48M	**98**		
Total	**500,001**		**131F/131M**	**262**	Dryden LBT-RBT[1] /TWD[2]	1:1

[1] Dryden LBT-RBT= Dryden Dam left and right bank trapping facilities.
[2] TWD=Tumwater Dam.

Priest Rapids Fall Chinook

Collection of fall Chinook broodstock at Priest Rapids Hatchery (PRH) will generally begin in early September and continue through about mid-November. Juvenile release objectives specific to Grant PUD (5,599,504 sub-yearlings), and Federal (1,700,000 sub-yearlings at PRH + 3,500,000 smolts at Ringold Springs Hatchery – collection of broodstock for the federal programs are conditional upon having contracts in place with the ACOE), mitigation commitments. Biological assumptions are detailed in Appendix A. For the Ringold Springs production, adult collection, holding, spawning and incubation occurs at PRH until the eyed-egg stage. Eyed eggs are transferred to Bonneville Hatchery until they are transferred for spring acclimation and release at Ringold Springs.

For 2017 up to 1,000 adipose present, non-coded wire tagged (high proportion of natural origin) fall Chinook adults will be targeted at the OLAFT). Additional NO adults targeted as a continued pilot evaluation through hook-and-line angling efforts in the Hanford Reach to increase the proportion of natural origin adults in the broodstock to meet integration of the hatchery program will also be incorporated into the program. It is estimated that approximately 400 adults may be collected through the hook-and-line efforts. Close coordination between broodstock collections at the volunteer channel, the OLAFT and through hook-and-line efforts in the Hanford Reach will need to occur so over collection is minimized. Fish surplus to production needs will be culled at the earliest possible life-stage (e.g, brood collected, brood spawned, eggs). Presumed NOR's collected and spawned from either hook-and-line caught broodstock or OLAFT collections will be prioritized for PRH programs (i.e. OLAFT and Hanford Reach angler caught fish will be externally marked, held in a separate pond from volunteer collected fish, spawned first each week, and to the extent possible segregated and reserved for the GPUD program).

Grant PUD staff will work closely with WDFW hatchery and M&E staff to maintain separation of gametes/progeny of OLAFT and angling collected adults at spawning and through incubation/early rearing.

Based upon the biological assumptions in Appendix A, an estimated 4,219 females will need to be collected (3,536 spawned) to meet the 10,799,054 smolts required to meet the current three up-river bright (URB) programs which rely on adults collected at the Priest Rapids Hatchery volunteer channel trap, hook-and-line efforts on the Hanford Reach, and/or the Priest Rapids Dam off ladder trap (OLAFT; Table 14).

To increase the probability of incorporating a higher percentage of NOR's from the volunteer channel, adipose present, non-CWT males and females will be prioritized for retention and males older than 3 will be prioritized. In addition, preliminary information suggests that the pNORs is higher in the later part of the trapping period than the earlier period. As data become available, the PRCC-HSC may choose, in-season, to retain a disproportionately high number of broodstock from the latter half of the returns to the volunteer trap.

<u>Implementation Assumptions</u>

1) Broodstock may be collected at any or all of the following locations/means: the PRD off ladder trap (OLAFT – operated 4-days per week/8 hrs/day to collect up to 1,000 presumed NOR's), hook-and-line angling (ABC) in the Hanford Reach (actual numbers collected are uncertain but will contribute to the overall brood program and pNOB), and the Priest Rapids Hatchery volunteer channel trap.

2) Assumptions used to determine egg/adult needs is based upon current program performance metrics.

3) Broodstock retained from the volunteer channel will exclude to the degree possible, age-2 and 3 males (using length at age; i.e. retain males ≥ 75 cm) to address genetic risks/concerns of younger age-at-maturity males producing offspring which return at a younger age (decreased age-at-maturity) and also decrease the probability of using hatchery origin fish in the broodstock that are skewed towards earlier ages at maturity.

4) Only adipose present, non-CWT males and females will be retained for broodstock from volunteer channel collected broodstock unless a shortage is expected.

5) Only progeny of adipose present, non-wired fish encountered through hook-and-line angling and at the OLAFT will be prioritized for retention into the program.

6) Broodstock collected from the OLAFT and by hook-and-line will exclude age-2 and to the degree possible age-3 fish (<75 cm) to minimize genetic risks/concerns of younger age-at-maturity males producing offspring which return at a younger age (decreased age-at-maturity) and to ensure the highest proportion of NOR's in the collection (e.g. collection of 1 in 5 age-3 fish for broodstock from the OLAFT).

7) All gametes of fish spawned from hook-and-line broodstocking efforts and/or OLAFT collections will be incorporated into the PRH based programs.

8) Real time otolith reading and an alternative mating strategy will be implemented in 2017 similar to 2015 and 2016 unless the PRCC-HSC agrees that the PNI objective in 2017 can be met without implementing 1x4 matings. Otoliths from males from the OLAFT and ABC collections will be collected during the peak spawning week and read prior to spawning. If the male is natural origin, then it will be spawned with 4 females, otherwise it will be spawned with two females or the milt discarded if it is a known hatchery male and there are sufficient numbers of unknown males available for spawning.

9) All eggs or juveniles leaving PRH (including surplus) will have a unique otolith mark so that returning adults can be identified. Exceptions to this could occur if there are guarantees of a suitable mark/tag from a receiving hatchery.

10) Natural origin broodstock collection at the volunteer trap will be prioritized for the GPUD program by collecting fish when the probability of encountering natural origin fish is highest and balancing run-time representation.

Table 14. Number of broodstock needed for the combined Grant PUD and ACOE fall Chinook production obligations of 10,799,504 sub-yearling smolts at Priest Rapids and Ringold Springs hatcheries, collection location, and mating strategy.

Program	Production target	Number of Adults	**Total**	Collection location	Mating protocol
Grant PUD	5,599,504	2,234F/1,145M	**3,379**		
ACOE-PRH	1,700,000	681F/350M	**1,031**		
ACOE – Ringold[1]	3,500,000	1,397F/716M	**2,113**		
Total	**10,799,504**	**4,312F/2,211M**	**6,523**		

Collection location	Estimated number of adults		Total		
	Hatchery	Wild			
Priest Rapids Hatchery	**3,266F/1,683M**	**119F/55M**	**5,123**	PRH volunteer trap	1:2
OLAFT[2]	**307F/153M**	**360F/180M**	**1,000**	PRD off-ladder trap	1:2, 1:4
ABC[3]	**23F/45M**	**113F/219M**	**400**	Hanford Reach	1:2, 1:4
Total	**3,596F/1,881M** (5,477; 84.0%)	**592F/454M** (1,046; 16.0%)	**6,523**		

[1] As of brood year 2009, Priest Rapids Hatchery is taking sufficient eggs to meet the 3,500,000 sub-yearling smolt release at Ringold-Meseberg Hatchery funded by the ACOE – late incubation of this program occurs at Bonneville.
[2] Estimated number of fall Chinook females and males to be acquired from the OLAFT in 2017. F/M ratios were derived through run at large data. Estimates of H/W were derived through otolith results.
[3] ABC fish are adults collected from hook and line collection efforts on the Hanford Reach. Estimates of F/M were derived through 2012-2014 spawn numbers. Estimates of and H/W were derived through otolith results from 2012 and 2014.

2018	Okanogan WxW (CCT/GPUD)	Up to 100K [6]	Body and snout CWT[8]	Up to 20,000 PIT [7,9]	Okanogan/Similkameen Omak, Salmon, Wildhorse Ck.,, other tribs. (TBD)	2019	5-8	Volitional from St. Mary's pond. The numbers going to Omak Creek and other tributaries will be determined by fall of 2018.

[1] Release of fish at the Goat Wall Pond remote acclimation site operated by the YN is conditional upon HC and HSC approval.
[2] Externally marking of this group is presently funded by WDFW. Marking of this 1M fish is contingent on *US v. Oregon* Policy Committee approval for 2017.
[3] Presently all CWT's are applied to the snout.
[4] The Okanogan SPC program derives its juveniles from a 200K transfer of Methow SPC from WNFH as part of a reintroduction effort. Fish are released into the Okanogan Basin.
[5] The Chief Joe Hatchery SPC program presently receives surplus adults from the Leavenworth NFH. Juveniles are released on station from CJH.
[6] Total Okanogan release not to exceed 100K + 10%.
[7] PIT number s to each release site are estimated and not actual.
[8] The Okanogan steelhead HGMP and NOAA's BiOp for the TRMP state that WxW progeny will receive a unique internal tag (CWT or PIT) and/or receive an alternative fin clip. At this time, CCT does not intend to use an alternative fin clip until/unless a high proportion of the released fish have WxW parents and there is an acceptable survival risk/benefit of the alternative fin clip.

[9] Total PIT tag release in the Okanogan 20,000
[10] Beginning with the 2017 brood, adult returns from the Nason conservation program will be utilized to meet the Nason safety net program and will receive a supplemental body tag (blank wire either at the base of the adipose or the caudal peduncle) in addition to the adipose clip.
[11] With the recent detection inbreeding depression effects in the Twisp conservation program, parties are currently working on developing a new plan for the program. Once developed and agreed to, this table will be updated to reflect any changes.

Appendix C

Return Year Adult Management Plans

At a gross scale, adult management plans will include all actions that *may* be taken within the current run year to address surplus hatchery fish (if any). At the time of submission for this document, spring Chinook will probably be the only group where a reasonable pre-season forecast may be available to lay out what the expected surplus is, how many can be expected to be removed through each action, etc. Preseason forecasts for steelhead will be available in September.

Wenatchee Spring Chinook

Pre-season estimates for age-4 and age-5 adults project a total of 5,410 (773 natural origin [14.3%] and 4,637 hatchery origin [85.7%]) spring Chinook back to Tumwater Dam in the Wenatchee Basin. Approximately 3,827 Chiwawa and 1,491 Nason spring Chinook are to reach Tumwater Dam in 2017, of which about 681 (12.8%) and 4,637 fish (87.2%) are expected to be natural and hatchery origin spring Chinook, respectively. The balance of about 92 natural origin spring Chinook expected back are destined to the remaining spawning aggregates (Table 1). In-season assessment of the magnitude and origin composition of the spring Chinook return above Tumwater Dam will be used to provide in-season adjustments to hatchery/wild composition and total broodstock collection, consistent with ESA Section 10 Permits 18118 and 18121.

Table 1. Age-4 and age-5 class return projection for wild and hatchery spring Chinook to Tumwater Dam during 2017.

	Chiwawa Basin[1]			Nason Cr. Basin[1]			Wenatchee Basin to Tumwater Dam[2]		
	Age-4	Age-5	Total	Age-4	Age-5	Total	Age-4	Age-5	Total
Estimated wild return	418	108	**526**	123	32	**155**	614	159	**773**
Estimated hatchery return	3,238	63	**3,301**	1,336	0	**1,336**	4,574	63	**4,637**
Total	3,656	171	**3,827**	1,459	32	**1,491**	**5,188**	**222**	**5,410**

[1] Reflects NOR estimates to Tumwater Dam and has not been adjusted for pre-spawn mortality.
[2] Wenatchee Basin to Tumwater Dam total includes NORs to the White, Little Wenatchee, and Chiwawa rivers and Nason Creek.

Absent conservation fisheries or adult removal at Tumwater Dam (TWD), the expected number of age-4 and age-5 Hatchery Origin Returns (HOR) for the upper Wenatchee River Basin as a whole is estimated to be approximately six times the expected number of Natural Origin Returns (NORs; 6.3 times the number of NOR’s in the Chiwawa River and 8.6 times the number of NOR’s in Nason Creek). The combined HO and NO returns will represent about 4.2 times the number of adults needed to meet the interim Chiwawa run escapement to TWD of 900 fish indicating a disproportionate number of hatchery origin spring Chinook will be on the spawning grounds in the fall of 2017 (Table 2). The combined HO and NO returns will represent about 3 times the number of adults needed to meet the interim Nason run escapement to TWD of 500 fish indicating a disproportionate number of hatchery origin spring Chinook will be on the spawning grounds in the fall of 2017 (Table 3).

Additional Adult Management

2017 adult management actions are intended to provide for near 100% removal of age-3 hatchery males (jacks), and unknown hatchery origin adults (ad-/cwt-) and up to about 93% of the age-4 and age-5 hatchery origin adults (about 1,717 males and 1,288 females according to current models, Table 2). In addition, approximately 68 HO and 144 NO adults will be removed between TWD and the Chiwawa Weir and retained for broodstock to support meeting the combined Grant and Chelan PUD Wenatchee spring Chinook obligation, the balance will be surplused at TWD and used for tribal and/or food bank disbursements or nutrient enhancement projects.

Table 2. Run escapement and spawning escapement of Chiwawa River hatchery and natural origin fish to Tumwater Dam and the Chiwawa River in 2017.

	To Tumwater Dam		To Chiwawa River		Adults surplused at TWD[3]	Total Chiwawa spawners
	Wild	Hatchery	Wild[1,2]	Hatchery[2]		
Females[4]	305	1,850	228	73	1,717	**301**
Males[4]	221	1,388	156	55	1,288	**211**
Sub-total	526	3,238	384	128	3,005	**512**
Pre-spawn survival[6]			0.85	0.55		
Expected PNI						**0.80**
Expected pHOS						**0.25**

[1] Wild broodstock needs of 74 wild NO fish (37 females/37 males) for the Chiwawa conservation program have already been accounted for in this total as well as pre-spawn mortality.
[2] Adjusted for pre-spawn mortality.
[3] Does not include age-3 hatchery males "jacks" removed during adult management activities at TWD or through a conservation fishery.
[4] Age-4 and age-5 fish only. Gender proportions were made based upon a 5-year average sex ratio for hatchery and wild fish of the same age class.
[5] This should result in approximately 301 redds in the Chiwawa Basin under the assumption that each female produces only one redd.
[6] Estimated survival from Tumwater to spawn.

Table 3. Run escapement and spawning escapement of Nason Creek hatchery and natural origin fish to Tumwater Dam and Nason Creek in 2017.

	To Tumwater Dam		To Nason Creek		Adults surplused at TWD[3]	Total Nason spawners
	Wild	Hatchery	Wild[1,2]	Hatchery[2]		
Females[4]	90	763	47	159	440	**206**
Males[4]	65	573	26	120	321	**146**
Sub-total	155	1,336	73	279	761	**352**
Pre-spawn survival[6]			0.85	0.55		
Expected PNI						**0.56**

Expected pHOS	**0.79**

[1] Wild broodstock needs of 70 wild NO fish (35 females/35 males) for the Nason conservation program have already been accounted for in this total as well as pre-spawn mortality.
[2] Adjusted for pre-spawn mortality and HO broodstock needs of 68 fish (34 females/34 males).
[3] Does not include age-3 hatchery males "jacks" removed during adult management activities at TWD or through a conservation fishery.
[4] Age-4 and age-5 fish only. Gender proportions were made based upon a 5-year average sex ratio for hatchery and wild fish of the same age class.
[5] This should result in approximately 206 redds in Nason Creek under the assumption that each female produces only one redd.
[6] Estimated survival from Tumwater to spawn.

Wenatchee Summer Steelhead

Depending on the outcome of preseason and in-season estimates of hatchery and natural origin steelhead to the Wenatchee Basin during the annual run cycle monitoring at the Priest Rapids Dam Off Ladder Trap (OLAFT), removal of surplus adult steelhead may occur at Tumwater Dam or in combination with a conservation fishery.

A more detailed run forecast will be available in September 2017. Adult management plans will be finalized then and appended to this document.

Methow Spring Chinook

Pre-season estimates project a total of 3,265 (973 natural origin [29.8%] and 2,292 hatchery origin [70.2%]) spring Chinook back to Methow Basin. Of the 2,292 hatchery returns, about 748 are estimated to be from the conservation program with the balance of 1,544 from the WNFH safety net program (Table 5).

Table 5. Brood year 2012-2014 age class and origin run escapement projection for UCR spring Chinook at Wells Dam, 2017.

	Projected Escapement											
	Origin								**Total**			
	Hatchery				**Wild**				**Methow Basin**			
Stock	**Age-3**	**Age-4**	**Age-5**	**Total**	**Age-3**	**Age-4**	**Age-5**	**Total**	**Age-3**	**Age-4**	**Age-5**	**Total**
MetComp	188	473	12	**673**	54	619	126	**799**	242	1,092	138	**1,472**

Winthrop (MetComp)	324	1,189	31	**1,544**					324	1,189	31	**1,544**
%Total				53.9%								33.7%
Total	528	1,709	55	**2,292**	75	761	137	**973**	603	2,470	192	**3,265**

Some level of adult management will be required to limit the number of hatchery spring Chinook on the spawning grounds. Because a conservation fishery is not yet possible under current permit limitations, adult management will need to occur through operation of the volunteer channel traps located at both the Methow Hatchery (MH) and Winthrop NFH (WNFH).

Presently hatchery fish from MH are prioritized to: a) contribute to the supplementation of the natural populations (up to either the escapement objectives or PNI/pHOS goal), b) make up shortfalls in natural-origin brood for the MH conservation program, and c) to support the 400K safety-net program at WNFH. As such WNFH will operate volunteer hatchery ladder to support removal of excess safety-net and conservation fish (when needed) fish. MH will operate its volunteer trap and will provide surplus hatchery adults (in excess to the MH and conservation needs) to WNFH to support the safety-net program, to support removal of excess safety-net and conservation fish, or retain adults to facilitate testing translocation of conservation fish to under-seeded spawning areas as approved by the HCP HC and PRCC HSC. The translocation of conservation program adults will be prioritized over their use as broodstock for the safety net program as long as both programs can meet full production. The intention of adult translocation is to increase natural production which is the primary function of the Methow Hatchery.

Specific actions are as follows:

Adult management actions will be used to support achieving hatchery production levels and escapement/sliding-scale PNI targets identified in the Methow Spring Chinook BiOp (2017) and Permits #18925, #18927 and #20533. Adult management removal targets identified in this document may be revised based on best available inseason run estimates.

Twisp River Spring Chinook: spring Chinook in the Twisp River will be managed separately from the rest of the basin.

a. Adipose-clipped fish encountered at the Twisp Weir will be removed (putative WNFH returns or strays from outside of the basin).
b. Age-3 hatchery males will be removed and euthanized or transported to WNFH.
c. Adult management will be performed to maintain pHOS ≤0.50. pNOB will be >0.50 and may be allowed to fluctuate between 0.50 and 1.0 in order to achieve a pHOS ≤0.50.
d. Wild fish will be collected as broodstock – up to ~18 individuals, but not to exceed 33% of the wild run. Hatchery fish may be collected as broodstock dependent on collection success of wild fish and provided that Twisp-program pNOB may not be less than 0.50.
e. The Twisp Weir will be fished for the duration of the broodstock collection, only, in 2017. Adult management activities will be incidental to broodstock collection. Once broodstock collection is completed, the weir will be opened to fish passage to limit delay/trapping effects on bull trout. Tentatively, during broodstock collection, the weir will be fished from 6:00 AM to 9:00 PM on a daily basis. Deviation from this schedule may be implemented based on the run size and catch efficiency for broodstock.

Methow River (MFH and WNFH) and Chewuch River Spring Chinook (MetComp):

a. Stock assessment will be performed at Wells Dam during the spring Chinook broodstock collection. This information on stock, hatchery:wild, and male:female composition in conjunction with fish counts at Wells Dam will be used to adjust in-season adult management targets.

b. MetComp returns will be managed by removing volunteers at WNFH and Methow Hatchery using the outfall traps at these facilities.

   i. All hatchery-origin age-3 males will be removed

      1. Gender identified by ultrasound.

   ii. The Methow and Winthrop FH volunteer traps will be fished continuously (24 h per day/7 d per week) throughout the run and fish removed at least once daily (depending on specific facility limitations), or as often as needed when fish are present. Adjustments to the operation of the trapping facilities will be made based upon capture/extraction rates as well as bull trout encounters and take limitations.

   iii. Trapping will cease at Methow Hatchery if:

      1. Removal of MFH and WNFH origin adults meets the targets established (in this document and as adjusted in-season), or

      2. If overall hatchery bull trout take is likely to be exceeded. However, in-season adjustment may be made to reduce the likelihood of bull trout encounters including, but not limited to: limiting 1) the time of day trap is fished, 2) hours per day fished, 3) days per week fished.

   iv. Trapping will cease at Winthrop NFH if:

      1. Removal of WNFH and MFH origin adults meets the targets established (in this document and as adjusted in-season), or

      2. If overall hatchery bull trout take is likely to be exceeded. However, in-season adjustment may be made to reduce the likelihood of bull trout encounters including, but not limited to: limiting 1) the time of day trap is fished, 2) hours per day fished, 3) days per week fished.

   v. All adipose clipped returns encountered at WNFH and MFH volunteer traps will be removed.

      1. Returns to WNFH will be retained at WNFH for broodstock (WNFH safety net and Okanogan 10(j) programs) or surplusing.

      2. Returns to MFH will be transferred to WNFH for broodstock (WNFH safety net and Okanogan 10(j) programs) or surplusing.

   vi. Conservation program returns may also be transported to specific reaches of the Methow and/or Chewuch Rivers to meet the minimum spawning escapement objective or to experimentally augment spawner distribution (such an action will require an approved study or implementation plan by the HCP HC and PRCC HSC, and be permissible under current ESA permits).

Based on the preseason forecast for wild and hatchery spring Chinook to the Methow Basin, once NO broodstock requirements are fulfilled and accounting for an estimated prespawn mortality for NO fish of 50% (42% for HO fish), there will be approximately 426 NO spawners. Based upon the sliding PNI scale for NO run sizes >300 fish, the initial goal for 2017 will be to manage for a minimum spawning escapement of 548 spawners; to achieve this, an estimated 67.4% of the hatchery returns (1,862 HO fish) will need to be removed (Table 6). This will result in approximately 122 hatchery origin spawners on the spawning grounds after accounting for prespawn mortality.

Table 6. Calculated targets and projected adult management results for Methow spring Chinook in 2017.

Wild Spawning Escapement	pNOB[2]	pHOS	PNI Target[3]	Allowable Hatchery Spawners	Hatchery surplus	Hatchery Broodstock (WNFH + 10j)	Proportion of Hatchery Fish to Remove	Total spawning escapement
426[1]	1.00	0.223	0.82	122	0 MH	472	0.674[4]	548
					1,544 WNFH			
				Adjusted for Pre-spawn loss	Total Surplus			
				290	1,390			

[1] Adjusted for prespawn mortality. Includes about 78 NO fish expected to go into the Twisp River basin.
[2] pNOB of conservation program only.
[3] Based on 3-pop model and assumes a minimum of 75% conservation program adults for WNFH broodstock.
[4] Assumes a 90% conversion of hatchery fish to hatchery outfalls. Value includes hatchery adults needed to meet WNFH and Okanogan 10(j) production components.

In-season assessment of the magnitude and origin composition of the spring Chinook return above Wells Dam will be used to provide in-season adjustments to hatchery/wild composition and total broodstock collection, consistent with ESA Section 10 Permits 18925, 18927, and 20533.

Methow Summer Steelhead

Depending on the outcome of preseason and in-season estimates of hatchery and natural origin steelhead to the Methow Basin during the annual run cycle monitoring at the Priest Rapids Dam Off Ladder Trap (OLAFT), removal of surplus adult steelhead may occur at the Twisp Weir (primarily as an action related to the steelhead RSS to meet a 1:1 hatchery:wild spawning composition upstream of the weir), the Wells Hatchery Volunteer Channel, volunteer returns to the Methow Hatchery and Winthrop NFH, or in combination with a conservation fishery.

A more detailed run forecast will be available in September 2017. Adult management plans will be finalized then and appended to this document.

Okanogan Summer Steelhead

Depending on the outcome of preseason and in-season estimates of hatchery and natural origin steelhead to the Okanogan Basin during the annual run cycle monitoring at the Priest Rapids Dam Off Ladder Trap (OLAFT), removal of surplus adult steelhead may utilize a conservation fishery or in combination with removal through spring Okanogan tributary weir operations.

A more detailed run forecast will be available in September 2017. Adult management plans will be finalized then and appended to this document.

Appendix D

Site Specific Trapping Operation Plans

Tumwater Dam

For 2017, WDFW and Chelan PUD are proposing the following plan (a summary of activities by month for Tumwater Dam is summarized in Table 1):

1) **Real-time monitoring and trap operations:** Throughout all trapping activities described in this plan, the two PIT tag antennae arrays within the Tumwater Dam ladder (weir 15 and 18 see Appendix 2), will be monitored by WDFW and Chelan PUD and detections of previously PIT tagged fish will be evaluated to determine the median passage time of fish between first detection at weir 15 and last detection at weir 15 or weir 18. Median passage estimates will be updated with every 10 PIT-tagged fish encountering weir 15. If the median passage time is greater than 48 hours, trapping will cease and fish will be allowed to exit via the ladder (i.e., bypass the trap). If trapping has been stopped, PIT tag passage monitoring will continue and trapping will resume if and when the median passage time is less than 24 hours. In summary, real-time PIT tag monitoring will occur both when the trap is operational and when fish are bypassed. This will provide an opportunity to evaluate trapping effects versus baseline passage rates through the ladder for future operations.

2) **Improved Fish Handling Efficiency**: Several infrastructure improvements at Tumwater allow WDFW and other operators to cycle through sampled fish more quickly. These improvements consist of an additional holding tank and an improved conveyance system between the trap and holding tank. The facility improvements and additional staffing by WDFW (3 operators instead of 2) during peak spring Chinook and sockeye passage (i.e. June 1 and July 15), will ensure that the trapping denil is operated constantly allowing unimpeded passage through the trap. Historically, the trapping denil has been periodically shut down while fish were being processed.

3) **Enhanced effort for Tumwater trapping operations from June 1 and July 15**: The Tumwater trap will be operated in an active-manned trapping condition (the ladder bypass will not be used however, fish may still ascend the denil [steep pass] unimpeded). The trap will be checked a minimum of 1x per day. More frequent trap checks will be made as fish numbers increase. Between June 16 and July 15 the Tumwater trap will be actively manned 24 hours/day 7 days/week utilizing two- three person crews (two people will sample fish and the third will maintain operation of the steep pass so that it will not be closed to passage). This represents an additional person to keep the denil operating

constantly. If during this period staff are not available (due to logistical, funding, or other issues) to keep the denil operating continuously, the trap will be opened to allow for nighttime passage (this is in addition to passage required under a detected delay event).

4) **Enhanced effort and limited Tumwater trapping operations from July 16 to August 31**: The trap will be operated 3 days/week for up to 16 hours/day (not to exceed 48 hours per week) to support broodstock collection activities for summer Chinook and sockeye run composition sampling (CRITFC) and sockeye spawner escapement PIT tagging. Video enumeration and full passage will occur when trapping is not occurring.

5) **Planned Tumwater trapping operations from September 1 until mid-December:** The trap will return to a 24 hours/7days/week manned or unmanned active trapping for steelhead and Coho broodstock collection and adult steelhead management. During this time period bull trout are rare and spring Chinook are not present at Tumwater. For this trapping period, real-time monitoring will continue to be implemented.

6) **Operations at Tumwater from mid-December until about mid-February:** During this period the trapping facility is not operated due to having been winterized. Only video enumeration and full passage are available during this period.

7) **Planned Tumwater trapping operations from mid-February through May:** The trap will return to a 24 hours/7days/week manned or unmanned active trapping for adult steelhead management and spawner escapement tagging. Beginning on or about May 1, limited spring Chinook broodstocking, run comp sampling, etc. may also occur. For this trapping period, real-time monitoring will continue to be implemented.

8) **Limitation in staffing or other unforeseen problems**: If WDFW staff are not available to operate the trapping facility (according to this plan) for any reason, then full passage will be allowed (fish will be allowed to bypass the trap and exit the ladder directly), until staff are able to return.

9) **Unforeseen scenarios and in season observations**: If during the trapping period, observations from field staff warrant reconsideration of any part of the plan as described above, WDFW and Chelan PUD will alert the Hatchery Committee and work cooperatively with the Services to determine whether changes are needed to further minimize incidental take or otherwise ensure that take is maintained at the manner and extent previously approved by the Services

Table 1. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and reproductive success activities anticipated to be conducted at Tumwater Dam in 2017. Blue denotes steelhead, brown spring Chinook, orange sockeye, pink summer Chinook, and green Coho.

Activity	Month											
	Jan	Feb	Mar	Apr	May	June	Jul	Aug	Sep	Oct	Nov	Dec
SHD pHOS mgt[1]		15 Feb				15 June			1 Sep			15 Dec

Su. SHD Spawner Esc. tagging[3]		15 Feb				15 June			1 Sep			15 Dec
Spring Chinook RSS[4]					1 May		15 Jul					
Sp Chinook run comp[5]					1 May		15 Jul					
Sp Chinook pHOS mgt[6]					1 May		15 Jul					
Sp Chin stray mgt[7]					1 May		15 Jul					
Sockeye run comp[8]							15 Jul	15 Aug				
Sockeye spawner esc tagging[9]							15 Jul	15 Aug				
Su. Chin BS collection[10]							1 Jul		15 Sep			
Coho BS collection[11]									1 Sep		30 Nov	

[1] Adult management of the 2017 brood will end in June 2017. However it is anticipated that adult management will occur for the 2018 brood beginning 1 September or earlier if conducted in conjunction with broodstock collection activities at Tumwater Dam for other species.
[2] Summer steelhead broodstock collection will be prioritized at Dryden Dam traps. However if broodstock objectives cannot be met at Dryden then trapping may occur at Tumwater concurrent with other activities.
[3] SHD spawner composition tagging at Tumwater Dam will run concurrent with SHD adult management and other (broodstock) activities at Tumwater Dam.
[4] The spring Chinook RSS will run from 1 May through about 15 July or at such time or at such time the sockeye return develops at Tumwater Dam.
[5] Spring Chinook run composition sampling will run concurrent with the RSS.
[6] Spring Chinook pHOS management will end in July consistent with the arrival of the sockeye return and run concurrent with RSS activities.
[7] Removal of unknown hatchery origin spring Chinook strays at Tumwater Dam will run concurrent with the RSS.
[8] Sockeye run composition sampling will occur at Tumwater Dam beginning no earlier than 15 July. Trapping at Tumwater Dam for run composition sampling will follow a 3d/week, 16hrs/d (48 hrs/week) trapping schedule consistent with permit 1347.
[9] Sockeye spawner escapement sampling will occur at Tumwater Dam beginning no earlier than 15 July. Trapping at Tumwater Dam for spawner escapement tagging will follow a 3d/week, 16hrs/d (48 hrs/week) trapping schedule consistent with permit 1347.
[10] Summer Chinook broodstock collection will be prioritized at Dryden Dam. However if broodstock objectives cannot be met at Dryden Dam then trapping may occur at Tumwater Dam. Trapping at Tumwater Dam for summer Chinook broodstock will follow a 3d/week 16hr/day (48 hrs/week) trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities.
[11] Coho trapping will be conducted at both Dryden and Tumwater Dams. Trapping at Tumwater Dam for Coho broodstock will follow a 3d/week 16hr/day (48 hrs/week) trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities. Collection is permitted through December 7 of each year but typically ceases by the end of November.

Dryden Dam

For 2017, WDFW and Chelan PUD are proposing the following plan (a summary of activities by month for the right and left bank Dryden Dam traps is summarized in Table 2):

The Dryden Dam left and right bank trapping facilities will operate up to five days per week, 24 hours per day beginning July 1 and continue until as late as November 15. Both traps, if operated, will do so on concurrent days and will be checked and cleared every 24 hours, or sooner if it appears that run contribution to the facilities exceeds reasonable limits for adult holding.

If daily river temperatures meet or exceed 21° C (69.8° F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

Table 2. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and/or reproductive success activities anticipated to be conducted at Dryden Dam trapping facilities in 2017. Blue denotes steelhead, pink summer Chinook, and green Coho.

[1] Summer steelhead broodstock collection will be prioritized at Dryden Dam traps. However if broodstock objectives cannot be met at Dryden then trapping may occur at Tumwater concurrent with other activities.
[2] SHD spawner composition tagging at Dryden Dam will run concurrent with other (broodstock or M&E) activities at Dryden Dam.
[3] Summer Chinook broodstock collection will be prioritized at Dryden Dam. However if broodstock objectives cannot be met at Dryden Dam then trapping may occur at Tumwater Dam. Trapping at Dryden Dam for summer Chinook broodstock will follow an up to 5d/week 24hr/day trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities.
[4] Coho trapping will be conducted at both Dryden and Tumwater Dams. Trapping at Dryden Dam for Coho broodstock will follow an up to 5d/week 24hr/day trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities. Collection is permitted through December 7 of each year but typically ceases by the end of November.

Wells Dam Ladder and Hatchery Volunteer Traps

For 2017, WDFW and Douglas PUD are proposing the following plan (A summary of activities by month for the Wells Dam East/West ladder and Wells FH volunteer traps is summarized in Table 3):

1). **East Ladder Trap:**

The East ladder trap will only be operated as needed to meet broodstock collection objectives and other management activities if they cannot be adequately fulfilled through the West ladder and Wells FH volunteer trap operations or if construction activities on the hatchery modernization preclude use of either the West ladder or volunteer traps.

If the East ladder trap is used, it may begin as early as May 1 and, with two exceptions, will operate under a maximum 3-day per week/16 hours per day or 48 cumulative hours per week and will run concurrent with any trapping activities occurring at the West ladder trap. The first exception to the above is that for spring Chinook between May 1 and June 20, the trap may operate a maximum of 5-days per week (but no more than three consecutive days)/16 hours per day and will run concurrent with any trapping activities occurring at the West ladder trap. The second exception is for coho trapping after September 26. Anticipated trap operation is not expected to go beyond November 15.

For coho trapping, the East ladder trap may be operated, concurrent with the West ladder trap, 5 days per week/ 9 hours per day September 27 through October 9, and 7 days per week/16 hours per day beginning October 10. Trap operators will bypass Chinook, steelhead, and sockeye during coho trapping. Anticipated trap operation is not expected to go beyond November 15.

The CRITFC will also trap sockeye at Wells Dam for tagging and stock assessment. They have not yet submitted a specific request for trapping in 2017, but their preference in past years has been to use the East ladder, and to begin the last week of June and end the third week of August.

If daily river temperatures meet or exceed 21º C (69.8º F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

2). **West Ladder Trap:**

The West ladder may begin as early as May 1 for spring Chinook broodstock collection and, with two exceptions, will operate under a maximum 3-day per week/16 hours per day or 48 cumulative hours per week. The first exception to the above is that for spring Chinook between May 1 and June 20, the trap may operate under a maximum 5-days per week (but no more than three consecutive days)/16 hours per day and will run concurrent with any trapping activities occurring at the East ladder trap. The second exception is for coho trapping after September 26. Anticipated trap operation is not expected to go beyond November 15.

For coho trapping, the West ladder trap may be operated 5 days per week/ 9 hours per day September 27 through October 9, and 7 days per week/16 hours per day beginning October 10. Trap operators will bypass Chinook, steelhead, and sockeye during coho trapping. Anticipated trap operation is not expected to go beyond November 15.

The CRITFC will also trap sockeye at Wells Dam for tagging and stock assessment. They have not yet submitted a specific request for trapping in 2017, but their preference in past years has been to use the East ladder, but they also use the West ladder in some years. CRITFC trapping generally begins the last week of June and end the third week of August.

If daily river temperatures meet or exceed 21° C (69.8° F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

3). **Wells FH Volunteer Trap:** The Wells FH volunteer trap may begin as early as July 1 for summer Chinook broodstock collection and operate through mid-June of the following year for steelhead broodstock collection and adult management if needed. The trap may operate up to seven days per week/24 hours per day to facilitate broodstock collection and adult management actions.

If daily river temperatures meet or exceed 21° C (69.8° F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

Table 3. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and/or reproductive success activities anticipated to be conducted at Wells Dam in 2017. Blue denotes steelhead, brown spring Chinook, pink summer Chinook, orange sockeye, and green Coho.

Activity	Month											
	Jan	Feb	Mar	Apr	May	June	Jul	Aug	Sep	Oct	Nov	Dec
East/West Ladders												
Su. SHD BS collection[1]									1 Sep		15 Nov	
Su. SHD run comp.									1 Sep		15 Nov	
Su. SHD Spawner Esc. Tagging[2]									1 Sep		15 Nov	
Sp Chinook BS collection					1 May	30 Jun						
Sp Chinook run comp					1 May		15 Jul					
Sockeye SA tagging[3]						26 June		18 Aug				
Su. Chin BS collection[4]							1 Jul		15 Sep			
Coho BS collection[5]									15 Sep		15 Nov	
Wells Volunteer Trap												
Su. SHD BS collection[1]									1 Sep		15 Nov	
SHD pHOS mgt.[6]		15 Feb				15 June			1 Sep			15 Dec
Su. Chin BS collection[7]							1 Jul		15 Sep			
Su. Chin Surplussing							1 Jul			30 Oct		

[1] Summer steelhead broodstock collection will be prioritized at West ladder and volunteer traps. However if broodstock objectives cannot be met at either of those two locations then trapping may occur at the East ladder concurrent with other activities.
[2] SHD spawner composition tagging at Wells Dam will run concurrent with other (broodstock or M&E) activities at Wells Dam.
[3] Summer Chinook broodstock collection for the Methow (Carlton) program will be prioritized at the West ladder trap. However if broodstock objectives cannot be met at the West ladder then trapping may occur at the East ladder. Trapping at the west and/or East ladders for summer

Chinook broodstock will follow an up to 3d/week 16hr/day (48 cumulative hours) trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities.

[4] CRITFC trapping of sockeye for stock assessment and tagging typically begins the last week of June and extends through the third week of August, following an up to 3d/week 16hr/day (48 cumulative hours) coordinated with WDFW spring or summer Chinook and steelhead broodstock collection and stock assessment trapping, preferring to trap on the East ladder.

[5] Coho trapping may be conducted at both East and/or West ladders. Trapping at Wells Dam ladder traps for Coho broodstock will follow an up to 3d/week 16hr/day trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities. Trapping at the Wells Dam ladder will cease no later than November 15.

[6] Adult management of the 2017 brood will end in June 2017. However it is anticipated that adult management will occur for the 2018 brood beginning 1 September or earlier if conducted in conjunction with broodstock collection activities at the Wells Hatchery volunteer channel for other species.

[7] Summer Chinook broodstock collection for the Wells Hatchery programs will be prioritized at the Wells Hatchery volunteer trap. Trapping at the volunteer channel may occur up to 7 days per week, 24 hours per day and may include broodstock collection and/or adult management.

Methow Hatchery Volunteer and Twisp Weir Traps

For 2017, WDFW and Douglas PUD propose the following plan (A summary of activities by month for Methow Hatchery volunteer trap and the Twisp Weir is summarized in Table 4):

Specific operation details for the Methow Hatchery volunteer trap and Twisp Weir are still being worked through. Once those details have been fleshed out more thoroughly, this section will be updated.

If daily river temperatures meet or exceed 21º C (69.8º F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

Table 4. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and/or reproductive success activities anticipated to be conducted at Methow Hatchery and the Twisp Weir in 2017. Blue denotes steelhead and brown spring Chinook.

Activity	Month											
	Jan	Feb	Mar	Apr	May	June	Jul	Aug	Sep	Oct	Nov	Dec
Methow Hatchery[1]												
SHD pHOS mgt.			1 Mar			15 Jun			1 Sep		15 Nov	
Sp. Chinook BS collection					1 May			30 Aug				
Sp. Chinook pHOS mgt.[2]					1 May			30 Aug				
Twisp Weir[3]												
Steelhead RSS			1 Mar		30 May							
Su. SHD BS collection				1-30 Apr								
SHD pHOS mgt.			1 Mar		30 May							
Sp. Chinook BS collection						1 June		15 Aug				
Sp. Chinook pHOS mgt.						1 June		22 Aug				

[1] Specific details on how operation of the Methow Hatchery volunteer trap will work for SHD adult management are still being worked out at this time.

[2] Adult management for spring Chinook at the Methow Hatchery volunteer trap will run concurrent with broodstock collection.

[3] Specific details on how operation of the Twisp Weir will work for 2017 to include the steelhead RSS, broodstock collection, and adult management and spring Chinook broodstock collection and adult management is still being worked out at this time.

Priest Rapids Dam Off-Ladder-Adult-Fish-Trap (OLAFT)

Table 5. Summary of broodstock collection, VSP monitoring, and/or run composition sampling activities anticipated to be conducted at the Priest Rapids Dam Off-Ladder-Adult-Fish-Trap (OLAFT) in 2017. Blue denotes steelhead, purple fall Chinook, and orange sockeye.

Activity	Month											
	Jan	Feb	Mar	Apr	May	June	Jul	Aug	Sep	Oct	Nov	Dec
SHD VSP Monitoring[1]							1 Jul				15 Nov	
Fall Chin. BS collection[2]									1 Sep		15 Nov	
Fall Chinook Run Comp.[3]									1 Sep		15 Nov	
Sockeye BS Collection[4]						22 Jun	10 Jul					

[1] Steelhead VSP monitoring targets up to 15% of the annual return over Priest Rapids Dam. Presently that requires operation of the OLAFT up to 3 days/ week, 8 hours per day. The trap is opened to passage each night.
[2] To acquire the target 1,000 adipose present, non-CWT adult fall Chinook for broodstock, the OLAFT is operated up to 5 days per week, 8 hours per day. Three of the five days are concurrent with the SHD VSP monitoring. The trap is opened to passage each night.
[3] Fall Chinook run composition runs concurrent with SHD VSP monitoring and/or fall Chinook broodstock collection activities.
[4] Sockeye broodstock collection to support YN reintroduction efforts in the Yakima is based upon abundance based sliding scale. Depending on the strength of the return and allowable allocation, the trap may be operated up to 5 days per week, 8 hours per day beginning about 22 June and running through about 10 July. The trap is opened to passage each night.

Appendix G

DRAFT

Hatchery Production Management Plan

The following management plan is intended to provide life-stage-appropriate management options for Upper Columbia River (UCR) PUD salmon and steelhead mitigation programs. Consistent, significant over-production or under-production risks the PUD's not meeting the production objectives required by FERC and overages in excess of 110% of program release goals violates the terms and conditions set forth for the implementation of programs under ESA and poses potentially significant ecological risks to natural origin salmon communities.

Under RCW 77.95.210 (Appendix A) as established by House Bill 1286, the Washington Department of Fish and Wildlife has limited latitude in disposing of salmon and steelhead eggs/fry/fish. While this RCW speaks more specifically to the sale of fish and/or eggs WDFW takes a broader application of this statute to include any surplus fish and/or eggs irrespective of being sold or transferred.

We propose implementing specific measures during the different life-history stages to both improve the accuracy of production levels and make adjustments if over-production occurs. These measures include (1) Improved Fecundity Estimates, (2) Adult Collection Adjustments, (3) Within-Hatchery Program Adjustments, and (4) Culling at the earliest life-stage.

<u>Improved Fecundity Estimates</u>

A) Develop broodstock collection protocols based upon the most recent 5-year mean in-hatchery performance values for female to spawn, fecundity, green egg to eye, and green egg to release.
B) Use portable ultrasound units to confirm gender of broodstock collected (broodstock collection protocols assume a 1:1 male-to-female ratio). Ultrasonography, when used by properly trained staff will ensure the 1:1 assumption is met (or that the female equivalents needed to meet production objective are collected). Spawning matrices can be developed such that if broodstock for any given program are male limited sufficient gametes are available to spawn with the females.

<u>Adult Collection Adjustments</u>

C) Make in-season adjustments to adult collections based upon a fecundity-at-length regression model for each population/program and origin composition need (hatchery/wild). This method is intended to make in-season allowances for the age structure of the return (i.e. age-5 fish are larger and therefore more fecund than age-4 fish), but will also make allowances for age-4 fish that experienced more growth through better ocean conditions compared to an age-5 fish that reared in poorer ocean conditions.

Within-Hatchery Program Adjustments

D) At the eyed egg inventory (first trued inventory), after adjustments have been made for culling to meet BKD management objectives, the over production will be managed in one or more of the following actions as approved by the HCP-HC or PRCC-HSC:
   - Voluntary cooperative salmon culture programs under the supervision of the department under chapter 77.100 RCW;
   - Regional fisheries enhancement group salmon culture programs under the supervision of the department under this chapter;
   - Salmon culture programs requested by lead entities and approved by the salmon funding recovery board under chapter 77.85 RCW;
   - Hatcheries of federally approved tribes in Washington to whom eggs are moved, not sold, under the interlocal cooperation act, chapter 39.34 RCW; and
   - Governmental hatcheries in Washington, Oregon, and Idaho; or
   - Culling for diseases such as BKD and IHN, consistent with the Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State; or
   - Distribution to approved organizations/projects for research.

E) At tagging (second inventory correction) fish will be tagged up to 110% of production level at that life stage. If the balance of the population combined with the tagged population amounts to more than 110% of the total release number allowed by Section 10 permits then the excess will be distributed in one or more of the following actions as approved by the HCP-HC or PRCC-HSC:
   - Voluntary cooperative salmon culture programs under the supervision of the department under chapter 77.100 RCW;
   - Regional fisheries enhancement group salmon culture programs under the supervision of the department under this chapter;
   - Salmon culture programs requested by lead entities and approved by the salmon recovery funding board under chapter 77.85 RCW;
   - Hatcheries of federally approved tribes in Washington to whom eggs are moved, not sold, under the interlocal cooperation act, chapter 39.34 RCW; and
   - Transfer to another resource manager program such as CCT, YN, or USFWS program;
   - Governmental hatcheries in Washington, Oregon, and Idaho;
   - Placement of fish into a resident fishery (lake) zone, provided disease risks are within acceptable guidelines; or
   - Culling for diseases such as BKD and IHN, consistent with the Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State; or
   - Distribution to approved organizations/projects for research.

F) In the event that a production overage occurs after the above actions have been implemented or considered, and deemed non-viable for fish health reasons in accordance with agency aquaculture disease control regulations (i.e. either a pathogen is detected in a population that may pose jeopardy to the remaining population or other programs if retained or could introduce a pathogen to a watershed where it had not previously been detected) then culling of those fish may be considered.

All, provisions, distributions, or transfers shall be consistent with the department's egg transfer and aquaculture disease control regulations as now existing or hereafter amended. Prior to department determination that eggs of a salmon stock are surplus and available for sale, the department shall assess the productivity of each watershed that is suitable for receiving eggs.

Appendix A 20

1. INTRODUCTION

The Habitat Conservation Plan (HCP) specifies that a monitoring and evaluation plan will be developed for the hatchery program. The approach to monitoring the hatchery programs was guided by the "*Monitoring and Evaluation Plan for PUD Hatchery Programs: 2013 Update*" (Hillman et al. 2013) and the "*Conceptual Approach to Monitoring and Evaluating the Chelan County Public Utility District Programs*" (Murdoch and Peven 2005).

The purpose of this document is to define the tasks associated with the approved scope of work to implement Chelan PUD's (CPUD's) hatchery monitoring and evaluation (M&E) plan for 2018. Additionally, monitoring and evaluation activities for Lake Wenatchee sockeye in 2018 are included in this document. As monitoring tasks are completed in 2017 and are evaluated for their efficacy, methodologies to accomplish the tasks defined in the 2018 Implementation Plan may be modified [with Habitat Conservation Plan's Hatchery Committee (HCP-HC) approval].

