## Attachment 2

Presentation by Cody Gillin and Robes Parrish on the Status of the Beaver Fever Project

A presentation slide titled "BDA PROJECT UPDATE" with a background image of a stream. The slide contains a bulleted list of project updates and two logos at the bottom right: "TROUT UNLIMITED" and the "U.S. FISH & WILDLIFE SERVICE" logo.

**BDA PROJECT UPDATE**

- January 2017 Trib Comm discussion guided additional analysis
  - Watershed scale, direct fish benefit, H2O effects, habitat effects, temperature effects
- Primary Ranking Factors: gradient, site accessibility
  - 100 streams where BDA analysis yielded potential
- Secondary Ranking Factors: Overlay fish distribution and temperature data; consider social-recreation-land use
- Watershed by watershed inventory and categorization
  - 51 high Primary Ranking potential
  - 5 high Primary and Secondary Ranking potential
- Literature provided further guidance: what is known, what are data gaps?

**CRITERIA TO ACHIEVE HIGH PRIMARY RANKING FACTOR POTENTIAL**

- Many dots or dot clusters in the first run BDA suitability analysis
  - < 2% slope, within 200 feet of a road

High Primary Ranking Potential

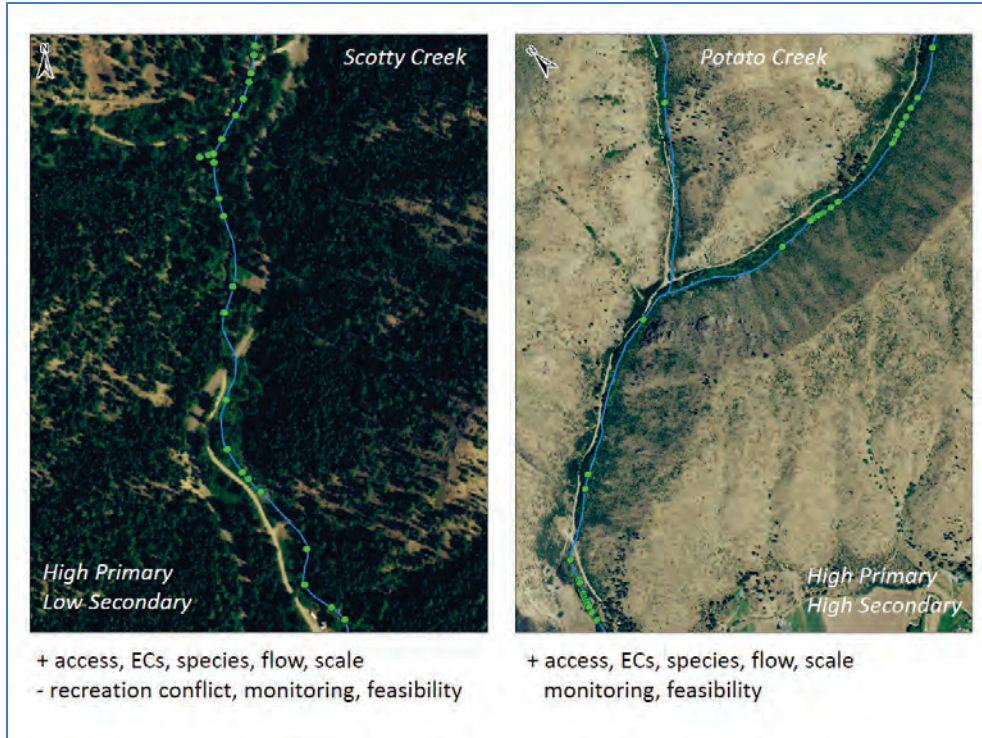

Low Primary Ranking Potential

**CRITERIA TO ACHIEVE HIGH SECONDARY RANKING POTENTIAL**

- ESA and other salmonid species use (UCSRB, SWIFD)
- Addressing top Ecological Concerns in the Assessment Unit
- Perennial or near perennial flow (but not too much discharge)
- No social-recreation-land use challenges
- Watershed-scale implementation potential AND/OR opportunity for significant physical and hydrological improvements
- Validation of Primary Ranking Factors geospatial analysis
- Opportunities for robust monitoring and data gathering
- Considered historic / predicted stream temperatures
- Some objective, some based on knowledge / experience

### Entiat River Basin Primary-Secondary Ranking Factor Results

| HIGH-HIGH                     | HIGH-MEDIUM | HIGH-LOW   |
|-------------------------------|-------------|--|
| Roaring Creek<br>Potato Creek |             | Mud Creek<br>Mainstem Entiat River<br>Mainstem Mad River |

5 of 22 Entiat streams with high Primary Ranking  
2 with high Primary and Secondary Ranking

### THE CASE FOR ROARING AND POTATO

- ESA species
  - Roaring known Entiat STHD stronghold
  - STHD and Chinook in Potato (relative abundance unknown)

| Last Antenna Group Name      | Release Date<br>MMDDYYYY | Species Code | Species Name | Run Code | Run Name | Rear Type Code | Rear Type Name                  | Release Site Name                                |
|------------------------------|--------------------------|--------------|--------------|----------|----------|----------------|---------------------------------|--|
| DSM BYPASS SURFACE COLLECTOR | 7/13/2011                | 3            | Steelhead    | 2        | Summer   | W              | Wild Fish or Natural Production | POTATC - Potato Creek, tributary to Entiat River |

- Flow: Perennial / near perennial, some large substrate
- Social constraints: None to our knowledge, single to few landowners
- Scale: Multi-reach (Lower Roaring Ck.) to watershed (Potato Ck.) potential
- Validation of Primary Ranking: So far, yes, more work needed

|                                      | Beavers | BDAs | Notes  |
|--------------------------------------|---------|------|--|
| <b>Biological Effects</b>            |         |      |  |
| Increased fish density               | ●       | ●    | Shown for many species; higher linear and areal densities in BC  |
| Increased fish survival              | ●       | ●    | Shown for STHD, Chinook, coho. +52% in Bridge Cr. BDA sthd.  |
| Increased fish growth                | ○       | ○    | Decreased growth in Bridge Cr. study   |
| Fish Productivity                    | ●       | ●    | +175% juv. STHD in BC after 4yrs (density, growth, survival)   |
| Overwinter refuge                    | ●       | ⊙    | -86% in Stillaguamish coho ovw capacity; freezing (eg. Wilson)?  |
| Invertebrates                        | ●       | ⊙    | >diversity but largely changes from lotic to lentic taxa   |
| Fish barriers                        | ○       | ○    | Highly speculative, variable., no effect in Bridge Cr. w/236 dams for adult or juvenile upstream or downstream |
| <b>Hydrologic-Geomorphic Effects</b> |         |      |  |
| Change Flow Regime                   | ●       | ⊙    | Shown under both removal and addition of dams  |
| Aggradation/Incision                 | ●       | ●    | 1" to > 0.5m; more lit. on natural dams than BDAs  |
| Groundwater storage                  | ●       | ●    | Shown for small check structures and BDAs  |
| Peak flow amelioration               | ●       | ⊙    | Up to 5%. Recent paper shows not dependent on confinement  |
| Temperature reduction                | ●       | ●    | Positive with >depth and GW exchange. -1.5C in BC. Less flux   |
| Channel complexity                   | ●       | ●    | Most of BDA results from Bouwes 2016.  |
| Riparian expansion                   | ●       | ⊙    | Can be expansive; change in veg. types/mosaic; No lit. on BDAs   |
| Sediment storage                     | ●       | ⊙    | Can be large effect: varies by age, vegetation, u/s dam failure  |
| Heterogeneity                        | ●       | ●    | Incr. depths, 3x side channels, deeper pools, inundation area  |