The work described in this plan has Endangered Species Act (ESA) coverage provided by NFMS Section 10(a)(1)(A) permits 18121 and 1395 and Section 10(a)(1)(B) permit 1347. All activities conducted under this Implementation Plan shall adhere to all terms and conditions as specified in the referenced permits. These permits allow for changes to monitoring or research protocols with the caveat that such modifications are approved by NMFS prior to implementing those changes. Terms and conditions relevant to monitoring and evaluating the hatchery programs have been used to inform the various measurements below and associated scopes of work with entities performing the work. A report summarizing compliance with the terms and conditions set forth under the above-references permits is required for submittal to NMFS; a copy of this completed report will be provided to the HCP HC.

The Implementation Plan includes all four components of the hatchery M&E Program including: (1) aquaculture monitoring; (2) juvenile monitoring; (3) adult monitoring; and (4) data, analysis and reporting. Under each component are study design elements that will be used to inform the overarching program components. Figure 1 illustrates the relationship of the components and study design elements used to address each component. Table 1 depicts which study design element is being performed by entity, and the associated objectives for each study design element as referred to in Hillman et al. 2013. For Lake Wenatchee sockeye salmon, the proposed M&E activities cover juvenile and adult life history stages and provide the data necessary to track or estimate viable salmonid population parameters (VSP) and is described in Section 6.0.

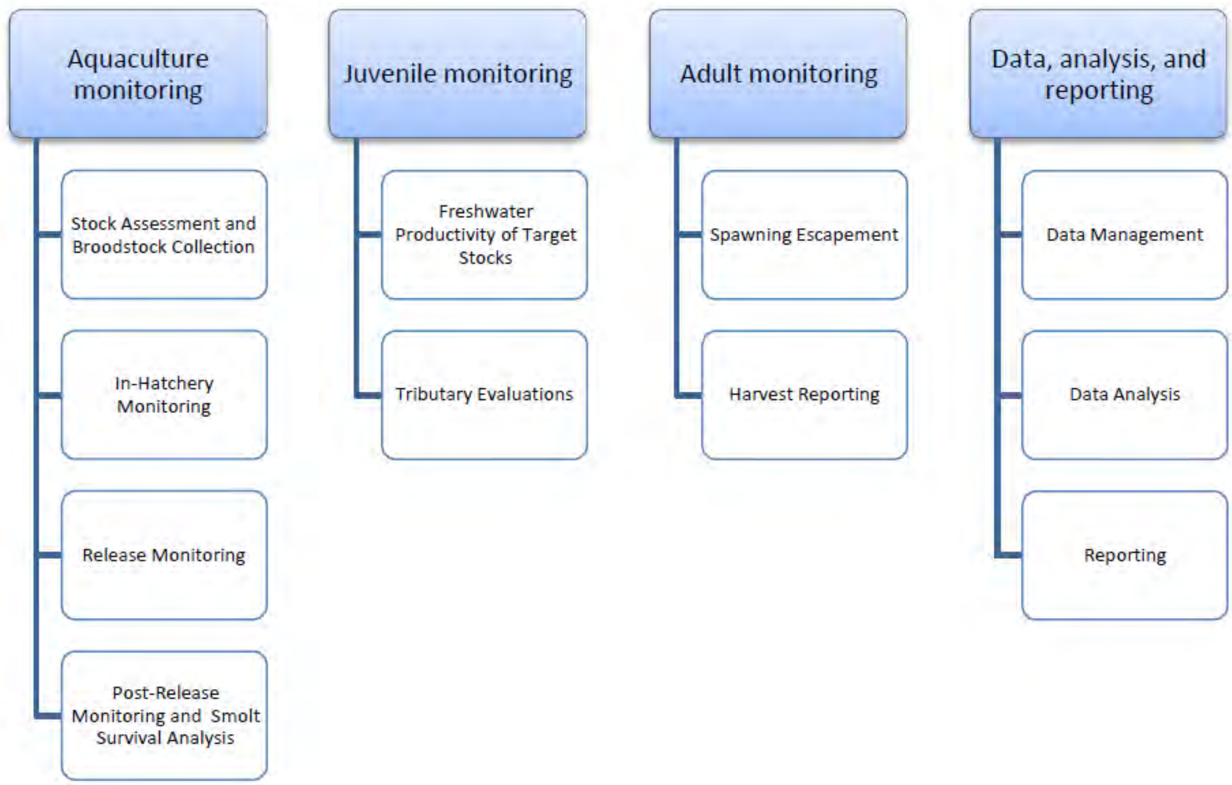

Figure 1. The four components of the hatchery monitoring and evaluation program and the study design elements within each component.

Table 1. Study design elements performed by entity, and the associated objectives for each study design element as referred to in Hillman et al. 2013.

Monitoring and evaluation component	Objectives[1]	Study Design Elements	Chiwawa spring Chinook	Wenatchee summer Chinook	Methow spring Chinook[4]	Chelan Falls summer Chinook[5]	Wenatchee Steelhead

[1] Monitoring questions relative to Objective 7 will be addressed at the next 10 year HCP check-in.
[2]CPUD crews will PIT tag in-hatchery fish.
[3]Biomark will PIT tag in-hatchery fish.
[4]In 2018, monitoring and evaluation for the Methow spring Chinook program is described in “Implementation of Comprehensive Monitoring and Evaluation of Wells Hatchery Complex Programs”.
[5]Because the Chelan summer Chinook program is primarily an augmentation program, monitoring and evaluation efforts focus on straying, release characteristics, and harvest.

2. AQUACULTURE MONITORING

The aquaculture monitoring component is comprised of two basic elements: (1) stock assessment and broodstock collection at adult trapping locations and (2) in-hatchery monitoring including spawning, rearing, and release of juveniles. Data collected during these elements primarily support monitoring questions 5.1.1, 5.2.1, 8.1.1, 8.2.1, 8.3.1, 8.3.2, 8.4.1, 9.1.1, 9.2.1, 9.3.1 and 9.4.1, but also contribute data to monitoring questions 3.2.1, and 3.2.2 (Hillman et al. 2013). Table 2 below provides a summary of the variables to be measured in 2018 under the aquaculture monitoring component and what objective the measure(s) supports. The text that follows in this section further describes the activities.

Table 2. Monitoring and Evaluation Plan (Hillman et al. 2013) objectives and the associated measured variables for the aquaculture monitoring component.

Objectives	**Measured Variables** *(Applicable Study Component(s))*
<u>Objective 3:</u> Determine if the hatchery adult-to adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.	• Number of hatchery and naturally produced fish collected for broodstock (*Broodstock Collection and Stock Assessment*) • Number of broodstock used by brood year (hatchery and naturally produced fish) (*Broodstock Collection and Stock Assessment*)
<u>Objective 5:</u> Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.	• Ages of hatchery and naturally produced fish sampled via PIT tags or stock assessment monitoring (*Broodstock Collection and Stock Assessment*) • Time (Julian date) of ripeness of hatchery and natural origin steelhead captured for broodstock (*Broodstock Collection and Stock Assessment*)
<u>Objective 8:</u> Determine if hatchery programs have caused changes in phenotypic characteristics of the natural populations.	• Size (length), gender, and total/salt age of broodstock (*Broodstock Collection and Stock Assessment*) • Assess age of fish (*Broodstock Collection and Stock Assessment*) • Length, weight, and age (covariate) of hatchery and natural-origin broodstock after eggs have been removed (*Broodstock Collection and Stock Assessment*) • Number and weight of eggs (*Broodstock Collection and Stock Assessment*)
<u>Objective 9:</u> Determine if hatchery fish were released at the programmed size and number.	• Fork length and weights of random samples of hatchery juveniles at release (*Release Monitoring*) • Monthly individual lengths and weights of random samples of hatchery juveniles (*In-Hatchery Monitoring*) • Numbers of smolts released from the hatchery (*Release Monitoring*)

2.1 Broodstock Collection and Stock Assessment

Broodstock collection and stock assessment for Wenatchee summer steelhead, Wenatchee summer Chinook, Methow spring Chinook, Chelan Falls summer Chinook, and Chiwawa River spring Chinook, hatchery programs will, in most instances, occur concurrent to and consistent with the Broodstock Collection Protocol approved annually by the HCP-HC and relevant permits. Data collection during broodstock collection will be consistent with Murdoch and Peven (2005). A representative sample of fish trapped throughout the entire run, either collected for broodstock or released back to the river, will be sampled for origin, age, sex, size, and migration timing. Biological sampling of all fish trapped will include presence of internal (CWT or PIT) and external (VIE) tags or marks, scales, length, and sex (determined by ultrasound). PIT tags will be injected into all target species (Chinook and steelhead), whether collected for broodstock or released back to the river to monitor for potential fallbacks. All non-target species will be enumerated daily. Measures of central tendency and spread will be calculated and reported for each metric.

2.2 In-Hatchery Monitoring

The in-hatchery monitoring component will begin when adult fish are collected and retained for broodstock and ends when juvenile fish are released. Life stage specific in-hatchery survival and growth rates, disease monitoring, and an estimate of the number of fish released will be collected and analyzed according to Murdoch and Peven (2005). Additional data to be collected includes individual lengths and weights of juveniles during monthly sampling, and the weight of gonadal mass and body of spawned broodstock. Measures of the central tendency and spread will be calculated and reported for each metric.

Fish Marking

All of Chelan PUD's hatchery fish will be coded-wire tagged (CWT) and externally marked or marked as otherwise agreed to by the HCP HC. A comprehensive marking strategy will be developed by the HCP-HC and included as an Addendum to this Plan. The identification of these hatchery-produced fish is needed for a suite of adult metrics and may be used for adult management and/or fisheries as contemplated by the co-managers.

Using methods described in Keller and Murauskas (2012), hatchery fish will be PIT-tagged (Table 3) at Eastbank Hatchery approximately two to four weeks before the fish are transferred to acclimation ponds or in the spring prior to release. Additional PIT-tagging may occur for program specific studies/comparisons as approved by the HCP-HC. The data collected from the PIT-tags will assist in release monitoring, migration timing, juvenile survival, and smolt-to-adult survival. For all fish marking, quality control check will be performed during and immediately following tagging and prior to release.

Table 3. Chelan PUD's hatchery program release goals and recommended number of fish PIT tagged.

Program	Release goals	Number of fish PIT tagged[1]	PIT tag rate (%)
Chiwawa spring Chinook	144,026	10,000	6.9
Wenatchee steelhead	247,300	20,000	8.0
Wenatchee summer Chinook	318,816 (CPUD Program) 181,184 (GPUD Program)	20,600	4.1
Methow spring Chinook	60,156	5,000	8.3
Chelan Falls summer Chinook	576,000	10,000	1.7

[1] Additional PIT tagging may take place for Chelan PUD approved studies and/or comparisons.

2.3 Release Monitoring

Hatchery fish will be released during smoltification in the spring, typically between 15 April and 1 June. Whenever possible, the exact release dates will coincide with environmental conditions that promote a rapid emigration that minimizes both the potential negative ecological interactions of hatchery fish with naturally produced fish and predation on hatchery fish by avian or other predators. The default release method will incorporate a volitional approach, as approved by the HCP HC, unless it can be demonstrated other approaches are better. The monitoring data collected for each stock are described below.

Chiwawa and Methow Spring Chinook

Pre-release sampling data will be conducted consistent with Murdoch and Peven (2005), including individual weights to the nearest 0.1 gram. Data collected will support monitoring questions 9.1, 9.2, 9.3 and 9.4 in the updated monitoring and evaluation plan (Hillman et al. 2013). PIT tag monitoring of spring Chinook released in the Chiwawa River will occur during the release period (April). Juvenile Chinook will pass through two 92-cm diameter PIT-tag antennas connected to Allflex 310 readers and Quantitative Sampling Technologies (QST) QuBE data logger. The release location and type (i.e., volitional, forced, or trucked) are recorded for each observation file created and uploaded to the PTAGIS database maintained by the Pacific States Marine Fisheries Commission after each year of release. PIT-tagged fish in each observation (release) file are assumed to represent untagged fish. Observation files contain the PIT tags associated with the original tag files and will be used for analysis (see Post-release Monitoring Section). The total number of fish released will be based on the population size at CWT tagging (100%), subtracting mortality enumerated by hatchery staff that occurred from tagging to release.

Wenatchee Summer Steelhead–

Pre-release sampling will be conducted consistent with Murdoch and Peven (2005), including individual weights to the nearest 0.1 gram. Data collected will support monitoring questions 9.1, 9.2, 9.3 and 9.4 in the updated monitoring and evaluation plan. Monitoring of steelhead released in the Wenatchee River sub-basin will occur during loading of fish into transport trucks, unless fish are released directly into the Chiwawa River. Steelhead will pass through a series of PIT-tag antennas, each connected to a data logger, thereby allowing the creation of a PIT-tag observation file for each truckload of steelhead consisting of unique tag records. The release location (stream and rkm), release type (volitional or forced), and hatchery group (HxH or WxW) will be recorded for each tag file created. PIT-tagged fish in each observation (release) file are assumed to represent untagged fish. However, because PIT-detection efficiency during loading will not be 100%, the number of fish in each truckload will be estimated using volumetric displacement. Observation files contain the PIT tags associated with the original tag files and will be used for analysis (see Post-release Monitoring Section). The total number of fish released will be based on the population size at CWT tagging (100%), subtracting mortality enumerated by hatchery staff that occurred from tagging to release.

Wenatchee and Chelan Falls Summer Chinook

Pre-release sampling will be conducted consistent with Murdoch and Peven (2005), including individual weights to the nearest 0.1 gram. Data collected will support monitoring questions 9.1, 9.2, 9.3 and 9.4 in the updated monitoring and evaluation plan. Should PIT tagging occur, a monitored release strategy consistent with other Chinook stocks (i.e., Chiwawa Spring Chinook) will be implemented. The total number of fish released will be based on the population size at CWT tagging (100%), subtracting mortality enumerated by hatchery staff that occurred from tagging to release.

2.4 Post-Release Monitoring and Survival Analysis

Data will be collected during rearing, acclimation, release, and the emigration period that may prove valuable in explaining variability in adult survival (Murdoch and Peven 2005). Rearing densities have been reported to influence the survival of hatchery fish (Martin and Wertheimer 1989; Banks 1994) and may also be linked to disease prevalence during rearing (Banks 1994; Ogut and Reno 2004). Acclimation of hatchery fish before release has been found to increase survival and reduce stray rates when the duration of the acclimation period is sufficient (Clarke et al. 2010, 2012; Rosenberger et al. 2013). These metrics (i.e., rearing density and acclimation period) will be collected annually to determine their influence on fish survival.

PIT-tagged groups of hatchery fish will be used to estimate survival during their emigration. Variation in survival during the emigration period may also inform observed adult survival rates. Survival during emigration and travel will be estimated using interrogation or release files and the standard Cormack-Jolly-Seber (CJS) estimator. CJS estimates are termed apparent survival estimates because it is unknown whether fish suffered mortality (e.g., size or time of release) or simply failed to emigrate (i.e., residualized or were precocial males). In the latter case, the proportion of PIT-tagged fish detected in the Methow sub-basin, Wenatchee or Columbia rivers after the emigration period is complete may explain variation in smolt survival rates. The post-release performance of PIT-tag groups will be estimated and monitored annually, consistent

with methods in Murdoch and Peven (2005). Additionally, precocity of hatchery releases will be evaluated by examining the proportion of PIT tag releases detected in adult fish ladders and tributaries within the same year as release.

3. JUVENILE MONITORING

Data collected during these elements primarily support monitoring questions 2.1.1 and 2.2.1. and the monitoring objectives described in Table 4 (Hillman et al. 2013). Table 4 below provides a summary of the variables to be measured in 2018 under the juvenile monitoring component and what objective the measure supports. The text that follows in this section further describes the activities.

Table 4. Monitoring and Evaluation Plan (Hillman et al. 2013) objectives and the associated measured variables for the juvenile monitoring component.

Objective	Measured Variables *(Applicable Study Component(s))*
Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.	• Number of juveniles (smolts, parr [where appropriate], and emigrants) (*Freshwater Productivity of Supplemented Stocks*)

3.1 Freshwater productivity of Supplemented Stocks

Steelhead, Spring Chinook, and Summer Chinook

The freshwater productivity of supplemented stocks in the Wenatchee sub-basin will be monitored using smolt traps in the Chiwawa River and the lower Wenatchee River consistent with historical trapping efforts. Additionally, a newly derived analytical method which uses PIT-tag mark-recapture data will be utilized that reduces bias and increases precision by including estimates of emigration during the winter non-trapping periods. Up to 3,000 parr will be PIT tagged in the Chiwawa River in the fall, based on the spatial distribution and abundance estimated during parr snorkel surveys, to generate estimates of migration during the non-trapping periods. A random sample of a minimum of 10 percent of fish per remote site will be held in a live box for 24 hours to evaluate tag loss and delayed mortality. Using PIT tagged parr detections at the lower Chiwawa PIT array during the non-trapping period, the total number of PIT-tagged parr that emigrated will be estimated, and then expanded by the tag rate. Overwinter mortality of PIT-tagged parr is assumed to be the same as non-PIT-tagged parr. Overwinter survival estimates of Chiwawa River parr will be derived by estimating survival to the lower Wenatchee PIT tag array and analyses with the TribPit Survival software program and/or estimating survival of fall parr and spring smolts to McNary. PIT-tag mark-recapture trials conducted during the trapping period in the fall will also be used to estimate detection probabilities of the PIT-tag array at a given discharge level. Abundance and variance will be estimated using the same methods as those used in the smolt trap estimate. The estimated abundance and variance from each method and time period (trapping and non-trapping

periods) will be summed to estimate a total production estimate. Under the proposed methodology, unbiased estimates of abundance during the entire migration period will be generated with relatively high precision (PSE < 15%), which is consistent with NOAA Fisheries' recommendations (Crawford and Rumsey 2011). Historical estimates will be revised using the new estimation techniques.

Specific actions to monitor the freshwater productivity of supplemented spring Chinook salmon in the Methow sub-basin have yet to be determined. As these become available, the plan will be amended and presented to the HC by December.

3.2 Tributary Evaluations

Chiwawa River

Snorkel surveys will be utilized to estimate parr abundance within the Chiwawa subwatershed during the summer. This approach has been used in the Chiwawa subwatershed since 1992. In parallel to addressing Objective 2, additional juvenile data can help to assess the habitat carrying capacity in each tributary. This information can add value to the overall M&E plans and help inform management decisions.

Sampling will follow a stratified random sampling design. Landscape classification will be used to stratify streams in the Chiwawa subwatershed that support juvenile Chinook salmon. In the Chiwawa subwatershed, WDFW found that classification "explained" most of the variability in fish numbers caused by geology, land type, valley bottom type, stream state condition, and habitat type (Hillman 2013). The same classification method was used to identify sections of the Little Wenatchee River (reference area) that corresponded to discrete reaches in the supplemented subwatersheds, but that had no release of hatchery Chinook. Consistent with previous efforts, habitat types within each land-class or reach will be identified and quantified annually. At least three units of each habitat type within each reach will be randomly selected for estimating densities of salmon and trout. Thus, overall sampling consists of a stratified- random sampling design, which increases the accuracy and precision of population estimates.

Densities of salmon and trout will be estimated in August and September by direct underwater observation within the randomly-selected habitat units. Underwater methods will follow those described by Thurow (1994), Dolloff et al. (1996), and O'Neal (2007). Habitat surface areas and volumes will be estimated during fish sampling. Numbers of fish counted will be adjusted for detection probabilities using the models published in Hillman et al. (1992). For each habitat type within a state type and reach stratum, the mean density of salmon and trout will be calculated as the ratio of mean numbers to mean area or volume sampled (Cochran 1977). Total numbers of fish will be estimated per habitat type within a state type and reach stratum as the product of mean density of fish in a given habitat type, times total area or volume of that habitat type within the stratum (Cochran 1977). Total numbers of fish within the supplemented subwatershed will be estimated as the sum of all population numbers per habitat type in state type/reach strata. Bootstrapping methods will be utilized to estimate variance and percent errors (based on 95% confidence interval) for total numbers of fish.

4. ADULT MONITORING

The adult monitoring component is comprised of two basic elements: (1) estimating spawning escapement and (2) harvest monitoring. Data collected during these elements primarily support monitoring questions 1.1.1, 1.2.1, 2.1.1, 2.2.1, 3.2.1, 3.2.2, 4.1.1, 5.1.1, 5.2.1, 5.3.1, 5.3.2, 6.3.1, but also contribute data to monitoring questions 6.1.1, 6.2.1, 8.1.1, 8.2.1, 8.4.1, 10.1.1, 10.1.2, 10.1.3 and 10.1.4. Table 5 below provides a summary of the variables to be measured in 2018 under the adult monitoring component and what objective the measure(s) supports. The text that follows in this section further describes the activities.

Table 5. Monitoring and Evaluation Plan (Hillman et al. 2013) objectives and the associated measured variables for the adult monitoring component.

Objective	**Measured Variables** *(Applicable Study Component(s))*
Objective 1: Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.	• Number of hatchery and naturally produced fish on spawning grounds *(Spawning Escapement Estimates)* • Number of hatchery and naturally produced fish taken for broodstock (*Broodstock Collection and Stock Assessment*) • Number of hatchery and naturally produced fish taken in harvest (if recruitment is to the Columbia) *(Harvest Reporting)*
Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.	• Number of hatchery and naturally produced fish on the spawning grounds (*Spawning Escapement Estimates*) • Number of redds *(Spawning Escapement Estimates)*
Objective 3: Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.	• Number of hatchery and naturally produced fish on spawning grounds *(Spawning Escapement Estimates)* • Number of hatchery and naturally produced fish harvested *(Harvest Reporting)*
Objective 4: Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.	• Number of hatchery and naturally produced fish on spawning grounds *(Spawning Escapement Estimates)*
Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.	• Time (Julian date) of hatchery and naturally produced salmon carcasses or marked steelhead detected on spawning grounds within defined reaches *(Spawning Escapement Estimates)* • Time (Julian date) of arrival at mainstem projects and within tributaries (e.g., traps, PIT arrays) with

Objective	Measured Variables *(Applicable Study Component(s))*
	the intent to identify biologically significant differences *(Spawning Escapement Estimates)* • Location (GPS coordinates) of female salmon carcasses observed on spawning grounds *(Spawning Escapement Estimates)*
<u>Objective 6:</u> Determine if stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.	• Number of hatchery fish collected for broodstock (*Broodstock Collection and Stock Assessment*) • Number of hatchery fish taken in fishery (*Harvest Reporting*) • Locations of live and dead strays (used to tease out overshoot) *(Spawning Escapement Estimates)* • Number of hatchery carcasses (PIT-tagged and/or CWT) found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas (stray data into the Entiat sub-basin will be obtained from USFWS Fisheries Resource Office-Leavenworth) *(Spawning Escapement Estimates)*
<u>Objective 8:</u> Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.	• Total and salt (ocean) age and gender of hatchery and naturally produced salmon carcasses collected on spawning grounds *(Spawning Escapement Estimates)* • Whenever possible, age at maturity and sex ratio will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling or ultrasound on live fish) *(Spawning Escapement Estimates)* • Assess age of fish, including harvested fish *(Spawning Escapement Estimates and Harvest Reporting)*
<u>Objective 10:</u> Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.	• Numbers of hatchery fish taken in harvest *(Harvest Reporting)* • Numbers of natural-origin fish taken in harvest *(Harvest Reporting)*

4.1 Spawning Escapement Estimates

Chelan Summer/Fall Chinook

Chinook spawning ground surveys will be conducted in the Chelan River and (see Appendix A for survey reaches). Spawning ground surveys will be conducted via foot or raft beginning late September and continuing until spawning has ended (usually mid-November). Frequency of surveys will vary depending on method.

Summer Chinook carcass surveys will be conducted in the Chelan River beginning in September and ending in November consistent with methods described in Murdoch and Peven (2005). A representative sample (i.e., 20%) of spawners as determined by spawner abundance and distribution (typically 100% of the carcasses encountered in the Chelan River) will be sampled. Biological data will include collection of scale samples for age analysis, length measurements (POH and FKL), gender, egg voidance, and a check for tags or marks. DNA samples (five-hole punches from operculum) will be collected as needed to address different objectives. These data will be used to assess length-at-age, size-at-age, egg voidance, origin (hatchery or naturally produced), stray rates, and genetics. All carcass surveys will be conducted within the historical reaches.

Wenatchee Steelhead

The number of hatchery and naturally produced steelhead returning to the Wenatchee sub- basin will be estimated using a PIT tag mark recapture model. The estimated spawner abundance for the Wenatchee steelhead population will be a combination of PIT tag-based tributary and redd-based mainstem Wenatchee River estimates. Steelhead redd counts will be conducted weekly in all major spawning areas in the mainstem Wenatchee River (see Appendix A for survey reaches); minor spawning areas in the mainstem Wenatchee River will be surveyed once, based on the spawn timing in adjacent major spawning areas, to estimate redd abundance at peak spawning. The estimated total number of redds in the Wenatchee River mainstem will be expanded by the sex ratio of the population to estimate spawner abundance. Spawner abundance in tributaries of the Wenatchee River will be estimated using a PIT tag mark recapture model.

Chiwawa Spring Chinook

Chiwawa spring Chinook spawning escapement will be estimated based on the total number of redds found in each tributary (Murdoch et al. 2010) using methods described in Murdoch and Peven (2005). Weekly redd and carcass surveys will be conducted simultaneously from the first week of August through September (see Appendix A for survey reaches). Redd-based estimates assume that each female constructs one redd, which WDFW has found to be appropriate for this population (Murdoch et al. 2009). The total number of redds in each reach will be estimated using methods described in Millar et al. (2012) and using the observer efficiency model currently under development by WDFW. Redd counts will be expanded and the number of hatchery and naturally produced fish will be estimated using methods in Murdoch et al. (2010). Carcasses encountered during surveys will be sampled according to methods outlined in Murdoch and Peven (2005). All CWTs (i.e., snout or adipose) from carcasses will be read and the data entered into the Regional Mark Processing Center database within one year of collection.

Additionally, all redds and female carcasses will be geo-referenced using hand-held GPS devices. Carcass recovery bias has been detected in the Chiwawa spring Chinook population (Murdoch et al. 2010) and if not corrected will bias estimates of hatchery and naturally produced fish on the spawning grounds. While it may be appropriate to correct for carcass recovery bias for some monitoring questions (e.g., 2.2), when comparisons to reference populations are made in monitoring questions 1.1.and 1.2, carcass bias will not be corrected because other monitoring programs have not corrected for a similar bias.

Wenatchee Summer Chinook
Wenatchee summer Chinook spawning ground counts will begin the first week in September and continue through the end of spawning in November (see Appendix A for survey reaches). Total census redd counts will be conducted by foot or raft depending on stream size, flow, and density of spawners within the stream reach (see Appendix A for survey reaches). All stream reaches will be surveyed once per week. Redd data will be collected using methods described in Murdoch and Peven (2005). The total number of redds in each reach will be estimated using methods described in Millar et al. (2012) and using the observer efficiency model currently under development by WDFW. Weekly ground-based census counts and the true number of redds (determined via intensive surveys) will be compared in order to generate observer efficiency. River characteristics (e.g., channel width, water depth, discharge, visibility, and habitat complexity), observer experience, and survey effort will be incorporated into a model to predict observer efficiency in all river reaches. Predicted redd generate observer efficiency for each river reach will be used to adjust ground-based redd counts to estimate the total reach redd count. Ground-based surveys will also be used to estimate redd life for each river reach. The estimated spawner abundance in the Wenatchee River and an associated level of precision will be calculated using the estimated total redd count for each reach, mean redd life, and the sex ratio of the population similar to methods described in Millar et al. (2012). Salmon carcass data collected during spawning ground surveys will be consistent with Murdoch and Peven (2005). All CWTs (i.e., snout or adipose) from carcasses will be sent to the WDFW lab in Olympia. The CWT lab will extract and read CWTs and submit all required information to RMIS within one year of collection.

4.2 Harvest Reporting
In years when the expected hatchery adult returns are in excess of the levels needed to meet the hatchery program goals (i.e., broodstock and/or escapement), surplus fish may be available for harvest. Harvesting or removal of surplus hatchery fish may have benefits to the natural populations by reducing potential negative ecological and genetic impacts (e.g., density dependent effects, loss of fitness, and loss of genetic variation). The contribution of hatchery fish to fisheries will be monitored using CWT recoveries on a brood-year basis supporting Objective 10.

To obtain the necessary data to determine if the harvest rates are meeting objectives, a statistically valid creel program will be designed and implemented for all sport and/or conservation fisheries in the Upper Columbia River to estimate harvest of hatchery fish from

both Chelan and Grant County PUD funded hatchery programs (Murdoch and Peven 2005). Information collected during creel surveys are an integral component to calculating the HRR (Objective 3), particularly given most CWT recoveries for PUD mitigation programs occur in the Upper Columbia River and its tributaries, with the exception of summer Chinook where most CWT recoveries occur in ocean fisheries. Because of considerable time lags in reporting of CWT's to the Regional Marking Information System (RMIS) database, it requires an ongoing query of recovery data until the number of estimated fish does not change.

5. Data Management , Analysis, and Reporting

5.1 Data Management

A Microsoft Access database maintained by WDFW will contain all the monitoring data collected for hatchery evaluations. The database will contain and manage all data associated with aquaculture monitoring, juvenile monitoring, and adult monitoring.

All data entered into the database are evaluated for quality control and quality assurance by WDFW. Quality control checks using analyses such as modified Z-scores, boxplots, and the Generalized Extreme Studentized Deviate Procedure (Iglewicz and Hoaglin 1993) will be conducted for all data entry. In the event outliers are identified, discussion will occur on whether identified outliers are true data points or transcription errors. This process ensures that the data used to test statistical hypotheses are correct and accurate.

5.2 Data Analysis

The analyses proposed are consistent with the Monitoring and Evaluation Plan for PUD Hatchery Programs: 2013 Update (Hillman et al. 2013). Each of the objectives will be addressed using the appropriate statistical tests, as well as graphic analyses that convey relevant information.

5.3 Reporting

An annual M&E report will be generated following the completion of each calendar year and will be available for HCP-HC review by June 1 of the following year. Additionally, monthly progress reports will be made available to the HCP-HC.

6. Lake Wenatchee Sockeye Salmon

The Chelan PUD will conduct monitoring and evaluation (M&E) activities to track key population attributes related to Lake Wenatchee sockeye salmon in 2018(Table 6). In the absence of a sockeye hatchery program, M&E activities are no longer rooted in the context of evaluating the effects of sockeye salmon supplementation, but instead focus directly on the performance of the natural population, which is a unique departure from historic monitoring obligations. Broadly, the proposed M&E activities cover juvenile and adult life history stages and provide the data necessary to track or estimate viable salmonid population parameters (VSP): abundance, productivity, spatial structure and diversity (McElhaney et al. 2000). The data collected may also have utility in future hatchery compensation recalculation efforts.

Chelan PUD is conducting these M&E activities to support commitments made under the 2011 hatchery recalculation effort, which also included a steelhead production commitment for a sockeye species swap (SOA 2011). This section of the implementation plan describes the specific commitments by juvenile and adult life history stages.

6.1 Juvenile Monitoring

Chelan PUD will conduct or fund activities to monitor and evaluate the temporal distribution and age/size of out-migrating smolts, and estimate smolt production (Table 6). Smolt production will be estimated from data collected at the lower Wenatchee smolt trap and via back calculations based on collected adult return data (i.e., age-at-return estimates, SARs, and adult escapement to the tributaries). Collectively, these activities include: (1) funding of the lower Wenatchee River smolt trap concurrent with efforts aimed at evaluating Chelan PUD funded supplemented populations in the Wenatchee River sub-basin; (2) tagging up to 5,000 PIT tags for natural-origin juveniles encountered during smolt trapping activities and collecting scale samples at this location; and (3) estimating adult escapement estimates to the tributaries, and collection of adult return data at Tumwater (see the *Adult Monitoring* section for details) to back-calculate smolt production.

The monitoring data obtained will provide a useful set of tools for evaluating the performance of natural origin sockeye salmon within the sub-basin and downstream and also support the evaluation of VSP parameters [e.g., outmigration timing and size (diversity); and PIT tagging juveniles for SAR estimates (productivity)].

6.2 Adult Monitoring

Several M&E activities associated with adult returns of Lake Wenatchee sockeye salmon will be conducted and/or funded by Chelan PUD (Table 6). These efforts include (1) continuation of accurate adult counts at Rock Island, Rocky Reach, and Tumwater dams; (2) sampling of scales for age distribution, sex ratio determination, and returns of PIT-tagged adults at Tumwater Dam; (3) reach-specific conversion estimates between Rock Island Dam and spawning grounds in the White and Little Wenatchee rivers (i.e., Rock Island to Tumwater Dam to spawning tributaries); and (4) providing between 250 to 1,000 PIT tags to estimate adult spawning escapement in the Little Wenatchee and White rivers utilizing PIT tags and mark-recapture techniques (the software program Sample Size 2.0.7, developed by the University of Washington School of Aquatic and Fisheries Science (P. Westhagen, J. Lady, and J. Skalski) was used to determine the minimum number of tags required (i.e., 250) to estimate adult sockeye escapement at a +/- 7 percent confidence interval). Chelan PUD will adjust the number of PIT-tagged individuals in order to maintain precision in estimates at the lowest rate of interference to migrating populations, if it is warranted due to annual changes in escapement and detection probabilities. In an effort to PIT tag the run at large, adults will be PIT tagged at Tumwater consistent with the Tumwater Operations Protocol, daily throughout the run.

Collectively, these data will provide reliable metrics of adult returns and spawning escapement (abundance), recruits-per-spawner (productivity), distribution of spawners among tributaries (spatial structure), and run-timing and age structure for adult immigrants (diversity).

Table 6. Chelan PUD's proposed Lake Wenatchee sockeye salmon monitoring and evaluation activities.

Life History Stage	M&E Activity	Entity Performing the Activity	Related analysis	VSP parameter addressed
Juvenile	Concurrent operation of the lower Wenatchee smolt trap to collect juvenile outmigration data	WDFW	Generate distribution of outmigration timing, estimate smolt production and determine average smolt size.	Diversity and productivity
Juvenile	PIT tagging smolts at lower Wenatchee smolt trap (up to 5,000 fish annually) and collecting/aging scale samples	WDFW	Estimate smolt-to-adult returns.	Productivity
Juvenile	Develop adult return based smolt production estimates	WDFW	Use collected data (i.e., adult age-at-return data, SARs, adult escapement to the tributaries) to back-calculate smolt production.	Productivity
Adult	Rock Island and Rocky Reach Dam adult counts	CPUD	Initial spawner abundance (Okanogan stock separation)	Abundance and spatial structure
Adult	PIT tag subsample (250 adults) of returning adults at Tumwater Dam to support mark-recapture evaluation	WDFW	Calculate spawner abundance and relative distribution among ~~in~~ tributaries	Abundance and spatial structure
Adult	Collect and age scales[1] and determine sex via ultrasound from returning adults at Tumwater Dam	WDFW	Estimate age-at-return, sex ratio, and relative productivity of contributing spawner cohorts	Productivity and diversity
Adult	Tumwater Dam adult counts	WDFW	Estimate potential spawner abundance (pre Lake-Wenatchee harvest), potential productivity (recruits/spawner), and run timing distribution	Abundance and diversity
Adult	Operate PIT detection arrays on Little Wenatchee and White River	WDFW	Calculate spawner abundance (post-Lake Wenatchee harvest and other mortality), actual productivity (recruits/spawner), and entry-to-spawning-habitat timing distribution, and spatial spawner distribution among tributaries	Abundance, productivity, spatial structure, and diversity
All	Data management, analysis, and reporting	BioAnalysts CPUD	------	NA

[1] Scales would be collected concurrently from adults that are PIT tagged at Tumwater Dam.

Appendix A

Designated survey reaches for Methow subbasin summer Chinook spawning ground surveys.

River	Reach	Code	RM
Methow	Mouth to Methow Bridge	M1	0.0-14.78
	Methow Bridge to Carlton Bridge	M2	14.78-27.17
	Carlton Bridge to Twisp Bridge	M3	27.17-39.55
	Twisp Bridge to MVID	M4	39.55-44.85
	MVID to Winthrop Bridge	M5	44.85-49.80
	Winthrop Bridge to Hatchery Dam	M6	49.80-51.55

Designated survey reaches for Wenatchee River basin summer Chinook spawning grounds surveys. Asterisks denotes reaches where redd observer efficiency will be assessed.

Reach Code	Reach Section	River Mile
W10	Lake Wenatchee to Bridge	54.20-53.58
	Bridge to Swamp *	53.58-52.66
	Swamp to Chiwawa River	52.66-48.39
W9	Chiwawa River to Schugart Flats	48.39-47.93
	Schugart Flats to Old Plain Bridge	47.93-46.21
	Old Plain Bridge to RR Bridge	46.21-41.91
	RR Bridge to RR Tunnel	41.91-39.28
	RR Tunnel to Swing Pool *	39.28-36.67
	Swing Pool to Tumwater Br	36.67-35.55
W8	Tumwater Br to Swiftwater Campground *	35.55-33.50
	Swiftwater Campground to Unimproved Campground	33.50-33.08
	Unimproved Campground to Tumwater Dam	33.08-30.91
W7	Tumwater Dam to Penstock Br	30.91-28.66
	Penstock Br to Icicle Road Br *	28.66-26.43
W6	Icicle Road Br to Icicle Mouth	26.43-25.61

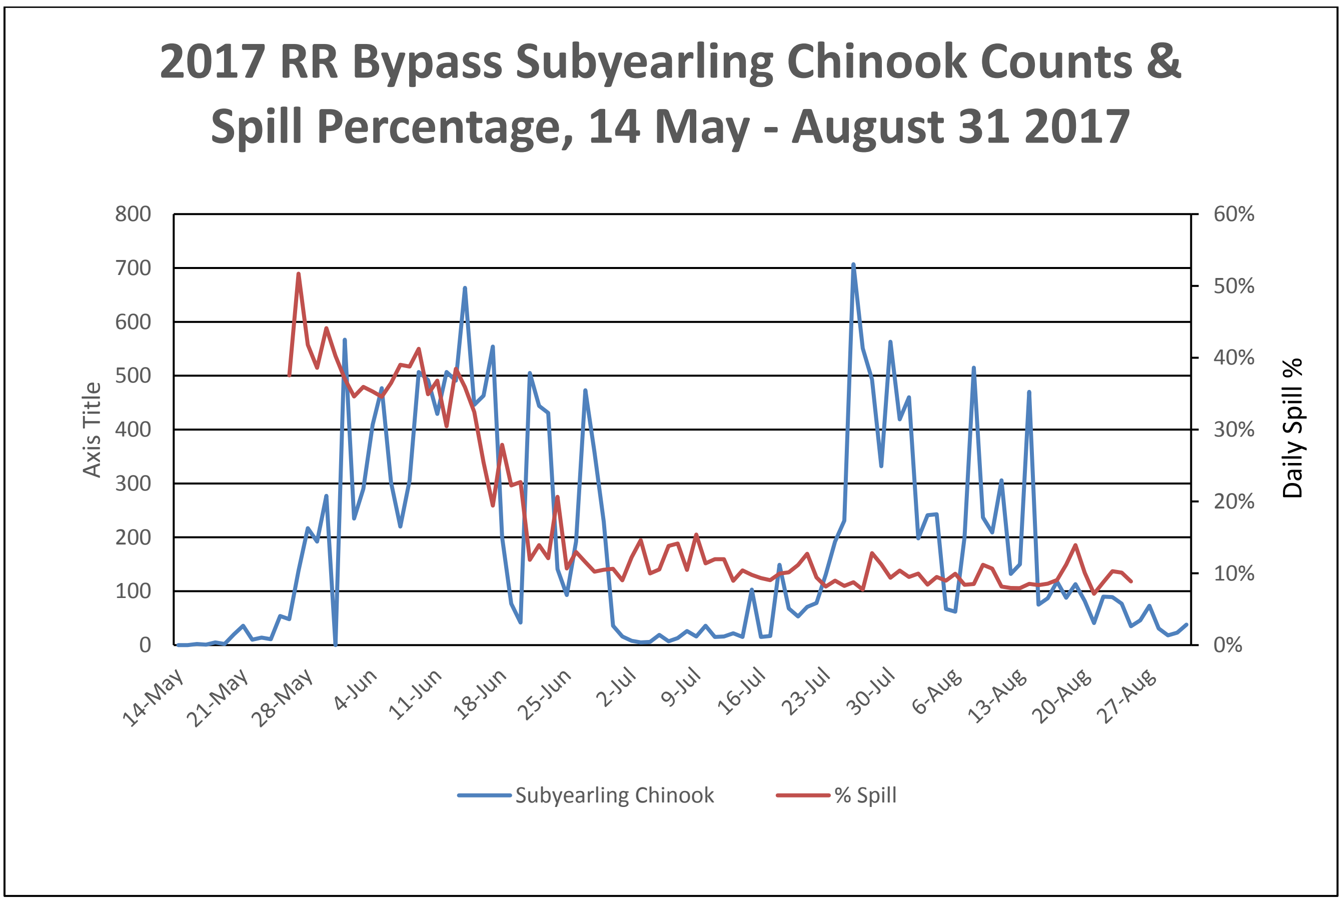
Chelan PUD Rocky Reach and Rock Island HCPs Final 2017 Fish Spill Report

Chelan PUD
Rocky Reach and Rock Island HCPs
Final 2017 Fish Spill Report

2017 ROCKY REACH
Summer Spill

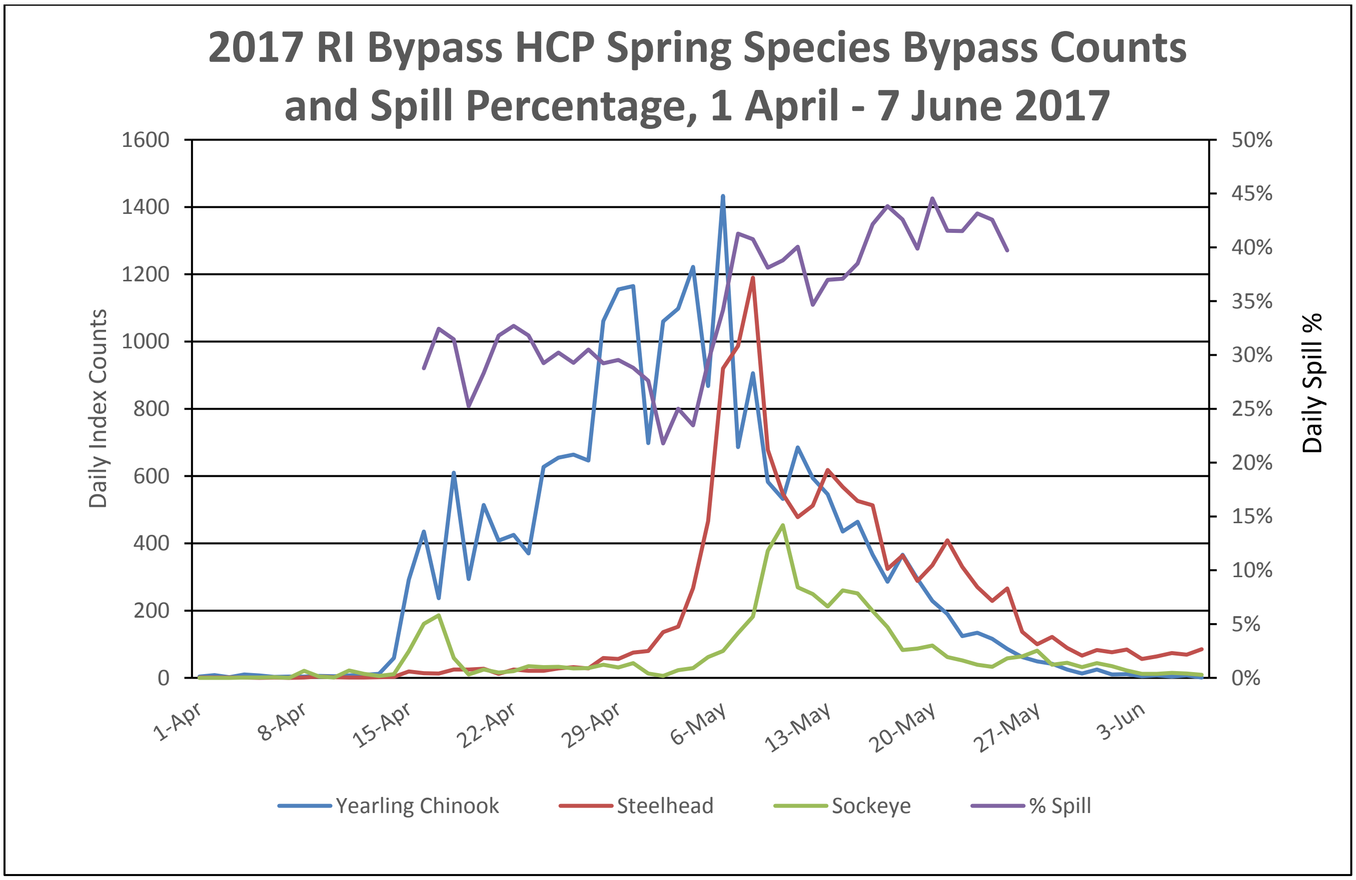
Target species:	Subyearling Chinook
Spill target percentage:	9% of day average river flow
Spill start date:	26 May, 0001 hours
Spill stop date:	25 August, 2400 hours
95% Est. passage date:	14 August
Percent of run with spill:	98.5% on 25 August (estimated as of 31 August)
Cumulative index count:	27,404 subyearling Chinook (as of 31 August)
Summer spill percentage:	21.74% (9.06% fish spill, plus 12.68% forced spill)
Avg river flow at RR:	149,598 cfs (26 May - 25 August)
Avg spill rate at RR:	32,518 cfs (26 May - 25 August)
Total spill days:	92



2017 ROCK ISLAND

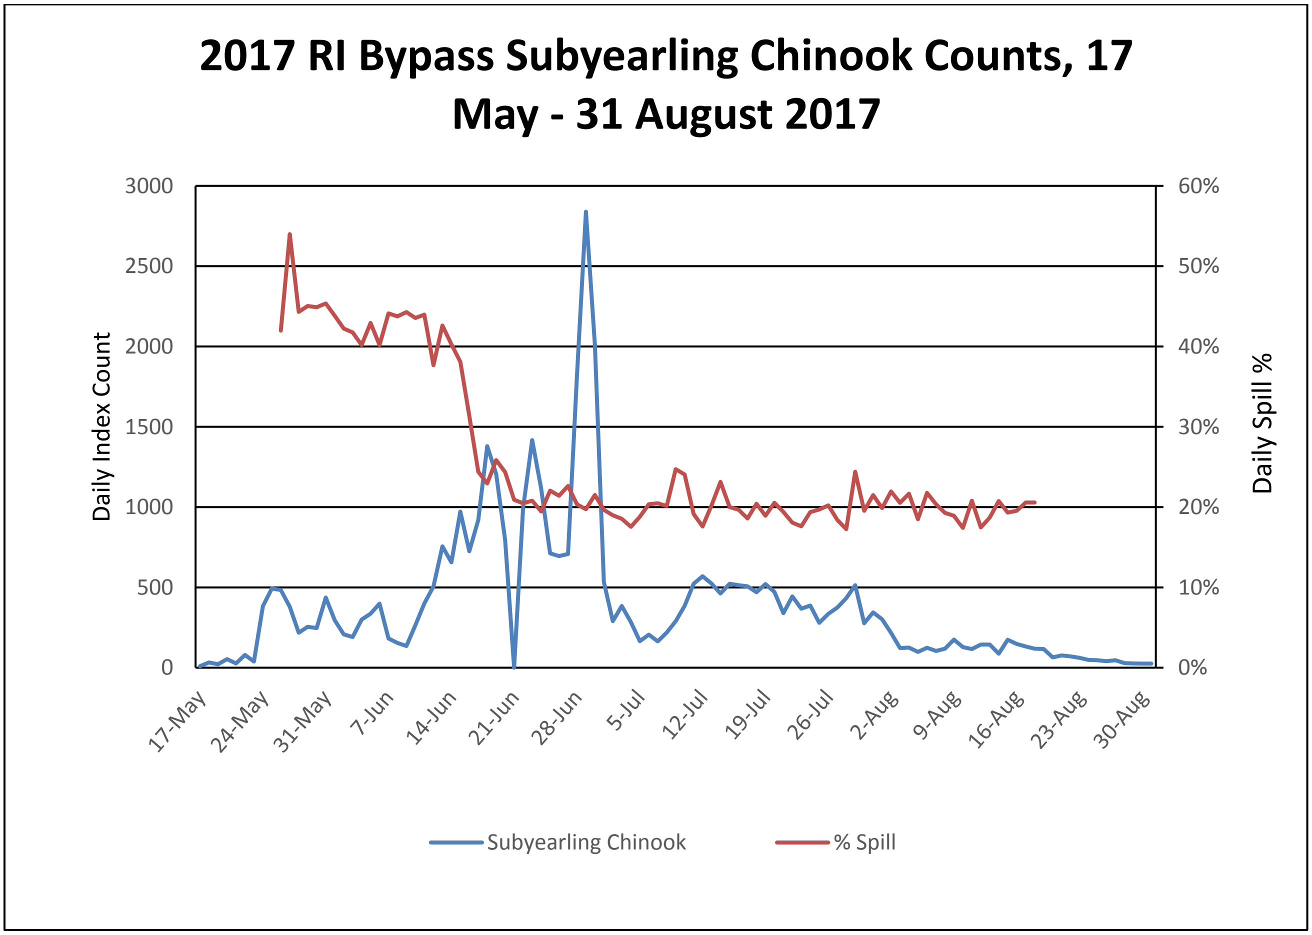
Spring Spill

Target species:	Yearling Chinook, steelhead, sockeye
Spill target percentage:	10% of day average river flow
Spill start date:	16 April, 0001 hours
Spill stop date:	25 May, 2400 hours (immediate increase to 20% summer spill)
Percent of run with spill:	Yearling Chinook – 98.4%; steelhead – 99.8%; sockeye – 97.0% (spring and summer fish spill combined)
Cumulative index count:	50,604 yearling Chinook; 32,135 steelhead; 11,117 sockeye (as of 31 August)
Spring spill percentage:	35.22% (9.69% fish spill, plus 25.53% forced spill)
Avg river flow at RI:	227,790 cfs (16 April – 25 May)
Avg spill flow at RI:	80,222 cfs (16 April – 25 May)
Total spill days:	40



Summer Spill

Target species:	Subyearling Chinook
Spill target percentage:	20% of day average river flow
Spill start date:	26 May, 0001 hours
Spill stop date:	18 August, 2400 hours
95% Est. passage date:	5 August
Percent of run with spill:	97.5% on 18 August (estimated as of 31 August)
Cumulative index count:	63,579 subyearling Chinook (as of 31 August)
Summer spill percentage:	29.47% (19.89% fish spill, plus 9.58% forced spill)
Avg river flow at RI:	162,085 cfs (26 May - 18 August)
Avg spill flow at RI:	47,774 cfs (26 May - 18 August)
Total spill days:	85



Juvenile Index Counts 2007-2017 from the Rocky Reach Juvenile Fish Bypass Sampling Facility and Rock Island Bypass Trap Smolt Monitoring Program (SMP) 1 April – 31 August (Tables 1 and 2).