|   | Beavers | BDAs  | Notes  |
|---|---------|---|--|
| <b>Chemical Effects</b>   |         |   |  |
| Biogeochemical cycling  | ●       | ⊙   | Ponds trap WM and beaver caches store organic material   |
| Deposition/Retention  | ●       | ⊙   | See above: Naiman 1994 constitutes much of published work  |
| Nutrient amelioration   | ●       | ●   | Easily bound with sediment but also released upon dam failure; some European studies show retention times of 6-8 days is sufficient to remove excess nitrogen, phosphorus, and herbicides; small check dams store sediment |
| <b>Kemp et al. (2012) meta analysis</b>   |         |   |  |
| <b>Potential Impacts of Beaver Modifications on Fish Species</b>  |         |   |  |
| <u>Potential Positive Impacts</u>   |         | <u>Potential Negative Impacts</u>   |  |
| <ul style="list-style-type: none"> <li>Increased fish productivity/abundance</li> <li>Increased habitat and habitat heterogeneity</li> <li>Increased rearing and overwintering habitat</li> <li>Enhanced growth rates</li> <li>Providing flow refuge</li> <li>Improved production of invertebrates</li> </ul>   |         | <ul style="list-style-type: none"> <li>Barriers to fish movement</li> <li>Siltation of spawning habitat</li> <li>Low oxygen levels in beaver ponds</li> <li>Altered temperature regime</li> </ul> |  |
| <p>Kemp et al. noted that many of the positive effects cited (51.5 percent) were supported by data, while many more of the negative impacts (71.4 percent) were speculative and not supported by data collected in the field. Furthermore, the most commonly cited negative impact of beaver dams—as barriers to fish movement—was highly speculative, as 78.4 percent of the studies did not support this claim with data.</p> |         |   |  |

### **MONITORING IN ROARING AND POTATO**

- Floodplain reconnection: wetted perimeter, wetted width
- Groundwater storage: wells/piezometers
- Aggradation: raising bed level of incised reaches
- Temperature: pre and post installation, US and DS
- Riparian Vegetation: expansion, density, species
- Intermittent to ephemeral conversion: North Fork Potato? Upper Potato?
- Sediment storage
- LWD and structural complexity
- Rehabilitation of diversions
- Floodplain interaction
- Side channel and wetland development
- Passage barriers?
- Fish population response?

## Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 8 June 2017

---

**Members Present:** Lee Carlson (Yakama Nation), Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Steve Hays (Chelan PUD), Tom Kahler (Douglas PUD), Kate Terrell (USFWS), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

**Others Present:** Becky Gallaher (Tributary Project Coordinator).

---

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Thursday, 8 June 2017 from 9:30 am to 12:30 pm.

### **I. Review and Adopt Agenda**

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda with revisions. Two budget amendments and an update on the Beaver Creek road damage were added to the agenda.

### **II. Review and Approval of Meeting Minutes**

The Committees reviewed and approved the 13 April 2017 meeting notes.

### **III. Monthly Update on Ongoing Projects**

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- MVID Instream Flow Improvement Project – The project sponsor (Trout Unlimited; TU) reported that they are completing the final punch list items.
- Clear Creek Fish Passage and Instream Flow Project – The sponsor (TU) reported that they completed the installation of two, 6-inch pipes that will provide a conduit for the electrical and water lines. This system will connect the new treatment plant to the water-storage cistern. Ecology recently approved the water-right change application. The Source Approval Package was compiled and submitted to the Department of Health. Finally, the sponsor initiated the bid package development process and began compiling bid and contract documents.
- Barkley Irrigation – Under Pressure Project – The sponsor (TU) reported they have been working with Barkley Irrigation Company on pump site planning and project coordination. They also spent time coordinating the Barkley and MVID ditches and continue to work through the water-right change process. They are nearing completion of the Righty of Entry.
- Similkameen RM 3.8 Project – The sponsor (Okanogan Conservation District; OCD) reported that permits, based on the updated design, have been submitted to DNR and WDFW. A paper copy will be sent to the Corps of Engineers. A Request for Proposals will be prepared and distributed in early June.