SECTION 1: INTRODUCTION

This document is an update of the monitoring and evaluation (M&E) plan of the salmon and steelhead hatchery programs funded by Douglas, Chelan, and Grant County Public Utility Districts (PUDs). Programmatic changes, evaluation of data collection methods, and M&E results from the past several years, along with shifting management paradigms affect M&E needs, all of which have occurred under advancing fish culture and monitoring techniques. As required by the programs, this document is a result of a five-year review intended to expand on and coalesce previous M&E documents (BAMP 1998; Cates et al. 2005; Murdoch and Peven 2005; Hays et al. 2006; Pearsons and Langshaw 2009a, 2009b; Hillman et al. 2013) with inclusion of new information.

Fishery management agencies developed the following general goal statements for hatchery programs, which were adopted by the HCPs Hatchery Committees and PRCC Hatchery Sub-Committee (hereafter, Hatchery Committees):

1. Support the recovery of ESA-listed species by increasing the abundance of the natural adult population, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity.
2. Increase the abundance of the natural adult population of unlisted plan species, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity. In addition, provide harvest opportunities in years when spawning escapement is sufficient to support harvest.
3. Provide salmon for harvest and increase harvest opportunities, while segregating returning adults from natural tributary spawning populations.

Following the development of Hatchery and Genetic Management Plans (HGMPs), artificial supplementation programs are now characterized into three categories. The first type, integrated conservation programs, are intended to support or restore natural populations. These programs focus on increasing the natural production of targeted fish populations. A fundamental assumption of this strategy is that hatchery fish returning to the spawning grounds are reproductively similar to naturally produced fish. The second type, safety-net programs, are extensions of conservation programs, but are intended to function as reserve capacity for conservation programs in years of low returns. The safety-net provides a demographic and genetic reserve for the natural population. That is, in years of abundant returns they function like segregated programs, and in low return years they can be managed as conservation programs. Lastly harvest augmentation programs are intended to increase harvest opportunities while limiting interactions with wild-origin counterparts.

Monitoring is needed to determine if the hatchery programs are meeting the intended management objectives of conservation, safety-net, or harvest augmentation programs. Objectives for hatchery programs are generally grouped into three categories of performance indicators:

1. In-Hatchery: Is the program meeting the hatchery production objectives?
2. In-Nature: How do fish from the program perform after release?
    a. Conservation Program:

- How does the program affect target population abundance and productivity?
- How does the program affect target population long-term fitness?

b. Safety-Net Program:

- How does the program affect target population long-term fitness?

c. Harvest Augmentation Program:

- Does the program provide harvest opportunities?

3. Risk Assessment: Does the program pose risks to other populations?

Objectives in this plan have been organized in a hierarchy where productivity indicators are the primary metrics used to assess if conservation and safety-net program goals have been met; harvest rates and effects on non-targeted populations are used for harvest programs. In cases where productivity indicators are not available or results are equivocal, monitoring indicators may be used to help evaluate the performance of the program. Evaluations of monitoring indicators may not provide sufficiently powerful conclusions on which to base management actions, although they may provide insight as to why a productivity indicator did or did not meet the program goal. Therefore, the relationship between hatchery programs and indicators can be viewed in a chain-of-causation: management actions within the hatchery programs affect the status of monitoring indicators, which in turn influence productivity indicators (Figure 1).

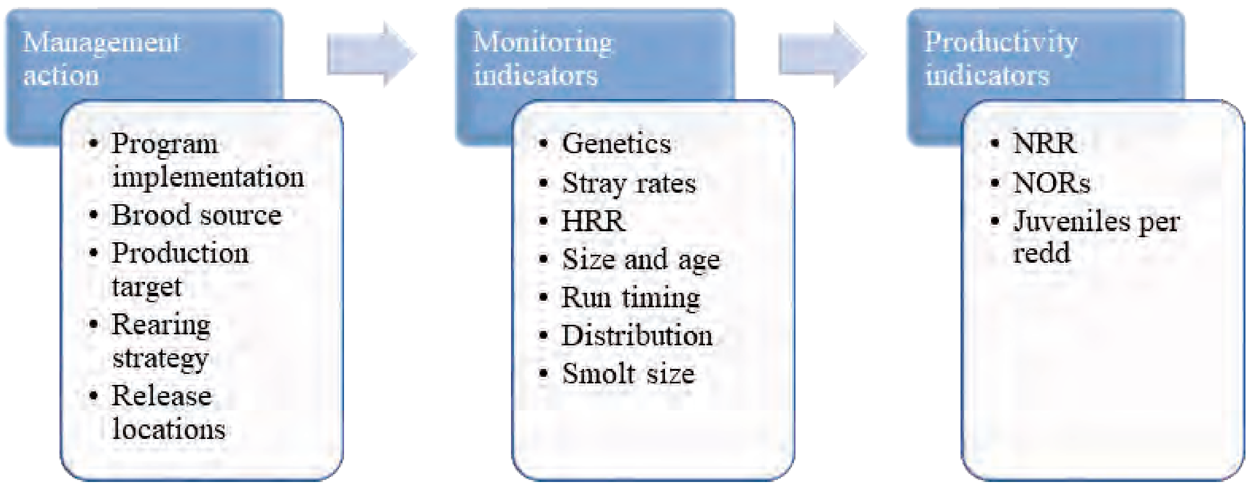

Figure 1. Relationship of indicators to the assessment of supplementation programs. Management actions affect monitoring indicators, which influence productivity indicators. Monitoring indicators may be used to hypothesize the magnitude of influence on productivity.

The primary goal of a conservation program is to contribute to the rebuilding and recovery of naturally reproducing populations within their native habitat. In this plan, natural replacement rates (NRR), recruitment of naturally-produced fish (NOR), and juvenile productivity (juveniles per redd) are important indicators for assessing the success of supplementation. These indicators are difficult to measure precisely and are quite variable in space and time. Therefore, monitoring indicators can be evaluated to help assess if productivity was related to the hatchery programs or other factors (Table 1).

Table 1. Program objectives, indicators, and goals for conservation hatchery programs including productivity and monitoring indicators (also applies to safety-net programs when used to support a conservation program).

	Objective	Indicator	Target	Program goals: Rebuild natural populations	Program goals: Maintain genetic diversity	Program goals: Opportunity for harvest
Productivity indicators	Determine if the program has increased the number of naturally spawning adults	Abundance of natural spawners	Increase	✓		✓
		Adult productivity (NRR)	No decrease	✓		
	Determine if the proportion of hatchery fish affects freshwater productivity	Residuals vs. pHOS	No relationship	✓		
		Juveniles per redd vs. pHOS	No relationship	✓		
Monitoring indicators	Determine if run timing and distribution meets objectives	Migration timing	No difference	✓	✓	
		Spawn timing[1]	No difference	✓	✓	
		Redd distribution[2]	No difference	✓	✓	
	Determine if program has affected genetic diversity and population structure	Allele frequency (hatchery vs. wild)	No difference		✓	
		Genetic distance between populations	No difference		✓	
		Effective population size	Increase		✓	
		Age and size at maturity	No difference		✓	
	Determine if hatchery survival meets expectations	HRR	HRR > NRR	✓		
		HRR	HRR ≥ Goal[3]	✓		
	Determine if recipient stray rate of hatchery fish is acceptable	Out of basin	≤ 5%	✓	✓	
		Within basin	≤ 10%	✓	✓	
	Determine if hatchery fish were released at program targets	Size and number	= Target[4]	✓		
	Provide harvest opportunities when appropriate	Harvest	Escapement goals			✓

[1] Hatchery and natural-origin fish should spawn at the same time across the range of elevations within the spawning distribution of each stock.

[2] Hatchery and natural-origin fish should spawn in the same locations. Exceptions are the Carlton and Dryden Summer Chinook programs (see Appendix 4).

[3] HRR targets are identified in Appendix 2.

[4] Number and size targets are identified in Table 3 and Appendix 5.

A flow of information following sequential, logical steps will be employed to evaluate supplementation programs, consistent with the indicators described in Table 1. For example, a hatchery program, at a minimum, must be able to produce more adults per spawner than would occur in the natural environment. Should the program fail this test, hatchery operations should be evaluated to determine if improvements can correct the problem. If a program successfully replaces the required number of adults, it is then evaluated against a reference population or condition, if available, to determine if it has increased the overall number of naturally spawning fish (including both hatchery- and natural-origin adults), increased the number of natural-origin spawners, and to test if productivity of the natural population has changed. When these goals are met, the program is considered successful. When these goals are not met, monitoring indicators may infer why the program is not achieving its goals

If suitable reference populations are not available, other comparisons can be used to help evaluate treatment responses. Evaluation of programs may pursue the following approaches:

- Comparison to reference population(s) that do not contain pre-treatment data.
- Before treatment and after treatment comparisons.
- Comparison to standard(s).
- Comparison to other suitable reference conditions.

Methodologies for selecting reference streams, analyzing data from treatment and reference stream comparisons, and other comparisons are presented in Hillman et al. (2012) (see Appendix 6).

The primary goals of a safety-net program are to provide demographic and genetic reserves for a population that is supplemented by a conservation program (Table 2). Harvest and adult management may be used to control escapement of spawners when appropriate. Monitoring focuses on estimating the number of fish that escape to spawn naturally and stray rates and in-hatchery performance evaluation.

Table 2. Program objectives, indicators, and goals for segregated harvest augmentation hatchery programs including monitoring indicators.

	Objective	Indicator	Target	Program goals: Rebuild natural populations	Program goals: Maintain genetic diversity	Program goals: Opportunity for harvest
Monitoring indicators	Determine if hatchery survival meets expectations	HRR	HRR > NRR			✓
		HRR	HRR ≥ Goal[1]			✓
	Determine if stray rate of hatchery fish is acceptable	Out of basin	≤ 5%		✓	
		Within basin	≤ 10%		✓	
	Determine if hatchery fish were released at program targets	Size and number	= Target[2]			✓
	Provide harvest opportunities when appropriate	Harvest	When greater than escapement goals			✓

[1] HRR targets are identified in Appendix 2.

[2] Number and size targets are identified in Table 3 and Appendix 5.

The primary goal of a harvest augmentation program is to increase harvest opportunities, while segregating adults from natural spawning populations. In this plan, harvest opportunity, survival rates, and stray rates are important indicators for assessing the success of harvest augmentation. These indicators are more readily quantified compared to productivity indicators (Table 2). A flow of information will be employed to evaluate harvest augmentation programs. Since harvest augmentation programs are typically segregated, monitoring indicators will be used to determine the success of a program.

Both monitoring and productivity indicators will be used to evaluate the success of hatchery programs. In the event that the statistical power of tests that involve productivity indicators is insufficient to inform sound management decisions, some of the monitoring indicators may be used to guide management. Figure 2 show the categories of indicators associated with each component of monitoring.

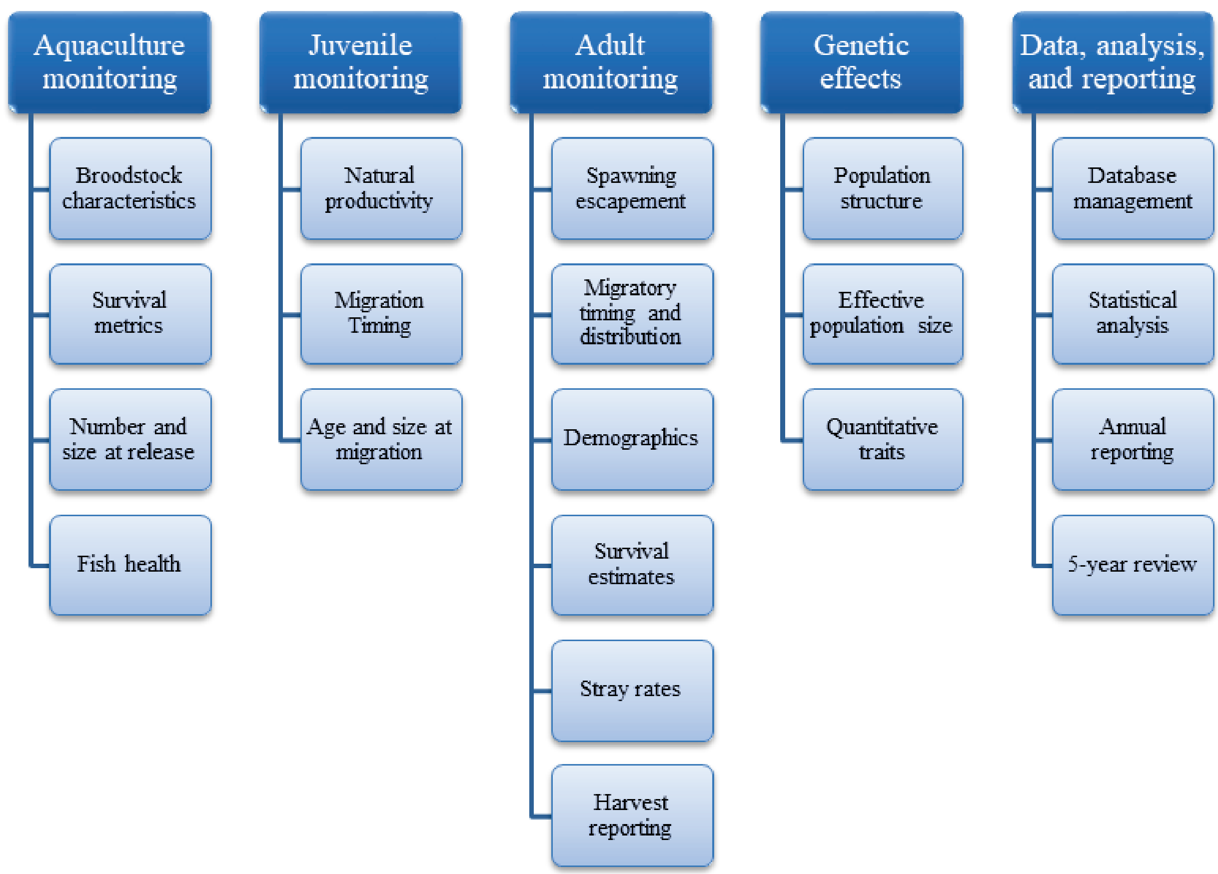

Figure 2. Overview of Monitoring and Evaluation Plan Categories and Components (not including regional objectives).

The overarching goals of conservation, safety-net, and harvest augmentation programs, as described above, are shown in detail in Figure 3. The flow chart (Figure 3) shows the relationship of overarching program goals, the strategies used to meet the goals, the monitoring and evaluation objectives used to evaluate the strategies and determine if goals are being met, and the adaptive

management cycle associated with the programs (see Tables 1 and 2 for the indicators under each objective). The logic depicted in this flow chart shall be used to assess M&E results and apply those results to management decisions. Table 3 presents the current hatchery programs releasing fish in the Upper Columbia Basin.

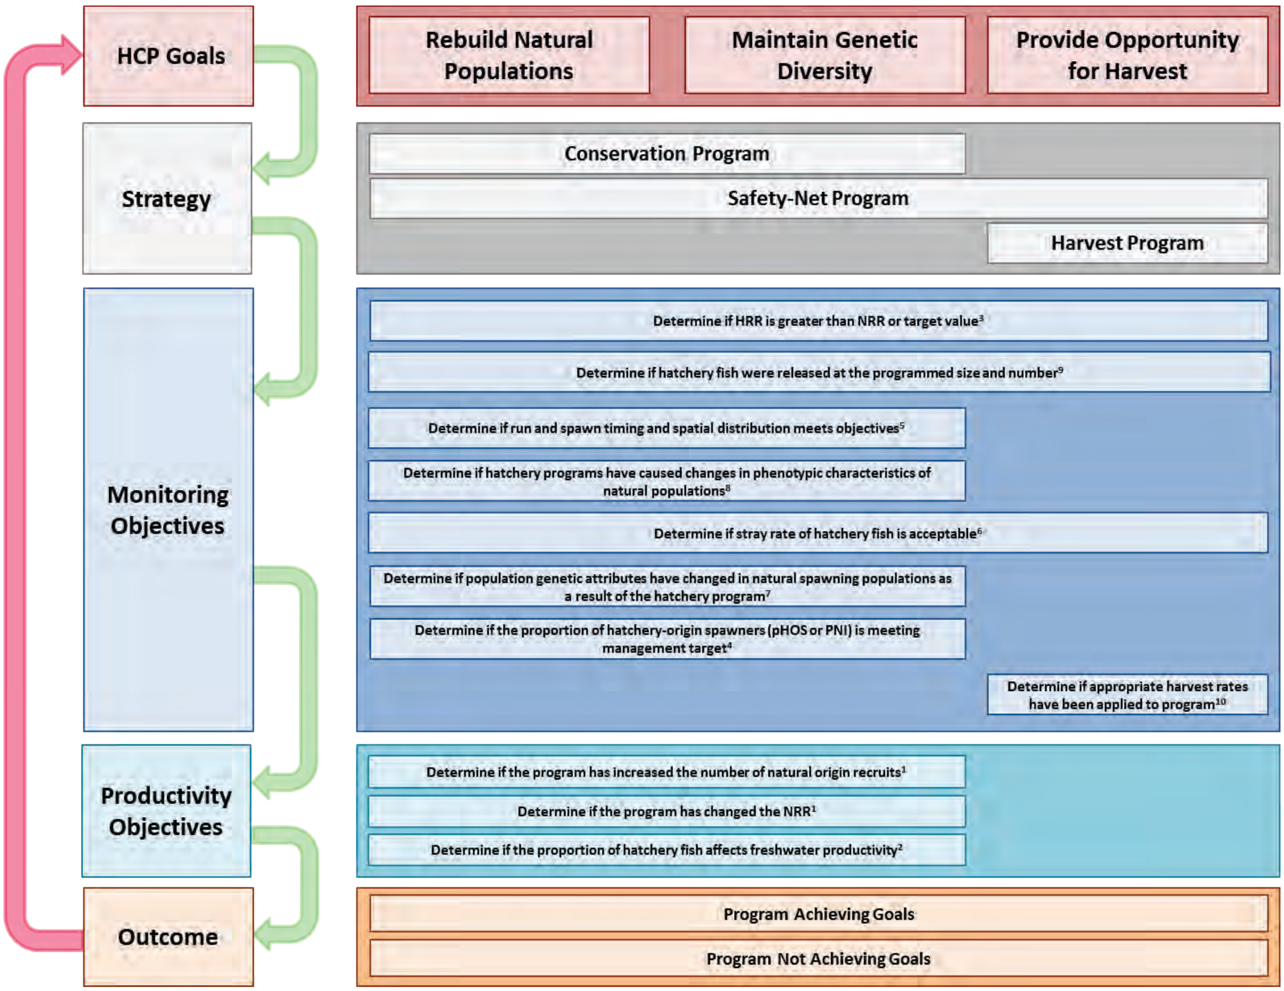

Figure 3. Adaptive management flow chart depicting HCP goals, associated strategies to meet the goals, the monitoring and evaluation objectives (indicated in superscript), and the adaptive management feedback cycle. The strategies, objectives, and outcomes are aligned vertically under the corresponding goals.

Table 3. Hatchery programs in the mid-Columbia River Basin, 2012. Funding entities included Douglas PUD (D), Chelan PUD (C), Grant PUD (G), Bonneville Power Administration (B), Bureau of Reclamation (O), and Army Corps of Engineers (A) and are listed in order of contribution. Total artificial production targets in the mid-Columbia River exceeds 20 million juveniles annually.

[6] Program also partially covered by CCT M&E Plan.
[7] Program affects PUD-funded programs covered by this plan.
[8] Planned to increase to 1,000,000.
[9] Part of the Mitchell Act suite of mitigation programs under the FCRPS BiOp.

SECTION 2: ADULT PRODUCTIVITY

2.1 Natural Replacement Rates of Supplemented Populations[1]

Objective 1: **Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.**

At the core of a conservation program is the objective of increasing the number of spawning adults (i.e., the combined number of naturally produced and hatchery fish) in order to affect a subsequent increase in the number of returning naturally produced fish or natural-origin recruits (NOR). In order for the natural population to remain stable or to increase, the Natural Replacement Rate (NRR), or the ratio of NORs to the parent spawning population, must be at a level where parents are being replaced by their offspring as spawners in the next generation. It is possible to affect an increase in natural-origin spawners through supplementation with a stable or decreasing NRR. However, if the NRR is below replacement (NRR<1.0), termination of the supplementation program will result in a declining natural population should that state of NRR persist. The proportion of the hatchery-origin spawners (pHOS) that will increase natural production without creating adverse effects to the genetic diversity or reproductive success rate of the natural population is unknown, and may be dependent on how individual hatchery programs are operated, as well as available spawning and rearing habitat. Some programs restrict pHOS to reduce the risk to the natural population with the intent of optimizing productivity, concomitantly reducing the overall number of spawners. All other objectives of the M&E Plan either directly support this objective or seek to minimize negative effects of the conservation programs on non-target stocks of concern.

Differences in carrying capacities of supplemented and non-supplemented streams can confound the analysis of the effects of supplementation on total number of spawners returning to the streams. For example, if the supplemented population is at carrying capacity and the non-supplemented population is not, the total number of spawners returning to the non-supplemented population may show an increasing trend over time, while the supplemented population would show no increasing trend. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on total spawners, density corrections should be included in the analyses. Hypotheses that may require density corrections are noted under each monitoring question. Appendix 1 describes methods for estimating carrying capacities.

Monitoring Questions:

Q1.1.1 Has the supplementation program changed the adult productivity (NRRs) of the supplemented populations?[2]

Target Species/Populations:

[1] Supplementation programs may include a safety-net component.

[2] Because adult productivity is affected by the abundance of the population (i.e., productivity decreases with increasing abundance), the goal of supplementation is to increase or maintain productivity, but not decrease it.

- Q1.1.1 applies to all conservation and safety-net stocks.

Statistical Hypotheses 1.1.1[3]:

- $Ho_{1.1.1.1}$: Slope in NRRs before supplementation ≤ slope in NRRs after supplementation.
- $Ho_{1.1.1.2}$: Differences in slopes in NRRs between supplemented and reference populations before supplementation ≤ differences in slopes in NRRs between supplemented and reference populations after supplementation.
- $Ho_{1.1.1.3}$: Mean NRRs before supplementation ≤ mean NRRs after supplementation.
- $Ho_{1.1.1.4}$: Mean ratio scores in NRRs before supplementation ≤ Mean ratio scores in NRRs during supplementation.
- $Ho_{1.1.1.5}$: Mean ratio scores in NRRs (adjusted for density dependence) before supplementation ≤ Mean ratio scores in NRRs (adjusted for density dependence) during supplementation. [This hypothesis adjusts NRRs for density-dependent effects (see Hillman et al. 2012 for details; Appendix 6).]
- $Ho_{1.1.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds
- Number of naturally produced fish harvested

Derived Variables:

- Number of naturally produced recruits by brood year for both naturally produced parents and hatchery parents (≥age-3).
- NRRs (calculated as NORs/spawner).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NRRs (requires reference population[s]).
- Includes calculation of ratios NORs (requires reference population).
- Appendix 1: Spawning escapement and carrying capacity information (as applicable)

Spatial/Temporal Scale:

- Calculated annually based on brood year.
- Time series.

Possible Statistical Analysis:

---

[3] Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 6) for details.

- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 6). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NRRs.
- On a five-year period, correlate productivity with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

2.2 Natural-Origin Recruits of Supplemented Populations

Monitoring Questions:

Q1.2.1: Has the supplementation program changed the abundance of NORs within the supplemented population?

Target Species/Populations:

- Q1.2.1 applies to all supplemented or safety net stocks.

Statistical Hypotheses 1.2.1[4]:

- $Ho_{1.2.1.1}$: Slope in NORs[5] before supplementation ≥ slope in NORs after supplementation.
- $Ho_{1.2.1.2}$: Differences in slopes in NORs between supplemented and reference populations before supplementation ≥ differences in slopes in NORs between supplemented and reference populations after supplementation.
- $Ho_{1.2.1.3}$: Mean NORs before supplementation ≥ mean NORs after supplementation.
- $Ho_{1.2.1.4}$: Mean ratio scores in NORs before supplementation ≥ Mean ratio scores in NORs during supplementation.
- $Ho_{1.2.1.5}$: Mean ratio scores in NORs/Maximum Recruitment before supplementation ≥ Mean ratio scores in NORs/Maximum Recruitment during supplementation. [This hypothesis adjusts NORs for the capacity of the habitat; it tests the fraction of the habitat saturated with NORs (see Hillman et al. 2012 for details).]
- $Ho_{1.2.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and NORs; rho = 0. [If there is a significant negative association between

4 Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 7) for details.

5 "Slope in NORS" refers to abundance of NORs across time (years).

pHOS and NORs, then hatchery fish may be reducing the reproductive success of the wild population.]

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish taken for broodstock.
- Number of hatchery and naturally produced fish taken in harvest (if recruitment is to the Columbia).

Derived Variables:

- NORs (number of naturally produced recruits (total recruits) by brood year for both naturally produced parents and hatchery parents [≥age-3]).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NORs (requires reference population[s]).
- Estimates of carrying capacity (see Appendix 1).

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NORs.
- On a five-year period, correlate NORs with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

SECTION 3: JUVENILE PRODUCTIVITY

3.1 Freshwater Juvenile Productivity

Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.

Out-of-basin effects (e.g., smolt passage through the hydro system, harvest, and ocean productivity, etc.) influence the survival of smolts after they migrate from the tributaries. These effects introduce substantial variability into the adult-to-adult survival rates (NRRs and HRRs) and may mask in-basin effects (e.g., habitat quality, density-dependent mortality, and differential reproductive success of hatchery and naturally produced fish). Therefore, an estimate of freshwater productivity may help inform the performance of hatchery and natural-origin spawners.

The objective of estimating freshwater productivity in the Upper Columbia ESU/DPS is to estimate the survival from egg to a critical juvenile life stage(s) of target stocks. Smolt or juvenile production models generated from the information obtained through these programs will provide a level of predictability with greater sensitivity to in-basin effects than spawner-recruitment models that consider all effects.

Differences in the current carrying capacities of supplemented and non-supplemented streams can confound the effects of supplementation on numbers of juveniles per redd. For example, if the supplemented population is at or above carrying capacity and the non-supplemented population is not, numbers of juveniles per redd in the non-supplemented population may be significantly greater than the number of juveniles per redd in the supplemented population. In addition, pHOS may be correlated with overall spawner abundance. In these cases, it is difficult or impossible to separate density-dependent effects from the influence of pHOS on freshwater productivity. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on juveniles per redd, the capacity of the habitats must be included in the analyses. The Supplementary Hypotheses presented below are designed to address the confounding effects of different densities on the analyses.

Monitoring Questions:

Q2.1.1: Has the supplementation program changed the number of juveniles (smolts, parr, and/or emigrants) per redd within the supplemented population?

Q2.2.1: Does the number of juveniles per redd decrease as the proportion of hatchery spawners increases?[6]

Target Species/Populations:

- Both Q2.1.1 and Q2.2.1 apply to all conservation stocks.

Statistical Hypotheses for 2.1.1[7]:

[6] Information is needed to estimate the effects of density dependence on these questions. Consider spatial distribution of redds.

[7] Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. (2012) for details.

- $Ho_{2.1.1.1}$: Slope in juveniles/redd before supplementation ≤ slope in juveniles/redd after supplementation.
- $Ho_{2.1.1.2}$: Differences in slopes in juveniles/redd between supplemented and reference populations before supplementation ≤ differences in slopes in juveniles/redd between supplemented and reference populations after supplementation.
- $Ho_{2.1.1.3}$: Mean juveniles/redd before supplementation ≤ mean juveniles/redd after supplementation.
- $Ho_{2.1.1.4}$: Mean ratio scores in juveniles/redd before supplementation ≤ Mean ratio scores in juveniles/redd during supplementation.
- $Ho_{2.1.1.5}$: Mean ratio scores in juveniles/redd (adjusted for density dependence) before supplementation ≤ Mean ratio scores in juveniles/redd (adjusted for density dependence) during supplementation. [This hypothesis adjusts juveniles/redd for density-dependent effects (see Hillman et al. 2012 for details; Appendix 6).]
- $Ho_{2.1.1.6}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

Statistical Hypotheses for 2.2.1:

- $Ho_{2.2.1.1}$: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve; rho = 0. [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]
- $Ho_{2.2.1.2}$: The slope between proportion of hatchery spawners and juveniles/redd is ≥ 0.

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Numbers of redds.
- Number of juveniles (smolts, parr [where appropriate], and emigrants).

Derived Variables:

- Number of juveniles per spawner.
- Number of juveniles per redd.
- Carrying capacity (see Appendix 1).

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- These analyses shall be performed every five-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 6). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and juveniles/redd.

Analytical Rules:

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

SECTION 4: NATURAL ENVIRONMENT MONITORING INDICATORS

4.1 Hatchery Replacement Rates (HRRs)

Objective 3: **Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.**

The survival advantage from the hatchery (i.e., egg-to-smolt) must be sufficient to produce a greater number of returning adults than if broodstock were left to spawn naturally. If a hatchery program cannot produce a greater number of adults than naturally spawning fish, then the program should be modified or discontinued. Production levels were initially developed using historical run sizes and smolt-to-adult survival rates (BAMP 1998). Using the stock specific NRR and agreed upon target values (see Appendix 2), comparisons to actual survival rates will be made to ensure the expected level of survival has been achieved.

Monitoring Questions:

Q3.2.1: Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the adult-to-adult survival rate (NRR) of naturally produced fish?

Q3.2.2: Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the Target Value identified in Appendix 2[8]?

Target Species/Populations:

- Q3.2.1 applies to all conservation stocks.
- Q3.2.2 applies to all stocks.

Statistical Hypothesis 3.2.1:

- $Ho_{3.2.1.1}$: $HRR_{\text{Year }x} \geq NRR_{\text{Year }x}$

Statistical Hypothesis 3.2.2:

- $Ho_{3.2.2.1}$: HRR ≥ Target Value identified in Appendix 2

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish harvested.
- Number of hatchery and naturally produced fish collected for broodstock.
- Number of broodstock used by brood year (hatchery and naturally produced fish).

Derived Variables:

- Number of hatchery and naturally produced adults by brood year (≥age-3).

8 Target values may be adjusted by the hatchery committees.

- HRR (number of returning adults per brood year/broodstock)
- NRR (from Objective 1)
- Appendix 2: HRR targets identified in Appendix 2

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- For Q3.2.1 use graphic analysis and paired-sample quantile tests to compare HRR to NRR
- For Q3.2.2 use graphic analysis and one-sample quantile tests to compare HRR to the target value.
- On a five-year period, correlate HRRs with extraneous factors such as ocean productivity indices.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.2 Proportion of Hatchery-Origin Spawners (pHOS or PNI)

Objective 4: **Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.**

Certain hatchery programs have pHOS or PNI targets, while other do not. HGMPs and permits inform the selection of targets, which are identified in Appendix 3.

Monitoring Questions:

Q4.1.1: Is the estimated proportion of hatchery-origin spawners (pHOS) less than or equal to the management target, and/or, is the estimated Percent Natural Influence (PNI) greater than or equal to the management target identified in Appendix 3?

Target Species/Populations:

- Q4.1.1 applies to all conservation and safety-net stocks that have a defined pHOS or PNI target or sliding scale (see Appendix 3).

Statistical Hypothesis 4.1.1:

- $Ho_{4.1.1.1}$: pHOS > target value or $PNI_{\text{Supplemented population}}$ < target value identified in Appendix 3

Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds

Derived Variables:

- pHOS or PNI
- Appendix 3: PNI and pHOS targets and sliding scales identified in Appendix 3

Spatial/Temporal Scale:

- Calculate annually.
- Analyzed as time series.

Possible Statistical Analysis:

- Use graphic analysis and summary statistics to compare pHOS or PNI to the target value in Appendix 3.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

4.3 Run Timing, Spawn Timing, and Spawning Distribution

Objective 5: Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.

Strategies for conservation programs typically intend that hatchery and natural-origin fish spawn together and in similar locations. However, in some cases, strategies may differ from this paradigm (e.g., summer Chinook salmon in the Wenatchee and Methow rivers; see Appendix 4). Phenotypic plasticity or selection resulting from the hatchery environment (i.e., domestication) may affect run (migration) timing, spawn timing, and spawning distribution. If conservation programs do not adequately represent the genetic diversity of the natural population, and if phenotypic traits in supplementation fish related to fitness deviate from the naturally produced spawning population, the goals of supplementation may not be achieved. Hatchery adults that migrate and/or spawn at different times or are spatially segregated from natural-origin fish may be subject to reduced fitness. Hatchery adults that spawn at different times or locations than natural-origin fish would be reproductively isolated from the natural population. The extent of such isolation, ranging from no isolation to substantial isolation, may be exploited for management purposes in some cases.

Migration Timing

Monitoring Questions:

Q5.1.1: Is the migration timing of hatchery and natural-origin fish from the same age class similar?

Target Species/Populations:

- Q5.1.1 applies to all conservation stocks.

Statistical Hypotheses 5.1.1:

- $Ho_{5.1.1.1}$: Migration timing $_{\text{Hatchery Age X}}$ = Migration timing $_{\text{Naturally produced Age X}}$

- $Ho_{5.1.1.2}$: The cumulative frequency of migration timing of hatchery-origin fish = the cumulative frequency of migration timing of natural-origin fish.
- $Ho_{5.1.1.3}$: The 10^{th} percentile, 50^{th} percentile (mode), 90^{th} percentile, and mean migration timing of hatchery-origin fish = the 10^{th} percentile, 50^{th} percentile (median), 90^{th} percentile, and mean migration timing of natural-origin fish.

Measured Variables:

- Ages of hatchery and natural-origin fish sampled via PIT tags or stock assessment monitoring.
- Time (Julian date) of arrival at mainstem projects and within tributaries (e.g., traps, PIT arrays) with the intent to identify biologically significant differences.

Derived Variables:

- Mean Julian date for a given age class.

Spatial/Temporal Scale:

- Calculate annually based on return year and age class.
- Time series.

Possible Statistical Analysis:

- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Spawn Timing

Monitoring Questions:

Q5.2.1: Is the timing of spawning similar for conservation hatchery and natural-origin fish?

Target Species/Populations:

- Q5.2.1: Applies to all semelparous species and populations supplemented by conservation programs. Steelhead can only be assessed for natural spawning in situations where hatchery and natural-origin fish can be appropriately marked and detected.

Statistical Hypotheses 5.2.1:

- $Ho_{5.2.1.1}$: The cumulative frequency of spawn timing of hatchery-origin fish = the cumulative frequency of spawn timing of natural-origin fish.
- $Ho_{5.2.1.2}$: The 10^{th} percentile, 50^{th} percentile (mode), 90^{th} percentile, and mean spawn timing of hatchery-origin fish = the 10^{th} percentile, 50^{th} percentile (mode), 90^{th} percentile, and mean spawn timing of natural-origin fish.

- $Ho_{5.2.1.3}$: The relationship between elevation and spawn timing of hatchery-origin fish = the relationship between elevation and spawn timing of natural-origin fish.

Measured Variables:

- Time (Julian date) and elevation (m) of hatchery and natural-origin salmon carcasses or marked steelhead detected on spawning grounds within defined reaches.
- Time (Julian date) of ripeness of hatchery and natural-origin steelhead captured for broodstock.

Derived Variables:

- Mean Julian date.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.
- Use graphic analyses, ANCOVA, and/or regression analysis to assess relationships between elevation and spawn timing.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Spatial Distribution of Redds

Monitoring Questions:

Q5.3.1: Is the distribution of redds similar for conservation hatchery and natural-origin fish?

Q5.3.2: Is the distribution of redds similar to defined management targets (see Appendix 4)?

Target Species/Populations:

- Q5.3.1 applies to all conservation program stocks.
- Q5.3.2 applies only to conservation program stocks with specific spawning distribution targets (Carlton and Dryden summer Chinook programs; Appendix 4).

Statistical Hypothesis 5.3.1:

- $Ho_{5.3.1.1}$: The distribution of hatchery-origin redds (hatchery females) = the distribution of natural-origin redds (natural-origin females).

Statistical Hypothesis 5.3.2:

- $Ho_{5.3.2.1}$: The distribution of hatchery-origin redds (hatchery females) = the target distribution identified in Appendix 4.

Measured Variables:

- Location (GPS coordinate) of female salmon carcasses observed on spawning grounds. The distribution of hatchery and naturally produced steelhead redds may be evaluated if marking or tagging efforts provide reasonable results.

Derived Variables:

- Location of female salmon carcass at the historic reach scale and at the 0.1 km scale.
- Calculate percent overlap in distribution across available spawning habitat or historical reaches.
- Appendix 4: Management targets for spatial distribution of spawners or redds (as applicable).

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates' Chi-square analysis for both Q5.3.1 and Q5.3.2.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.4 Stray Rates

<u>Objective 6</u>: Determine if the recipient stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.

Maintaining locally adapted traits among independent fish populations requires that returning hatchery fish have a high rate of site fidelity to the target population or stream. Hatchery practices (e.g., imprinting on water sources at key life history stages, release methodology, release location, age at return, broodstock used, spawner density, spawning habitat quality and access, and environmental conditions) are the main variables thought to affect stray rates. Regardless of the magnitude of homing of adult returns, if adult hatchery fish do not contribute to the natural population, the program will not meet the basic condition of a supplementation program.

Independent populations are populations that are genetically differentiated from other populations. In some cases, genetic differentiation may be assumed based on phenotypic traits or geographic isolation when molecular genetics analyses are not available. When populations are not independent, straying among them does not pose a risk of genetic homogenization. In addition, stray rates of hatchery-origin fish cannot be expected to be lower than for natural-origin fish. When estimates of stray rates for natural-origin fish are available and if they exceed the 5% among population stray rate or 10% within population stray rate thresholds identified in this plan, analysis

and interpretation of stray rates must take into account the concept that hatchery programs may be held to unattainable standards based on the natural stray rate. Current criteria established by the ICBTRT (2005) and the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) indicate that fish that do stray to other non-target populations should not comprise greater than 5% of the non-target spawning population. Likewise, fish that stray into non-target spawning areas within an independent population should not comprise greater than 10% of the non-target spawning aggregate (see Tables 6.1 and 6.2).

This plan identifies three stray rate metrics; brood-year stray rate, among population return-year stray rate, and within population return-year stray rate. The return-year stray rates have specific targets that are from the ICBTRT (2005) and Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007), and are linked to extinction risk. That is, hatchery strays from other populations cannot make up more than 5% of the spawning escapement within a non-target, recipient population. In addition, hatchery strays from other spawning aggregations within a population (e.g., Chiwawa spring Chinook) cannot make up more than 10% of the spawning escapement within a non-target, recipient spawning aggregate (e.g., White River). Brood-year stray rate, on the other hand, is not discussed in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) or ICBTRT (2005) and therefore has no specific target. Nevertheless, it is important to track brood-year stray rates to determine if hatchery operations affect the homing and straying of specific brood years. These data support the return-year stray metrics and are used to inform possible changes in genetic variation among stocks.

Brood-Year Stray Rates

Monitoring Questions:

Q6.1.1: What is the brood-year stray rate of hatchery fish?

Target Species/Populations:

- Q6.1.1 applies to all hatchery stocks.

Statistical Hypothesis 6.1.1:

- $Ho_{6.1.1.1}$: None.

Measured Variables:

- Number of hatchery carcasses found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.
- Number of hatchery fish collected for broodstock.
- Number of hatchery fish taken in fishery.
- Locations of live and dead strays (used to tease out overshoot).

Derived Variables:

- Total number of hatchery carcasses and take in fishery estimated from expansion analysis.
- Percent of the total brood return that strays.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphical analysis to track brood-year stray rates over time.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Among-Population Return-Year Stray Rates

Monitoring Questions:

Q6.2.1: Do hatchery strays make up less than 5% of the spawning escapement within their non-target independent populations?

Target Species/Populations:

- Q6.2.1 applies to all hatchery stocks.

Statistical Hypothesis 6.2.1:

- $Ho_{6.2.1.1}$: Stray hatchery fish make up ≥ 5% of the spawning escapement (based on run year) within other independent populations [9]

Measured Variables:

- Number of hatchery carcasses (PIT-tagged steelhead) found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

Derived Variables:

- Total number of hatchery salmon carcasses (PIT-tagged steelhead, spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target population that is made up of hatchery strays.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

[9] This stray rate is suggested based on a literature review and recommendations by the ICBTRT (2005) and is identified in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007). It can be re-evaluated as more information on naturally-produced Upper Columbia salmonids becomes available. This will be evaluated on a species and program specific basis and decisions made by the HCP HC and PRCC HSC. It is important to understand the actual spawner composition of the population to determine the potential effect of straying.

- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (5%) stray rate.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Within-Population Return-Year Stray Rates

Monitoring Questions:

Q6.3.1: Do hatchery strays make up less than 10% of the spawning aggregate within non-target spawning areas within the target population?

Target Species/Populations:

- Q6.3.1 applies to all hatchery stocks.

Statistical Hypothesis 6.3.1:

- $Ho_{6.3.1}$: Stray hatchery fish make up ≥ 10% of spawning escapement (based on run year) within non-target spawning areas within the target population

Measured Variables:

- Number of hatchery carcasses (possibly PIT-tagged steelhead) found in non-target and target spawning aggregates or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

Derived Variables:

- Total number of hatchery salmon carcasses (possibly PIT-tagged steelhead or spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target spawning aggregate that is made up of hatchery strays.

Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

Possible Statistical Analysis:

- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (10%) stray rate.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.5 Population Genetics

<u>Objective 7</u>: Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.

The genetic component of the M&E Plan specifically addresses the potential for changes in genetic diversity in natural populations as a result of a hatchery program(s). The long-term fitness of populations is assumed to be related to maintaining the genetic diversity of natural populations. However, hatchery programs select a subset of individuals from the population to pass on genetic material to the next generation. This is often a relatively small number of individuals that produce a large number of offspring, and can result in changes in allele frequencies and reductions of effective population size. Therefore, it is important to monitor the genetic status of the natural populations to determine if there are signs of changes in genetic distance among populations, changes in allele frequencies, and to estimate effective population size. Assessing the genetic effects of the hatchery program does not require annual sampling, but does require regular sampling at generational scales. Meeting stray-rate targets (hypotheses tested under Objective 5) should reduce significant changes in population genetics. Stray rates may inform population genetic analyses. Testing statistical hypotheses associated with genetic components (Hypotheses 3.1, 3.2, and 3.3) should be conducted every ten years or two generations.

Allele Frequency

Monitoring Questions:

Q7.1.1: Is the allele frequency of hatchery fish similar to the allele frequency of naturally produced and donor (broodstock) fish?

Target Species/Populations:

- Q7.1.1 applies to all conservation stocks.

Statiscial Hypotheses 7.1.1:

- $Ho_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ = Allele frequency $_{\text{Naturally produced}}$ = Allele frequency $_{\text{Donor pop.}}$
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ ≠ Allele frequency $_{\text{Naturally produced}}$ = Allele frequency $_{\text{Donor pop.}}$ or
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ = Allele frequency $_{\text{Naturally produced}}$ ≠ Allele frequency $_{\text{Donor pop.}}$ or
- $Ha_{7.1.1.1}$: Allele frequency $_{\text{Hatchery}}$ ≠ Allele frequency $_{\text{Naturally produced}}$ ≠ Allele frequency $_{\text{Donor pop.}}$

Measured Variables:

- SNP genotypes

Derived Variables:

- Allele frequency

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples within drainages.

Possible Statistical Analysis:

- Population differentiation tests, analysis of molecular variance (AMOVA), and relative genetic distances.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Genetic Distance Between Populations

Monitoring Questions:

Q7.2.1: Does the genetic distance among subpopulations within a supplemented population remain the same over time?

Target Species/Populations:

- Q7.2.1 applies to all conservation and safety-net stocks.