- White River Floodplain (RM 3.4) Connection Project – The sponsor (CCFEG) reported they will be coordinating with WDFW to select an appropriate time for construction. The sponsor ordered 100 cedar trees and riparian plants for revegetation work along a portion of the project.
- Icicle Boulder Field Project – The sponsor (TU) reported they have been working with their consultants to set up the scope of work for the City of Leavenworth waterline and Geotech work. Fieldwork this summer will focus on geotech work. In addition, the sponsor continues to work on permitting and they are preparing the JARPA for geotech and project implementation.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – The sponsor (WDFW) will submit the second-year monitoring report on 31 December 2017.
- Permitting Nutrient Enhancement Project – The sponsor (CCFEG) reported they have finalized the proposal for implementation and monitoring and sent it to the Forest Service and other project partners. They will hold a meeting with project partners on Friday, 9 June, to discuss project feasibility and next steps.
- Burns-Garrity Design Project – The sponsor (CCFEG) reported that selection of a restoration concept was put on hold when a landowner listed his property for sale. The sponsor continues to do landowner outreach, delineate wetlands, and discuss potential effects of restoration alternatives.
- Beaver Fever Project – The sponsor (TU) reported that they initiated site-specific research and are developing a permitting strategy. Because BDA projects have not been implemented on Okanogan-Wenatchee forest lands, the sponsor and the USFWS are reaching out to BDA implementers to learn how to permit these projects on Forest Service lands.
- Wenatchee Sleepy Hollow Floodplain Acquisition Project – The sponsor (CDLT) reported they are still waiting for funding approval from Washington Wildlife and Recreation. The legislature failed to pass a budget in the regular session or first special session. As soon as the capital budget is passed, the sponsor will prepare the boundary line adjustment to separate the house from the rest of the property. The property will then be reappraised.

#### IV. Budget Amendments

##### Clear Creek Fish Passage Project

In May, the Rocky Reach Tributary Committee received a budget amendment request from Trout Unlimited on the *Clear Creek Fish Passage Project*. The sponsor asked to move \$2,000 from “Project Materials and Supplies” to Professional Services and Permitting.” Via email, *the Rocky Reach Tributary Committee approved the budget amendment*. The amendment will not change the total budget amount.

##### Permitting Nutrient Enhancement in the Chiwawa River Basin Project

The Rock Island Tributary Committee received a budget amendment request from CCFEG on the *Permitting Nutrient Enhancement in the Chiwawa River Basin Project*. The sponsor asked to move \$1,028 from “Professional Services” and “Indirect/Admin/Overhead” to “Sponsor Salaries and Benefits.” *The budget amendment was approved*. The amendment will not change the total budget amount.

##### White River Floodplain Connection (RM 3.4) Project

The Rock Island Tributary Committee received a budget amendment request from CCFEG on the *White River Floodplain Connection (RM 3.4) Project*. The sponsor asked to take all the available funds in “Excavation and Heavy Equipment” (\$5,000) and “Project Materials and Equipment” (\$500) and move those into “Salaries and Benefits,” “Overhead and Administration,” and “Permit Fees.” According to the request, this amendment will leave no money for excavation and haul. The Committee questioned how the project will be completed if there is no money available to conduct excavation and heavy equipment

work. As a result, *the Rock Island Tributary Committee denied the request until the sponsor can describe how the project will be completed without excavation and haul.*

## V. Time Extension

### Barkley Irrigation Project

In May, the Rock Island Tributary Committee received a time extension request from Trout Unlimited on the *Barkley Irrigation Project*. Because construction on the project is unlikely to begin until this fall, the sponsor asked to extend the project from 31 May 2017 to 31 December 2018. Via email, *the Rock Island Tributary Committee approved the time extension.*

## VI. General Salmon Habitat Program Draft Proposals

The Committees received nine General Salmon Habitat Program draft proposals. The Committees reviewed each draft proposal and selected those that they believe warranted a final proposal. Projects that the Committees dismissed were either inconsistent with the intent of the Tributary Fund, did not have strong technical merit, or had low benefits per cost. The Committees assigned draft proposals to one of two categories: Fundable and Not Fundable. It is important to note that these are ratings of draft proposals and do not reflect ratings of final proposals. The Committees directed Tracy Hillman to notify sponsors with appropriate projects to submit a final proposal, with a discussion of the questions/comments identified for each draft proposal listed below. Tracy will also notify sponsors with projects that have no chance or a low likelihood of receiving funding from the Tributary Committees.

### Stormy Preserve – Restore Wood Recruitment Project (Not Fundable)

The Committees recommend that this project, sponsored by Cascade Columbia Fisheries Enhancement Group, should not be submitted as a full proposal to the Tributary Committees for the following reason:

- At this time, the Committees are not interested in funding the construction of large wood structures in the Stormy Preserve. However, they would accept applications that address levee removal and floodplain reconnection projects.

### Icicle RM 0.3-1.1 Habitat Design Project (Not Fundable)

The Committees recommend that this project, sponsored by Chelan County Natural Resources Department, should not be submitted as a full proposal to the Tributary Committees for the following reason:

- The Committees believe the project is too expensive for a conceptual design and they recommend that the sponsor spend time discussing the project with the landowner to find out what level of restoration the landowner will allow on their property. For example, riparian vegetation along the meander bend will need to be widened to allow for meaningful process-based restoration. It is unknown if the landowner is willing to allow widening of the riparian area at this site.

### M2 WDFW Flow Connection Project (Fundable)

The Committees recommend that the project sponsor (Methow Salmon Recovery Foundation) address the following comment/suggestion as they develop the full proposal:

- The sponsor needs to describe what type of fence will be installed and who will be responsible for maintaining the fence.

### M2 Mid-Sugar Acquisition Project (Fundable)

The Committees recommend that the project sponsor (Methow Salmon Recovery Foundation) address the following comment/suggestion as they develop the full proposal:

- For accounting purposes, the sponsor should include the Tributary Committees' match (\$43,690) in the land purchase cost, not in the other line items.

**Wenatchee LiDAR Acquisition Watershed Assessment Project (Not Fundable)**

The Committees recommend that this project, sponsored by Chelan County Natural Resources Department, should not be submitted as a full proposal to the Tributary Committees for the following reasons:

- It is not clear what the project will provide in terms of restoration and protection that does not already exist. For example, roads that are likely to contribute significant amounts of fine sediments to streams have been identified or can be identified during road surveys and/or aerial photography.
- The proposal did not describe how LiDAR data combined with temperature data will be used to map the distribution of invasive species.
- A better approach would be to use Green LiDAR, at least within the floodplains.

**Piscine Passage Design for Brush and Minnow Creeks Project (Fundable)**

The Committees recommend that the project sponsor (Cascade Columbia Fisheries Enhancement Group) address the following comments/suggestions as they develop the full proposal:

- Because this is a design project, the sponsor needs to consider ways to reduce the cost of the project. The Committees believe the project is too expensive.
- The sponsor needs to provide information on the status of the roads. For example, will the roads, especially the one crossing Brush Creek be removed or abandoned.

**Sleepy Hollow Side Channel Feasibility Study Project (Not Fundable)**

The Committees recommend that this project, sponsored by Chelan County Natural Resources Department, should not be submitted as a full proposal to the Tributary Committees for the following reason:

- The Committees believe the side channel and floodplain are currently functioning to the benefit of salmonids. Indeed, the goal of the acquisition was to protect the existing habitat.

**Tillicum Creek Culvert Replacement Project (Not Fundable)**

The Committees recommend that this project, sponsored by Chelan County Natural Resources Department, should not be submitted as a full proposal to the Tributary Committees for the following reasons:

- The Committees believe there is limited usable habitat upstream from the culvert (there appears to be a total or partial fish passage barrier just upstream from the old road crossing).
- The channel upstream and downstream from the culvert is a confined, relatively steep channel that provides limited fish benefit. Thus, the potential benefits of the project do not justify the cost of the project.

**Methow Basin Barrier and Diversion Assessment Project (Fundable)**

The Committees recommend that the project sponsor (Cascade Columbia Fisheries Enhancement Group) address the following comments/suggestions as they develop the full proposal:

- Given the extensive spawning surveys conducted in the Methow River basin, the sponsor needs to describe how much more information this project will provide beyond what is currently known.
- The sponsor needs to provide a summary of what was learned from implementing a similar

project in the Wenatchee River basin.