Statistical Hypothesis 7.2.1:

- $Ho_{7.2.1.1}$: Genetic distance between subpopulations $_{\text{Year x}}$ = Genetic distance between subpopulations $_{\text{Year y}}$

Measured Variables:

- SNP genotypes

Derived Variables:

- Allele frequencies

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples among spawning aggregates.

Possible Statistical Analysis:

- Population differentiation tests, AMOVA, and relative genetic distances.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Effective Spawning Population

Monitoring Questions:

Q7.3.1: Is the ratio of effective population size (N_e) to spawning population size (N) constant over time?

Target Species/Populations:

- Q7.3.1 applies to all supplemented stocks.

Statistical Hypothesis 3.3:

- $Ho_{7.3.1.1}$: $(N_e/N)_{t0} = (N_e/N)_{t1}$ for each population

Measured Variables:

- SNP genotypes

Derived Variables:

- Allele frequencies

Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.

Possible Statistical Analysis:

- Population differentiation tests, relative genetic distances, statistics to calculate effective population size (e.g., harmonic means).

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

4.6 Phenotypic Traits

Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.

Fitness, or the ability of individuals to survive and pass on their genes to the next generation in a given environment, includes genetic, physiological, and behavioral components.[10] Maintaining the long-term fitness of supplemented populations requires a comprehensive evaluation of genetic and phenotypic characteristics. Evaluation of some phenotypic traits (i.e., run timing, spawn timing, spawning location, and stray rates) is addressed under Objective 5. Objective 8 assess the potential effects of domestication, including size at maturity, age at maturity, sex ratio, and fecundity. Age and size at maturity shall be assessed for both fish arriving in the Columbia system, and those recovered on the spawning grounds. Size (or age) selective mortality during migration through the Columbia system, such as through fisheries, could alter the age and size of fish on the spawning grounds.

[10] These metrics are difficult to measure, and phenotypic expression of these traits may be all we can measure and evaluate.

Age at Maturity

Monitoring Questions:

Q8.1.1: Is the age at maturity of hatchery and natural-origin fish similar at the time they enter the Columbia River and when they spawn?

Target Species/Populations:

- Q8.1.1 applies to all conservation program stocks.

Statistical Hypotheses 8.1.1:

- $Ho_{8.1.1.1}$: Age at Maturity $_{\text{Hatchery produced spawners Gender X}}$ = Age at Maturity $_{\text{Naturally produced spawners Gender X}}$
- $Ho_{8.1.1.2}$: Age at Maturity $_{\text{All hatchery produced adults Gender X}}$ = Age at Maturity $_{\text{All naturally produced adults Gender X}}$

Measured Variables:

- Total and salt (ocean) age of hatchery and natural-origin salmon carcasses collected on spawning grounds.
- Total and salt age of broodstock.
- Total and salt age of fish at stock assessment locations (e.g., Dryden, Tumwater, Wells, Priest Rapids).
- Whenever possible, age at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).
- Assess age of fish, including harvested fish.

Derived Variables:

- Total age and saltwater age
- Age of fish entering the Columbia River.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates' Chi-square.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Size at Maturity

Monitoring Questions:

Q8.2.1: Is the size (length) at maturity of a given age and sex of hatchery fish similar to the size at maturity of a given age and sex of natural-origin fish?

Target Species/Populations:

- Q8.2.1 applies to all conservation and safety-net stocks.

Statistical Hypothesis 8.2.1:

- $Ho_{8.2.1.1}$: Size (length) at Maturity $_{\text{Hatchery Age X and Gender Y}}$ = Size (length) at Maturity $_{\text{Naturally produced Age X and Gender Y}}$
- $Ho_{8.2.1.2}$: Size (length) at Maturity $_{\text{All hatchery adults Gender X}}$ = Size (length) at Maturity $_{\text{All naturally produced adults Gender X}}$

Measured Variables:

- Size (length), age, and gender of hatchery and natural-origin salmon carcasses collected on spawning grounds.
- Size (length), age, and gender of broodstock.
- Size (length), age, and gender of fish at stock assessment locations (e.g., Priest Rapids, Dryden, Tumwater, Wells, Twisp Weir).
- Whenever possible, size at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).

Derived Variables:

- Total age and saltwater age

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and three-way ANOVA by origin, gender, and age

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Fecundity at Size[11]

Monitoring Questions:

Q8.3.1: Is the fecundity vs. size relationship of hatchery and natural-origin fish similar?

[11] May not apply to all programs.

Q8.3.2: Is the gonadal mass vs. size relationship of hatchery and natural-origin fish similar?

Target Species/Populations:

- Both Q8.3.1 and Q8.3.2 apply to all conservation stocks using both natural- and hatchery-origin broodstock.

Statistical Hypothesis 8.3.1:

- $Ho_{8.3.1.1}$: Slope of Fecundity vs. Size $_{\text{Hatchery}}$ = Slope of Fecundity vs. Size $_{\text{Naturally produced}}$

Statistical Hypothesis 8.3.2:

- $Ho_{8.3.2.1}$: Gonadal Mass vs. Size $_{\text{Hatchery}}$ = Gonadal Mass vs. Size $_{\text{Naturally produced}}$

Measured Variables:

- Length, weight, and age (covariate) of hatchery and natural-origin broodstock after eggs have been removed.
- Number and weight of eggs

Derived Variables:

- Total age and saltwater age.
- Mean weight per egg.

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis, regression, t-test, and ANCOVA.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Sex Ratio

Monitoring Questions:

Q8.4.1: Is the sex ratio of hatchery and natural-origin fish similar?

Target Species/Populations:

- Q8.4.1 applies to all conservation stocks.

Statistical Hypothesis 8.4.1:

- $Ho_{8.4.1.1}$: Sex Ratio $_{\text{Hatchery}}$ = Sex Ratio $_{\text{Naturally produced}}$

Measured Variables:

- Age and sex of hatchery and natural-origin salmon carcasses collected on spawning grounds or sampled at dams or weirs.
- Whenever possible sex ratio will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling or ultrasound on live fish).

Derived Variables:

- Ratio of sexes based on brood year returns

Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and Yates'Chi-square.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 5: HATCHERY ENVIRONMENT MONITORING INDICATORS

5.1 Release Targets

Objective 9: Determine if hatchery fish were released at the programmed size and number.

The HCP outlines the number and size of fish that are to be released to meet NNI and inundation compensation levels. The size of the fish at release may be altered according to an adaptive management process in the Hatchery Committee(s), and the number of fish can be altered by survival study results and adjustment of hatchery production for population dynamics. Size of fish at release can affect survival, sex ratios, age at return, stray rate, and fecundity. In addition, the variation in size at release may affect performance of the fish.

The coefficient of variation (CV) will be evaluated to ascertain if program performance is related to variation in size at release. Note also that variation in a population is a natural condition and striving to control this variation could result in directional or stabilizing artificial selection that could have unforeseen long-term consequences. Attaining uniform or multi-modal growth in a hatchery environment may not be adaptive for fitness in the wild. Therefore, pursuit of a CV target should be seen as an informative exercise, but is not in itself indicative of success or failure of a hatchery program. Furthermore, growth regimes may prove to be important in affecting adult returns and age structure. Although many factors can influence both the size and number of fish released, past hatchery cultural experience with these stocks should assist in meeting program production levels. Appendix 5 presents the target size at release and CVs for the programs. These targets shall be assessed annually to ensure they are optimized to inform management decisions.

Size at Release of Hatchery Fish

Monitoring Questions:

Q9.1.1: Is the size (fish per pound; fpp) of hatchery fish released equal to the program goal identified in Appendix 5?

Target Species/Populations:

- Q9.1.1 applies to all hatchery stocks.

Statistical Hypothesis 9.1.1:

- $Ho_{9.1.1.1}$: Hatchery fish $_{\text{fpp at release}}$ = Programmed $_{\text{fpp at release}}$ (see Appendix 5)

Measured Variables:

- Fork length and weights of random samples of hatchery juveniles at release.

Derived Variables:

- Mean length (FL), mean weight, and fish per pound
- Appendix 5: Rearing targets

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated fpp of hatchery fish at time of release with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Coefficient of Variation (CV) of Hatchery Fish Released

Monitoring Questions:

Q9.2.1: Is the CV of hatchery fish released equal to the program target identified in Appendix 5?

Target Species/Populations:

- Q9.2.1 applies to all hatchery stocks.

Statistical Hypothesis 9.2.1:

- $Ho_{9.2.1.1}$: Hatchery fish $CV_{\text{at release}}$ = Programmed CV in Appendix 5

Measured Variables:

- Length and weights of random samples of hatchery smolts.

Derived Variables:

- Coefficient of Variation: $cv = (1 + 1/4n) \times (s/x)$ (where s = standard deviation, x = estimated mean, n = sample size)
- Appendix 5: Rearing targets

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated CV of size of hatchery fish released with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.

Condition Factor (K) of Hatchery Fish Released

Monitoring Questions:

Q9.3.1: Is the K of hatchery fish released equal to the program target identified in Appendix 5?

Target Species/Populations:

- Q9.3.1 applies to all hatchery stocks.

Statistical Hypothesis 9.3.1:

- $Ho_{9.3.1.1}$: Hatchery fish $K_{\text{at release}}$ = Programmed K identified in Appendix 5

Measured Variables:

- Monthly individual lengths and weights of random samples of hatchery juveniles.

Derived Variables:

- Condition Factor: $K = W/L^3 \times 10^5$

Spatial/Temporal Scale:

- Calculate annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and descriptive statistics to compare the estimated K of released hatchery fish with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

Number of Hatchery Fish Released

Monitoring Questions:

Q9.4.1: Is the number of hatchery fish released equal to the program goal identified in Appendix 5?

Target Species/Populations:

- Q9.4.1 applies to all hatchery stocks.

Statistical Hypothesis 9.4.1:

- $Ho_{9.4.1.1}$: Hatchery Fish Number = Programmed Number identified in Appendix 5

Measured Variables:

- Numbers of smolts released from the hatchery.

Derived Variables:

- Appendix 5: Rearing targets

Spatial/Temporal Scale:

- Calculate annually.

- Time series.

Possible Statistical Analysis:

- Use graphic analysis and one-sample quantile tests to compare the estimated number of hatchery fish released with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 6: HARVEST MONITORING INDICATORS

6.1 Harvest Rates

<u>Objective 10</u>: **Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.**

Harvest will be applied to different types of programs in an effort to achieve the management objectives of those programs. Programs designed to augment harvest should routinely contribute to harvest at a rate that greatly reduces the incidence of straying to natural spawning grounds, but also allows the program to be sustained. Safety-net programs may be harvested as part of an adult management strategy to minimize excessive escapement of hatchery-origin fish to spawning grounds. Similarly, conservation programs may undergo harvest to manage returning adults, but the emphasis for these programs should be to achieve escapement goals. In all cases, harvest effort should not have the unintended consequence of removing excessive numbers of conservation or natural-origin fish. In years when the expected returns of hatchery adults are above the level required to meet program goals (i.e., supplementation of spawning populations and/or brood stock requirements), surplus fish may be available for harvest. The M&E Plan specifically addresses harvest and harvest opportunities upstream of Priest Rapids Dam. Harvest or removal of surplus hatchery fish from the spawning grounds may assist in reducing potential adverse ecological and genetic impacts to natural populations (e.g., loss of genetic variation within and between populations, loss of fitness, reduced effective population size, and density-dependent effects).

Monitoring Questions:

Q10.1.1: Conservation Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of conservation hatchery fish but low enough to sustain the hatchery program?

Q10.1.2: Safety-Net Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of safety-net hatchery fish but low enough to sustain the hatchery program?

Q10.1.3: Is the harvest on hatchery fish produced from harvest-augmentation programs high enough to manage natural spawning but low enough to sustain the hatchery program?

Q10.1.4: Is the escapement of fish from conservation and safety-net programs in excess of broodstock and natural production[12] needs to provide opportunities for terminal harvest?

Target Species/Populations:

- Q10.1.1 applies to conservation programs.
- Q10.1.2 applies to safety-net programs.

---

[12] The current best estimates of carrying capacity (maximum recruits) will be used, as available.

- Q10.1.3 applies harvest augmentation programs.
- Q10.1.4 applies to conservation and safety-net programs.

Statistical Hypothesis 10.1.1:

- $Ho_{10.1.1.1}$: Harvest rate ≤ Maximum level to meet program goals

Statistical Hypothesis 10.1.2:

- $Ho_{10.1.2.1}$: Harvest rate ≤ Maximum level to meet program goals

Statistical Hypothesis 10.1.3:

- $Ho_{10.1.3.1}$: Escapement ≤ Maximum level to meet supplementation goals

Statistical Hypothesis 10.1.4:

- $Ho_{10.1.4.1}$: Harvest rate ≤ Maximum level to meet program goals

Measured Variables:

- Numbers of hatchery fish taken in harvest.
- Numbers of natural-origin fish taken in harvest.

Derived Variables:

- Total harvest by fishery estimated from expansion analysis.

Spatial/Temporal Scale:

- Calculated annually.
- Time series.

Possible Statistical Analysis:

- Use graphic analysis and one-sample quantile tests to compare the estimated harvest of hatchery fish with the program goal.

Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

SECTION 7: REGIONAL OBJECTIVES

Hatchery programs have the potential to increase diseases that typically occur at low levels in the natural environment (Objective 9). In addition, hatchery fish can reduce the abundance, size, or distribution of non-target taxa through ecological interactions (Objective 10). In this section, we address incidence of disease and non-target taxa of concern.

7.1 Incidence of Disease

Objective 11: Determine if the incidence of disease has increased in the natural and hatchery populations.

The hatchery environment has the potential to amplify diseases that are typically found at low levels in the natural environment. Amplification could occur within the hatchery population (i.e., vertical and horizontal transmission) or indirectly from the hatchery effluent or commingling between infected and non-infected fish (i.e., horizontal transmission). Potential impacts to natural populations have not been extensively studied, but should be considered for programs in which the hatchery fish are expected to commingle with natural fish. This is particularly important for supplementation type programs. Specifically, the causative agent of bacterial kidney disease (BKD), *Renibacterium salmoninarum* (Rs), could be monitored at selected acclimation ponds, both in the water and fish, in which the risk and potential for transmission from the hatchery is highest. Although it is technologically possible to measure the amount of Rs in water or Rs DNA in smolts and adults non-lethally sampled, the biological meaning of these data are uncertain. Currently, the only metric available for M & E purposes is measuring the antigen level from kidney/spleen samples (i.e., ELISA, PCR). When available, non-lethal sampling may replace or be used in concert with lethal sampling.

Implementation of this objective will be conducted in a coordinated approach within the hatchery and natural environment. BKD management within the hatchery population (e.g., broodstock or juveniles) has the potential to reduce the prevalence of disease through various actions (e.g., culling or reduced rearing densities). BKD management must also take into account and support other relevant objectives of the M & E program (e.g., Hatchery Return Rate [HRR], number of smolts released). Hence, the goal of BKD management is to decrease the prevalence of disease and maintain hatchery production objectives (i.e., number and HRR).

As previously discussed, disease transmission from hatchery to naturally produced fish may occur at various life stages and locations. Of these, horizontal transmission from hatchery effluent, vertical transmission on the spawning grounds, and horizontal transmission in the migration corridor have been identified as disease interactions that could be examined under this objective, although others may also be relevant. Experimental designs addressing this objective may require technology not yet available, although in some instances samples may be collected, but not analyzed until a link can be established between bacteria levels in samples and disease prevalence.

Developing a complete set of questions and hypotheses statements for this objective may not be practical at this time, because there is currently no BKD Management Plan. However, while developing experimental designs for this objective, it may be feasible to incorporate both hatchery and natural environment monitoring under a single study design. Integration of the different

aspects of the objective would likely result in a more robust approach into understanding the effectiveness of disease management strategies.

Proposed Tasks:

T1: Assemble fish health data for fish used as brood (e.g., ELISA results).

T2: Conduct data exploration exercise to identify potential relationships between pathogen profiles and likely causative variables (e.g., rearing conditions and management actions).

T3: Develop hypotheses for potential testing to meet objective.

7.2 Non-Target Taxa of Concern (NTTOC)

Objective 12: Determine if the release of hatchery fish affects non-target taxa of concern (NTTOC) within acceptable limits.

Hatchery programs have the potential to affect non-target taxa through various types of interactions (e.g., competition and predation). These interactions can reduce the distribution, size, and abundance of non-target species. The non-target taxa of concern (NTTOC) ecological risk assessment was developed as a regional objective that would addressed ecological interactions on non-target taxa.

In 2008, the Wells HCP, Rocky Reach HCP, Rock Island HCP Hatchery Committees, and the Priest Rapids Hatchery Sub-Committee agreed to an approach to evaluate the potential effects of hatchery programs on NTTOC. The committees originally planned to convene a panel of experts to conduct a preliminary evaluation of the potential effects of Plan supplemented species on NTTOC. At the 15 October 2008 Hatchery Committees meeting, the members agreed to convene an expert panel to conduct a preliminary evaluation of potential effects of supplemented Plan Species on non-target taxa using an approach similar to that used in the Yakima Basin (Pearsons and Hopley 1999; Ham and Pearsons, 2001). The Committees agreed to convene the panel in spring or early summer 2009, and focus this initial effort on HCP Plan Species and the two non-Plan Species, westslope cutthroat trout and lamprey. The Committees identified species interactions, containment objectives for non-target species, and fisheries professionals who possessed the expertise to contribute as panel members. The Committees directed the Hatchery Evaluation Technical Team (HETT) to pursue assessment of the hatchery programs potential effects on NTTOC.

The HETT evaluated methods to conduct a risk assessment on NTTOC, and proposed using a combined modeling and a Delphi panel approach, whereby the modeling results would be compared and correlated with the Delphi panel results. The HETT identified the PCD Risk 1 model (Busack et al., 2005; Pearsons and Busack, 2012) to conduct the modeling evaluation. The PCD Risk 1 model is a data intensive, individual-based stochastic model. The HETT determined that the assembled data to be used as inputs for the PCD Risk 1 model would also serve to provide expert panelists the necessary data for them to conduct risk assessments. Hence, the HETT embarked on an extensive effort to gather, organize, and extract the required data from existing datasets, literature, and biologists familiar with the programs and/or particular NTTOC. Ultimately, the input data were assembled in a relational database that allowed the data to be output in user-friendly formats for modeling or Delphi panel use. The database also served to hold the modeling results, which could be extracted and summarized as needed. Following the modeling work, the Committees decided not to assemble the expert panel, because the panel would not be able to evaluate adequately the very large number of possible interactions.

A report titled *Ecological Risk Assessment of Upper-Columbia Hatchery Programs on Non-Target Taxa of Concern* was drafted in 2013 and finalized in 2014, which included the modeling results to date. The results in the report represent a very extensive effort to model the risk of all the upper Columbia hatchery programs for the identified NTTOC for which data and model runs were available. Should new information become available, the Committees agreed to assess the suitability of the data as it relates to conducting future NTTOC evaluations as a regional objective.

SECTION 8: ADAPTIVE MANAGEMENT

One of the challenges of evaluating PUD hatchery programs is that hatchery programs are modified resulting in hatchery treatments that are uneven throughout the duration of the hatchery program. Modifications occur as a result of recalculating hatchery release numbers every 10 years and also through adaptive management. To solve this evaluation challenge, we propose to conduct two scales of analysis. First, the entire duration of the program will be analyzed using the entire data set. This evaluation will analyze whether the overall adaptively managed program achieved objectives. Second, where appropriate, analyses will be compared across periods or programs to determine if major program changes have resulted in hypothesized changes to key response variables. We acknowledged that partitioning data into shorter periods will likely result in reduced statistical power so only the biggest changes will be evaluated. In the future, the hatchery committees will develop a table or figure that identifies major program changes in fish culture or M&E.

In the past, hatchery programs have been evaluated at the hatchery program scale (e.g., Nason Creek, Carlton summer Chinook). In some cases, it may be worthwhile to evaluate supplementation programs at different spatial scales. For example, the Nason Creek spring Chinook salmon program can be evaluated at the scale of Nason Creek, the combined effects of spring Chinook hatchery programs in the Wenatchee basin at the Wenatchee basin scale, and then all of the spring Chinook programs in the upper Columbia at the upper Columbia basin scale.

Comparisons of supplemented populations (treatments) to in-basin reference populations are the best way to evaluate whether treatments have caused changes to variables such as natural-origin recruits or productivity. Many suitable out-of-basin references are available (see Appendix 6), but these references do not control for unique factors that may be happening in the upper Columbia or areas outside the upper Columbia. For example, large fires that occur in the Upper Columbia may not occur at similar times in areas outside of this area. Candidate in-basin reference populations are not ideal for spring Chinook salmon because they are small and are above a lake (e.g., Little Wenatchee River) or they have had a long history of hatchery stocking (e.g., Entiat River). Every population of upper Columbia summer and fall Chinook is supplemented so in-basin references are not currently available. Without a suitable number of in-basin reference populations that are similar in size and distribution to treated populations, it will be difficult to unambiguously assess hatchery effects on certain variables. Although not ideal, the only way to increase in-basin reference comparisons is to strategically reduce the number of places where hatchery fish are released such as was done for the Entiat River.

Previous stocking history will lessen the value of reference populations; however, they can still be of value. For instance, the Committees can still test whether NORs are increased under supplementation compared to periods when other populations are not supplemented (i.e., a reverse BACI analysis).

SECTION 10: GLOSSARY

Adult-to-Adult survival (Ratio)	The number of parent broodstock relative to the number of returning adults.
Age at maturity	The age of fish at the time of spawning (hatchery or naturally).
Augmentation	A hatchery strategy where fish are released for the sole purpose of providing harvest opportunities.
Broodstock	Adult salmon and steelhead collected for hatchery fish egg harvest and fertilization.
Donor population	The source population for supplementation programs before hatchery fish spawned naturally.
Effective population size (Ne)	The number of reproducing individuals in an ideal population (i.e., Ne = N) that would lose genetic variation due to genetic drift or inbreeding at the same rate as the number of reproducing adults in the real population under consideration (Hallerman 2003).
ESA	Endangered Species Act passed in 1973. The ESA-listed species refers to fish species added to the ESA list of endangered or threatened species and are covered by the ESA.
Expected value	The number of smolts or adults derived from survival rates agreed to in the Biological Assessment and Management Plan (BAMP 1998).
Extraction rate	The proportion of the spawning population collected for broodstock.
Genetic diversity	All the genetic variation within a species of interest, including both within and between population components.
Genetic stock structure	A type of assortative mating, in which the gene pool of a species is composed of a group of subpopulations, or stocks, that mate panmictically within themselves.
Genetic variation	All the variation due to different alleles and genes in an individual, population, or species.
HCP	Habitat Conservation Plan is a plan that enables an individual or organization to obtain a Section 10 Permit which outlines what will be done to “minimize and mitigate” the impact of the permitted take on a listed species.

HCP-HC	Habitat Conservation Plan Hatchery Committee is the committee that directs actions under the hatchery program section of the HCP's for Chelan and Douglas PUDs.
HRR	Hatchery Replacement Rate is the ratio of the number of returning hatchery adults relative to the number of adults taken as broodstock, both hatchery and naturally produced fish (i.e., adult-to-adult replacement rate).
Long-term fitness	Long-term fitness is the ability of a population to self-perpetuate over successive generation.
Naturally produced	Progeny of fish that spawned in the natural environment, regardless of the origin of the parents.
Mean Ratio	The ratio between a treatment and control population, with the mean taken across a time period, such as years. Used in analysis in Before-After-Control-Impact studies.
Ne	Effective population size.
Non-target taxa of concern (NTTOC)	Species, stocks, or components of a stock with high value (e.g., stewardship or utilization) that may suffer negative effects because of a hatchery program.
NRR	Natural replacement rate is the ratio of the number of returning naturally produced adults relative to the number of adults that naturally spawned, both hatchery and naturally produced.
NTTOC	Non-target taxa of concern.
pHOS	Proportion of Hatchery Origin Spawners.
PNI	Proportionate Natural Influence.
pNOB	Proportion of Natural Origin Broodstock.
PRCC HSC	Priest Rapids Coordinating Committee Hatchery Subcommittee.
Productivity	The capacity in which juvenile fish or adults can be produced.
Reference population	A population in which no directed artificial propagation is currently directed, although may have occurred in the past. Reference populations are used to monitor the natural variability in survival rates and out of basin impacts on survival.
Smolt-to-adult survival rate (SAR)	Smolt-to-adult survival rate is a measure of the number of adults that return from a given smolt population.
Segregated	A type of hatchery program in which returning adults are spatially or temporally isolated from other populations.

Size at maturity	The length or weight of a fish at a point in time during the year in which spawning will occur.
Smolts per redd	The total number of smolts produced from a stream divided by the total number of redds from which they were produced.
SNP or single-nucleotide polymorphism	A single-nucleotide polymorphism is a variation in a single nucleotide that occurs at a specific position in the genome, where each variation is present to some appreciable degree within a population.
Spawning Escapement	The number of adult fish that survive to spawn.
Stray rate	The rate at which fish spawn outside of natal rivers or the stream in which they were released.
Supplementation	A hatchery strategy where the main purpose is to increase the relative abundance of natural spawning fish without reducing the long-term fitness of the population.
Target population	A specific population in which management actions are directed (e.g., artificial propagation, harvest, or conservation).

APPENDIX 1: ESTIMATION OF CARRYING CAPACITY

In the ecological literature, carrying capacity is often defined as the maximum population size that can be supported indefinitely by the environment (Cain et al. 2014). Said another way, carrying capacity is the maximum number or biomass of a species that a given habitat can support. This maximal environment load is often referred to as "habitat capacity" and is identified with the letter "C." In contrast, the carrying capacity parameter "K" in population models (e.g., logistic equation, Beverton-Holt model, hockey stick model, and the Ricker model) defines a maximum equilibrium population size. Maximum equilibrium population size is generated from density dependent mechanisms that reduce population growth rates as population size increases (negative density dependence). This is referred to as compensation. Population size fluctuates about the maximum equilibrium size because of variability in vital rates that are unrelated to density (density independent factors) and measurement error. Maximum equilibrium population size is often referred to as "population capacity." The two capacities (habitat capacity and population capacity) are related but not identical and therefore should not be confused. Habitat capacity will usually be greater than population capacity.

Estimation of carrying capacity is important because hatchery managers use it to inform supplementation programs, harvest managers use it to set appropriate harvest and escapement levels, modelers use it in life-cycle models to predict the effects of different recovery scenarios, and restoration practitioners use it to guide restoration actions. The purpose of this paper is to describe methods that can be used to estimate carrying capacity for stocks within the Upper Columbia River basin. We apply these methods to Wenatchee and Chiwawa River spring Chinook salmon.[13] Data used in this exercise are shown in Tables 1 and 2 and come from Hillman et al. (2017). We begin by identifying simple methods used to detect density dependence. We then describe the use of population models to estimate population capacity. We also discuss the use of habitat models and quantile regression to estimate habitat capacity. We end by comparing results of different methods and offering recommendations for estimating carrying capacity.

Table 1. Numbers of redds, adult spawners (estimated from redd surveys), eggs (estimated as the number of redds times average brood-year fecundity), summer parr (estimated using snorkel surveys), and yearling smolts (estimates using a rotary screw trap) by brood year for spring Chinook salmon in the Chiwawa River watershed. Smolts represent the number of yearling Chinook produced entirely within the Chiwawa River watershed. Date are from Hillman et al. (2017). NS = not sampled.

Brood year	Numbers of Chiwawa spring Chinook				
	Redds	Spawners	Eggs	Parr	Smolts
1991	104	242	478,400	45,483	42525
1992	302	676	1,570,098	79,113	39723
1993	106	233	556,394	55,056	8662
1994	82	184	485,686	55,241	16472
1995	13	33	66,248	5,815	3830

[13] Technically, Wenatchee River spring Chinook are one population. Chiwawa River spring Chinook are a subgroup of the Wenatchee spring Chinook population.

* From 2000-2010 the smolt trap operated near the Town of Monitor; from 2013 to present the trap operated near the Town of Cashmere.

Evidence of Density Dependence

To calculate population capacity, the size of the population or stock must be influenced to a large degree by density-dependent factors. That is, population growth is affected by mechanisms whose effectiveness increases as population size increases. As population density increases, factors such as competition, predation, and disease (and parasites) cause birth rates to decrease, death rates to increase, and dispersal to increase. When densities decrease, the opposite occurs; birth rates increase and death and emigration rates decrease. In general, when the density of the population becomes high enough, density-dependent factors decrease population size because food or space are in short supply (Chapman 1966). In the ecological literature, this is referred to as "population regulation."

A simple way to determine if density-dependent factors regulate population size is to plot population growth rate (or appropriate surrogate) against population size. If population regulation is occurring, the relationship between population size and population growth rate decreases exponentially (decreases linearly if data are log-transformed). Surrogates for population growth rate include survival rates, natality (birth rates), productivity, recruits, individual growth rates, and movement. Figure 1 shows the relationship between productivity (parr/spawner and smolts/spawner) and spawning escapement for Wenatchee River and Chiwawa River spring Chinook. One could use redd counts as a surrogate for spawning abundance. Because most female spring Chinook construct only one redd (Murdoch et al. 2009), redd counts reflect the number of female spawners in the population. In this report, we use number of spawners (spawning escapement) because most management decisions are based on spawning escapement.

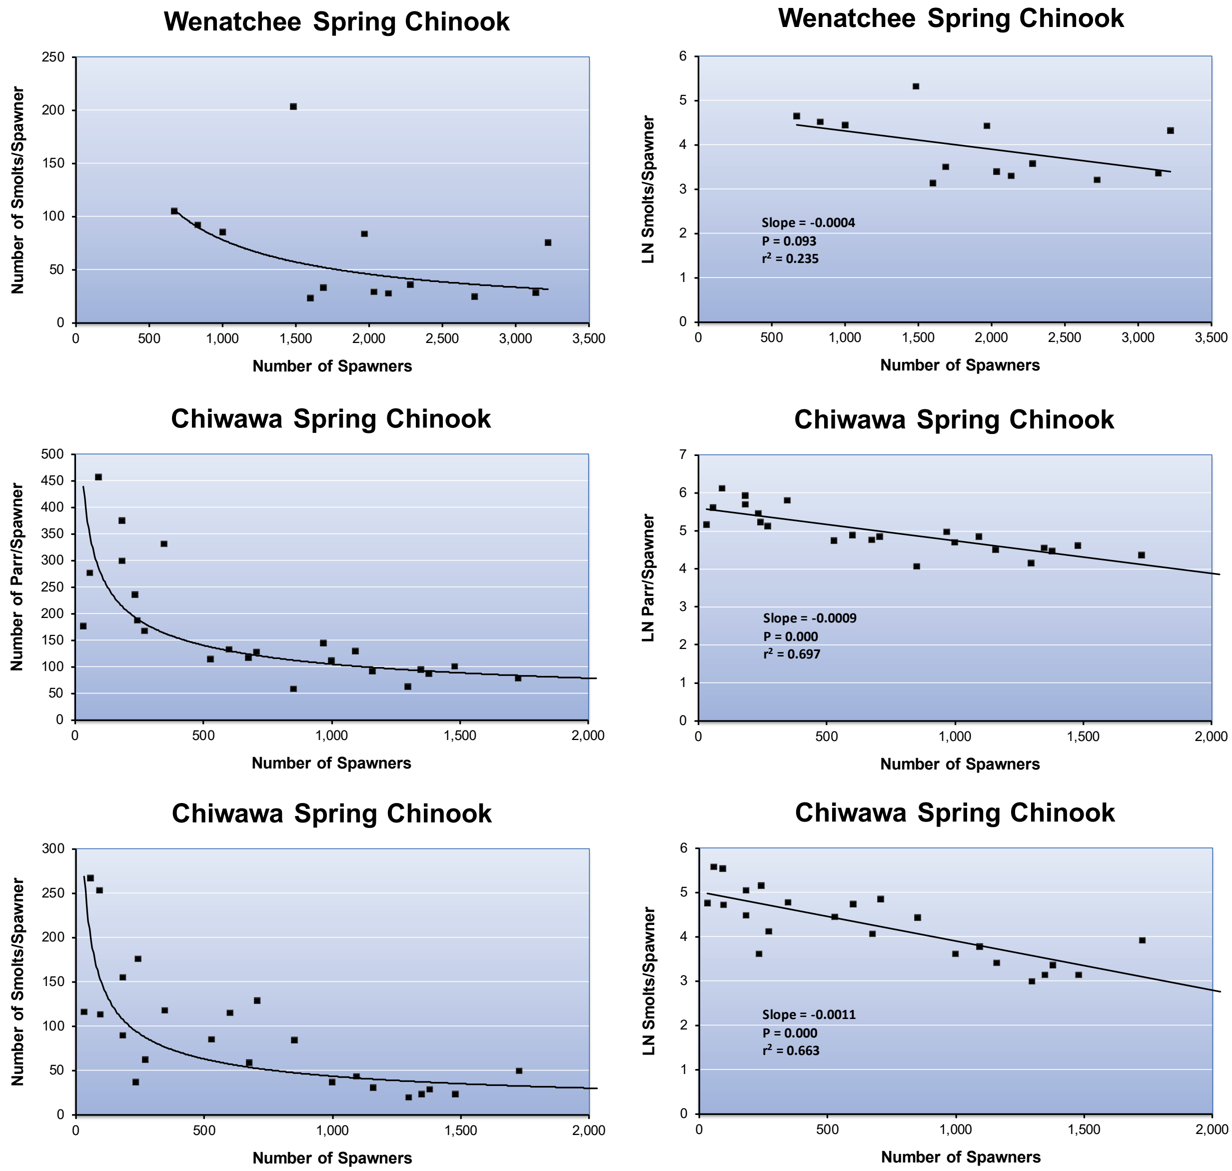

Figure 1. Relationship between spawner abundance and smolts/spawner for Wenatchee spring Chinook (top figures), spawner abundance and parr/spawner for Chiwawa spring Chinook (middle figures), and spawner abundance and smolts/spawner for Chiwawa spring Chinook (bottom figures). Figures on the right show natural log transformed productivity data.

The negative relationship between spawner abundance and juvenile productivity indicates the presence of density dependence in Chiwawa spring Chinook. Although there is a hint of density dependence in the Wenatchee River productivity data, the relationship was not significant statistically. This in part may be related to changes in sampling over the 13-year period. The negative relationship was significant for both summer parr and yearling smolts in the Chiwawa River watershed. We caution, however, that there may be a bias in the simple regression analysis presented in the figures. That is, the dependent (productivity) and independent (abundance) variables are not independent and this can produce a negative bias in regression estimates of slope. Nevertheless, the decline in juvenile productivity with increasing spawner abundance indicates the

presence of density dependence. Given the presence of density dependence, we should be able to estimate population capacity.

Estimating Carrying Capacity

Several different methods can be used to estimate population capacity. For example, time series analyses, including the logistic or Gompertz functions, or stock-recruitment models can be used to estimate population capacity. Common stock-recruitment models include Ricker, Beverton-Holt, and smooth hockey stick models. These models incorporate environmental variability and can be used to estimate the size of the spawning population needed to produce the maximum number of recruits. Habitat capacity, on the other hand, can be estimated using fish-habitat models. In general, these models estimate habitat capacity as the product of habitat area and fish/habitat relationships. These range from simple models such as percent habitat saturation models to more complex models including habitat suitability, quantile regression forest models, dynamic food-web models, and bioenergetic or net rate of energy intake models. In this report, we explore the use of stock-recruitment models to estimate population capacity. We apply quantile regression to stock-recruitment models to estimate habitat capacity and compare those results to a habitat model, the quantile regression forest model.

Population Capacity

To estimate population capacity, we evaluated the fit of three different stock-recruitment models to Chiwawa and Wenatchee River spring Chinook data: Ricker, Beverton-Holt, and smooth hockey stick models. In using these models, we assume:

- *Density-dependent mortality*—For some time period before recruitment, the brood instantaneous mortality rate is proportional to the number of parent spawners (Ricker 1954).
- *Lognormal variation*—At any particular spawning stock size, the variation in recruitment is log-normally distributed about its average, and acts multiplicatively (Quinn and Deriso 1999).
- *Measurement error*—Error in spawning stock size estimates (measurement error) is small relative to the range of spawning stock sizes observed (Hilborn and Walters 1992). Variation in realized recruitment at any particular spawning stock size (process error) dominates recruitment measurement error.
- *Stationarity*—The average stock-recruitment relationship is constant over time (Hilborn and Walters 1992). That is, environmental conditions randomly affect survival independent of stock size or time.

In general, the methods we used to fit the models to the data followed those outlined in Hilborn and Walters (1992) and Froese (2008). The Ricker model, which assumes that the number of recruits increases to a maximum and then declines as the number of spawners increases, takes the form:

$$\boldsymbol{E(R) = \alpha S e^{-\beta S}}$$

where E(R) is the expected recruitment, S is spawner abundance, α is the number of recruits per spawner at low spawning levels, and β describes how quickly the recruits per spawner drop as the number of spawners increases. We estimated population capacity (K) as:

$$K = \left(\frac{\alpha}{\beta}\right) e^{-1}$$

and the number of spawners (SP) needed to produce the maximum number of recruits as:

$$SP = \frac{1}{\beta}$$

The Beverton-Holt model assumes that the number of recruits increases constantly toward an asymptote as the number of spawners increases. After the asymptote is reached, the number of recruits neither increases nor decreases. The asymptote represents the maximum number of recruits the system can support (i.e., population capacity for the system; K). The Beverton-Holt curve takes the form:

$$E(R) = \frac{(\alpha S)}{(\beta + S)}$$

where E(R) and S are as above, α is the maximum number of recruits produced (i.e., α = K), and β is the number of spawners needed to produce (on average) recruits equal to one-half the maximum number of recruits. The number of spawners needed to produce the maximum number of recruits is ∞ in the Beverton-Holt model.

Like the Beverton-Holt model, the smooth hockey stick model assumes that the number of recruits increases toward an asymptote (population capacity; K) as the number of spawners increases. After the carrying capacity is reached, the number of recruits neither increases nor decreases. The carrying capacity represents the maximum equilibrium number of recruits the system can support. This curve takes the form (Froese 2008):

$$E(R) = R_\infty\left(1 - e^{-\left(\frac{\alpha}{R_\infty}\right)S}\right)$$

where E(R) and S are as above, α is the slope at the origin of the spawner-recruitment curve, and R_∞ is the carrying capacity of recruits (i.e., R_∞ = K). There is no direct estimate of SP in the smooth hockey stick model. Therefore, we estimated SP as the number of spawners needed to produce 0.95(K).

We used non-linear regression to fit the three models to spawner-recruitment data. Before fitting the models, we transformed recruitment data using natural logs. We estimated bias and uncertainty measures (95% CI) for the model parameters using bootstrap procedures, which assumed that the {R, S} sample represented or approximated the population. The number of bootstrap samples was 3,000. We computed and stored the non-linear regression results for each bootstrap sample. We then calculated the bootstrap 95% CI by arranging the 3,000 bootstrap parameter values in sorted order and selected the 2.5 and 97.5 percentiles from the list.

We used Akaike's Information Criterion for small sample size (AIC_c) to determine which model(s) best explained the relationship between spawners and recruitment in the supplemented and reference populations. AIC_c was estimated as:

$$AIC_c = -2log(\pounds(\theta|data)) + 2K + \left(\frac{2K(K+1)}{n-K-1}\right)$$

where $log(£(\theta|data))$ is the maximum likelihood estimate, K is the number of estimable parameters (structural parameters plus the residual variance parameter), and n is the sample size (Burnham and Anderson 2002). We used least-squares methods to estimate $log(£(\theta|data))$, which was calculated as $log(\sigma^2)$, where σ^2 = residual sum of squares divided by the sample size ($\sigma^2 = RSS/n$). AIC_c assessed model fit in relation to model complexity (number of parameters). The model with the smallest AIC_c value represented the "best approximating" model within the model set. Remaining models were ranked relative to the best model using AIC_c difference scores (ΔAIC_c), Akaike weights (w_i), and evidence ratios. Models with ΔAIC_c values less than 2 indicated that there is substantial support for these models as being the best-fitting models within the set (Burnham and Anderson 2002). Models with values greater than 2 had less support. Akaike weights are probabilities estimating the strength of the evidence supporting a particular model as being the best model within the model set. Models with small w_i values are less plausible as competing models (Burnham and Anderson 2002). If no single model could be specified as the best model, a "best subset" of competing models was identified using (1) AIC_c differences to indicate the level of empirical support each model had as being the best model, (2) evidence ratios based on Akaike weights to indicate the relative probability that any model is the best model, and (3) coefficients of determination (R^2) assessing the explanatory power of each model.

Chiwawa River Spring Chinook Parr

We successfully fit the three stock-recruitment curves to the Chiwawa spring Chinook parr data (Figure 2).

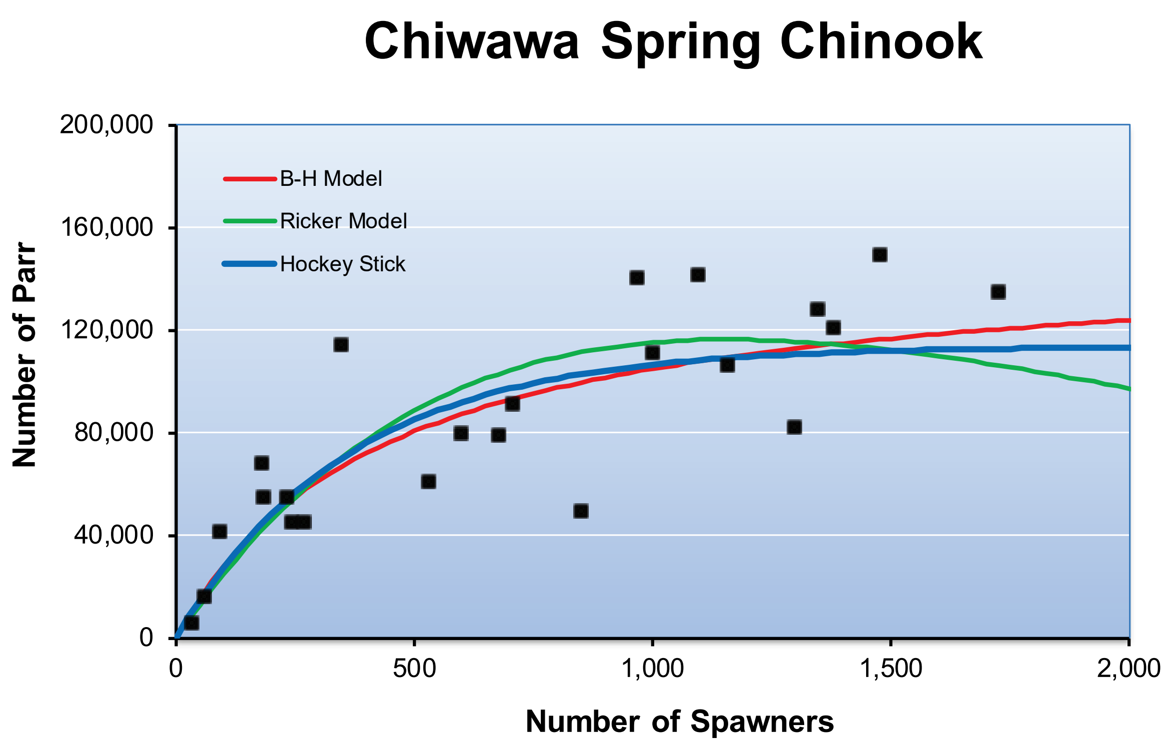

Figure 2. Relationship between numbers of spring Chinook parr and numbers of spawners in the Chiwawa River watershed, 1992-2016 (no sampling occurred in 2000). Figure shows the fit of the Beverton-Holt, Ricker, and smooth hockey stick models to the data.

For summer parr, the use of AIC_c indicated that the Beverton-Holt model best approximated the information in the productivity data. The estimated structural parameters for this model were:

$$Parr = \frac{(150{,}902 \times Spawners)}{(438 + Spawners)}$$

where the bootstrap estimated standard errors for the two parameters were 21,142 and 145, respectively. The adjusted $R^2 = 0.812$.

The second-best model was the smooth hockey stick model, which was 0.245 AIC_c units from the best model. The estimated parameters for this model were:

$$LN(Parr) = 11.6 + LN\left(1 - e^{-\left(\frac{312.9}{113{,}801}\right)Spawners}\right)$$

where the bootstrap estimated standard errors of the two parameters were 0.097 and 57.578, respectively, and the $R^2 = 0.810$.

The AIC_c difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for both the Beverton-Holt and smooth hockey stick models. There was less support for the Ricker model, which was > 2 AIC_c units from the best models. This was further supported by the fact that, relative to the best models, the Ricker model had an evidence ratio greater than 3.

Depending on the stock-recruitment model used, population capacity ranged from 113,801 to 150,902 parr (Table 3). The Beverton-Holt model estimated the highest capacity, while the smooth hockey stick model estimated the lowest. The number of spawners needed to produce the population capacity of parr ranged from 1,089 to 1,163 (Table 3).

Table 3. Estimates of Beverton-Holt, smooth hockey stick, and Ricker model parameters, parr capacity (K), parr productivity (parr per spawner), and the number of spawners needed to produce the maximum number of parr for Chiwawa River spring Chinook.

Model	Parameter		Population capacity (K)	Intrinsic productivity	Spawners
	A	B			
Beverton-Holt	150,902.145	437.655	150,902	345	∞
Smooth Hockey Stick	11.642	312.913	113,801	313	1,089
Ricker	272.696	0.0009	116,650	273	1,163

It is important to note that the population capacity estimates are based on the number of parr counted in the Chiwawa River watershed during August. There are spring Chinook fry and parr that move out of the Chiwawa River watershed during spring and early summer (Hillman et al. 2017). It is unknown if these fish leave because of density-dependent pressures, they are flushed out during high flows, it is a life-history characteristic, or a combination of these. Regardless of the mechanism or reason, some of these fish may survive and rear in the Wenatchee or Columbia rivers. These emigrants are not included in the capacity estimates shown in Table 3.

The capacity estimates for spring Chinook parr apply only to the Chiwawa River watershed, a watershed within the Wenatchee River basin. Estimating parr capacity for the entire Wenatchee River basin using stock-recruitment models is difficult because there is no long-term time series of parr data for the entire basin. However, we can extrapolate parr capacity estimates from the

Chiwawa River watershed to the entire Wenatchee River basin using intrinsic potential (IP). Multiplying the parr capacity per intrinsic potential within the Chiwawa River watershed by the total intrinsic potential within the Wenatchee River basin yields an estimate of parr capacity for the Wenatchee River basin (Table 4). The Interior Columbia Basin Technical Recovery Team estimated IP based on wetted width, valley width (confinement), and gradient (see Cooney and Holzer 2006). They used sedimentation and temperature to refine IP for each 200-m long reach. We used the total stream area (km^2) weighted by intrinsic potential and temperature limited to extrapolate parr capacity to the entire Wenatchee River basin.

Table 4. Estimates of Wenatchee River basin parr capacity based on intrinsic potential (IP). The amount of IP within the Chiwawa River watershed is 0.481 km^2; the total amount of IP within the Wenatchee River basin is 1.798 km^2.