- The sponsor should consider focusing their efforts in a few high-priority watersheds. This will reduce the need to repeat the surveys in the future.

## **VII. Small Projects Program Application**

### **Poison Canyon Restoration Project**

The Committees reviewed a Small Projects Program application from Chelan County Natural Resources Department titled, *Poison Canyon Restoration*. The purpose of the project is to aggrade incised reaches within Poison Canyon, a tributary to Sand Creek, which is a tributary to Mission Creek, by installing about 20 wood jams using onsite wood and hand tools. Aggrading the channel should improve instream flows and water quality in Mission Creek. The total cost of the project is \$73,330. The sponsor requested \$38,160 from HCP Tributary Funds. After careful consideration, ***the Committees declined the opportunity to fund the project.*** The Committees believe the project is overly engineered and too expensive. Based on implementation of similar projects, the Committees believe that two or more structures can be constructed per day. In addition, they see no need for highly engineered structures in this stream. Rather, simply adding appropriately sized wood to the channel should be appropriate. This will also reduce the cost of the project. Finally, they see no need to monitor the project with game cameras or piezometers. The Committees noted that if the sponsor addresses these concerns, the sponsor is welcome to submit a revised proposal for the Committees' consideration.

## **VIII. Methow Beaver Project Film**

Because of time constraints, the Committees were unable to watch the film, "One Stick at a Time." Members asked for the link to the film so they can watch it on their own time. Below is the link.

<https://youtu.be/EQNK7W-P-0>

## **IX. Information Updates**

The following information updates were provided during the meeting.

1. Approved Payment Requests in May and June:

Rock Island Plan Species Account:

- \$102.50 to Clifton Larson Allen for Rock Island financial administration in April 2017.
- \$40.00 to Clifton Larson Allen for Rock Island financial administration in May 2017.
- \$2,618.83 to Cascade Columbia Fisheries Enhancement Group for the White River Floodplain Connection Project.
- \$1,665.57 to Cascade Columbia Fisheries Enhancement Group for the Permitting Nutrient Enhancement in the Chiwawa River Project.

Rocky Reach Plan Species Account:

- \$102.50 to Clifton Larson Allen for Rocky Reach financial administration in April 2017.
- \$40.00 to Clifton Larson Allen for Rocky Reach financial administration in May 2017.

- \$17,110.26 to Okanogan Conservation District for work on the Similkameen RM 3.8 Rehabilitation Project.

Wells Plan Species Account:

- \$10,005.01 to Trout Unlimited for work on the MVID Instream Flow Improvement Project.
2. Tracy Hillman reported that project sponsors will give presentations to the Upper Columbia Regional Technical Team and the Tributary Committees on Wednesday, 14 June at the Sunnyslope Fire District on Easy Street. Tracy said final proposals are due on Friday, 30 June. The Committees will evaluate final proposals and make funding decisions on Thursday, 13 July.
  3. Tracy Hillman said the Independent Scientific Advisory Board (ISAB) will be in Wenatchee on 19-21 July for presentations and site visits as part of their evaluation of Upper Columbia Spring Chinook. An agenda for their visit has not yet been prepared, but it is likely the ISAB will want information and maybe presentations from the Tributary Committees. Tracy said he will share more information as it becomes available.
  4. Tracy Hillman and Becky Gallaher shared with the Committees possible logos for the Tributary Committees. The Committees identified one logo that with some modifications may work for the Committees. Tracy will work with the designer and present an updated version to the Committees in July.
  5. Chris Fisher shared with the Committees that a rain event in early May damaged a portion of the Upper Beaver Creek road. Chris said he met on site with County Commissioners, Methow Salmon Recovery Foundation, Bonneville Power Administration, Salmon Recovery Funding Board, and others to discuss the problem. The meeting started off with Commissioners blaming fish enhancement work in Beaver Creek for causing the road damage. Chris said the engineer of the enhancement work (Tracy Drury with Anchor QEA) indicated that the road would have been damaged regardless of the habitat enhancement work. Chris said by the end of the site visit, the parties involved expressed an interest in finding common ground and moving forward in some undefined way to make the existing road safe and passable, and identify changes, repairs, and improvements that would improve both the resilience of the road and the function of the floodplain.

Tracy Hillman noted that he received an email from Chris Johnson, Methow Salmon Recovery Foundation, asking if the Tributary Committees would support the idea of a cooperative action to help demonstrate a commitment to fish projects implemented in Beaver Creek. After a long discussion, the Committees agreed to continue to support the enhancement of fish habitat within Beaver Creek. However, they will not support the rebuilding of the road in its current location. They believe the road would have been damaged regardless of enhancement work in the stream. Thus, if the County is looking for support from the Tributary Committees to restore the existing road, the Committees are not interested. On the other hand, the Committees may support the relocation of the road, allowing Beaver Creek to use a larger portion of its floodplain. Relocating the road will make the road more resilient to future flood events and will improve the ability of Beaver Creek to sustain fish habitat. The sustainability of fish habitat is the common ground that the Committees would find compatible with a funding decision. The Committees directed Tracy to relay this information to Chris Johnson.

## **X. Next Steps**

The next meeting of the Tributary Committees will be on Thursday, 13 July 2017 at Grant PUD in Wenatchee. At that time, the Committees will review final proposals.

Meeting notes submitted by Tracy Hillman ([tracy.hillman@bioanalysts.net](mailto:tracy.hillman@bioanalysts.net)).

## Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 13 July 2017

---

**Members Present:** Lee Carlson (Yakama Nation)<sup>1</sup>, Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Steve Hays (Chelan PUD), Tom Kahler (Douglas PUD), Kate Terrell (USFWS), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

**Others Present:** Becky Gallaher (Tributary Project Coordinator).

---

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Thursday, 13 July 2017 from 10:00 am to 12:15 pm.

### I. Review and Adopt Agenda

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda.

### II. Review and Approval of Meeting Minutes

The Committees reviewed and approved the 8 June 2017 meeting notes.

### III. Monthly Update on Ongoing Projects

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- MVID Instream Flow Improvement Project – The project sponsor (Trout Unlimited; TU) reported that they are completing the final punch list items. They are also working with MVID and the Bureau of Reclamation (BOR) on a drainage issue near Wright Road, east of Twisp. Fires upslope from the pipeline have increased surface runoff in a small canyon. The ditch that used to capture the water is now a buried pipe. BOR is working on a conceptual design and cost analysis for piping the surface-water runoff to the Methow River.
- Clear Creek Fish Passage and Instream Flow Project – The sponsor (TU) reported they are preparing bid and contract documents for the construction bid package. They are currently planning construction in late summer or early fall. They also started planning for diversion dam removal, which will occur 1-2 years after the new water system is installed.
- Barkley Irrigation – Under Pressure Project – The sponsor (TU) reported they have an executed agreement with MVID and have finalized the pump site location. With both MVID and Barkley agreements signed, they now need to secure the relationship agreement between the two parties. The sponsor started working on the headworks design and held several meetings with Barkley

---

<sup>1</sup> Lee joined via phone.

Irrigation Company and MVID to review engineer alternatives. The sponsor is still working on changing the water rights from Barkley to MVID's diversion.