Model	Chiwawa parr capacity	Chiwawa parr/IP	Wenatchee parr capacity
Beverton-Holt	150,902	313,726	564,079
Smooth Hockey Stick	113,801	236,593	425,395
Ricker	116,650	242,516	436,043

Using this simple method, we estimate the Wenatchee River basin supports about 425,395-564,079 parr depending on which model is used. An important assumption of this simple method is that each unit of IP supports the same number of parr. This is clearly not true given that the quality of habitat within each unit of IP can vary greatly. That is, one unit of IP may contain more habitat structure (e.g., wood and cover) than another unit of IP. Importantly, the ratio of parr to IP comes from the Chiwawa River watershed, which contains some of the highest quality habitat within the Wenatchee River basin. Therefore, the estimated total parr capacity for the entire Wenatchee River basin is likely biased high. If habitat conditions throughout the Wenatchee River basin are enhanced to conditions similar to those in the Chiwawa River watershed, we may expect parr abundance to approach those estimated with this simple method.

Chiwawa River Spring Chinook Smolts

We successfully fit the three stock-recruitment curves to the Chiwawa spring Chinook smolt data (Figure 3). This information allows us to better understand the quality and quantity of overwintering habitat in the Chiwawa River basin.

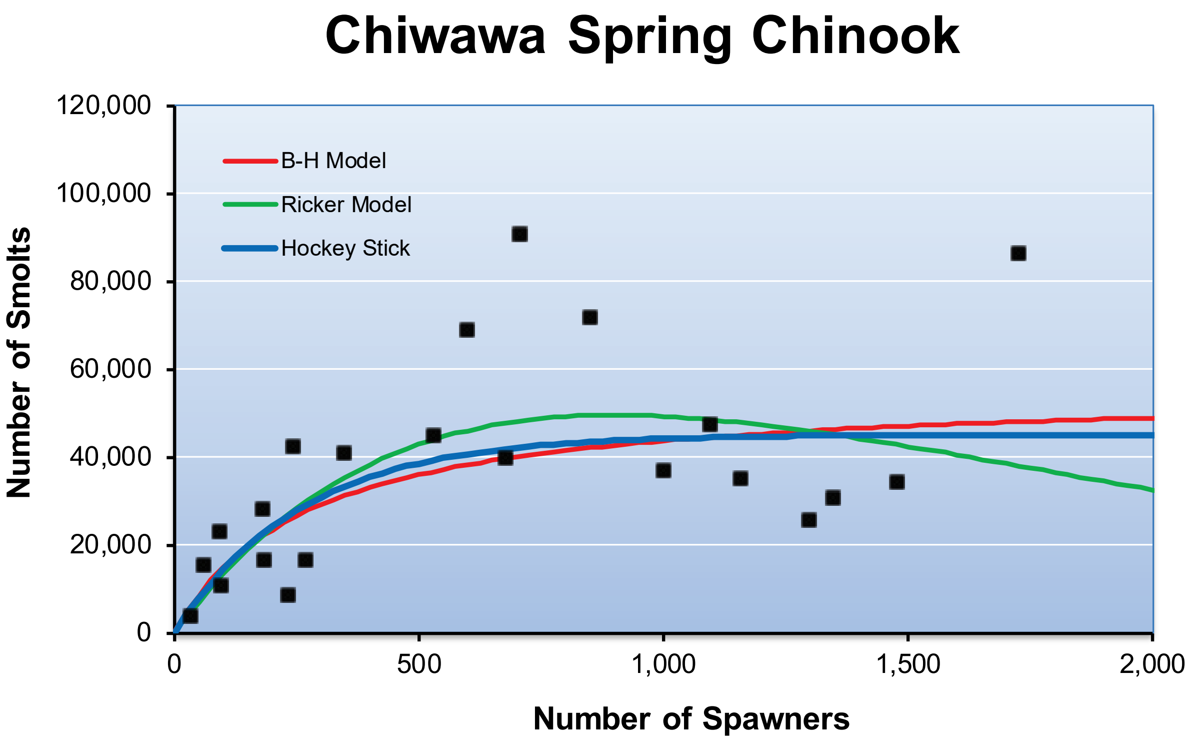

Figure 3. Relationship between numbers of spring Chinook smolts and numbers of spawners in the Chiwawa River watershed, 1992-2015. Figure shows the fit of the Beverton-Holt, Ricker, and smooth hockey stick models to the data.

For yearling smolts produced entirely within the Chiwawa River watershed, the use of AIC$_c$ indicated that the smooth hockey stick model best approximated the information in the productivity data. The estimated structural parameters for this model were:

$$LN(Smolts) = 10.7 + LN\left(1 - e^{-\left(\frac{174.1}{45,161}\right)Spawners}\right)$$

where the bootstrap estimated standard errors for the two parameters were 0.13 and 41.29, respectively. The adjusted $R^2 = 0.569$.

The second-best model was the Ricker model, which was 0.234 AIC$_c$ units from the best model. The estimated parameters for this model were:

$$Smolts = 149.45 \times Spawners(\mathrm{e}^{-0.00111 \times Spawners})$$

where the bootstrap estimated standard errors of the two parameters were 26.23 and 0.00018, respectively, and the $R^2 = 0.573$.

The third-best model was the Beverton-Holt model, which was 0.725 AIC$_c$ units from the best model. The estimated parameters for this model were:

$$Smolts = \frac{(55,702 \times Spawners)}{(273 + Spawners)}$$

where the bootstrap estimated standard errors of the two parameters were 10,421.9 and 123.0, respectively, and the $R^2 = 0.560$.

The AIC_c difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for all three models. Relative to the best model, the other two models had evidence ratios less than 1.5.

Depending on the stock-recruitment model used, population capacity ranged from 45,161 to 55,702 smolts (Table 5). The Beverton-Holt model estimated the highest capacity, while the smooth hockey stick model estimated the lowest. The number of spawners needed to produce the population capacity of smolts ranged from 777 to 901 (Table 5).

Table 5. Estimates of Beverton-Holt, smooth hockey stick, and Ricker model parameters, smolt capacity (K), smolt productivity (smolts per spawner), and the number of spawners needed to produce the maximum number of smolts for Chiwawa River spring Chinook.

Model	Parameter		Population capacity (K)	Intrinsic productivity	Spawners
	A	B			
Smooth hockey stick	10.718	174.077	45,161	174	777
Ricker	149.452	0.00111	49,532	149	901
Beverton-Holt	55,702.281	273.910	55,702	203	∞

It is important to note that the population capacity estimates are based on the number of smolts produced entirely within the Chiwawa River watershed. As noted earlier, there are spring Chinook fry and parr that move out of the Chiwawa River watershed during spring, early summer, and fall (Hillman et al. 2017). Fall emigration is common and occurs even when densities of juveniles are very low, indicating that fall emigration is a life-history characteristic. Regardless of why the fish emigrate as fry and parr, some of these fish survive and rear in the Wenatchee or Columbia rivers. Some survive to smolt (unpublished WDFW data), but are not included in the smolt capacity estimates shown in Table 5.

As with parr, the capacity estimates for spring Chinook smolts apply only to the Chiwawa River watershed. As before, we can extrapolate smolt capacity estimates from the Chiwawa River watershed to the entire Wenatchee River basin using intrinsic potential (IP). In this case, we multiply the smolt capacity per intrinsic potential within the Chiwawa River watershed by the total intrinsic potential within the Wenatchee River basin. This yields an estimate of smolt capacity for the Wenatchee River basin (Table 6).

Table 6. Estimates of Wenatchee River basin smolt capacity based on intrinsic potential (IP). The amount of IP within the Chiwawa River watershed is 0.481 km^2; the total amount of IP within the Wenatchee River basin is 1.798 km^2.

Model	Chiwawa smolt capacity	Chiwawa smolts/IP	Wenatchee smolt capacity
Beverton-Holt	55,702	115,805	208,218
Smooth Hockey Stick	45,161	93,891	168,816
Ricker	49,532	102,976	185,152

Using this simple method, we estimate the population capacity for the Wenatchee River basin at 168,816-208,218 smolts depending on which model is used. Based on smolt trapping in the lower Wenatchee River over a 13-year period, total smolt abundance has ranged from 36,752 to 302,116 smolts (average = 107,300 smolts) (Table 2).[14] Thus, recent (2000-2014) smolt production appears to be below capacity estimates for most years but higher in some years.

An important assumption of this simple method is that each unit of IP supports the same number of smolts. As we noted earlier, this is not the case given that the quality of habitat within each unit of IP can vary greatly. Nevertheless, the ratio of smolts to IP comes from the Chiwawa River watershed, which contains some of the highest quality habitat within the Wenatchee River basin. Therefore, the estimated total smolt capacity for the entire Wenatchee River basin is likely biased high. If habitat conditions throughout the Wenatchee River basin are enhanced to conditions similar to those in the Chiwawa River watershed, we may expect smolt abundance to approach those estimated with this simple method.

Wenatchee River Spring Chinook Smolts

Rather than extrapolate results from the Chiwawa River watershed to the entire Wenatchee River basin, we can fit stock-recruitment models to the smolt data collected in the lower Wenatchee River and estimate population capacity directly from the population models. We successfully fit the three stock-recruitment curves to the Chiwawa spring Chinook smolt data; although, the models explained little of the variation in the stock-recruitment data ($R^2 < 0.05$) (Figure 3).

[14] It is important to point out that the trapping location has changed over time. During the period 2000-2008 and 2011-2012, the trap was located near the Town of Monitor. During the period 2013-present, the trap was located near the Town of Cashmere.

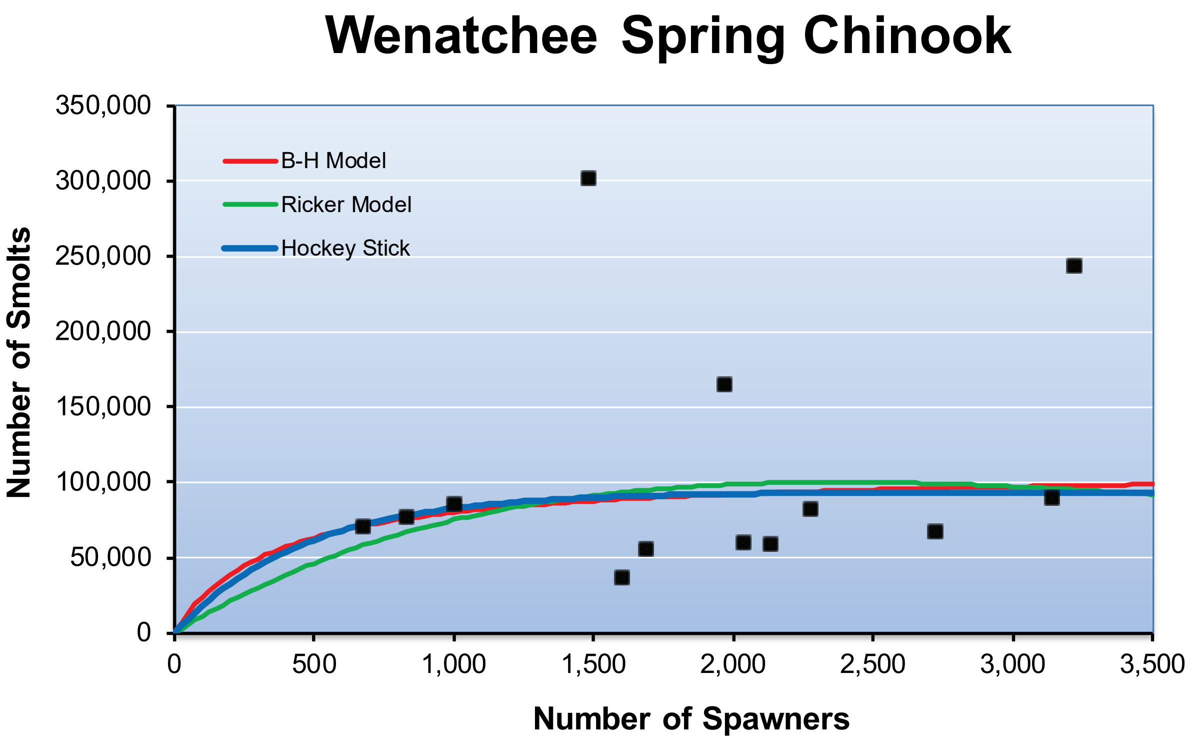

Figure 4. Relationship between numbers of spring Chinook smolts and numbers of spawners in the Wenatchee River basin, 2000-2014 (no data were collected in 2009 or 2010). Figure shows the fit of the Beverton-Holt, Ricker, and smooth hockey stick models to the data.

For yearling smolts produced within the Wenatchee River basin, the use of AIC_c indicated that the Beverton-Holt model best approximated the information in the productivity data. The estimated structural parameters for this model were:

$$Smolts = \frac{(108{,}696 \times Spawners)}{(359 + Spawners)}$$

where the bootstrap estimated standard errors for the two parameters were 49,948 and 836, respectively. The adjusted $R^2 = 0.026$.

The second-best model was the smooth hockey stick model, which was 0.112 AIC_c units from the best model. The estimated parameters for this model were:

$$LN(Smolts) = 11.4 + LN\left(1 - e^{-\left(\frac{20.72}{93{,}560}\right)Spawners}\right)$$

where the bootstrap estimated standard errors of the two parameters were 30.74 and 225.43, respectively, and the $R^2 = 0.017$.

The third-best model was the Ricker model, which was 0.0.808 AIC_c units from the best model. The estimated parameters for this model were:

$$Smolts = 114.10 \times Spawners(\mathrm{e}^{-0.00042 \times Spawners})$$

where the bootstrap estimated standard errors of the two parameters were 56.16 and 0.00021, respectively, and the $R^2 = 0.001$.

The AIC_c difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for all three models. Relative to the best model, the other two models had evidence ratios less than 2.0.

Depending on the stock-recruitment model used, population capacity for the Wenatchee River basin ranged from 93,560 to 108,696 smolts (Table 7). The Beverton-Holt model estimated the highest capacity, while the smooth hockey stick model estimated the lowest. The number of spawners needed to produce the population capacity of smolts ranged from 1,389-2,381 (Table 7).

Table 7. Estimates of Beverton-Holt, smooth hockey stick, and Ricker model parameters, smolt capacity (K), smolt productivity (smolts per spawner), and the number of spawners needed to produce the maximum number of smolts for Wenatchee River spring Chinook.

Model	Parameter		Population capacity (K)	Intrinsic productivity	Spawners
	A	B			
Smooth hockey stick	11.446	201.724	93,560	202	1,389
Ricker	114.104	0.00042	99,944	114	2,381
Beverton-Holt	108,696.009	358.616	108,696	303	∞

The population capacity estimates reported here are based on the number of smolts produced within the Wenatchee River basin. It is likely that some juvenile spring Chinook rear in the Columbia River and survive to smolt. Those fish are not included in these estimates of capacity.

Habitat Capacity

Habitat capacity can be estimated using fish-habitat models and creative modeling of stock-recruitment data. As we noted earlier, there are several different fish-habitat models that can be used to estimate habitat capacity. In this paper, we explore the use of two different methods, quantile regression applied to stock-recruitment functions and the Quantile Regression Random Forest model. The former relies on simple stock and recruitment data, while the latter requires estimates of habitat quality and quantity, and functional relationships between maximum fish density and habitat conditions.

Quantile Regression Analysis of Stock-Recruitment Data

To estimate population capacity, we used non-linear regression techniques to fit stock-recruitment functions to the data. These techniques approximate the conditional mean of the recruitment data given the range of stock sizes. As such, the functions (curves) estimated from the analyses lie near the center of the distribution of data resulting in data points above and below the curve. Although this technique is useful for estimating population capacity, it is not appropriate for estimating habitat capacity. The fact that there are actual recruitment data above the estimated population capacity indicates that habitat capacity must be greater than the population capacity, or that measurement error is high. The former explanation is more likely than the latter.

One way to possibly estimate habitat capacity with stock-recruitment data is to fit stock-recruitment functions to the juvenile spring Chinook data using quantile regression techniques. Quantile regression estimates quantiles of the recruitment data given the range of stock sizes. Thus,

we can use quantile regression to fit a stock-recruitment function to, say, the upper 90% or 95% of the recruitment distribution. In other words, we fit a stock-recruitment function to the upper limits of the recruitment data given the range of stock sizes. In this case, the resulting stock-recruitment curve is above most of the recruitment data and therefore few data points lie above the curve. Calculation of capacity from these functions should more closely represent habitat capacity, provided there is an adequate range of stock sizes. Quantile regression gives results similar to those obtained from calculating reference intervals (RI).

In this exercise, we calculated the upper 90% RI for the Beverton-Holt and Ricker functions. We assume the 90% RI will closely represent the habitat capacity for juvenile spring Chinook. We calculated the 90% RI only for the Beverton-Holt and Ricker models, because these functions can be transformed into linear function (see Hilborn and Walters 1992). RIs are easier to calculate on linear functions than non-linear functions. We were unable to transform the smooth hockey stick model into a linear function and therefore we did not calculate RIs for this function.

Chiwawa River Spring Chinook Parr—We calculated 90% RIs for Chiwawa Chinook parr data for both the Ricker and Beverton-Holt models (Figure 5). The estimated parameters for the 90% RI for the Ricker model were:

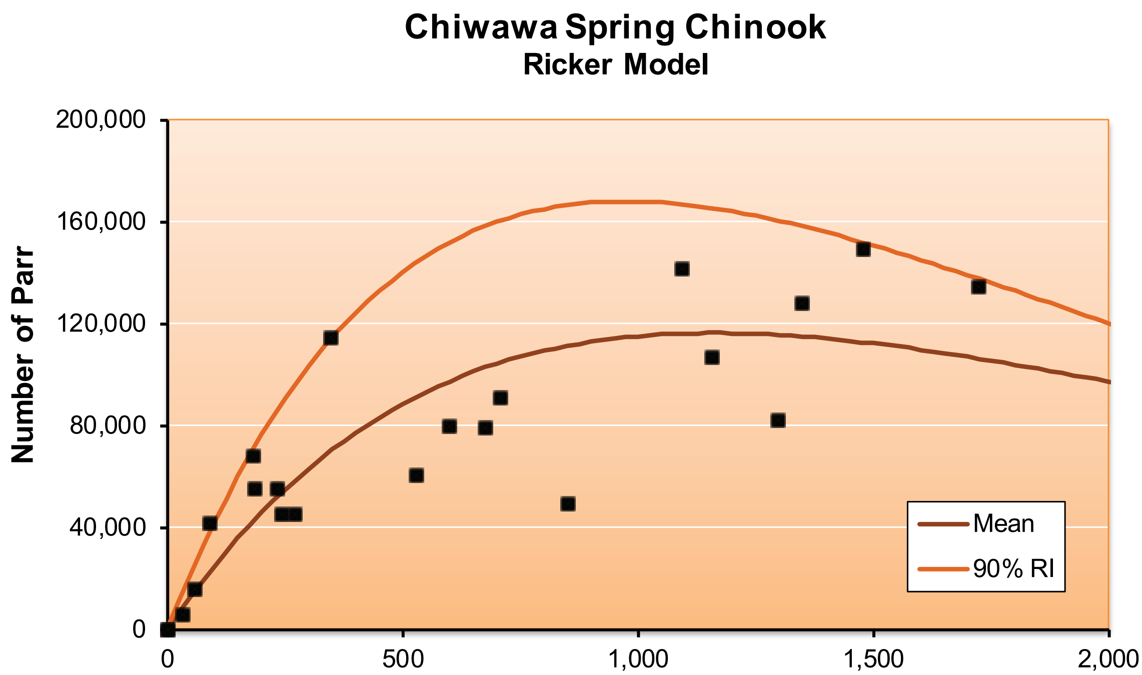
$$\log\left(\frac{Parr}{Spawners}\right) = 6.152 - \frac{6.152}{5{,}984.436}(Spawners)$$

This resulted in an estimated habitat capacity of 168,071 parr, which is about 1.4 times greater than the population capacity estimated with the Ricker model.

The estimated parameters for the 90% RI for the Beverton-Holt model were:

$$\frac{Spawners}{Parr} = \frac{196.91}{181{,}818} + \frac{1}{181{,}818}(Spawners)$$

This function resulted in an estimated habitat capacity of 181,818 parr, which was about 1.2 times greater than the population capacity estimated with the Beverton-Holt model.



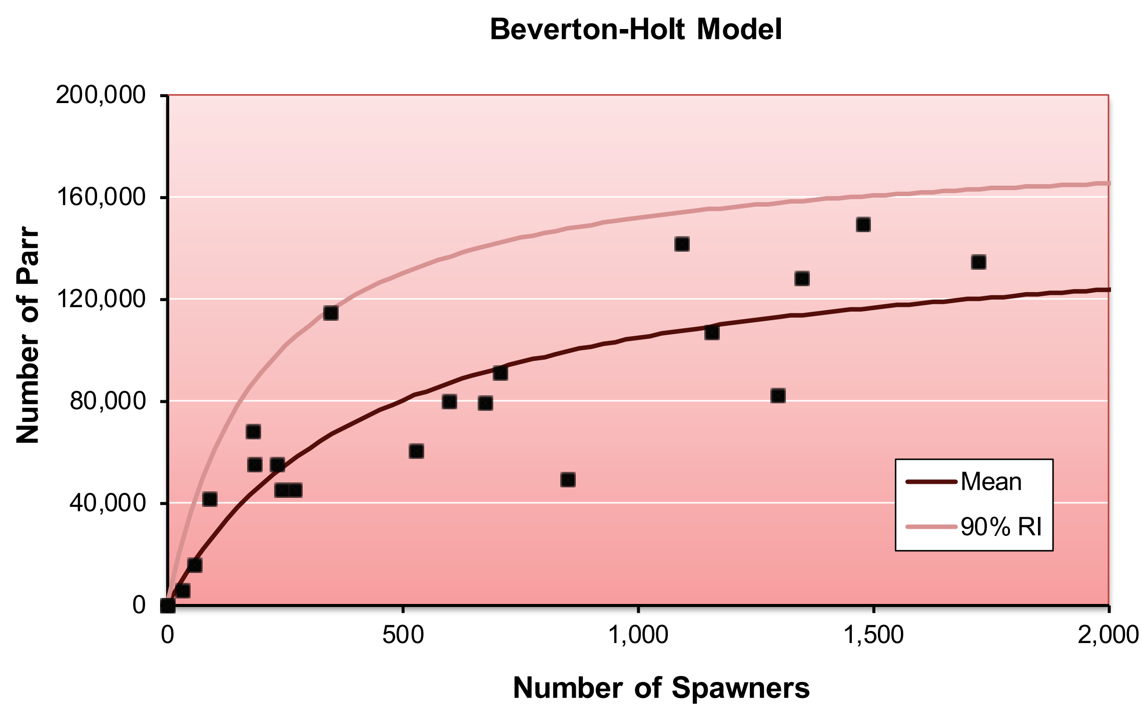


Figure 5. Relationship between numbers of spring Chinook parr and numbers of spawners in the Chiwawa River watershed, 1992-2016. Upper figure shows the fit of the Ricker model and its 90% reference interval to the data; lower figure shows the fit of the Beverton-Holt model and its 90% reference interval.

If we extrapolate the habitat capacity estimates for Chiwawa spring Chinook parr to the entire Wenatchee River basin (using the IP method described earlier), we estimate the habitat capacity for the Wenatchee River basin to be 628,256 parr from the Ricker model and 679,645 parr from the Beverton-Holt model.

Chiwawa River Spring Chinook Smolts—As with parr, we calculated 90% RIs for Chiwawa Chinook smolt data for both the Ricker and Beverton-Holt models (Figure 6). The estimated parameters for the 90% RI for the Ricker model were:

$$\log\left(\frac{Smolts}{Spawners}\right) = 5.687 - \frac{5.687}{4{,}687.964}(Spawners)$$

This resulted in an estimated habitat capacity of 89,425 smolts, which is about 1.8 times greater than the population capacity estimated with the Ricker model.

The estimated parameters for the 90% RI for the Beverton-Holt model were:

$$\frac{Spawners}{Smolts} = \frac{102.129}{64{,}516} + \frac{1}{64{,}516}(Spawners)$$

This function resulted in an estimated habitat capacity of 64,516 smolts, which was about 1.2 times greater than the population capacity estimated with the Beverton-Holt model.

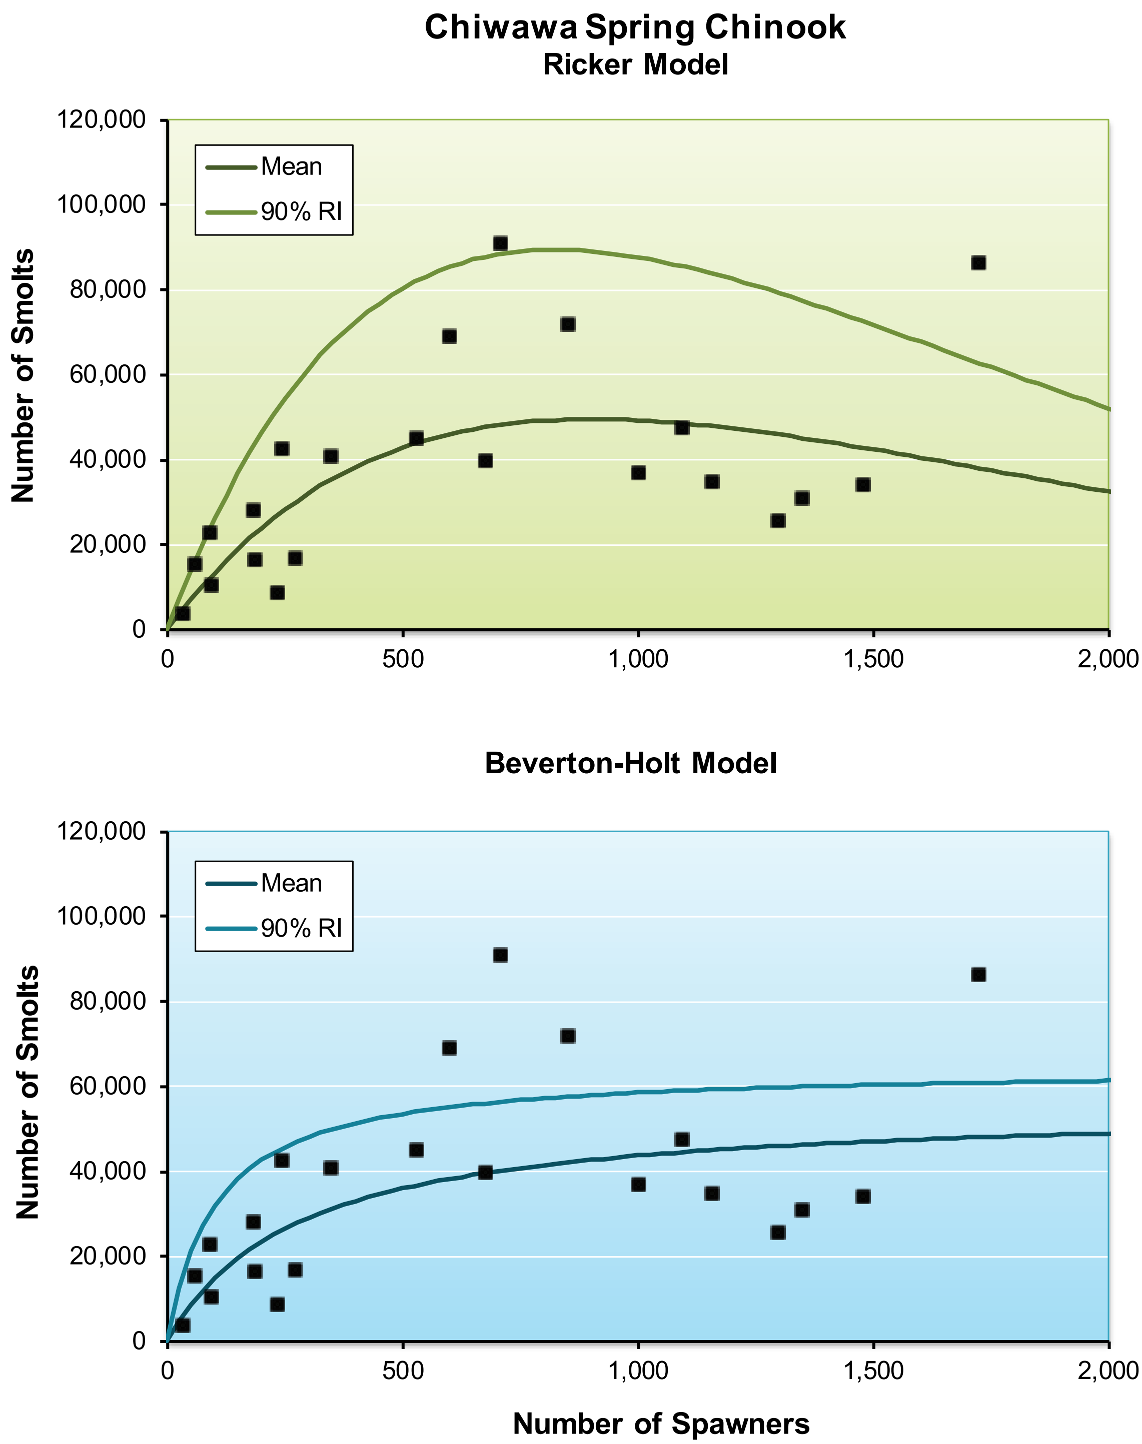

Figure 6. Relationship between numbers of spring Chinook smolts and numbers of spawners in the Chiwawa River watershed, 1992-2015. Upper figure shows the fit of the Ricker model and its 90% reference interval to the data; lower figure shows the fit of the Beverton-Holt model and its 90% reference interval.

If we extrapolate the habitat capacity estimates for Chiwawa spring Chinook smolts to the entire Wenatchee River basin (using the IP method described earlier), we estimate the habitat capacity

for the Wenatchee River basin to be 334,276 smolts based on the Ricker model and 241,164 smolts from the Beverton-Holt model.

Wenatchee River Spring Chinook Smolts—We calculated 90% RIs for Wenatchee River Chinook smolt data for both the Ricker and Beverton-Holt models (Figure 7). The estimated parameters for the 90% RI for the Ricker model were:

$$\log\left(\frac{Smolts}{Spawners}\right) = 5.320 - \frac{5.320}{16{,}642.420}(Spawners)$$

This resulted in an estimated habitat capacity of 235,131 smolts, which is about 2.4 times greater than the population capacity estimated with the Ricker model.

The estimated parameters for the 90% RI for the Beverton-Holt model were:

$$\frac{Spawners}{Smolts} = \frac{357.593}{186{,}567} + \frac{1}{186{,}567}(Spawners)$$

This function resulted in an estimated habitat capacity of 186,567 smolts, which was about 1.7 times greater than the population capacity estimated with the Beverton-Holt model.

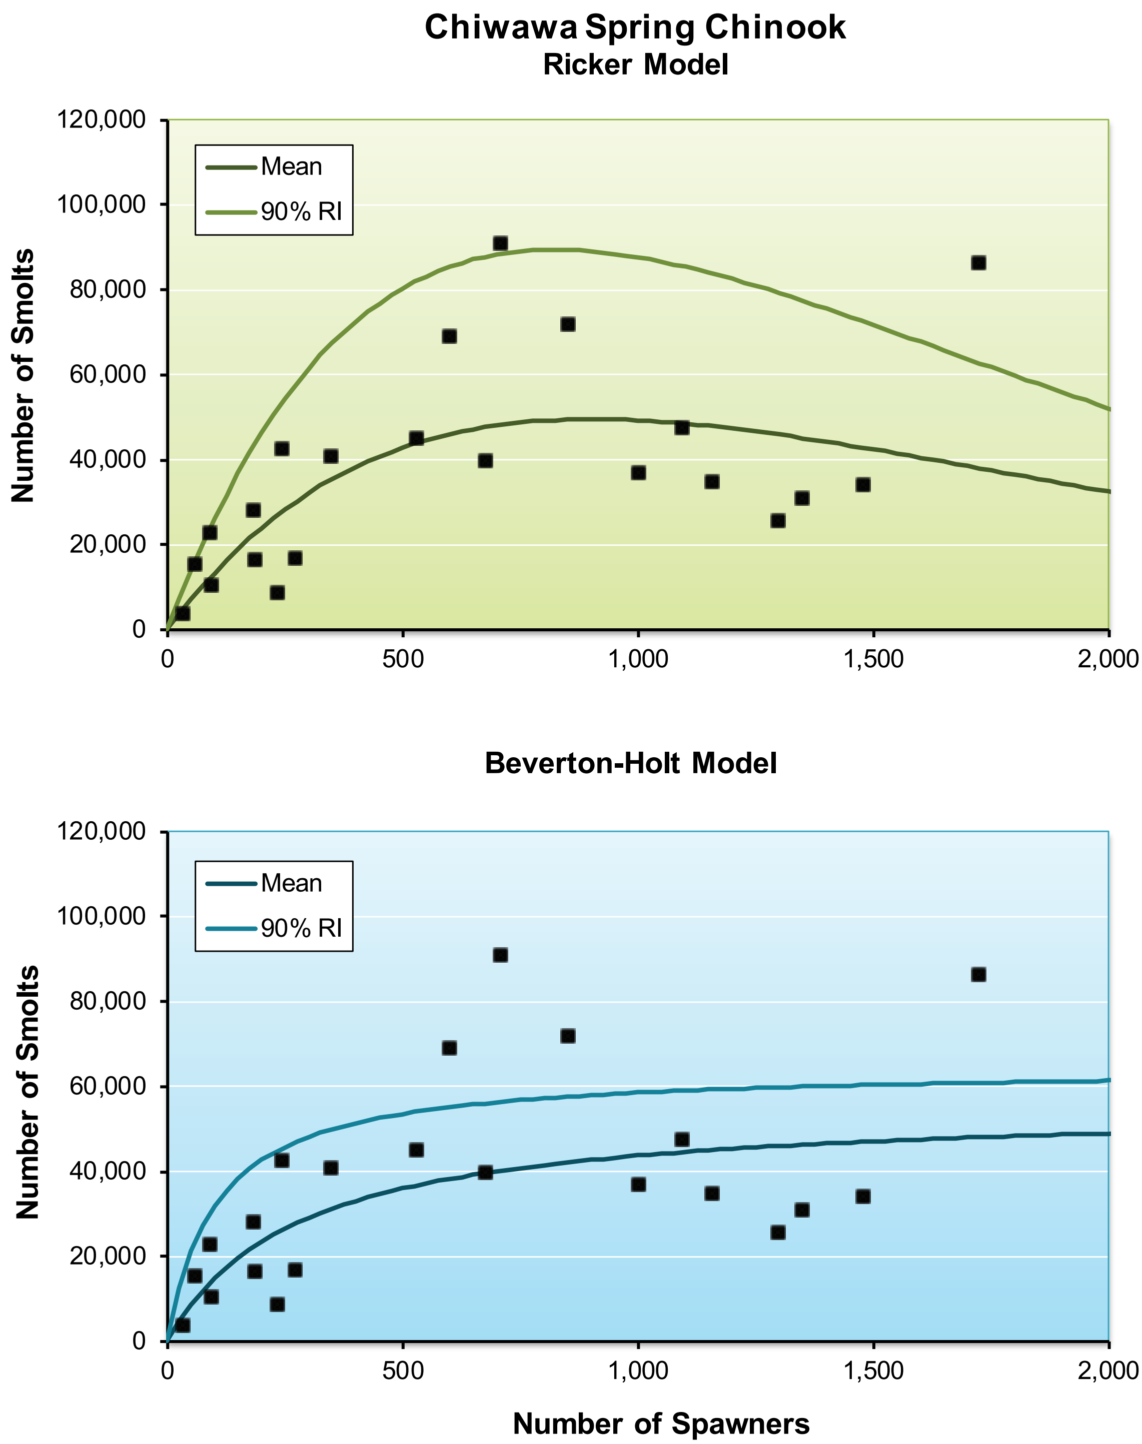

Figure 7. Relationship between numbers of spring Chinook smolts and numbers of spawners in the Wenatchee River basin, 2000-2015 (no data were collected in 2009 or 2010). Upper figure shows the fit of the Ricker model and its 90% reference interval to the data; lower figure shows the fit of the Beverton-Holt model and its 90% reference interval.

Quantile Regression Random Forest Model

Researchers with the Integrated Status and Effectiveness Monitoring Program (ISEMP) developed a model that estimates Chinook parr habitat capacity based on fish-habitat relationships (ISEMP/CHaMP 2015). Based on extensive sampling throughout the Columbia River basin, these researchers developed relationships between maximum densities of Chinook parr (summer estimates) and various habitat variables. Quantile regression forest (QRF) models use these relationships to estimate carrying capacities for juvenile Chinook. Very simply, QRF analysis develops non-linear relationships between fish density and different habitat variables. In this case, however, QRF analysis predicts the 90% quantile of fish density rather than the mean or median density. The researchers assume that the 90% quantile represents habitat capacity. This is important because the numbers of fish counted in some field sampling sites may not have been at maximum capacity. That is, it is likely that not all sites sampled were fully "seeded" with Chinook salmon. Thus, using the mean or median (50% quantile) would not represent habitat capacity, but some level below habitat capacity.

Researchers fit the QRF model to parr density data and 12 habitat variables that were collected from 227 sites within the distribution of Chinook throughout the Columbia River basin (within CHaMP/ISEMP watersheds). These variables were selected to represent a variety of types of habitat variables (e.g., substrate, riparian, complexity, temperature, etc.), contain the most "fish information," and be as uncorrelated as possible (ISEMP/CHaMP 2015). The 12 habitat variables and their relative importance are shown in Figure 8.

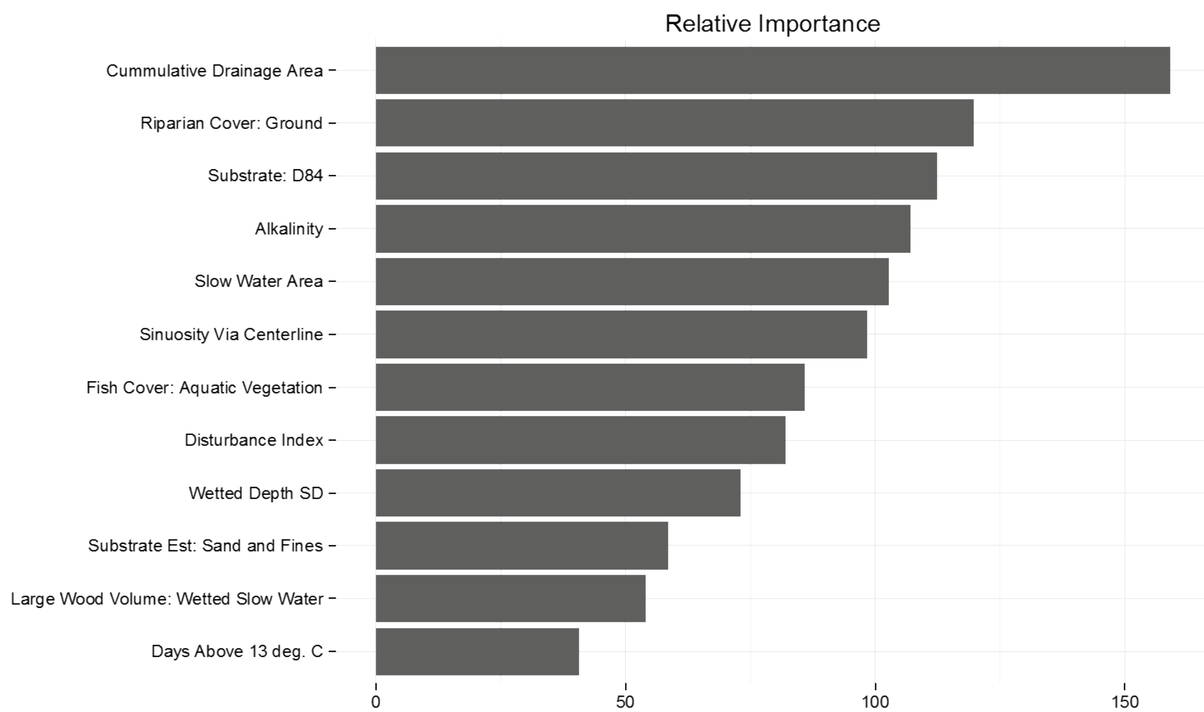

Figure 8. Relative importance of habitat variables included in juvenile Chinook salmon quantile regression forest models (Figure is from ISEMP/CHaMP 2015).

As a way of testing the model, ISEMP researchers used their QRF model to estimate Chinook parr capacities in different watersheds, including the Chiwawa River watershed, and compared their

estimates to those generated from fish population data using stock-recruitment modeling. Figure 9 shows the relationship between the QRF model results and population model results for the Chiwawa River watershed. The red curve was generated using the QRF model and the blue curve was generated using the Beverton-Holt model. At the time of this analysis, the Beverton-Holt model was fit to 21 years of parr data, not the 24 years of data used in the analyses above.

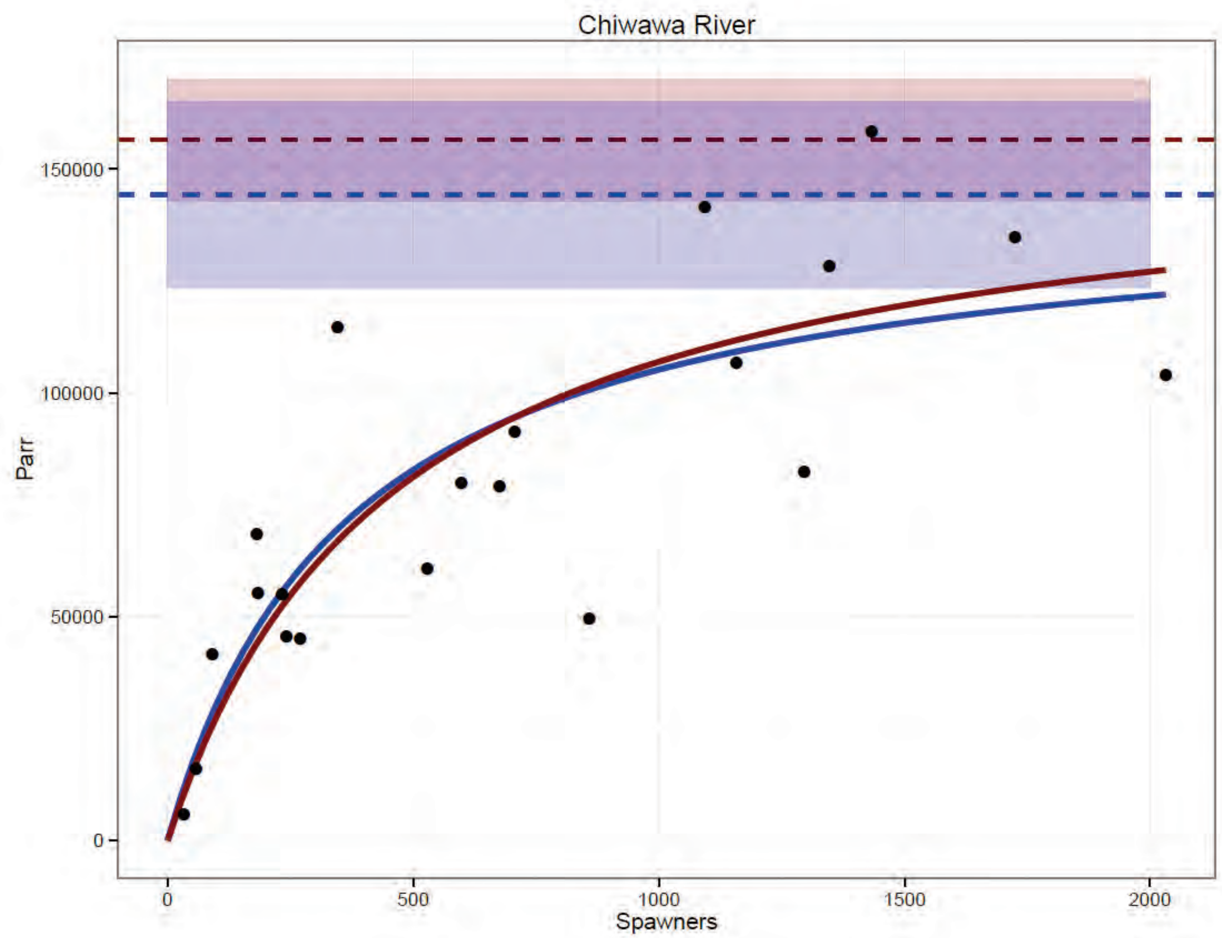

Figure 9. Comparison of productivity curves for Chiwawa spring Chinook parr generated from the QRF model (red line) and Beverton-Holt model (blue line). Dashed horizontal lines represent carrying capacity estimates. Shading about the capacity estimates represent the 95% confidence bounds. Figure is from ISEMP/CHaMP (2015).

The comparison shows that although the curves are very similar, the carrying capacity estimates (dashed horizontal lines) differed, with the habitat capacity generated from the QRF model being larger than the population capacity generated from the population data. That is, the QRF model estimated a habitat capacity of about 164,000 spring Chinook parr, while the population model estimated a population capacity of about 145,000 parr. Including more recent parr data in the Beverton-Holt model indicates that the population capacity estimate is about 151,000 parr for the Chiwawa River watershed. The 90% RI for the Beverton-Holt model estimated a habitat capacity of about 182,000, which is 1.1 times greater than the estimate from the QRF model. Note that the 90% RI for the Ricker model estimated a habitat capacity of about 168,000, which is close to the QRF model estimate.

Comparing Results

We estimated capacities for both spring Chinook parr and smolts for the Chiwawa River watershed and the entire Wenatchee River basin using different analytical tools. In this section, we compare the results from the different approaches.

Parr Capacity

Depending on the population model used, population capacity estimates for the Chiwawa River watershed ranged from 113,801 to 150,902 parr (Table 8). Not surprisingly, the Beverton-Holt model generally predicts the highest capacity estimates, while the smooth hockey stick model predicts the lowest. As expected, the population capacity estimates for Chiwawa parr were less than the habitat capacity estimates for parr. Habitat capacity estimates were about 1.2 to 1.5 times greater than the population capacity estimates (Table 8). Importantly, the fish-habitat model (QRF model) calculated a habitat capacity estimate that was close to that estimated from calculating 90% RI for the population models. Extrapolating Chiwawa capacity estimates to the entire Wenatchee River basin resulted in population capacities of 425,395 to 564,079 parr and habitat capacity estimates of 613,040 to 679,645 parr (Table 8).

Table 8. Comparison of spring Chinook parr capacity estimates for the Chiwawa River watershed and the Wenatchee River basin. Population capacities were estimated directly from the stock-recruitment functions; habitat capacities were estimated by calculating 90% reference intervals (using quantile regression; QR) for the stock-recruitment models and using a fish-habitat model (Quantile Regression Forest Model; QRF). Capacities for the Wenatchee River basin were estimated by extrapolating Chiwawa capacities using intrinsic potential.

Capacity type	Model	Chiwawa parr capacity	Wenatchee parr capacity
Population capacity	Beverton-Holt	150,902	564,079
	Smooth Hockey Stick	113,801	425,395
	Ricker	116,650	436,043
Habitat capacity	QR Beverton-Holt	181,818	679,645
	QR Ricker	168,071	628,256
	QRF Model	164,000	613,040

The number of spawners needed to achieve parr capacity also varied depending on the population model used (Table 9). For the Chiwawa River watershed, maximum spawners needed to achieve population capacity for parr ranged from 1,089 to 1,163 adults. Extrapolating Chiwawa results to the entire Wenatchee River basin resulted in maximum spawner estimates of 4,070 to 4,347 adults. We were able to estimate habitat capacity only with the Ricker model (Table 9). Using quantile regression to calculate the 90% RI for the Ricker model resulted in a maximum spawner abundance of 973 adults, which is less than the number needed to achieve population capacity. This is because the 90% RI for the Ricker function estimates a higher intrinsic productivity, which shifts the "hump" of the curve to the left resulting in a higher capacity estimate but a lower maximum spawner estimate (see Figure 5).

Table 9. Comparison of the number of spawners needed to achieve parr capacities in the Chiwawa River watershed and the Wenatchee River basin. For the Chiwawa River watershed, maximum spawners were estimated directly from the stock-recruitment functions. Maximum spawners for the entire Wenatchee River basin were estimated as the product of the extrapolated parr numbers times the ratio of maximum spawners to parr capacity for Chiwawa spring Chinook. Because of the nature of the Beverton-Holt model, no maximum spawners can be calculated from that model.

Capacity type	Model	Spawners need to achieve parr capacity	
		Chiwawa	Wenatchee
Population capacity	Smooth Hockey Stick	1,089	4,070
	Ricker	1,163	4,347
Habitat capacity	QR Ricker	973	3,636

Smolt Capacity

As with parr estimates, population capacity estimates for smolts varied depending on the population model used. For Chiwawa spring Chinook smolts, population capacities ranged from 45,161 to 55,702 smolts, with the smooth hockey stick providing the lowest estimate and the Beverton-Holt model providing the highest (Table 10). The population capacity estimates were about 55 to 86% of the habitat capacity estimates. Extrapolating Chiwawa capacity estimates to the entire Wenatchee River basin resulted in population capacities of 168,816 to 208,218 smolts and habitat capacity estimates of 241,164 to 334,276 smolts (Table 10). These were greater than those estimated using smolt and spawner data for the entire Wenatchee River basin. Fitting population models to smolt and spawner data for the entire basin resulted in population capacities of 93,560 to 108,696 smolts and habitat capacities of 186,567 to 235,131 smolts (Table 10).

Table 10. Comparison of spring Chinook smolt capacity estimates for the Chiwawa River watershed and the Wenatchee River basin. Population capacities were estimated directly from the stock-recruitment functions; habitat capacities were estimated by calculating 90% reference intervals (using quantile regression; QR) for the stock-recruitment models. Capacities for the Wenatchee River basin were estimated by extrapolating Chiwawa capacities using intrinsic potential and by fitting population models to the smolt and spawner data for the entire basin.

Capacity type	Model	Chiwawa smolt capacity	Wenatchee smolt capacity	
			Chiwawa extrapolation	Wenatchee data
Population capacity	Beverton-Holt	55,702	208,218	108,696
	Smooth Hockey Stick	45,161	168,816	93,560
	Ricker	49,532	185,152	99,944
Habitat capacity	QR Beverton-Holt	64,516	241,164	186,567
	QR Ricker	89,425	334,276	235,131

The number of spawners needed to achieve smolt capacity varied depending on the population model used (Table 11). For the Chiwawa River watershed, maximum spawners needed to achieve

population capacity for smolts ranged from 777 to 901 adults. Note that the maximum number of adults needed to achieve population capacity for smolts is less than those needed to achieve population capacity for parr. Extrapolating Chiwawa results to the entire Wenatchee River basin resulted in maximum spawner estimates of 2,904 to 3,368 adults. These estimates are considerably higher than those estimated from fitting population models to Wenatchee River basin data. The latter estimated maximum spawners ranging from 1,389 to 2,381 adults. We were able to estimate habitat capacity only with the Ricker model (Table 11). Using quantile regression to calculate the 90% RI for the Ricker model resulted in a maximum spawner abundance of 824 adults for the Chiwawa River watershed and 3,129 adults for the entire Wenatchee River basin. Extrapolating Chiwawa results to the entire Wenatchee River basin resulted in a maximum spawner estimate of 3,080, which is close to the estimate generated by fitting the model to Wenatchee River basin data.

Table 11. Comparison of the number of spawners needed to achieve smolt capacities in the Chiwawa River watershed and the Wenatchee River basin. Maximum spawners were estimated directly from the stock-recruitment functions. Maximum spawners for the entire Wenatchee River basin were also estimated as the product of the extrapolated smolt numbers times the ratio of maximum spawners to smolt capacity for Chiwawa spring Chinook. Because of the nature of the Beverton-Holt model, no maximum spawners can be calculated from that model.

Capacity type	Model	Spawners need to achieve smolt capacity		
		Chiwawa	Wenatchee	
			Chiwawa extrapolation	Wenatchee data
Population capacity	Smooth Hockey Stick	777	2,904	1,389
	Ricker	901	3,368	2,381
Habitat capacity	QR Ricker	824	3,080	3,129

As an additional exercise, we calculated smolt capacities and maximum spawners generated from fitting population models to smolt and spawner data in the Chiwawa River, Nason Creek, and White River watersheds, and compared the sum of those estimates to the Wenatchee River basin estimates. Only the Ricker model could be fit to the White River and Nason Creek data (see Hillman et al. 2017). Estimated population capacities from the Ricker model were 49,532 smolts in the Chiwawa, 4,412 smolts in Nason Creek, and 4,659 smolts in the White River, resulting in a cumulative population capacity of 58,603 smolts (1,550 spawners are needed to achieve this cumulative smolt capacity). The cumulative population capacity estimate is nearly 60% of the total population capacity calculated from fitting the Ricker model to the entire Wenatchee River basin data. If these estimates are correct, this means that about 40% of the current Wenatchee River basin smolt capacity is outside the Chiwawa River, Nason Creek, and White River watersheds. Hillman et al. (2017) report that over the period 1989 to 2016, on average, 76% of spring Chinook spawning occurs in the three watersheds. Thus, a large percentage of smolt capacity is generated outside the major spawning areas. We believe this highlights the importance of the mainstem Wenatchee River as a rearing area for juvenile spring Chinook.

Recommendations

Based on the simple analyses conducted in this report, we offer the following recommendations:

1. Where sufficient stock and recruitment data are available, and the data have sufficient contrast, then use population (stock-recruitment) modeling as the primary method to calculate population capacity and the number of spawners needed to produce the maximum number of recruits under current or average habitat conditions. Select the best fitting stock-recruitment model based upon AIC_c, unless other factors suggest otherwise, such as evidence for a biological mechanism. A biological mechanism supporting a Ricker function, for example, would be that there is a stock-dependent effect on the mortality of eggs and juveniles (i.e., mortality is proportional to the initial cohort size). When AIC_c values are not appreciably different, then select the model that is most useful (e.g., Ricker and smooth hockey stick models are easier to work with than the Beverton-Holt model).
2. Adult-to-adult data are the most relevant because they account for all life stages and delayed effects in freshwater (e.g., small size at migration), but they are also the most variable (i.e., low R^2). Therefore, adult-to-juvenile data (e.g., parr, yearling smolts, total migrants) are likely the most useful for determining freshwater population capacity. Where data are available, pre-spawn adult to spawning adult survival can also be assessed using population models to evaluate density dependence and pre-spawn adult capacity.
3. The population models used to estimate population capacity should also be used in reference streams so one can make comparisons of carrying capacities and density-corrected productivities. Unless there are good reasons for selecting a different juvenile life-stage, the default should be to use yearling smolts because they represent the capacity of the tributaries to produce yearlings and it is also a clear identification and quantification of a migrant life-stage.
4. In the absence of fish-habitat models, quantile regression can be used to estimate habitat capacity by calculating reference intervals for the population models. The percentage of the reference interval should be set using the error in the estimation of the recruits and the level of desire to exclude anomalous data. For example, if the 95% confidence interval is approximately 10% of the recruitment estimate, then the reference interval should be set at 90% (e.g., RI = 100% - C.I.%).
5. Where sufficiency conditions in (1) are not met, use habitat-based expansion of density at capacity for the most ecologically similar population. For example, use Twisp capacity estimates for habitat-based expansions in the Methow. The habitat expansion metric should be "total stream area weighted by intrinsic potential and temperature limited," unless there are good reasons for a different expansion. The primary idea is to exclude areas that are known to not produce fish because of passage, temperature, or other limitations.
6. Capacity estimates should be described within the context of the information that was used to derive estimates. For example, spawner distribution of hatchery-origin fish could influence estimates of capacity if they are within poor habitat. However, the capacity estimates do reflect the historic and current hatchery practices. It is unknown how the capacity estimates would change if a different hatchery program that produced different spawning distributions was to be implemented. However, if those data do become available, then capacity estimates can be revised. Similarly, significant enhancements (e.g.,

improved passage) or degradations (e.g., fire) in habitat can also change capacity and can be incorporated into future estimates of capacity.

7. Regardless of the method used to estimate capacity, always describe the limitations of the data and assumptions of the models. Note where assumptions are violated and how these violations could affect the results of the analysis.

APPENDIX 2: HATCHERY REPLACEMENT RATES

Based on ideas developed by the HETT, in February 2016, the HCP Hatchery Committees and PRCC Hatchery Subcommittee agreed to the following rules and HRR targets:

1. Use the estimated 40% HRR Target during 5-year statistical evaluation periods.
2. Use varying degrees of action depending on the numbers of years that annual HRR deviates from Target.
    a. Green Light (below Target for ≤ 2 years).
    b. Red Light (below Target for > 2 years).
3. Each program will have its own HRR target with the following exceptions.
    a. Nason Creek spring Chinook will use the Chiwawa Target (there are currently no data to calculate a target for Nason Creek spring Chinook).
    b. Methow and Chewuch spring Chinook will use the greater of their two Targets (they are MetComp stock and evaluated similarly).

Table 1. Release numbers and 5-year hatchery replacement rates (HRR) targets for Upper Columbia River Hatchery Programs.

Species	Owner	Program (Hatchery)	Basin (Purpose)	Smolts released[1]	5-Year HRR[2]
Steelhead	CPUD	Eastbank (Chiwawa)	Wenatchee (Conservation)	123,650	6.9
Steelhead	CPUD	Eastbank (Chiwawa)	Wenatchee (Safety Net)	123,650	6.9
Steelhead	DPUD	Wells (Wells)	Columbia (Safety Net)	160,000	26.5
Steelhead	DPUD	Wells (Wells)	Methow (Safety Net)	100,000	26.5
Steelhead	DPUD	Wells (Wells)	Twisp (Conservation)	48,000	26.5
Steelhead	GPUD	Wells (Omak)	Okanogan (Conservation)	100,000	7.3 [3]
SUM Chinook	CPUD	Eastbank (Chelan Falls)	Chelan (Conservation)	176,000	5.7
SUM Chinook	CPUD	Eastbank (Chelan Falls)	Chelan (Harvest)	400,000	5.7
SUM Chinook	CPUD, GPUD	Eastbank (Dryden)	Wenatchee (Conservation)	500,000	5.7

[2] Derived from Annual Reports.
[3] Harvest not included.

APPENDIX 3: PNI and pHOS Targets and Sliding Scales

Select CPUD, DPUD, and GPUD funded hatchery mitigation programs have PNI management targets, while others do not. Table 1 summarizes management strategies by species and population. Detailed information can be found in the sections that follow. Descriptions provided in the following sections are taken directly from HGMPs and/or issued and draft permits.

Table 1. Summary of management strategies by species and population.

Species	Population	Management Strategy	Comments
Spring Chinook	Wenatchee	Sliding Scale of PNI management	Details can be found in Section 2.0
	Methow	Two—population sliding scale PNI management	Details can be found in Section 3.0
	Okanogan	None Currently	Details can be found in Section 4.0
Steelhead	Wenatchee	Two-zone management.	Details can be found in 5.0
	Methow	In-development	Details forthcoming; Section 6.0
	Okanogan	None Currently	Details can be found in Section 7.0
Summer Chinook	Wenatchee	None Currently	Details can be found in Section 9.0
	Methow	None Currently	Details can be found in Section 10.0
	Okanogan	0.67; pHOS 0.30	Details can be found in Section 11.0
	Upper Columbia River	None Currently	Details can be found in Section 12.0
Fall Chinook	Hanford Reach	0.67	Details can be found in Section 13.0

2.0 Wenatchee Spring Chinook

Wenatchee spring Chinook will be managed according to the sliding scale identified in the Wenatchee Spring Chinook Management Plan (2010) and Permit Numbers 18118 and 18121. The sliding scale is based upon the estimated number of natural origin spring Chinook over Tumwater Dam. As more information becomes available the sliding scale may be adjusted as a result of gaining a better understanding of the pre-spawn mortality rate and carrying capacity.

Table 2. Sliding scale of PNI goals based on natural origin spring Chinook run size expected to the Wenatchee River basin. Percentiles are based on adult returns observed between 1999 and 2008.

Percentile	NOR Run Size				PNI
	Chiwawa	Nason Creek	White	Wenatchee River (above TWD)	
>75th	>372	>350	>87	>910	≥ 0.80
50% - 75%	278-372	259-349	68-86	631-909	≥ 0.67
25% - 50%	209-277	176-258	41-67	525-630	≥ 0.50
10%-25%	176-208	80-175	20-40	400-524	≥ 0.40

<10th	<175	<80	<20	<400	Any PNI

3.0 Methow/ Chewuch Spring Chinook

The following sliding scale (Table 3) is presented in the April 14, 2016 draft Methow Hatchery Spring Chinook Section 10-Draft. It is anticipated that no further changes will be made to the sliding scale prior to issuance of the final permits.

Table 3. PUD PNI sliding scale calculations for a range of natural run sizes.

Natural Origin Returns	PUD pHOS	WNFH pHOS	PUD pNOB	2-Pop PNI	PUD PNI (equation)
<300	Ensure minimum of 500 total spawners				
300	0.40	0.2	0.75	0.67	0.67
500	0.40	0.2	0.80	0.68	0.76
900	0.30	0.15	1.00	0.78	0.80
1500	0.25	0.1	1.00	0.8	0.80
2000	0.25	0.1	1.00	0.8	0.80
2500	0.25	0.1	1.00	0.8	0.80

4.0 Okanogan Spring Chinook

The Okanogan spring Chinook program is a re-introduction effort implemented as a non-essential experimental population under ESA Section 10j to re-introduce spring Chinook into the Okanogan River. As a non-essential experimental population targeting re-introduction and establishment of a local population of spring Chinook, the Okanogan spring Chinook program will not conduct adult management actions to reduce the proportion of 10j hatchery fish on the spawning grounds or conduct broodstocking efforts in the Okanogan for a 10-year period (2014 – 2023), as such, no PNI or pHOS objectives have been identified for this program in this 10-year period.

CJH Program segregated production released into the mainstem Columbia River are non-listed Leavenworth stock released reared/acclimated/released at CJH. Although no PNI or pHOS targets are identified for the Okanogan 10j population, minimizing strays from the CJH segregated spring Chinook program is a program objective, as such, returning segregated program fish will be subject to directed harvest and aggressive adult surplusing at CJH to minimize straying to the Okanogan River Basin as well as other extant upper Columbia River spring Chinook populations. Stray targets for the segregated program are 5% or less stray rate (i.e. spawning contribution to other upper Columbia River spring Chinook populations).

5.0 Wenatchee Steelhead

Interim escapement goal for Wenatchee River steelhead will be 1,500 spawners with an additional goal of attaining an average PNI of 0.67 for the Wenatchee River basin population as a whole. To achieve the stated goal, the Wenatchee steelhead program will use a two-zone management approach wherein the upper basin (above TWD) will be managed for recovery using an integrated recovery program, a separate spawning escapement goal, and a PNI standard to achieve the overall basin goal of an average PNI over time of 0.67 (Table 4). Areas below TWD will be managed to minimize hatchery supplementation with a pHOS goal of < 0.10.

Steelhead returning upstream of TWD will be managed as an integrated recovery program with a pNOB goal of 1.0. The above TWD escapement goal will be 1,094 spawners. Working within this framework, pNOB will be maximized above TWD while pHOS will be minimized.

Table 4. Wenatchee steelhead two-zone management and PNI targets.

Location	Run Escapement Goal	pNOB Conservation Program	pNOB Safety Net Program	pHOS	PNI
Above TWD	1,094	1.0	0.0	Varies	Varies
Below TWD	406	N/A	N/A	< 0.10	< 0.67
Basin Total	1,500	N/A	N/A	Minimal	Average = 0.67

6.0 Methow Steelhead

Methow steelhead PNI targets are currently in development.

7.0 Okanogan Steelhead

Current program has no PNI goal. CTCR submitted an Okanogan steelhead HGMP to NOAA Fisheries on February 4, 2014. Within the HGMP provisions were included to allow a greater collection of natural-origin broodstock and multiple adult management strategies to address over-escapement of hatchery-origin steelhead to the spawning grounds. The HGMP also identified a near-term (1-4 years) and a long-term PNI objectives of 0.50 and > 0.67, respectively. Once NOAA has completed the consultation and issued a new permit, providing the opportunity to increase the proportion of natural-origin fish in the broodstock and additional adult management strategies, the program will adopt the PNI objectives and this Appendix can be amended accordingly.

8.0 Wells Columbia Mainstem Safety-net Steelhead

The Safety-Net Mainstem Columbia component released below Wells Dam will be managed primarily at the Wells Hatchery volunteer channel. The objective of the adult management of the Safety-Net Mainstem Columbia component is to prevent runs of this component from moving into natural spawning areas. This will be accomplished through in-river harvest and removal of volunteers at the Wells Hatchery outfall. There are no PNI goals for this component.

9.0 Wenatchee Summer Chinook

No PNI goals are established.

10.0 Methow Summer Chinook

No PNI goals are established.

11.0 Okanogan Summer Chinook

Okanogan summer/fall Chinook will be managed to achieve a 5-year rolling average PNI of 0.67 and pHOS of 0.30. Strategies to achieve that PNI target include up to 100% pNOB, aggressive removal of hatchery-origin Chinook in selective fisheries, at the Okanogan weir, and during surplusing at CJH ladder. Reduction in the number of juveniles released in the Okanogan River Basin (integrated program) is also a management option, should adult management actions be unable to control the proportion of hatchery fish on the spawning grounds to achieve that PNI target.

CJH segregated summer/fall Chinook program rears/acclimates/releases smolts into the mainstem Columbia River at CJH. Broodstock are 100% hatchery-origin, as such no PNI target for this production component. Stray rate (i.e. contribution to upper Columbia summer/fall Chinook populations) is 5% or less. Adult management on returning adults from the segregated program include fisheries, removal at the Okanogan weir, and removal at the CJH ladder.

12.0 Upper Columbia Summer Chinook (Chelan Falls and Wells)

No PNI goals are established. Chelan Falls and Wells FH summer Chinook programs are segregated harvest programs designed to provide opportunity for harvest. Adult returns are not intended to spawn naturally; therefore, there is no escapement goal for natural spawning areas. Adult returns will be managed to meet program objectives. Chelan Falls and Wells Hatchery summer Chinook are available for harvest in the ocean and Columbia River commercial, tribal, and recreational fisheries.

13.0 Priest Rapids Fall Chinook

The Hanford Reach fall Chinook population is intentionally supplemented by Grant PUD at the Priest Rapids Hatchery and the ACOE at the Priest Rapids and Ringold Springs hatcheries. Managers desire to achieve a population level PNI that includes all hatchery programs of $\geq$0.67. Grant PUD and the HSC do not have control over operation or expansion of the ACOE program and therefore will strive to operate the Priest Rapids Hatchery fall Chinook program in a way that does its fair share of achieving a population level PNI of 0.67.

APPENDIX 4: SPATIAL DISTRIBUTION OF SPAWNERS OR REDDS

Strategies for conservation programs typically intend that hatchery and naturally produced fish spawn together and in similar locations. However, in some cases, strategies may differ from this paradigm. In Table 1, conservation programs that have a spatial distribution management plan that deviates from similar to the natural spawning spatial distributions are presented. Otherwise, conservation programs are intended to have a spawning distribution similar to the natural origin spawning spatial distributions, as described by M&E Objective 5.3.

Table 1. Management targets for the spatial distribution of hatchery-origin redds for conservation programs that deviate from Objective 5.3.

Program	Target	Rational	Source
Carlton Summer Chinook	The observed spawning distribution of hatchery origin Methow summer Chinook from 2005-2010 represents the base-line spawner distribution for evaluating the performance of the hatchery program (i.e., M&E plan check-ins). It is acknowledged that this distribution is lower in the River than the spawning distribution of natural origin summer Chinook salmon.	Based upon an assessment of summer Chinook and ESA-listed spring Chinook abundance and spawner distribution, it was determined that an increase in summer Chinook spawning abundance in the upper most range of natural origin summer Chinook distribution or potentially above the current range may pose an unknown and potentially adverse impact to ESA listed spring Chinook. Due to the concern for spring Chinook, the HSC has endorsed an acclimation site in the Methow Basin that is lower in the basin than may be required to attain exact replication of natural and hatchery origin summer Chinook spawner distribution.	SOA 2011-02 Priest Rapids Coordinating Committee Hatchery Subcommittee Statement of Agreement on Monitoring & Evaluation (M&E) Objective for Spawning Distribution of Hatchery-Origin Summer Chinook
Dryden Summer Chinook	The observed spawning distribution of hatchery origin Wenatchee summer Chinook from 2008-2013 (previous 5 years to the current M&E check-in cycle) represents the base-line spawner distribution for evaluating the performance of the	The primary site endorsed by the HSC for Grant PUD overwinter acclimation of summer Chinook is the Dryden Pond, and is the current acclimation and release site for the existing summer Chinook supplementation program	Adapted from SOA 2011-02 Priest Rapids Coordinating Committee Hatchery Subcommittee Statement of Agreement on Monitoring & Evaluation (M&E) Objective for Spawning Distribution of Hatchery-Origin Summer Chinook

	hatchery program (i.e., M&E plan check-ins).	funded and owned by Chelan PUD. Because current data indicates that spawning distribution of hatchery summer Chinook from the existing program is lower in the Wenatchee River than natural origin spawners, expectations are that acclimation of Grant PUD's summer Chinook at Dryden Pond would continue to return hatchery origin summer Chinook that result in different spawning distributions for hatchery and natural summer Chinook.	

APPENDIX 5: WITHIN HATCHERY REARING TARGETS

Rearing Targets for Upper Columbia River Hatchery Programs. K-factor or fork length targets will be determined based on data from the pending "Five-Year Report."

Table 1. Numbers, fish per pound (fpp), coefficient of variation (CV), and condition factor (K) targets at release of Upper Columbia River Hatchery Programs.

Hatchery	Species	Life Stage	Basin	Release number	FPP	CV	K-factor
Methow	Spring Chinook	Yearling	Methow	193,765[1]	15	<10	TBD

Ringold	Fall Chinook	Subyearling	Columbia	3.5 M	50	<10	TBD

[1] The total release includes the release of 108,249 into the Methow River at the Methow Fish Hatchery, 25,000 into the Methow River at the Goat Wall site, and 60,516 into the Chewuch River at the Chewuch Acclimation Facility.

[2] These fish come from Winthrop National Fish Hatchery (MetComp) eyed eggs.

[3] The total release includes 125,000 conservation fish and 98,670 safety net fish.

[4] The combined Okanogan and Omak steelhead release number is 100,000.

[5] The total release includes 66,771 fish into Nason Creek, 53,170 into the Chiwawa River, 102,359 into the Wenatchee River, and 25,000 into Blackbird Pond.

[6] The Wells subyearling Chinook are not reared to achieve a specific size target. The fish are released on a date to optimize survival and are grown to the largest size possible before release.

[7] The total release is divided equally among the Omak, Riverside, and Similkameen Acclimation Ponds.

[8] The total release consists of 5.6 m fall Chinook for the Grant PUD program and 1.7 M fall Chinook for the Army Corps of Engineers program.

APPENDIX 6: IDENTIFYING AND ANALYZING REFERENCE POPULATIONS

An important goal of supplementation is to increase spawning abundance and natural-origin recruitment of the supplemented population, and not reduce the productivity of the supplemented population. Indeed, a successful supplementation program must increase spawning abundance and natural-origin recruitment to levels above those that would have occurred without supplementation. There are several methods that can be used to test the effects of supplementation programs on these population metrics. One important method is to compare the performance of population metrics (e.g., spawning abundance, natural-origin recruitment, and productivity) in the supplemented population to those in un-supplemented (reference) populations. By comparing supplemented populations to reference populations, one can determine if the supplementation programs benefit, harm, or have no effect on the supplemented populations. These comparisons, however, are only valid if the performance of the reference populations is similar to the performance of the supplemented population prior to the period of supplementation. If the performance of the two populations differs significantly before any supplementation occurs, then any results from comparing the two populations after supplementation will be suspect. It is therefore important to select reference populations that are as similar as possible to the supplemented populations.

One of the goals of the Conceptual Approach to Monitoring and Evaluating the Chelan County PUD Hatchery Programs (Murdoch and Peven 2005) is to use reference populations to analyze the potential effects of hatchery supplementation programs on natural-origin salmon and steelhead spawner abundance and productivity[15]. Murdoch and Peven (2005) identified specific objectives to evaluate the performance of the program. For example, Objective 1 determines if the supplementation programs have increased the number of naturally spawning and naturally produced adults of the target population (supplemented population) relative to a reference population. Objective 7 determines if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity (e.g., number of juveniles per redd) of supplemented streams when compared to reference streams. The relevant questions tested under each objective are as follows:

Objective 1:

- Is the annual change in the number of natural-origin recruits produced from the supplemented populations greater than or equal to the annual change in natural-origin recruits in an un-supplemented population?
- Is the change in natural replacement rates within the supplemented population greater than or equal to the change in natural replacement rates in an un-supplemented population?

Objective 7:

[15] Productivity is defined as adult recruits per spawner, where recruits are the number of adults produced from a given brood year (i.e., spawners plus adults harvested).

- Is the change in numbers of juveniles (smolts, parr, or emigrants) per redd in the supplemented population greater than or equal to that in an un-supplemented population?[16]

In this paper, we describe methods used to identify suitable reference streams and statistical techniques that can be used to compare reference populations with supplemented populations. Although we apply the methods described in this paper to Chiwawa spring Chinook salmon (hereafter referred to as Chinook), the methods should also apply to steelhead and other supplemented salmon stocks in the Upper Columbia Basin.

Identification of Reference Populations

Reference populations are an important component of an effectiveness monitoring design because they provide the standard by which treatment conditions are compared (ISRP and ISAB 2005; Murdoch and Peven 2005; Galbreath et al. 2008). Selecting appropriate reference areas and maintaining them over long periods of time is needed to establish the effectiveness of supplementation programs.

We developed a three-step process for identifying suitable reference populations (Figure 1). Each step serves as a filter. That is, potential reference populations are evaluated based on specific criteria under each step. Populations that pass through each step are considered suitable reference populations for a specific supplemented population.

[16] In this paper, we only address adult recruits, not juvenile recruits. This is because we were unable to find suitable reference populations for analysis of juveniles. However, the methods described in this paper would also apply to juveniles.

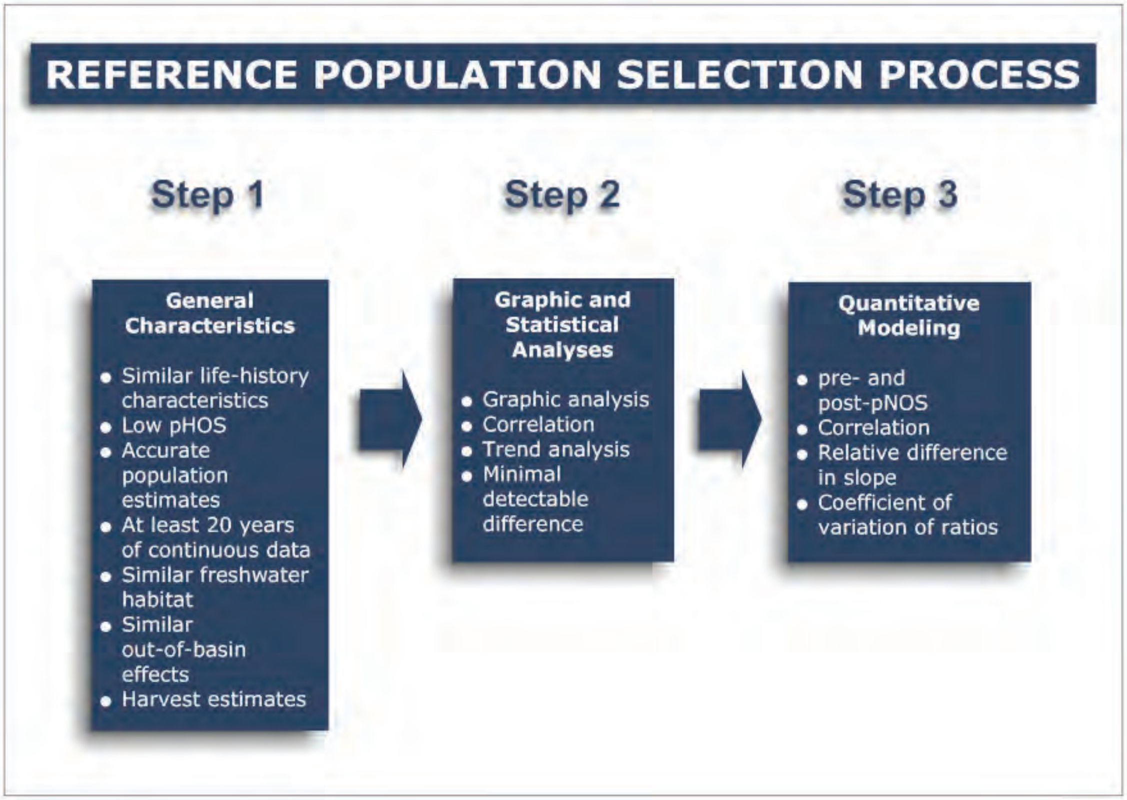

Figure 1. Criteria evaluated during each step in the process of identifying suitable reference populations.

Step 1: General Characteristics

Under step 1, potential reference populations are evaluated based on several general criteria. When compared to the supplemented population, potential reference populations should have:

- Similar life-history characteristics (e.g., run timing, migration characteristics, etc.).
- No or few hatchery fish in the reference area (pHOS < 10%).
- Accurate abundance estimates.
- Long time series of natural-origin abundance and productivity estimates (at least 20 years of continuous data).
- Similar trends in freshwater habitat.
- Similar out-of-basin effects (i.e., similar migration and ocean survivals).
- Harvest estimates for adjusting escapement estimates.

We used these criteria to begin the process of selecting suitable reference populations for the Chiwawa spring Chinook program. We began by identifying stream-type Chinook populations within the Columbia Basin. Galbreath et al. (2008; their Table 1) identified stream-type Chinook populations within the Columbia River Basin that may serve as suitable reference populations for hatchery programs. Supplementing their work with data from the NOAA Fisheries Salmon Population Summary Database, we identified 18 candidate stream-type Chinook populations that may serve as reference populations for the Chiwawa supplementation program (Table 1).

Table 1. Populations of stream-type Chinook salmon and their comparison to Chiwawa spring Chinook.

Population	Similar life-history	No or few hatchery fish	Accurate abundance estimates	Long time series (at least 20 years)	Similar freshwater habitat impairments	Similar out-of-basin effects	Comments

Little Wenatchee River	Yes	No	Yes	Yes	Yes	Yes	Hatchery strays (>10%)
Entiat River	Yes	No	Yes	Yes	No	No	Hatchery release ending

We then assessed the accuracy and length of the series of abundance estimates. We assumed that abundance estimates generated from expanded redd counts or adjusted weir counts would compare well with estimates in the Chiwawa Basin, which were based on expanded redd counts. In addition, we looked for populations that had an abundance data series that extended from at least 1981 to present. Based on this analysis, we identified 18 populations with abundance estimates that could be compared to those from the Chiwawa Basin (Table 1).

Next, we determined if the potential reference populations came from watersheds with habitat conditions similar to those in the Chiwawa Basin. For this exercise, we searched recovery plans and draft recovery plans to identify tributary factors that limit Chinook abundance, productivity, and survival within the reference populations. We compared these factors with those limiting

Chinook salmon in the Chiwawa Basin. Based on this analysis, we identified eight populations with habitat impairments similar to those in the Chiwawa Basin (Table 1).

Finally, we examined the potential reference populations to see if they experienced out-of-basin effects similar to spring Chinook from the Chiwawa Basin. In this case, we compared the number of mainstem dams that each potential reference population passes during migration. Six of the potential reference populations pass less than six mainstem dams; the other populations pass eight mainstem dams (Table 1). Only the Little Wenatchee population passes seven dams, similar to the Chiwawa population.

In sum, there were no reference populations that matched the Chiwawa spring Chinook population on all the criteria identified above. Differential out-of-basin effects and freshwater habitat conditions prevented most reference populations from matching with Chiwawa spring Chinook. However, some of the potential reference populations were similar to the Chiwawa population on several criteria and warranted further investigation. We selected the following populations for further investigation: Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River.

We included the Little Wenatchee because it is within the Wenatchee River basin and experiences similar out-of-basin effects and has the same climatic and environmental conditions as the Chiwawa. A confounding effect with the Little Wenatchee is that Chiwawa hatchery fish have strayed into the Little Wenatchee. However, straying of Chiwawa hatchery fish should decrease with the change in source water to the Chiwawa acclimation ponds in 2006. We also included the Entiat River because it is an adjacent basin to the Chiwawa and experiences similar climatic and environmental conditions. The spring Chinook hatchery program that has operated in the Entiat since 1975 has been discontinued. Therefore, this population offers a unique opportunity to compare the Chiwawa population to a population in which the hatchery program has been discontinued.

Step 2: Graphic and Statistical Analysis

Graphic Analysis

Although we were unable to find potential reference populations that matched with the Chiwawa population on all criteria considered under Step 1, spawner abundance, natural-origin recruits (NORs), and productivity of some of the potential reference populations may nevertheless track closely with the Chiwawa population. If the time series of abundance, NORs, and productivity of a potential reference population tracks closely with the abundance, NORs, and productivity of the Chiwawa population, the reference population may provide a reasonable reference condition for testing the effects of supplementation on the Chiwawa population.

Under Step 2, we used graphing techniques to examine the relationship of abundance, NORs, and productivity between the Chiwawa population and the five reference populations (Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River). We compiled spawner abundance, NORs, and productivity data from local biologists and the NOAA Fisheries Salmon Population Summary Database. We then compared time series plots of spawner abundance, NORs, and productivity data of potential reference populations with the Chiwawa population (Figures 2, 3, and 4; plots on the left side of figures). The time series only included the period 1981 to 1992, which represented the period before supplementation of the Chiwawa population (pre-treatment period). We also plotted the relationship between the abundance, NORs, and productivity of each

potential reference population to the Chiwawa population (Figures 2, 3, and 4; plots on right side of figures). These plots show whether the reference populations closely tracked the Chiwawa population. As a point of reference, data points that fall along the dashed line would represent a perfect relationship between the two populations (i.e., both populations have identical abundance, NORs, and productivity estimates). While a perfect relationship between two independent populations is unrealistic, a strong linear relationship between the two populations indicates populations with similar trends.

Based on analysis of spawner abundance, the Naches River time series tracked more closely with the abundance of Chiwawa spring Chinook than did the other potential reference populations. The poor relationship with the other potential reference streams was largely because of the relatively high abundance of Chiwawa spring Chinook during the mid-1980s. As with spawner abundance, analyses of NORs indicated a close relationship between the Naches and Chiwawa populations. The other potential reference populations tracked poorly with the Chiwawa. The analyses of productivity indicated close relationships between potential reference populations and the Chiwawa population. The Naches, Sesech, and Little Wenatchee populations tracked the closest with the Chiwawa population.

When analyzing the potential effects of a supplementation program on fish performance, it is common to transform the data to meet various assumptions of statistical analysis. The most common transformation used to adjust abundance, NORs, and productivity data is the natural logarithm (LN or $\log_e$). We therefore transformed the spawner abundance, NORs, and productivity data using LN and re-plotted the relationships between the potential reference populations and the Chiwawa population (Figures 5, 6, and 7). We added 1 to each observation before taking its logarithm to avoid taking the logarithm of 0, which is undefined (note that the LN of 1 is 0).

By transforming spawner abundance, NORs, and productivity data, most of the potential reference populations tracked more closely with the Chiwawa population. The Naches, Entiat, and Little Wenatchee abundance data tracked the closest with the Chiwawa abundance data (Figure 5). For NORs, Marsh Creek and the Little Wenatchee populations tracked the closest with the Chiwawa (Figure 6). For productivity, the Naches, Sesech, and Little Wenatchee tracked the closest with the Chiwawa (Figure 7).

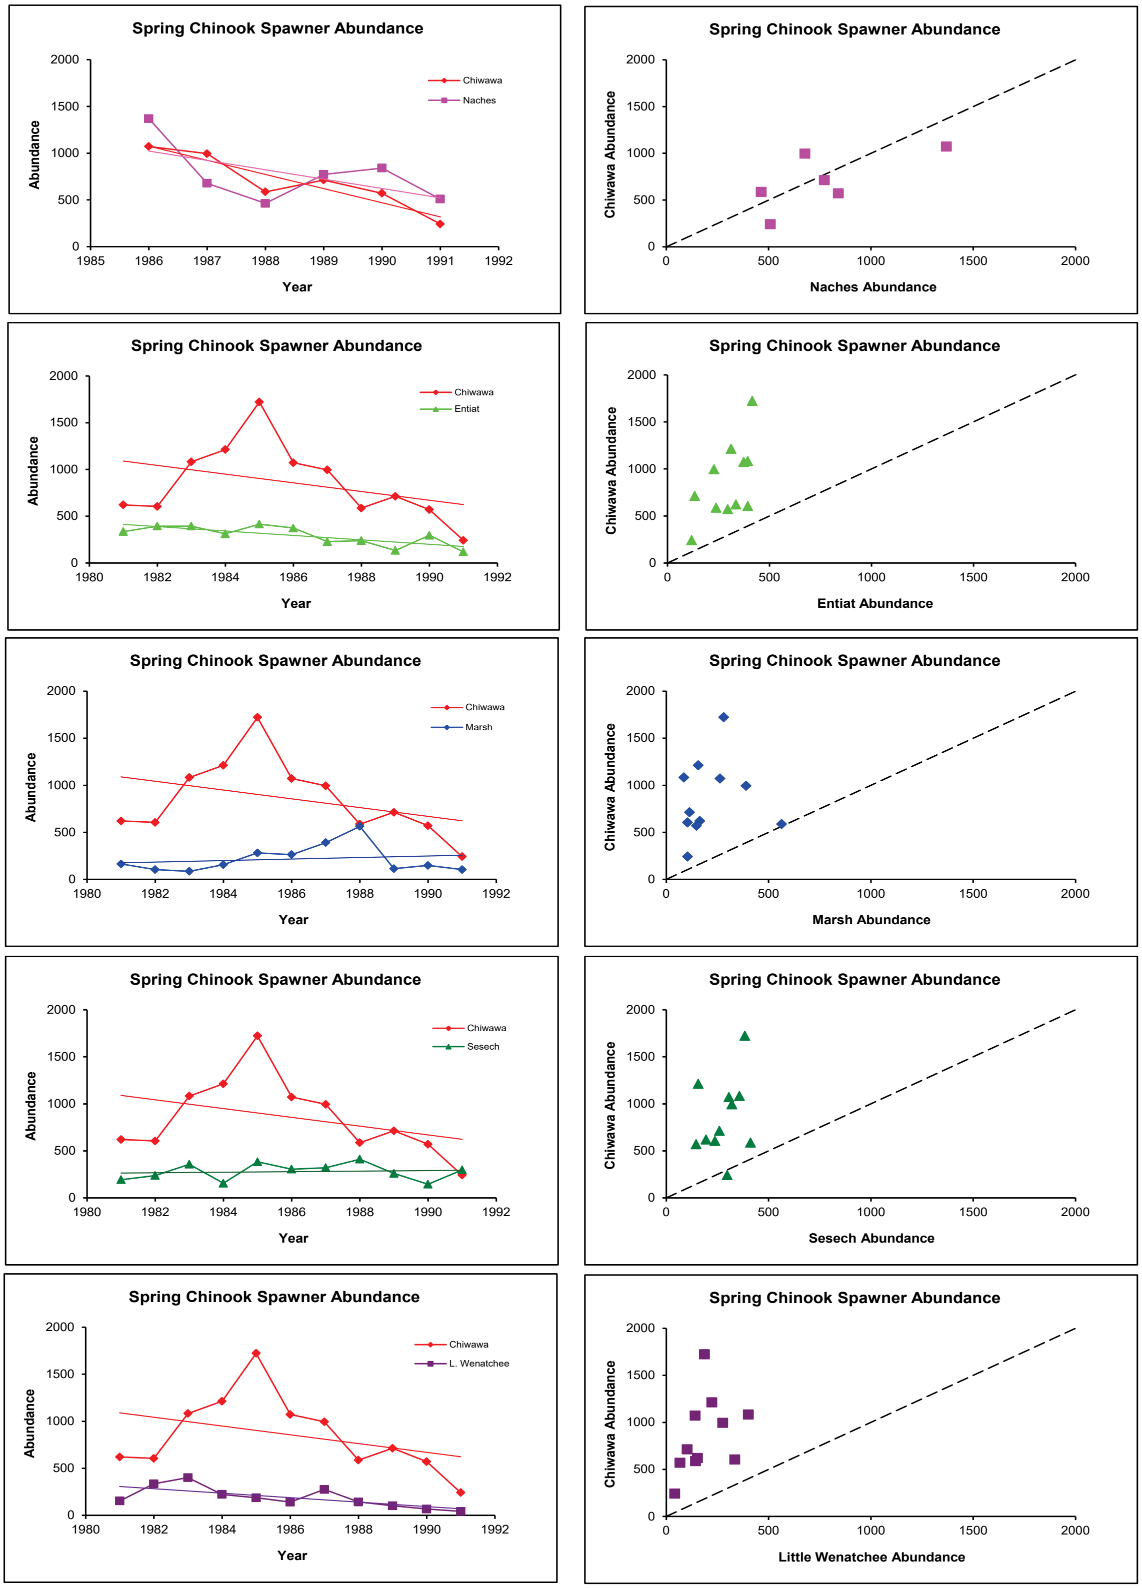

Figure 2. Time series of spawner abundance of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

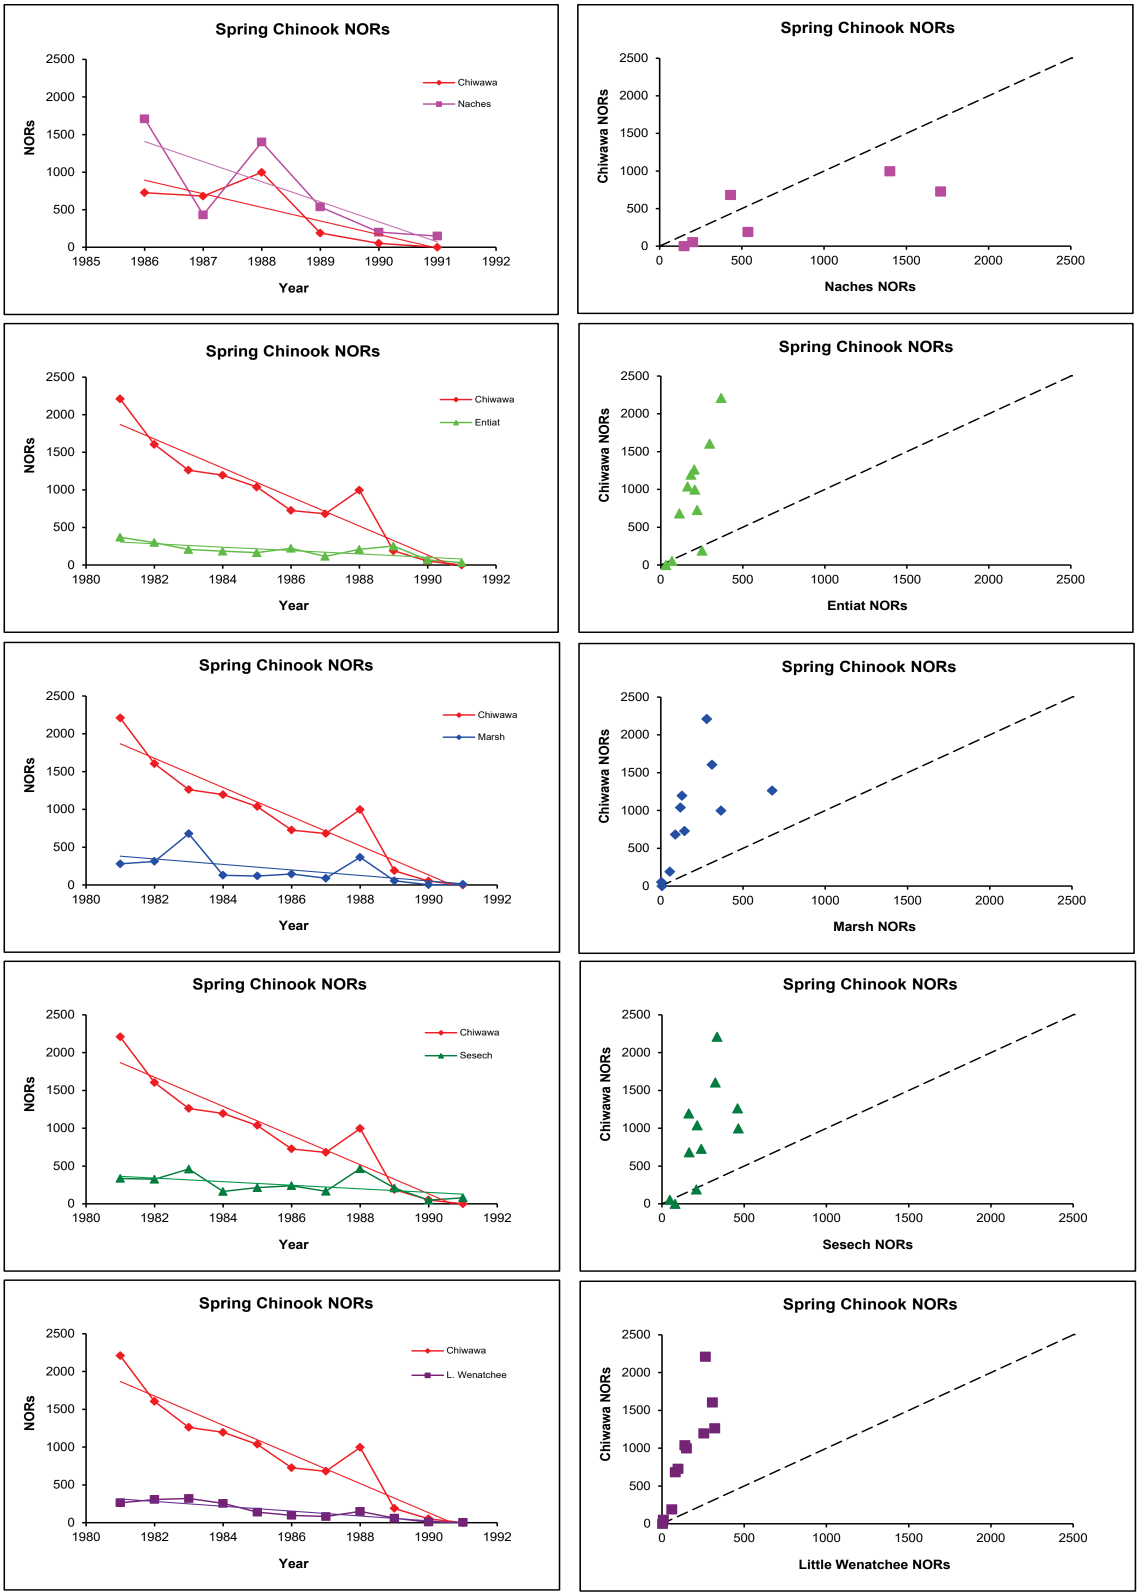

Figure 3. Time series of natural-origin recruits (NORs) of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

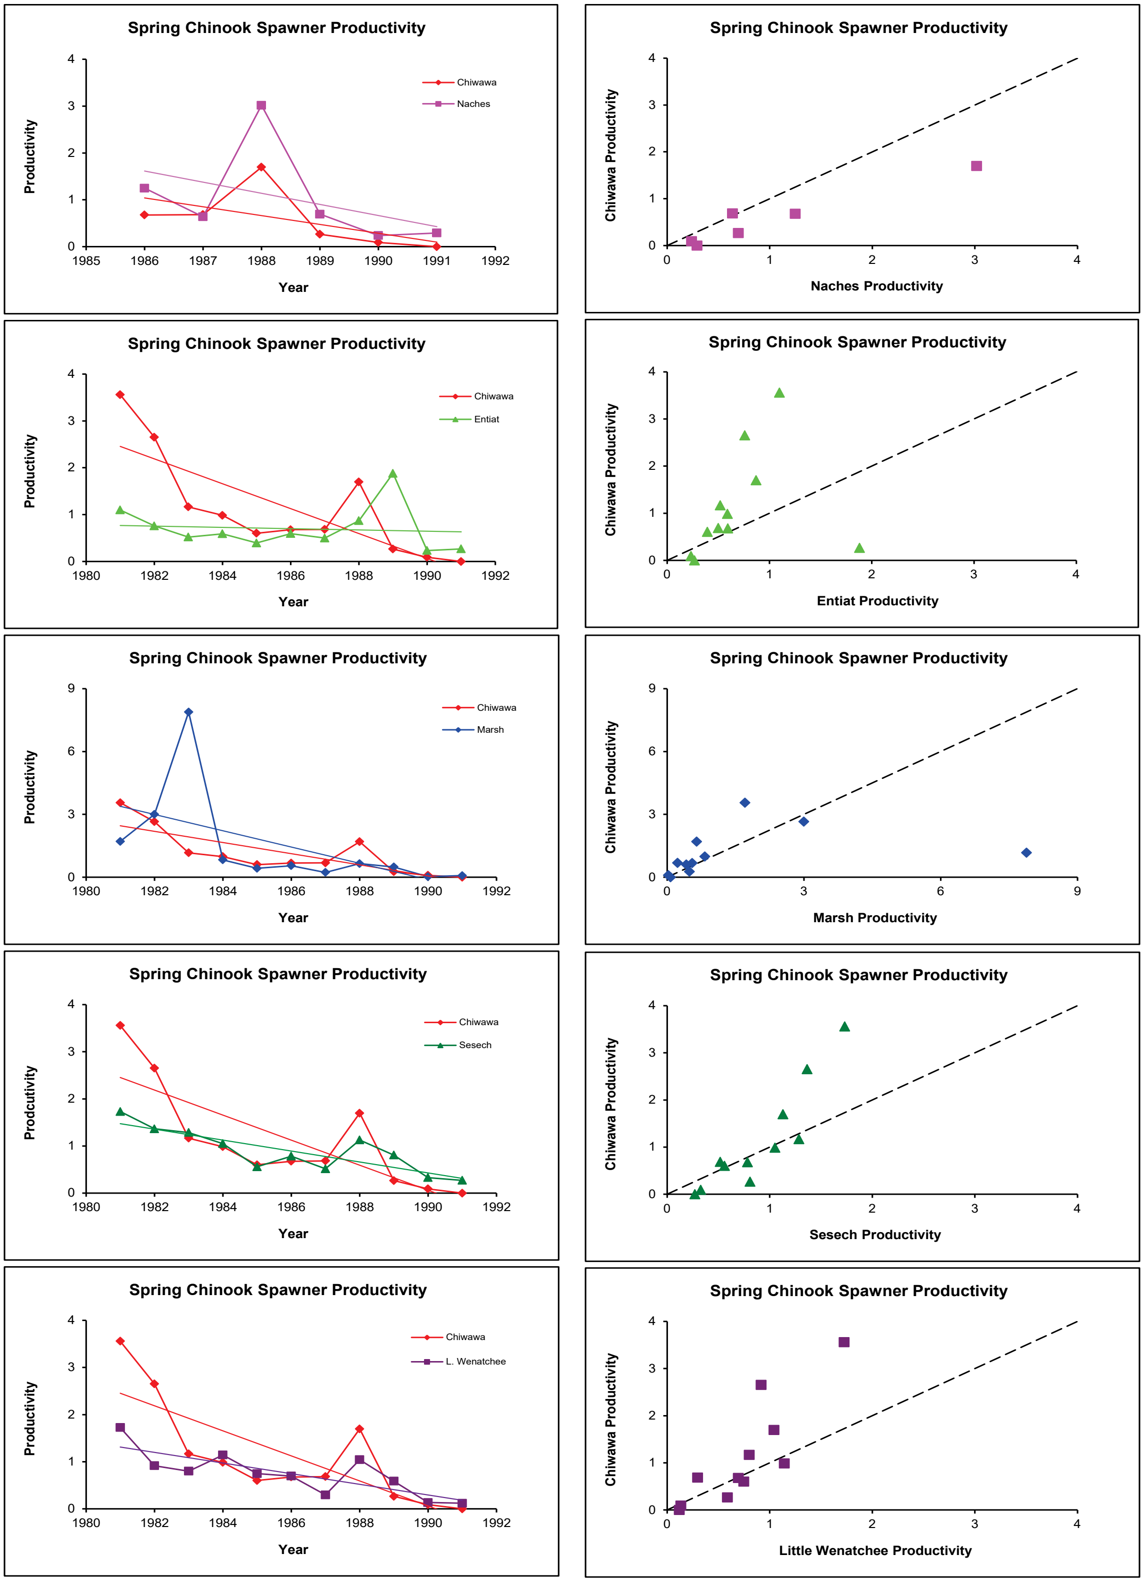

Figure 4. Time series of adult productivity of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

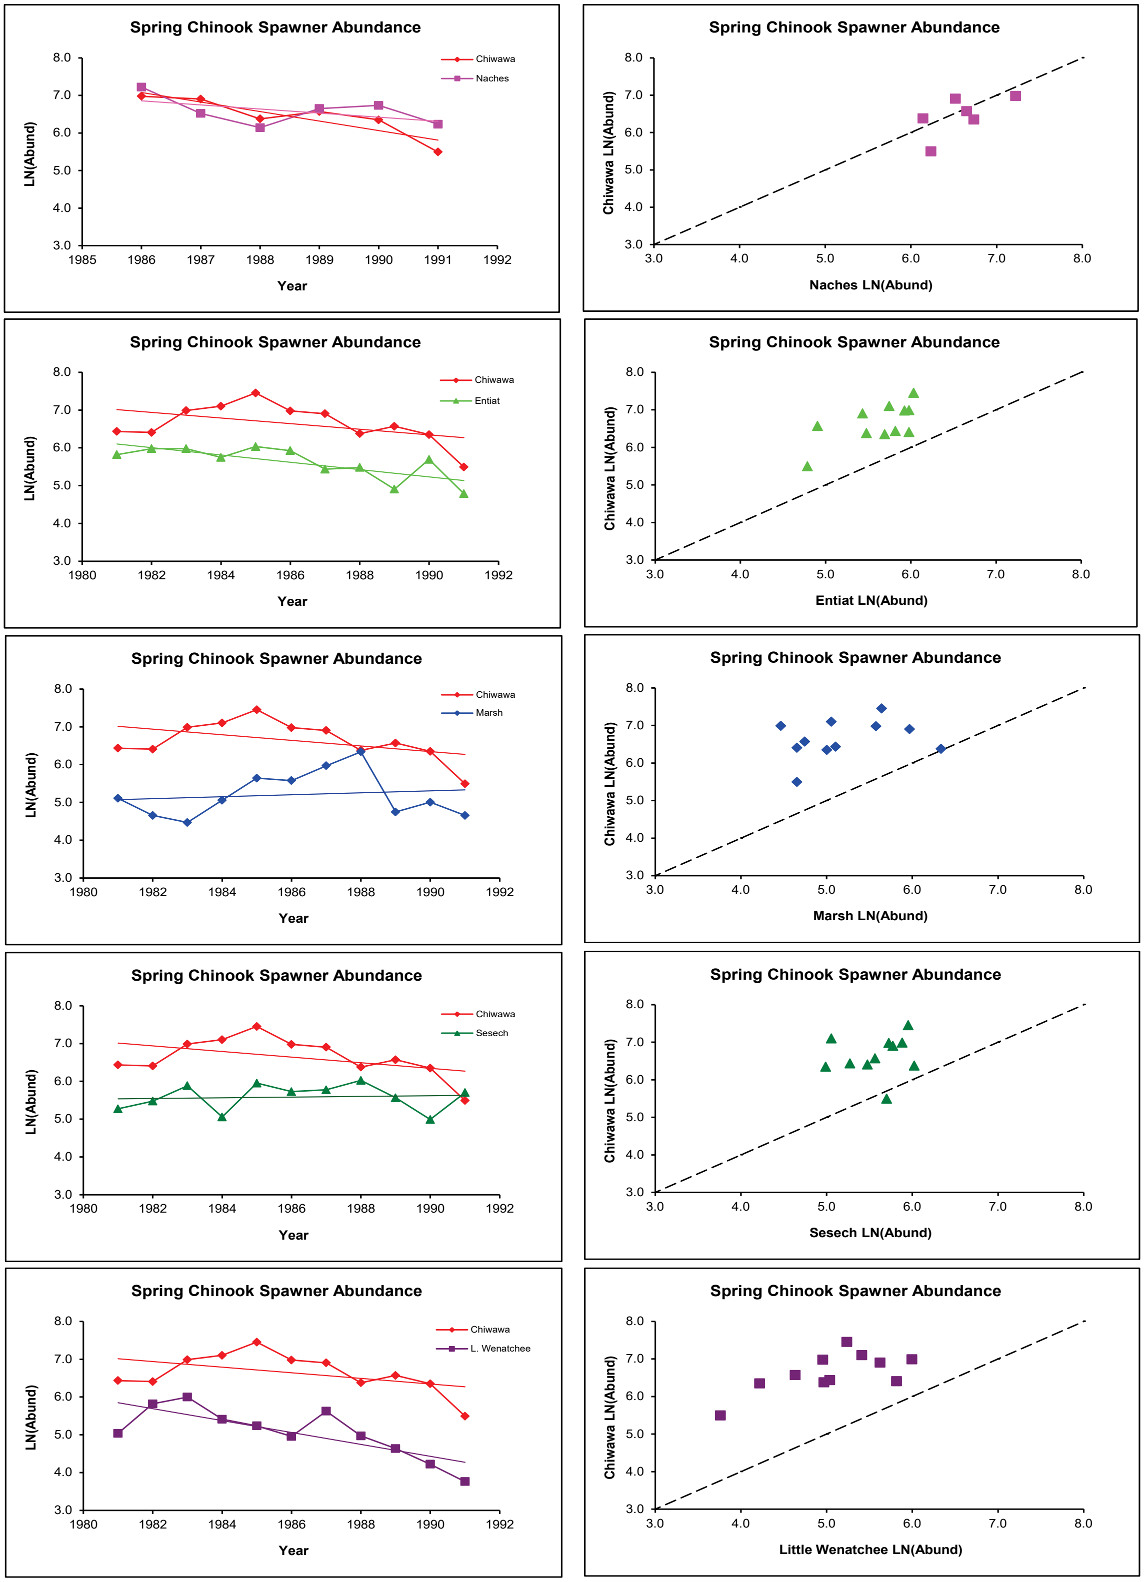

Figure 5. Time series of natural log spawner abundance of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

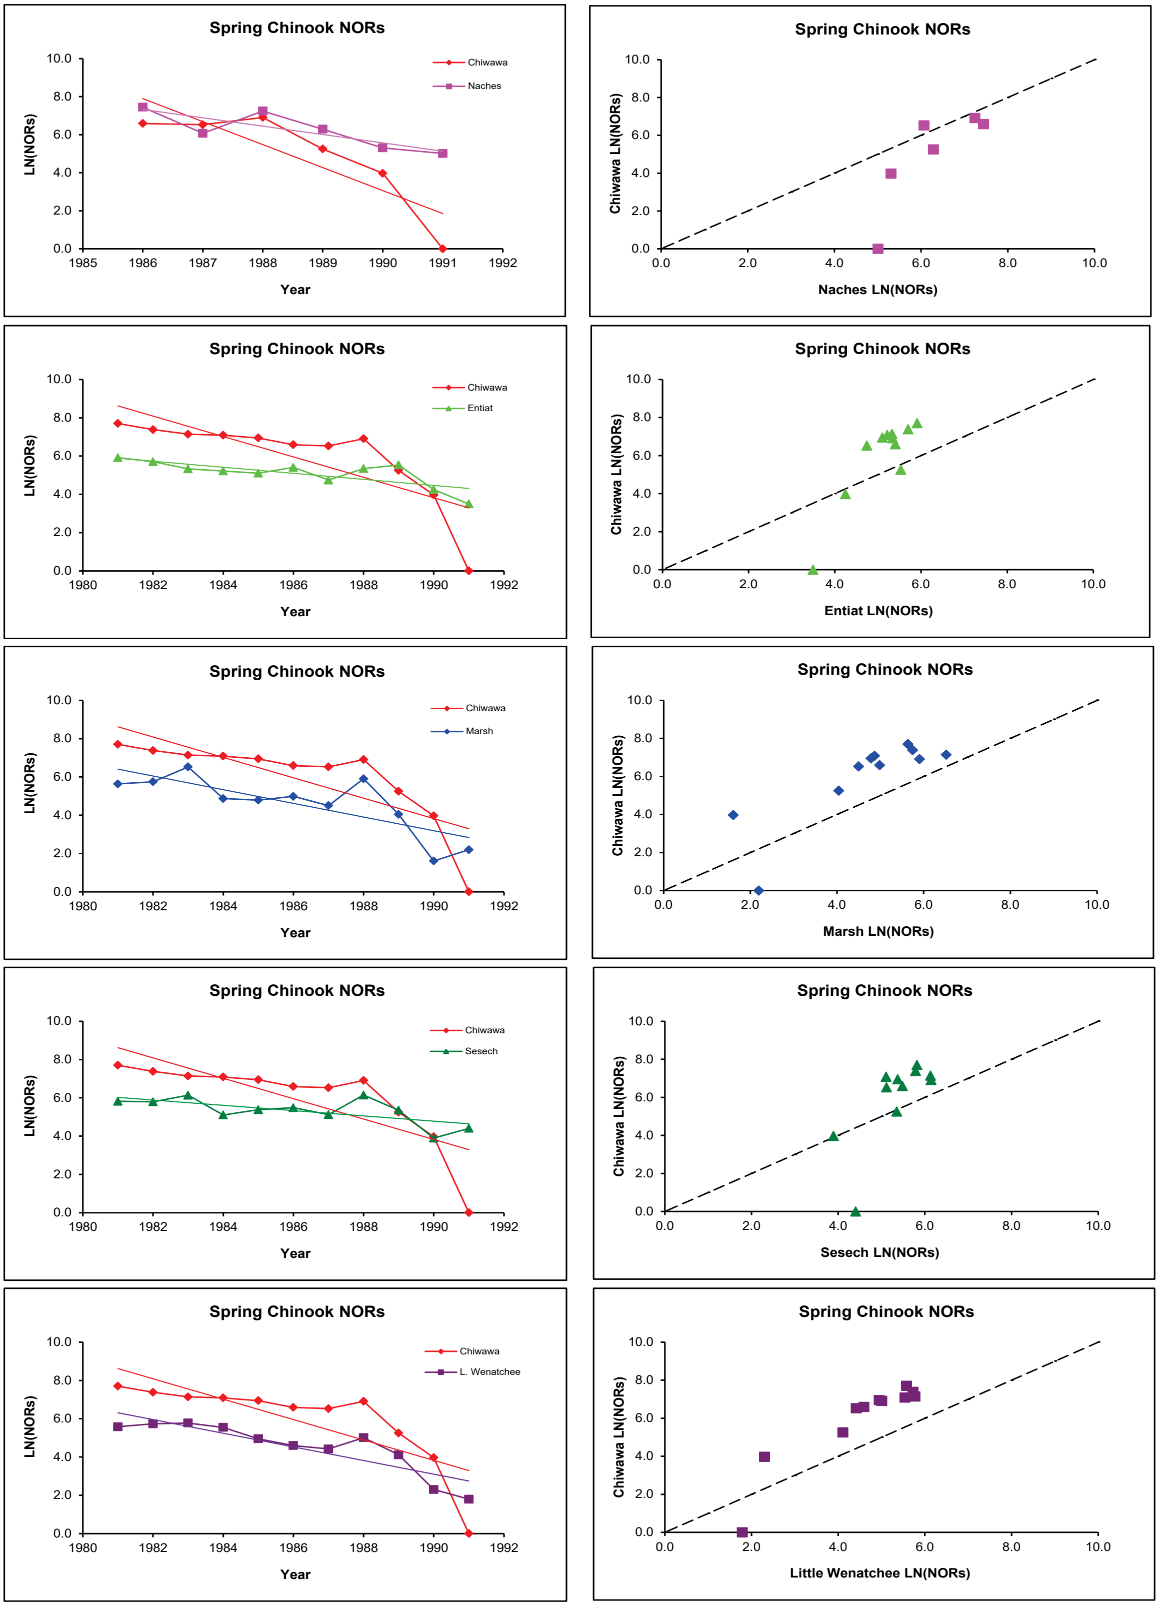

Figure 6. Time series of natural log natural-origin recruits (NORs) of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

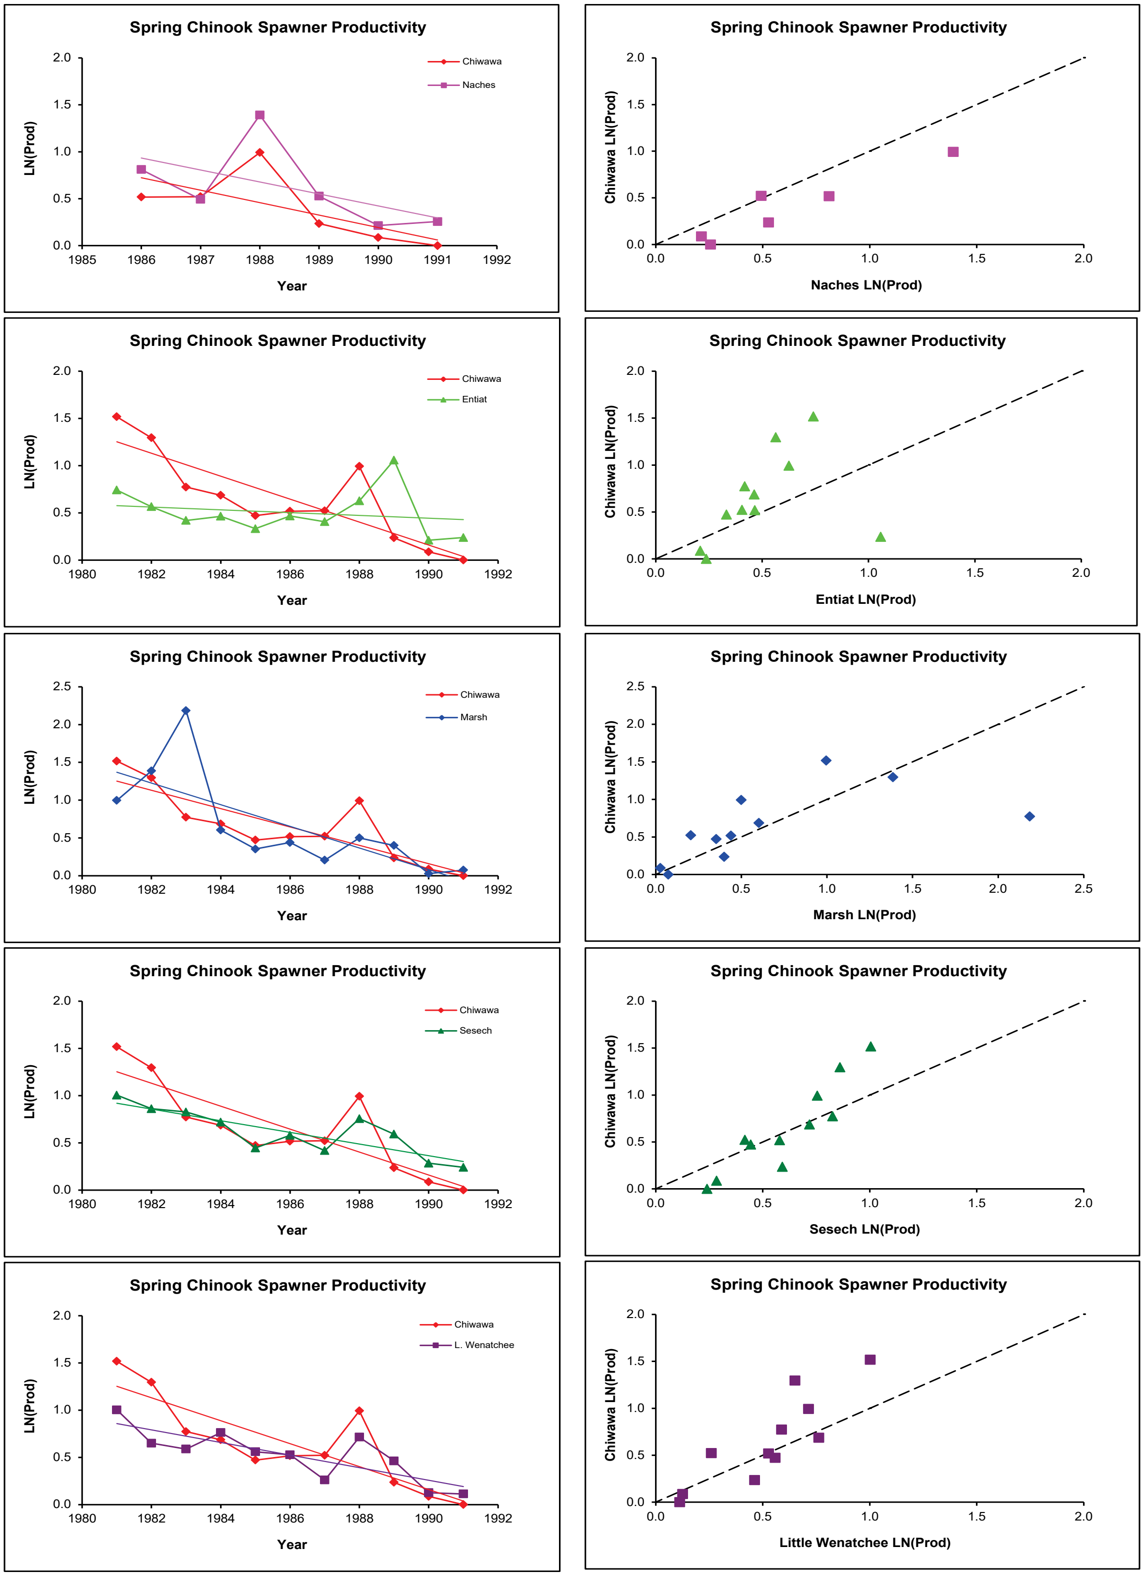

Figure 7. Time series of natural log adult productivity of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

Correlations and Trends

Other methods for evaluating the suitability of potential reference populations under Step 2 include correlation and trend analyses. For correlation analysis, we simply calculated the Pearson correlation coefficient, which is an index of the strength of the association between the potential reference populations and the Chiwawa population. The coefficient ranges from -1 to 1, where a value near 1 or -1 represents that strongest association between the populations. A value of 0 means no association. We used only spawner abundance, NORs, and productivity data during the pre-treatment period (1981-1992). We assumed that populations with coefficients greater than 0.6 represented reasonable reference conditions.

For trend analyses, we used least squares techniques to compute a straight-line trend through the spawner abundance and productivity data for the potential reference populations and the Chiwawa population. Trends were fit to the pre-treatment time series data (1981-1992). We then used t-tests to determine if the slopes of the trends between potential reference populations and the Chiwawa population differed significantly.

It is important to note that time-series trend analyses are susceptible to temporal correlations in the data. Autoregressive integrated moving average (ARIMA) models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). However, these models require a long time series (N > 40) and therefore we could not use them to model the spring Chinook data. As such, we were unable to correct for any temporal correlation that may exist within the time series.

Tests of correlation with spawner abundance data indicated that the Naches River closely correlated with the Chiwawa population (Table 2). There was no difference in abundance trends between the potential reference populations and the Chiwawa population (Table 2; Figure 2). For NORs, all potential reference populations correlated with the Chiwawa population (Table 2). However, trends in NORs of all reference populations, except Naches, differed significantly from the Chiwawa population (Table 2; Figure 3). For productivity, the Naches, Sesech, and Little Wenatchee correlated with the Chiwawa population (Table 2). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 2; Figure 4).

Table 2. Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (*) indicates significance at $P < 0.05$.

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Spawner Abundance Data				
Naches	0.684*	-0.659	8	0.528
Entiat	0.598*	-0.596	18	0.559
Marsh	0.147	-1.341	18	0.197
Sesech	0.274	-1.265	18	0.222
Little Wenatchee	0.399	-0.591	18	0.562
Natural-Origin Recruits				
Naches	0.803*	0.666	8	0.524
Entiat	0.795*	-7.495	18	0.000

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Marsh	0.605*	-5.786	18	0.000
Sesech	0.648*	-6.874	18	0.000
Little Wenatchee	0.880*	-7.206	18	0.000
Productivity Data				
Naches	0.960*	0.169	8	0.870
Entiat	0.272	-3.057	18	0.007
Marsh	0.320	0.605	18	0.553
Sesech	0.903*	-2.059	18	0.054
Little Wenatchee	0.848*	-2.065	18	0.054

We also ran correlation and trend analyses on natural-log transformed spawner abundance, NORs, and productivity data. These analyses indicated that the Naches, Entiat, and Little Wenatchee abundance data correlated with the Chiwawa population data (Table 3). None of the abundance trends of the potential reference populations differed significantly from the Chiwawa population trend (Table 3; Figure 5). For NORs, all potential reference populations correlated with the Chiwawa population (Table 3). Only trends in NORs of the Entiat and Sesech differed significantly from the Chiwawa population (Table 2; Figure 6). For productivity, the Naches, Marsh, Sesech, and Little Wenatchee correlated with the Chiwawa population data (Table 3). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 3; Figure 7).

Table 3. Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (*) indicates significance at $P < 0.05$. Analyses were conducted on natural-log transformed abundance and productivity data.

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
LN Spawner Abundance Data				
Naches	0.642*	-1.323	8	0.222
Entiat	0.652*	0.412	18	0.685
Marsh	0.294	-1.324	18	0.202

Little Wenatchee	0.927*	-1.150	18	0.265
LN Productivity Data				

Reference populations	Pearson correlation coefficient	t-test on slopes		
		t-value	d.f.	P-value
Naches	0.944*	-0.042	8	0.968
Entiat	0.373	-3.043	18	0.007
Marsh	0.610*	0.428	18	0.674
Sesech	0.913*	-2.050	18	0.055
Little Wenatchee	0.862*	-1.811	18	0.087

In summary, based on correlation, trend, and graphic analyses, the Naches, Entiat, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. For NORs, the Naches, Marsh, and Little Wenatchee appear to be reasonable reference populations. For productivity, the Naches, Marsh, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for the Chiwawa population.

Minimal Detectable Differences (MDD)

Given a suite of potential reference populations, it is important to conduct power analyses to determine the minimum differences that can be detected when comparing the reference populations to the supplemented population. As a final exercise under Step 2, we examined potential reference populations for the smallest minimal detectable differences. Before conducting power analyses, several decisions needed to be made, including what statistical procedures will be used to analyze the data, the desired level of statistical power (probability of rejecting a false null hypothesis), the size of the type-I error (the probability of rejecting a true null hypothesis of no difference), and the number of samples (i.e., years) included in the analysis. In this case, the number of samples represents the number of treatment (supplementation) years. The number of pre-treatment years (1981-1992) was based on the number of years of quality data available for Chiwawa spring Chinook and potential reference populations.

We designed the study as a modified BACI (Before-After, Control-Impact) design, which includes replication before and after supplementation in both the treated (T) population and the reference (R) populations. A common approach used to analyze data from BACI designs includes analysis of difference scores (Stewart-Oaten et al. 1992; Smith et al. 1993). Differences are calculated between paired treatment and reference population scores (i.e., T-R). Another approach is to calculate ratios (treatment/reference; T/R) for paired treatment and reference population scores (Skalski and Robson 1992). Finally, differences in annual changes in paired treatment and reference population scores can be calculated (i.e., ΔT-ΔR) (Murdoch and Peven 2005; Hays et al. 2006).[17] These derived difference and ratio scores are then analyzed for a before-after treatment effect with a two-sample t-test, Aspin-Welch modification of the t-test, or a randomization test. For power analyses, we calculated minimal detectable differences assuming the use of an independent two-sample t-test with a type-I error rate of 0.05, power of 0.80 (beta or type-II error rate of 0.20), and sample sizes (treatment years) of 5, 10, 15, 20, 25, and 50 years.

[17] The difference of annual difference scores was estimated by first subtracting the population parameter (e.g., spawner abundance) in year 2 from year 1. This continues for all years in the data series for both treatment ($T_{t+1} - T_t$) and reference populations ($R_{t+1} - R_t$). We then calculated differences between paired treatment and reference annual difference scores [$(T_{t+1} - T_t) - (R_{t+1} - R_t) = \Delta T - \Delta R$].

The power analysis calculated the minimal detectable difference between mean difference or ratio scores before and during supplementation. We used existing data to calculate variances for the pre-supplementation and supplementation periods. Thus, variances were known and unequal. For both spawner abundance and NORs, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was less than the mean difference during supplementation (one-tail test; Difference < 0). For productivity, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was greater than the mean difference during supplementation (one-tail test; Difference > 0).

Based on spawner abundance data, power analysis indicated that the Sesech-Chiwawa pairing consistently produced the smallest detectable differences (Table 4). However, when the abundance data were transformed using natural logs, the Entiat-Chiwawa pairing produced the smallest detectable difference (Table 5). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 334 to 394 adult spawners; transformed data ranged from 0.479 to 1.010. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

Table 4. Minimal detectable differences between mean difference and ratio scores before and during supplementation. Analyses were conducted on spawner abundance data.

Based on NORs, power analysis indicated that the Entiat-Chiwawa, Marsh-Chiwawa, and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 6). When NORs were transformed using natural logs, the Little Wenatchee-Chiwawa pairing produced the smallest detectable difference (Table 7). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 483 to 640 NORs; transformed data ranged from 0.958 to 2.262. These analyses indicate that the Entiat, Marsh, and Little Wenatchee populations appear to be reasonable reference populations for comparing NORs with Chiwawa data.

Using untransformed productivity data, power analysis indicated that the Little Wenatchee-Chiwawa pairing consistently produced the smallest detectable differences (Table 8). The Marsh-Chiwawa pairings produced the largest detectable differences. When we analyzed natural-log transformed productivity data, the Naches-Chiwawa and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 9). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 0.754 to 1.839; transformed data ranged from 0.277 to 0.477. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing productivity data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

Step 3: Quantitative Method for Ranking Selection Criteria

Not surprisingly, different selection criteria produced different results (Table 10). Determining whether a given population is or is not a suitable reference population based on selection criteria such as graphic analysis can be subjective. In addition, treating each selection criterion as equally important may not be appropriate. For example, using the information in Table 10, is it appropriate to select a reference population that has two or three "Yes" entries, or should only populations with four "Yes" entries be selected as suitable reference populations? This approach does not allow certain selection criteria to carry more weight in the overall selection process. That is, correlation may be more important than graphic analysis in the overall selection process. In order to reduce

subjectivity, we developed a method of scoring and weighting each selection criterion. This method allows a more quantitative process for selecting suitable reference populations.

Table 10. Summary of results from graphic analysis, correlations, trend analysis, and power analysis (minimal detectable differences). "Yes" indicates that the population is a suitable reference population for the Chiwawa population; "No" indicates that it may not be a suitable reference population.

Potential reference populations	Graphic analysis	Correlation	Trends	Minimal detectable differences
Spawner Abundance				
Naches	Yes	Yes	Yes	Yes
Entiat	Yes	Yes	Yes	Yes
Marsh	No	No	Yes	No
Sesech	No	No	Yes	Yes
Little Wenatchee	Yes	Yes	Yes	Yes
Natural-Origin Recruits				
Naches	Yes	Yes	Yes	No
Entiat	No	Yes	No	Yes
Marsh	Yes	Yes	Yes	Yes
Sesech	No	Yes	No	No
Little Wenatchee	Yes	Yes	Yes	Yes
Productivity				
Naches	Yes	Yes	Yes	Yes
Entiat	No	No	No	Yes
Marsh	No	Yes	Yes	No
Sesech	Yes	Yes	Yes	Yes
Little Wenatchee	Yes	Yes	Yes	Yes

We developed scoring methods for each of the following five selection criteria:

(1) The proportion of natural-origin spawners (pNOS) in the reference population for the period before supplementation (pre-pNOS);

(2) pNOS in the reference population for the period following supplementation (post-pNOS);

(3) The correlation between the reference and supplemented populations before supplementation;

(4) The relative difference in slopes between the reference and supplemented populations before supplementation; and

(5) The coefficient of variation (CV) of the ratio of supplemented to reference populations before the period of supplementation.

Each selection criteria was scored from 0 to 1, with 0 being the worst possible score and 1 being the best.

The pre- and post-pNOS values were calculated as the average pNOS values before and after supplementation, respectively. Because pNOS values range from 0-1, we did not need to rescale

these values. When using reference populations to evaluate the effects of supplementation programs, it is important that the reference populations maintain high values of pNOS throughout the life of the monitoring program. Therefore, we heavily weighted the mean pNOS scores. We assigned weights of 30 and 40 to the mean pre- and post-pNOS scores, respectively. The relatively larger weight for the post-supplementation period is to reduce the likelihood of retaining a reference population that becomes influenced by hatchery fish during the supplementation period.

We assessed the association between the reference and supplemented populations during the pre-supplementation period by calculating the Pearson correlation coefficient, which ranges from -1 to 1. To scale the coefficient between 0 and 1, we took the absolute value of the coefficient. Thus, a coefficient of -0.92 would be reported as 0.92. For our analyses, we were not concerned with the direction of the relationship, only the strength of the relationship. The correlation coefficient was given a weight of 12.5.

As noted earlier, we used least squares to fit a linear trend to each of the reference populations and the supplemented population during the pre-supplementation period. Using the slope estimates for each trend line, we calculated the relative difference in slopes as the slope of the supplemented population minus the slope of the reference population, divided by the slope of the reference population. To scale this value between 0 and 1, we used absolute values, and depending on the direction of the slopes, we subtracted the relative difference from 1. The latter was needed to make sure a larger relative difference value indicated a small difference in slopes between the supplemented and reference populations. The relative difference score was given a weight of 7.5.

Finally, as a means to score effect size, we calculated the CV of the ratio of supplemented to reference population parameters (i.e., T/R). The CV was calculated as the standard deviation of the ratios divided by the absolute value of the mean ratios. The CV was subtracted from 1. This scaled the value from 0 to 1 with larger values representing the best condition. The CV was given a weight of 10, which is greater than the weight for trend, but less than the weight for correlation.

The total score for a reference population was calculated by multiplying the estimated value, which ranged from 0 to 1, by its weight. The sum of the five weighted values provided a total score, which ranged from 0 to 100. Based on several simulations, we set the cut-off score at 81. That is, if the total score for a given reference population equaled or exceeded 81, the population was included as a suitable reference population. If the total score fell below 81, the population was not considered a suitable reference. Based on the distribution of all scores possible, a score of 81 or greater represented only 3% of the total distribution. Thus, a cut-off of 81 is quite conservative.

Under Step 3, we used this method to select the final suite of suitable reference populations. Table 11 shows results from scoring each of the reference populations using the quantitative method. Using the cut-off criterion of 81, only the Naches, Marsh, and Sesech populations would be considered suitable reference populations for the Chiwawa supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values).

Table 11. Results from scoring potential reference populations using the selection criteria (pNOS, correlation, trend, and effect size). Populations with scores less than 81 were considered unsuitable as reference populations. Populations with scores equal to or greater than 81 were considered suitable references. These results were based on natural-log transformed data.

Potential reference populations	Population metric		
	Abundance	NORs	Productivity
Naches	85	88	91
Entiat	23	21	16
Marsh	79	91	87
Sesech	84	85	88
Little Wenatchee	51	53	49

An important benefit from scoring the different selection criteria is that the total scores can be used to weight the outcome of differing statistical results. For example, analyses may show that when three suitable reference populations are compared to the supplemented population, two of the reference populations may indicate a significant treatment effect, while the third indicates no effect. Under this scenario it is not clear if the supplementation program has or has not affected the abundance or productivity of the supplemented population. If, however, the two reference populations that produced a significant result had higher total scores than the reference population that did not indicate a significant result, one can place more weight on the results from populations with higher total scores.

Conclusions

The purpose of this exercise was to develop a method for selecting suitable reference populations that could be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity. The selection process included a three-step process (Figure 8). Step 1 identified populations with similar life-history characteristics, few or no hatchery spawners, a long time series of accurate abundance and productivity estimates, and similar freshwater habitat impairments and out-of-basin effects. Populations that met these criteria were then examined for their graphical and statistical relationship with the supplemented population (Step 2). The statistical analysis under Step 2 were converted to a quantitative model (Step 3) that was used to generate a weighted score for pNOS, correlation, trends, and effect sizes for each potential reference population. Reference populations with total scores of 81 or greater were selected as suitable reference populations.

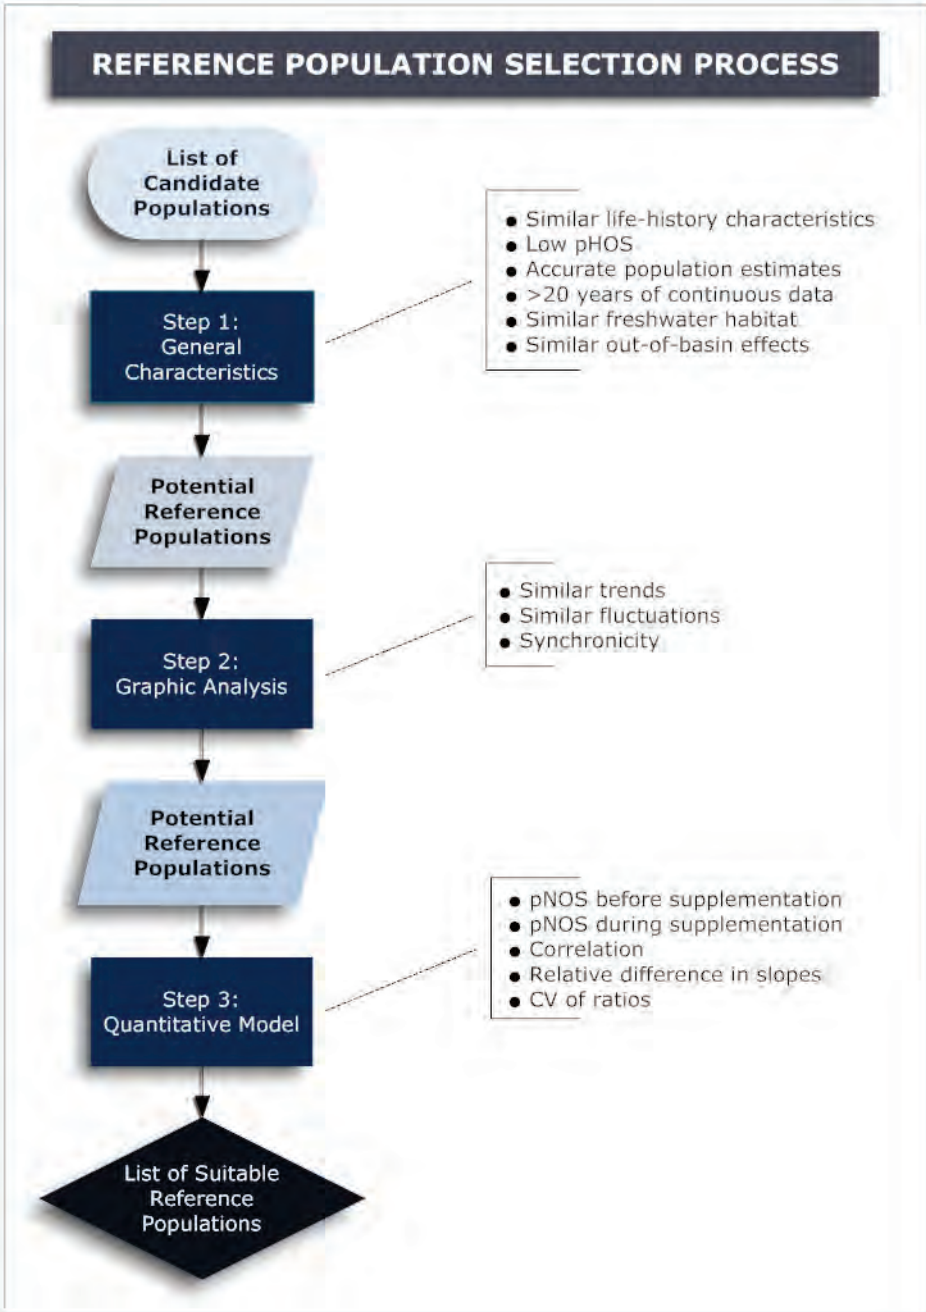

Figure 8. Three-step process for selecting suitable reference populations for supplemented populations.

We used this approach to select suitable reference populations for analyzing the effects of the Chiwawa spring Chinook supplementation program on fish abundance and productivity. The method indicated that the Naches, Marsh, and Sesech populations would serve as suitable reference populations for the Chiwawa spring Chinook supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values). However, because the presence of hatchery spring Chinook within those populations should decrease, they may serve as unique reference populations in which the comparisons change from all populations receiving

hatchery fish to only the Chiwawa population receiving hatchery fish. Therefore, we will continue to include both the Little Wenatchee and Entiat populations in future analyses.

An important assumption in the use of reference populations is that the supplemented and reference populations that tracked each other before supplementation would continue to track each other in the absence of supplementation. Given that the reference populations did not match the Chiwawa population on all criteria examined (Table 1) and some reference populations tracked the Chiwawa population more poorly than others (Figures 2-7; Tables 2-4), there may be some uncertainty as to whether differences observed between the Chiwawa and reference populations during the supplementation period are associated with the hatchery program, "nuisance" factors[18], or a combination of both. In addition, we have no ability to regulate or control activities in reference areas. Any large-scale change (man-made or natural) in reference areas could affect our ability to assess the effectiveness of the supplementation program.

Because we have no ability to maintain reference areas for long periods of time and may not be able to control all activities even within the supplemented populations, we propose the use of a "causal-comparative" approach to strengthen the certainty of our inferences (Pearsons and Temple 2010). The causal-comparative approach relies on correlative data to try and make a case for causal inference.[19] Correlation is used to rule out alternative hypotheses (note that we make our case as much if not more by disproving plausible alternatives as we do by showing that the data are consistent with a hypothesis). For example, large scale land-use activities or natural events can affect stream flows, fine sediment recruitment, and water temperatures. Changes in these factors can affect the freshwater survival and productivity of fish independently of supplementation programs. If changes in habitat, migratory, and ocean conditions do not affect reference and treatment populations similarly, inferences associated with supplementation programs may be confounded. By measuring and tracking these extraneous factors within reference and treatment areas, we can assess the effects of these state variables on population conditions independent of the supplementation programs. This allows us to more effectively assess the influence of supplementation programs on populations.

To that end, we recommend that the following state variables be measured and tracked within the Chiwawa Basin and each of the reference areas: mean annual precipitation, total and riparian forest cover, road density, impervious surface, and alluvium. These variables can be used to describe differences in water temperatures at different life stages (pre-spawning, egg incubation, and summer rearing) and substrate characteristics, including fine sediments and embeddedness (Jorgensen et al. 2009). They can be used to assess possible changes in spawner abundance, NORs, and productivity that are independent of supplementation.

---

[18] A "nuisance" factor is any factor that is outside the control of the experimenter and can affect the response variable (spawner abundance or productivity). In this case, nuisance factors may include differences in freshwater habitat trends and conditions, out-of-basin effects (e.g., migration and ocean survival), and hatchery strays that affect the Chiwawa and reference populations differently.

[19] It is important to point out that correlation does not demonstrate cause-and-effect. It only suggests a relationship between variables. Thus, inferences based on correlation lack the certainty that is associated with a design-based approach.

Analyses with Reference Populations

Once suitable reference populations are selected, methods for analyzing the supplemented and reference populations need to be identified. What follows is a description of different analyses that can be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity using reference populations. Later in this report we describe methods for assessing supplementation effects when reference populations are not available.

We used some of the reference populations selected for the Chiwawa program to illustrate the different methods for evaluating the effects of the supplementation program on spawner abundance, NORs, and productivity. For abundance, we selected the Naches, Entiat, Little Wenatchee, and Sesech populations as suitable references for the Chiwawa population. For NORs, we selected the Naches, Entiat, Marsh, and Little Wenatchee populations as suitable references. For productivity, we selected the Naches, Sesech, Little Wenatchee, and Marsh Creek as suitable references for the Chiwawa. As noted earlier, we included the Little Wenatchee and Entiat populations, even though they did not meet all the criteria for suitable reference populations.

Analysis of Trends

As a first step, we used trend analyses to assess the effects of the Chiwawa supplementation program on spring Chinook spawner abundance, NORs, and productivity. Here, we compared the slopes of the trends between each treatment/reference pair before and during supplementation using t-tests. If the hatchery program is successfully supplementing the natural spring Chinook population, trends in spawner abundance and NORs should deviate significantly (i.e., the slope of the supplemented population should be greater than the slopes of the reference populations during the supplementation period). For productivity, the slope of the supplemented population, relative to the reference population, should increase or remain the same.

Trend analysis indicated that the relationship of slopes of spawner abundance between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 9; Table 12). This was true for both transformed and untransformed abundance data. Before supplementation, spawner abundances trended down in both the Chiwawa and reference populations (Figure 9). During the period of supplementation, abundances in both the Chiwawa and reference populations trended upward. Interestingly, in nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the supplementation period than in the pre-supplementation period (Table 12). This was most evident in the transformed abundance data (Figure 9).

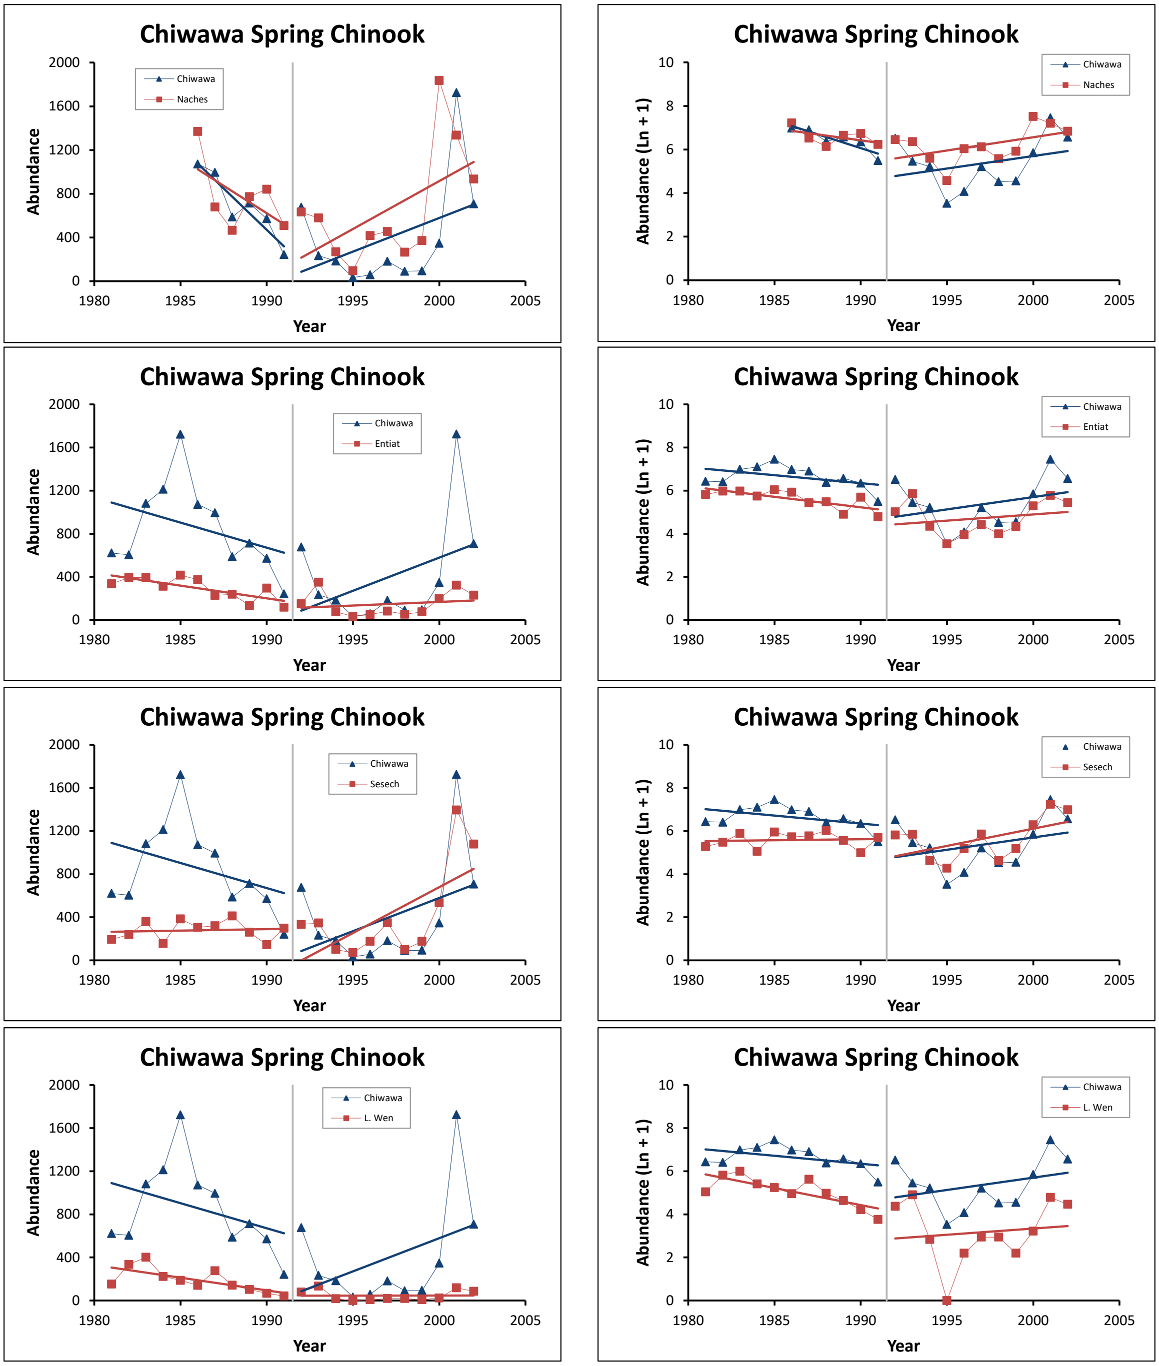

Figure 9. Trends in spring Chinook spawner abundance in the Chiwawa and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed spawner abundance data; those on the right include natural-log transformed data.

Table 12. Trend analysis indicated that the relationship of slopes of NORs between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 10; Table 13). Before supplementation, Chiwawa NORs trended downward more strongly than the reference populations (Figure 10). However, during the supplementation period, both the Chiwawa and reference population NORs trended upward in parallel. In nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the pre-supplementation period than in the supplementation period (Table 13).

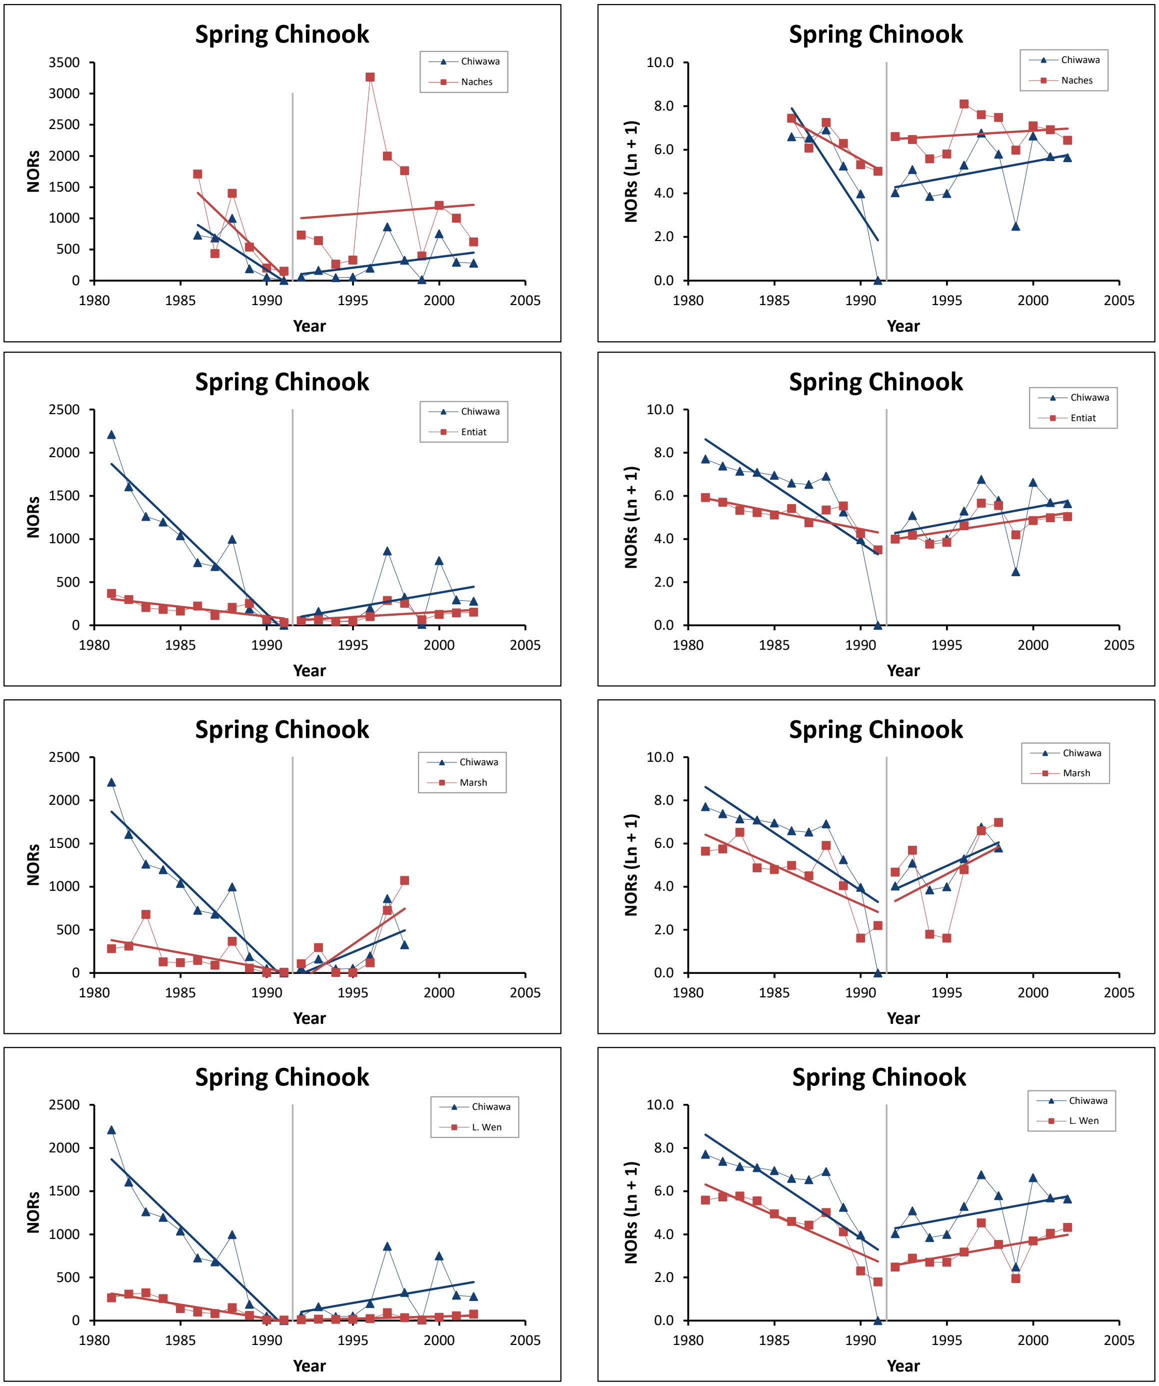

Figure 10. Trends in spring Chinook natural-origin recruits (NORs) in the Chiwawa and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed NORs; those on the right include natural-log transformed data.

Table 13. Pearson correlation coefficients and t-test results comparing slopes of natural-origin recruits trends between reference populations and the Chiwawa spring Chinook population before and during the supplementation periods; for correlation coefficients, an asterisk (*) indicates significance at $P < 0.05$. Analyses include both untransformed and natural-log transformed natural-origin recruits.

Little Wenatchee	0.927*	0.898*	-1.150	0.046	0.265	0.964

As with NORs and spawner abundance data, trend analysis indicated that the relationship of slopes of productivity (recruits/spawner) between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 11; Table 14). This was true for both transformed and untransformed productivity data. Before supplementation, productivities trended down in both the Chiwawa and reference populations (Figure 11). During the period of supplementation, productivities fluctuated widely in both the Chiwawa and reference populations. Nevertheless, during the supplementation period, productivities generally increased in both the reference and Chiwawa populations. Unlike with spawner abundance, the Pearson correlation coefficients resulting from analysis of productivity data were generally higher in the pre-supplementation period than during the supplementation period (Table 14).

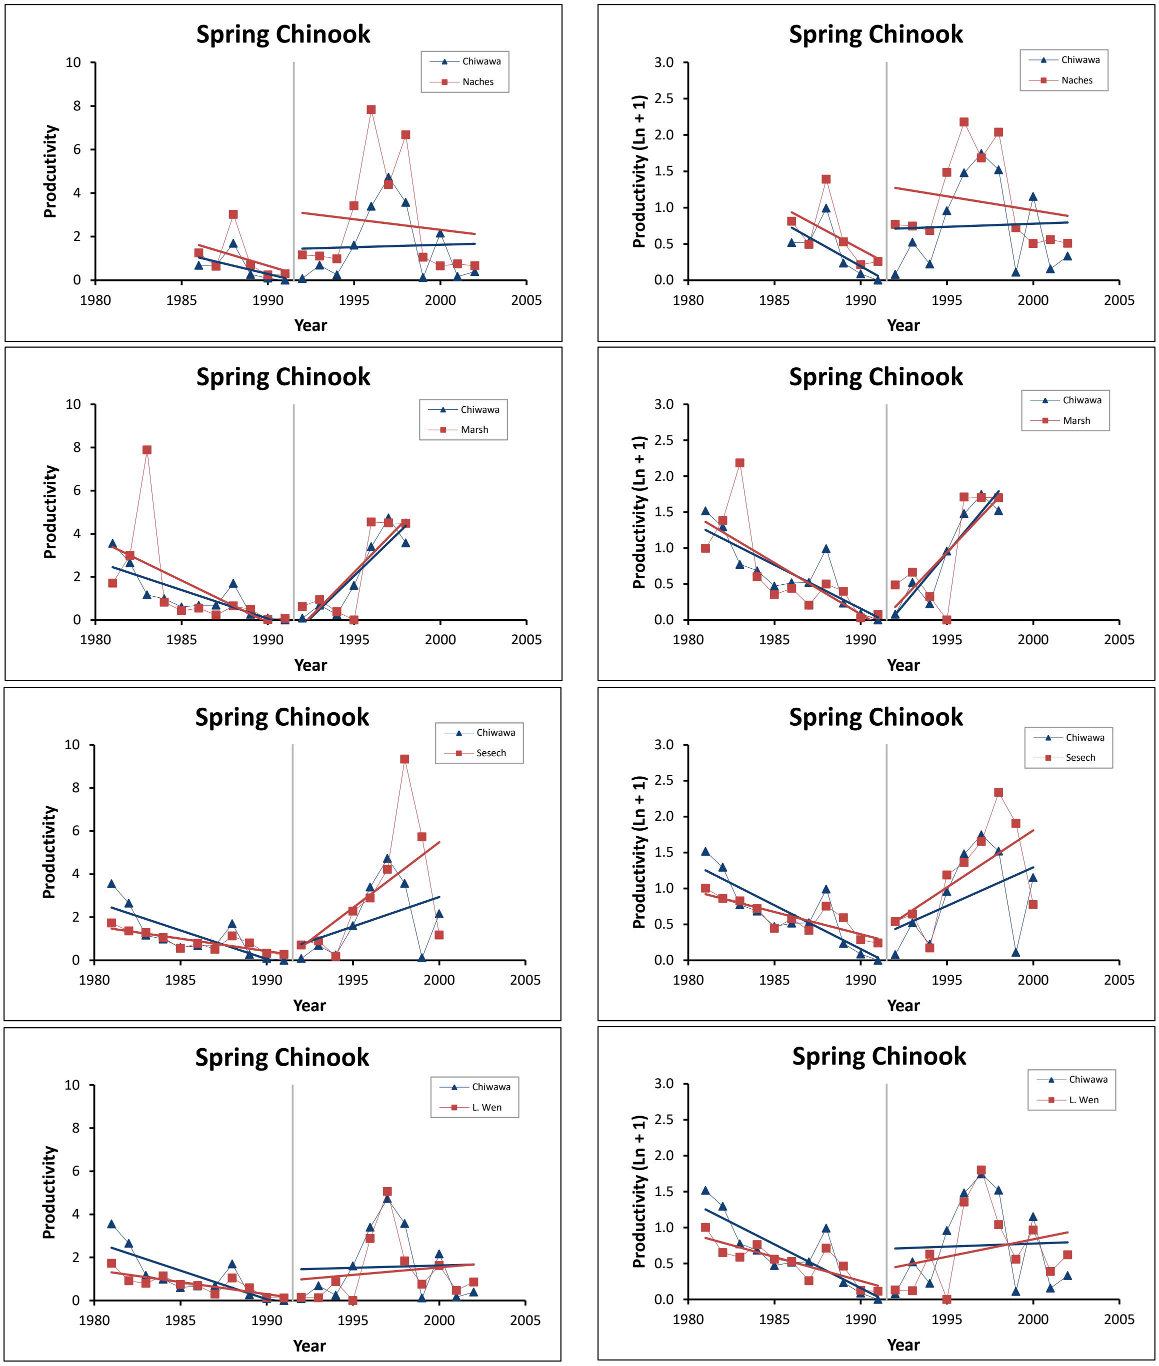

Figure 11. Trends in spring Chinook productivity (recruits/spawner) in the Chiwawa (supplemented) and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed productivity data; those on the right include natural-log transformed data.

Table 14. Little Wenatchee	0.862*	0.751*	-1.811	-0.480	0.087	0.637

Using trend analysis, we found no evidence that the supplementation program has significantly increased the spawner abundance and NORs of spring Chinook in the Chiwawa Basin. Even though we documented an increasing trend in spawner abundance and NORs during the supplementation period, a similar increase in spawner abundance and NORs was observed in the reference populations. In addition, we found no evidence that the supplementation program has increased the productivity of spring Chinook in the Chiwawa Basin. Importantly, the productivity of spring Chinook in the Chiwawa Basin did not trend downward during the supplementation period. Thus, based on trend analysis, it appears that the supplementation program has not increased or decreased the abundance and productivity of spring Chinook in the Chiwawa Basin.

We note that this exercise only tests the slopes of the trend lines. It does not test for differences in elevations of the trend lines. A supplementation program could increase spawner abundance, NORs, and productivity of the target population without changing the slopes of the trend lines. That is, supplementation could cause the elevation of the trend line to be greater during the supplementation period than during the pre-supplementation period. In the next section we evaluate elevation differences by testing mean differences before and after supplementation.

Analysis of Mean Differences, Ratios, and Rates

For assessing mean differences between supplemented and reference populations, we derived three different response variables using transformed and untransformed spawner abundance, NORs, and productivity data. The first included difference scores, which were calculated as the difference between paired treatment and reference data (T-R). The second included ratios, which were calculated as the ratio of paired treatment and reference data (T/R). Finally, we calculated the differences in annual changes in paired treatment and reference population data (ΔT-ΔR; see footnote #2).

If the hatchery program is successfully supplementing the natural spring Chinook population, the mean difference or ratio score of paired spawner abundance data and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean difference or ratio score during the supplementation period should be equal to or higher than the pre-supplementation period. We tested the following statistical hypotheses.

Spawner Abundance and NORs:

> Ho: Mean Difference (or Ratio) before supplementation ≥ Mean Difference (or Ratio) during supplementation.
>
> Ha: Mean Difference (or Ratio) before supplementation < Mean Difference (or Ratio) during supplementation (i.e., $\mu_{pre} - \mu_{post} < 0$).

Productivity (Recruits/Spawner):

> Ho: Mean Difference (or Ratio) before supplementation ≤ Mean Difference (or Ratio) during supplementation.
>
> Ha: Mean Difference (or Ratio) before supplementation > Mean Difference (or Ratio) during supplementation (i.e., $\mu_{pre} - \mu_{post} > 0$).[20]

For each set of response variables, we tested before/after supplementation effects using a one-tailed Aspin-Welch unequal-variance test. We used the Aspin-Welch unequal-variance test instead of Student's t-test, because in nearly every case, the variances of response variables in the pre-treatment and supplementation periods were unequal.[21] This was true even for natural-log transformed variables. We used the modified Levene equal-variance test to assess the equality of variance. In some cases, the distributions of response variables were not normal (based on the Omnibus Normality test and examination of histograms, normal probability plots, and box plots). Therefore, we also used a randomization test, based on 10,000 Monte Carlo simulations, to assess differences in response variables before and during supplementation. The randomization procedure only allowed the testing of two-tailed hypotheses. Therefore, we generated 95% confidence intervals on the mean difference ($\mu_{pre} - \mu_{post}$) using bootstrapping methods to determine the direction of the difference. We generated 5,000 bootstrap samples to calculate confidence intervals.

All these statistical methods assume that the samples of derived difference or ratio scores from the pre-supplementation and supplementation periods were independent. However, BACI designs, like time-series trend analysis, are repeated-measures designs and therefore are susceptible to temporal correlations in the data. This means that the two samples of difference or ratio scores may not be independent. Under this scenario, ARIMA models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). ARIMA models can be fit individually to the reference and supplemented time series data, or to a derived data series created by taking the ratio or difference of the supplemented/reference data at each time step. ARIMA models, however, require a long time series (N > 40) and therefore we could not use them to model

20 Because of the logic of null hypothesis testing, the rejection of the null hypothesis of no difference in productivity would mean that the supplementation program has reduced the productivity of the target population (here rejection of the null indicates "harm"). Notice that the rejection of the null hypothesis of no difference in spawner abundance means that the supplementation program has improved the spawner abundance in the target population (here rejection of the null indicates "benefit").

21 In cases in which the variances were equal, both the Aspin-Welch test and Student's t-test gave the same result.

the spring Chinook data. Thus, we acknowledge that our analyses may be confounded if the samples are not independent.

Difference Scores (T-R)

Analysis of supplementation effects on spawner abundance using difference scores indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 15; Figure 12). Only the Little Wenatchee-Chiwawa pairing using transformed abundance data indicated a significant increase in spawning abundance following supplementation. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction (i.e., CIs > 0). That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 12).

Table 15. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed spawner abundance data. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

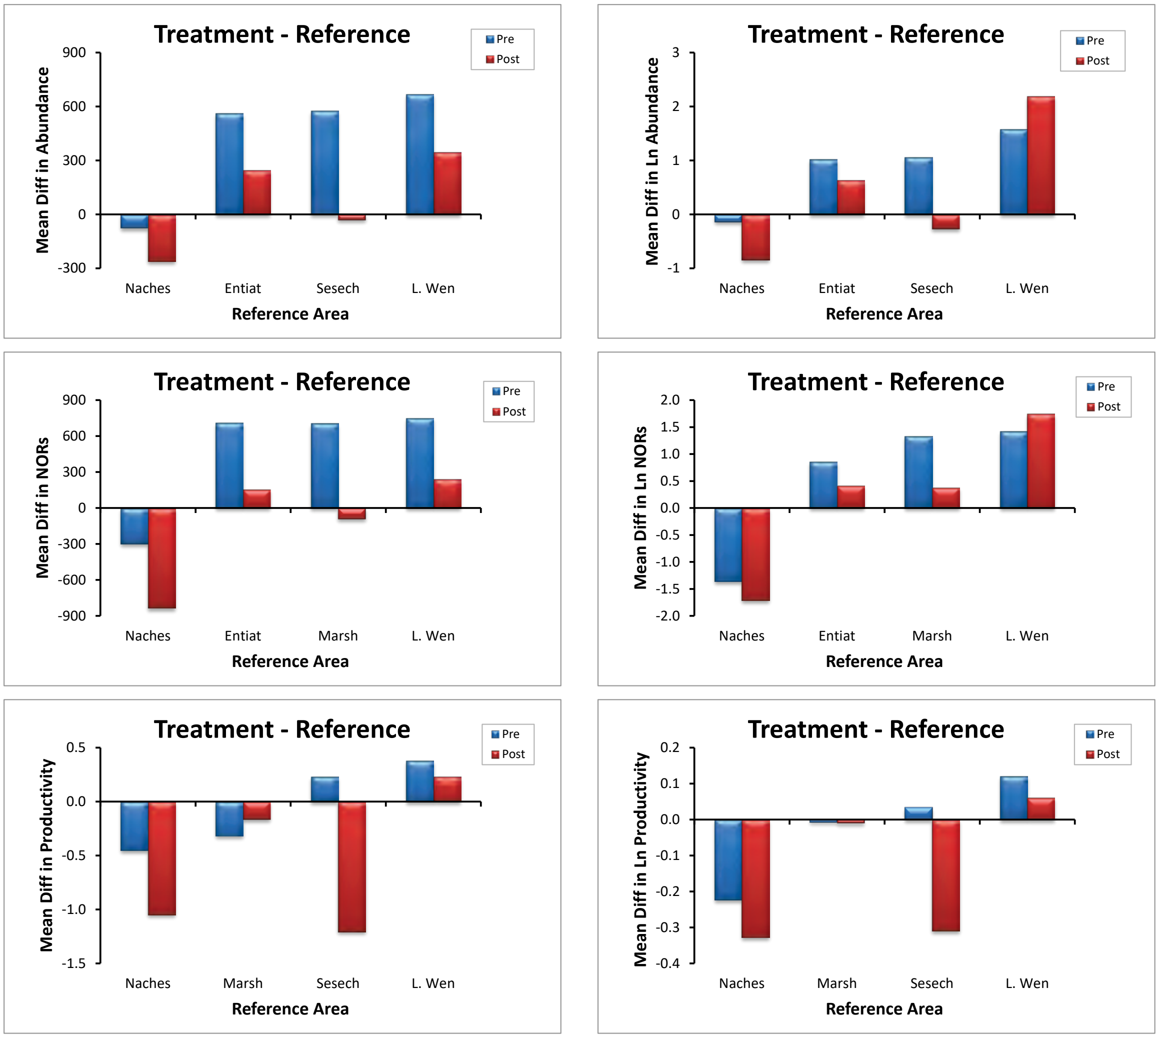

Figure 12. Mean difference (Treatment – Reference) scores of untransformed (figures on the left) and transformed (figures on the right) spawner abundance, natural-origin recruits (NORs), and productivity data before (pre) and after (post) spring Chinook supplementation in the Chiwawa Basin. Positive effects of supplementation on spawner abundance and NORs are indicated when the post-supplementation (red) bars are greater than their corresponding pre-supplementation (blue) bars. Negative effects of supplementation on productivity are indicated when the pre-supplementation (blue) bars are greater than their corresponding post-supplementation (red) bars.

Analysis of supplementation effects on NORs using difference scores indicated that supplementation did not significantly increase NORs in the Chiwawa Basin (Table 16; Figure 12). The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction. That is, compared to the reference populations, NORs decreased in the Chiwawa Basin during the supplementation period (Figure 12).

Table 16. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed natural-origin recruits. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

Ratio Scores (T/R)

As with difference scores, analysis of supplementation effects on spawner abundance using ratios indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 18; Figure 13). Only the Little Wenatchee-Chiwawa pairing indicated a significant increase in spawning abundance following supplementation. Analysis with both transformed and untransformed Little Wenatchee-Chiwawa data indicated a significant effect. In contrast, only difference scores derived from transformed data indicated a significant effect. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction. That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 13).

Analysis of supplementation effects on productivity (adult recruits/spawner) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 20; Figure 13). Although the Aspin-Welch test indicated a significant effect when comparing the Chiwawa to the Marsh Creek population, both the randomization test and the bootstrap CI did not indicate a significant effect. These tests indicate that supplementation has probably not negatively affected the productivity of spring Chinook salmon in the Chiwawa Basin.

We believe results from analysis of mean differences of annual change (ΔT-ΔR) in spawning abundance, NORs, and productivity are difficult to interpret and may be insensitive to treatment effects. A simpler analysis, which is also easier to interpret, is the use of trend analysis. Therefore, we recommend that analyses using differences of annual change be replaced with trend analysis.

Corrections for Density Dependence and Carrying Capacity

The analyses described above assume that the density of spawners or recruits does not affect the survival and productivity of fish. However, it is well known that the density of fish can affect the number of recruits as well as the productivity of the population. This occurs through the relationship between density and mortality. Mortality of fish can be generally classified as density independent and density dependent. In general, when densities are low, the mortality is density independent, but as densities increase, the amount of density-dependent mortality increases. Monitoring programs can make use of this information to derive density-corrected estimates of productivity. In this section, we describe two different methods for deriving density-corrected estimates of productivity.

The first method controlled the effects of density on productivity (adult recruits/spawner; R/S) by partitioning observed productivities into density-independent and density-dependent productivity. When abundance is below the minimum number of spawners (S) needed to produce the maximum number of recruits (K_{sp}), the observed productivity is used in statistical tests. However, when the abundance is equal to or above K_{sp}, the modeled value of productivity (R/K_{sp}) is used in statistical tests.

$$\boldsymbol{Adj\ R/S} = \begin{cases} \boldsymbol{R/S,} & \boldsymbol{if\ S < K_{sp}} \\ \boldsymbol{R/K_{sp},} & \boldsymbol{if\ S \geq K_{sp}} \end{cases}$$

The density-independent and density-dependent productivities were then combined in a single test.

The second method was based on one of the goals of supplementation, which is to fill the capacity of the environment with fish. This method corrects for differences in carrying capacities between the supplemented and reference populations. We did this by calculating the percent saturation of NORs. That is, we calculated the fraction of the habitat (τ) that was filled with NORs by dividing the observed NOR by the modeled maximum number of NORs (K_R) that the habitat could support.

$$\boldsymbol{\tau} = \frac{\boldsymbol{NOR_{obs}}}{\boldsymbol{K_R}}$$

Note that 1-τ represents the unused portion of the carrying capacity and is the term that is multiplied by the exponential growth equation to derive the logistic growth equation. We included τ in the statistical analyses.

These two methods require the estimation of carrying capacity (K_R) and the spawning abundance that produces the maximum number of recruits (K_{sp}). We estimated these parameters for both reference populations and the supplemented population using Ricker, Beverton-Holt, and smooth hockey stick stock-recruitment models. We used only spawner abundance as a predictor of subsequent brood recruitment. We made the following assumptions in proceeding with the analysis:

- Density-dependent mortality—For some time period before recruitment, the brood instantaneous mortality rate is proportional to the number of parent spawners (Ricker 1954).
- Lognormal variation—At any particular spawning stock size, the variation in recruitment is log-normally distributed about its average, and acts multiplicatively (Quinn and Deriso 1999).
- Measurement error—Error in spawning stock size estimates (measurement error) is small relative to the range of spawning stock sizes observed (Hilborn and Walters 1992). Variation in realized recruitment at any particular spawning stock size (process error) dominates recruitment measurement error.
- Stationarity—The average stock-recruitment relationship is constant over time (Hilborn and Walters 1992). That is, environmental conditions randomly affect survival independent of stock size or time.

In general, the methods we used to fit the models to the data followed those outlined in Hilborn and Walters (1992) and Froese (2008). The Ricker model, which assumes that the number of recruits increases to a maximum and then declines as the number of spawners increases, takes the form:

$$\boldsymbol{E(R) = \alpha S e^{-\beta S}}$$

where E(R) is the expected recruitment, S is spawner abundance, α is the number of recruits per spawner at low spawning levels, and β describes how quickly the recruits per spawner drop as the number of spawners increases. We estimated K_R as:

$$\boldsymbol{K_R = \left(\frac{\alpha}{\beta}\right) e^{-1}}$$

and K_{sp} as:

$$\boldsymbol{K_{sp} = \frac{1}{\beta}}$$

The Beverton-Holt model assumes that the number of recruits increases constantly toward an asymptote as the number of spawners increases. After the asymptote is reached, the number of recruits neither increases nor decreases. The asymptote represents the maximum number of recruits the system can support (i.e., carrying capacity for the system; K_R). The Beverton-Holt curve takes the form:

$$\boldsymbol{E(R) = \frac{(\alpha S)}{(\beta + S)}}$$

where E(R) and S are as above, α is the maximum number of recruits produced (K_R), and β is the number of spawners needed to produce (on average) recruits equal to one-half the maximum number of recruits. Because $K_{sp} = \infty$ in the Beverton-Holt model, we estimated K_{sp} as the number of spawners needed to produce 0.99(K_R).

Like the Beverton-Holt model, the smooth hockey stick model assumes that the number of recruits increases toward an asymptote (carrying capacity; K_R) as the number of spawners increases. After the carrying capacity is reached, the number of recruits neither increases nor decreases. The carrying capacity represents the maximum number of recruits the system can support. This curve

takes the form (Froese 2008):

$$\boldsymbol{E(R) = R_{\infty}\left(1 - e^{-\left(\frac{\alpha}{R_{\infty}}\right)S}\right)}$$

where E(R) and S are as above, α is the slope at the origin of the spawner-recruitment curve, and R_{∞} is the carrying capacity of recruits (note that $R_{\infty} = K_R$). As with the Beverton-Holt model, we estimated K_{sp} as the number of spawners needed to produce 0.99(K_R).

We used non-linear regression to fit the three models to spawner-recruitment data. Before fitting the models, we transformed recruitment data using natural logs. We estimated bias and uncertainty measures (95% CI) for the model parameters using bootstrap procedures, which assumed that the {R, S} sample represented or approximated the population. The number of bootstrap samples was 3,000. We computed and stored the non-linear regression results for each bootstrap sample. We then calculated the bootstrap 95% CI by arranging the 3,000 bootstrap parameter values in sorted order and selected the 2.5 and 97.5 percentiles from the list.

We used Akaike's Information Criterion for small sample size (AIC_c) to determine which model(s) best explained the relationship between spawners and recruitment in the supplemented and reference populations. AIC_c was estimated as:

$$\boldsymbol{AIC_c = -2log\left(£(\theta|data)\right) + 2K + \left(\frac{2K(K+1)}{n-K-1}\right)}$$

where *log(£(θ|data))* is the maximum likelihood estimate, *K* is the number of estimable parameters (structural parameters plus the residual variance parameter), and *n* is the sample size (Burnham and Anderson 2002). We used least-squares methods to estimate *log(£(θ|data))*, which was calculated as $log(\sigma^2)$, where σ^2 = residual sum of squares divided by the sample size ($\sigma^2 = RSS/n$). AIC_c assessed model fit in relation to model complexity (number of parameters). The model with the smallest AIC_c value represented the "best approximating" model within the model set. Remaining models were ranked relative to the best model using AIC_c difference scores (ΔAIC_c), Akaike weights (w_i), and evidence ratios. Models with ΔAIC_c values less than 2 indicated that there is substantial support for these models as being the best-fitting models within the set (Burnham and Anderson 2002). Models with values greater than 2 had less support. Akaike weights are probabilities estimating the strength of the evidence supporting a particular model as being the best model within the model set. Models with small w_i values are less plausible as competing models (Burnham and Anderson 2002). If no single model could be specified as the best model, a "best subset" of competing models was identified using (1) AIC_c differences to indicate the level of empirical support each model had as being the best model, (2) evidence ratios based on Akaike weights to indicate the relative probability that any model is the best model, and (3) coefficients of determination (R^2) assessing the explanatory power of each model.

Stock-Recruitment Analysis

We successfully fit stock-recruitment models to the Chiwawa and reference population data. The span of spawner data for the Chiwawa and reference populations was greater than 14 times the minimum observed spawners, which should provide sufficient contrast for estimation of model parameters. In addition, the span of recruitment data was greater than 12 times the minimum observed recruitment, again providing sufficient contrast for estimation of parameters. The relationship between natural log R/S and spawners indicated that some of the highest productivities occurred at the lower spawner levels and the lowest productivities generally occurred at the highest spawner levels (Figure 15). This is consistent with the assumption of density-dependent mortality.

Although model fits were generally poor, explaining less than 40% of the residual variation in natural-log recruitment data, we were able to estimate average maximum recruitment levels (K_R) and the spawning levels needed to produce maximum recruitment (K_{sp}) (Table 24; Figure 15). For all populations examined, Akaike information criterion was unable to identify a best approximating model (i.e., ΔAIC_c values were less than 2, indicating support for all three models). However, evaluation of 95% CIs and the asymptotic correlation coefficients indicated that the smooth hockey stick model may be the best approximating model for each population. Therefore, we used estimates of K_R and K_{sp} derived from the smooth hockey stick model to correct for density dependence and different carrying capacities in treatment-reference comparisons.

As part of the regression diagnostics, we examined the dependence of the model residuals on time and found a significant ($P < 0.05$), positive, one-year-lag autocorrelation for the Entiat (0.562), Marsh (0.551), Sesech (0.564), and Little Wenatchee (0.629) populations. For the purposes of our work here, we did not attempt to correct for this one-year-lag correlation in the residuals. Future analyses will explore the use of autoregressive models (e.g., AR1; Noakes et al. 1987) to correct for autocorrelation.

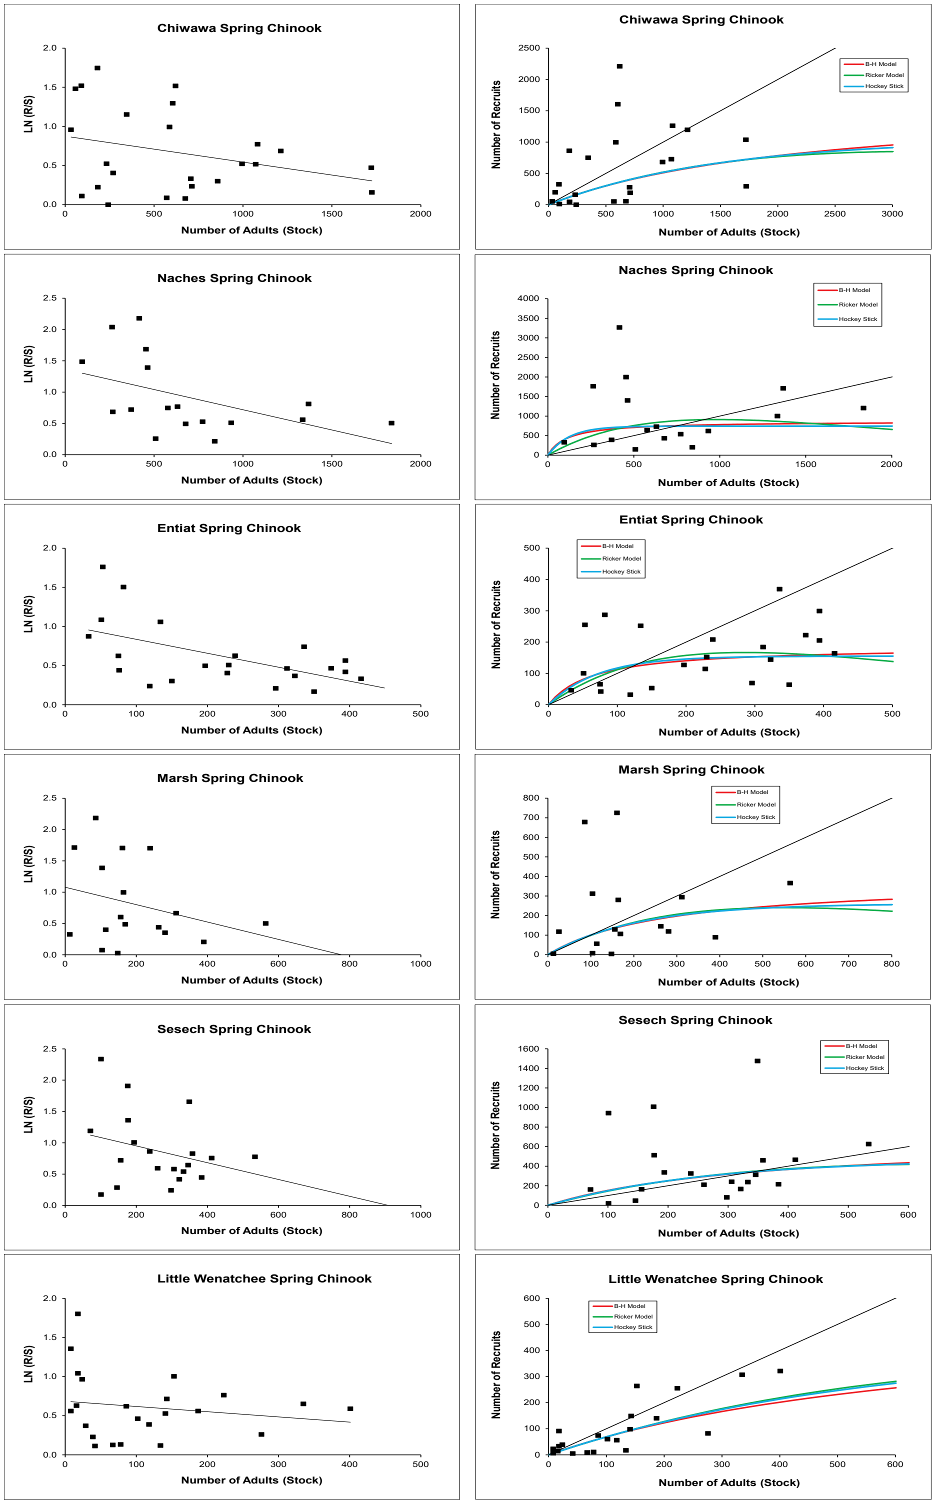

Figure 15. Relationships between natural log recruits/spawner (LN R/S) and spawners (Stock) in the Chiwawa and reference populations (figures on the left) and relationships between numbers of untransformed recruits and spawners in the Chiwawa and reference populations (figures on the right). Figures on the right also show the fit of the Ricker, Beverton-Holt, and the smooth hockey stick models to the data (black straight line represents R=S).

Table 24. Results from fitting Ricker, Beverton-Holt, and smooth hockey stick models to stock-recruitment data from the Chiwawa and reference populations. 95% CI on parameter estimates are based on 3,000 bootstrap trials; Corr coef = asymptotic correlation of the parameter estimates; K_R = maximum natural origin recruits (recruits at carrying capacity); K_{sp} = number of spawners needed to produce K_R; AICc = Akaike's Information Criterion for small sample size; Adj R^2 = coefficient of determination that is adjusted for the number of parameters in the model.

Method 1: Productivity Data Adjusted for Density Dependence

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects based on the smooth hockey stick model) using difference scores indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 25; Figure 16). All tests, regardless of treatment-reference pairs, indicated that productivity did not change significantly during the supplementation period, even though productivity did decrease during the supplementation period (Figure 16). These results are consistent with those based on unadjusted productivity data (Table 17). This is because most abundance estimates were below the level of assumed density dependence.

Table 25. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

Reference population	Aspin-Welch unequal-variance test			Randomization test P-value	Bootstrap 95% CI
	t-value	P-value	Effect size		
Productivity					
Naches	0.904	0.190	0.496	0.412	-0.511 – 1.497
Marsh	-0.203	0.579	0.152	0.927	-1.298 – 1.372
Sesech	1.607	0.071	1.435	0.146	-0.359 – 2.911
Little Wenatchee	0.431	0.335	0.147	0.668	-0.487 – 0.781
LN Productivity					
Naches	0.570	0.290	0.083	0.568	-0.168 – 0.362
Marsh	0.012	0.495	0.003	0.991	-0.373 – 0.480
Sesech	1.463	0.087	0.343	0.171	-0.125 – 0.732
Little Wenatchee	0.390	0.351	0.060	0.709	-0.218 – 0.365

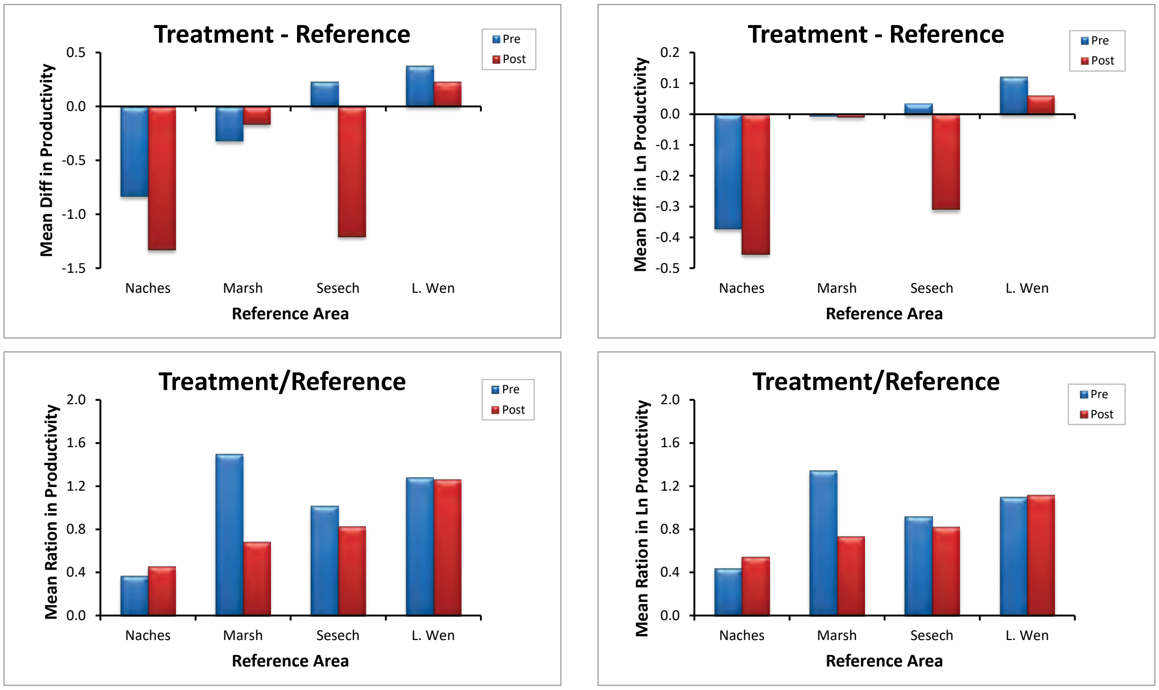

Figure 16. Mean differences (Treatment – Reference; figures on the top) and mean ratios (Treatment/Reference; figures on the bottom) of transformed and untransformed productivity data (adjusted for density dependence) before (pre) and after (post) spring Chinook supplementation in the Chiwawa Basin. Negative effects of supplementation on productivity are indicated when the pre-supplementation (blue) bars are greater than their corresponding post-supplementation (red) bars.

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 26; Figure 16). The Aspin-Welch test and the 95% CIs did indicate a significant effect when comparing the Chiwawa to the Marsh Creek population. These results are consistent with those using unadjusted productivity data (Table 20). Again, this is because most abundance estimates were below the level of assumed density dependence.

Table 26. Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean ratios during the supplementation period were less than mean ratios during the pre-supplementation period.

Reference population	Aspin-Welch unequal-variance test			Randomization test P-value	Bootstrap 95% CI
	t-value	P-value	Effect size

Naches	-0.621	0.726	0.104	0.536	-0.406 – 0.191

Reference population	Aspin-Welch unequal-variance test			Randomization test P-value	Bootstrap 95% CI
	t-value	P-value	Effect size		
Marsh	1.952	0.036	0.613	0.076	0.005 – 1.163
Sesech	0.447	0.330	0.098	0.649	-0.312 – 0.498
Little Wenatchee	-0.034	0.513	0.015	0.980	-0.697 – 0.852

Our analyses assume that there is a spawner abundance (K_{sp}) at which density-independent effects end and density-dependent effects begin. In reality, density-dependent effects occur at low spawning abundance and intensify as spawning abundance increases (evident in the changing slope of the three stock-recruitment curves used in our analyses). We did not account for these increasing density-dependent effects at spawner abundances less than K_{sp}. If we accounted for the increasing effects of density dependence at spawning abundances less than K_{sp}, the analysis with and without productivity adjustments may give different results.

Method 2: Fraction of Carrying Capacity Filled with NORs

We analyzed the effects of supplementation on filling the capacity of the habitat with natural-origin recruits. The smooth hockey stick model derived the carrying capacity (K_R) estimates for the Chiwawa and reference populations. The fraction of the carrying capacity filled with Chinook recruits before and during supplementation for the Chiwawa and reference populations is provided in Table 27. These data indicate that for the Chiwawa population, the mean fraction of the K_R filled with fish decreased significantly from the pre-supplementation period through the supplementation period (Table 27). Likewise, the Entiat and Little Wenatchee populations showed a significant decline in the mean fraction of K_R filled with adult recruits. In contrast, the mean fraction of K_R in the Naches and Marsh Creek populations increased during the same period (Table 27).[22] Interestingly, the fraction of K_R filled with adult recruits for all populations trended downward during the pre-supplementation period (Figure 17). During the supplementation period, however, the fraction of K_R filled with adult recruits trended upward for all populations. These results suggest that agents of mortality outside the Chiwawa and reference populations were reducing recruitment to the populations.

22 Although we do not show the results here, statistical analysis of the mean fraction of carrying capacity filled by adult recruits using natural-log transformed data produced the same result as using untransformed data. This was true for all populations.

Table 27. Fraction of the carrying capacity that was filled with Chinook salmon adult recruits in the Chiwawa and reference populations before (pre) and during (post) supplementation in Chiwawa Basin. The smooth hockey stick model estimated carrying capacity for each population. Statistical results from comparing the pre and post mean scores using the Aspin-Welch unequal-variance test are provided at the bottom of the table.