- Similkameen RM 3.8 Project – The sponsor (Okanogan Conservation District; OCD) and the Colville Tribes reported that BPA reviewed the updated plan and decided not to support the project. The sponsor is working on next steps.
- White River Floodplain (RM 3.4) Connection Project – The sponsor (Cascade Columbia Fisheries Enhancement Group; CCFEG) did not provide a project update.
- Icicle Boulder Field Project – The sponsor (TU) reported they are working on the JARPA permit for geotech explorations. They intend to file permits for the project this fall in anticipation for fall 2018 construction.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – The sponsor (WDFW) will submit the second-year monitoring report on 31 December 2017.
- Permitting Nutrient Enhancement Project – The sponsor (CCFEG) did not provide a project update; however, they did provide a draft Quality Assurance Project Plan (QAPP), which is being reviewed by Ecology. The sponsor expects a permit (Administrative Order) from Ecology soon.
- Burns-Garrity Design Project – The sponsor (CCFEG) did not provide a project update.
- Beaver Fever Project – The sponsor (TU) reported they continue project planning and due diligence. The focus has been on permitting, project task sequencing, and consideration of preliminary designs.
- Wenatchee Sleepy Hollow Floodplain Acquisition Project – The sponsor (Chelan-Douglas Land Trust; CDLT) did not provide a project update.

#### IV. Budget Amendments

##### White River Floodplain Connection (RM 3.4) Project

In June, the Rock Island Tributary Committee received a budget amendment request from Cascade Columbia Fisheries Enhancement Group on the *White River Floodplain Connection (RM 3.4) Project*. The sponsor asked to take all the available funds in “Excavation and Heavy Equipment” (\$5,000) and “Project Materials and Equipment” (\$500) and move those into “Salaries and Benefits,” “Overhead and Administration,” and “Permit Fees.” According to the request, this amendment would leave no money for excavation and haul. The Committee questioned how the project will be completed if there is no money available to conduct excavation and heavy equipment work. As a result, the Rock Island Tributary Committee denied the request until the sponsor can describe how the project will be completed without excavation and haul.

Following the meeting, Cascade Columbia Fisheries Enhancement Group provided additional information on the budget amendment. The sponsor noted that they have adequate funding through other sources to complete all excavation and construction work and will not need additional funds to complete the project. Given that, the *Rock Island Tributary Committee approved the budget amendment*.

##### Beaver Fever: Restoring Ecosystem Function Project

The Rock Island Tributary Committee received a budget amendment request from Trout Unlimited on the *Beaver Fever: Restoring Ecosystem Function Project*. The sponsor asked if they could use \$10,000 under Construction and Permitting to purchase a hydraulic post driver. The driver would be used to install BDAs. This would eliminate the need to rent the equipment and could be used on other projects. After discussion, *the Rock Island Committee denied the budget amendment*. This is because any equipment purchased by a project sponsor with Plan Species Account funds becomes the property of the Committee.

The Committee is not set up to deal with equipment storage, maintenance, management, and liability, and they do not want to be in a position of lending expensive equipment to project sponsors. Thus, they do not want project sponsors purchasing equipment with Plan Species Account funds.

## V. Time Extension

### Permitting Nutrient Enhancement in the Chiwawa

The Rock Island Tributary Committee received a time extension request from Cascade Columbia Fisheries Enhancement Group on the *Permitting Nutrient Enhancement in the Chiwawa*. Because of ongoing discussions with the Forest Service, USFWS, and Ecology, the sponsor asked to extend the period of the contract from 30 June 2017 to 30 June 2018. After discussion, ***the Rock Island Committee agreed to the one-year extension.***

## VI. Small Projects Program Application

### Poison Canyon Restoration Project

In June, the Committees reviewed a Small Projects Program application from Chelan County Natural Resources Department titled, *Poison Canyon Restoration*. The purpose of the project was to aggrade incised reaches within Poison Canyon, a tributary to Sand Creek, which is a tributary to Mission Creek, by installing about 20 wood jams using onsite wood and hand tools. Aggrading the channel should improve instream flows and water quality in Mission Creek. The total cost of the project was \$73,330. The sponsor requested \$38,160 from HCP Tributary Funds. The Committees declined the opportunity to fund the project because the project was overly engineered and too expensive. The Committees also found no need for game cameras or piezometers. The Committees noted if the sponsor addresses these concerns, the sponsor is welcome to submit a revised proposal for the Committees' consideration.

Chelan County Natural Resources Department resubmitted the Small Projects Program application, which addressed the Committees' concerns. The proposed project will still construct 20 wood structures to aggrade incised reaches within Poison Canyon, but the project will use a less engineered approach and include onsite wood/brush and hand tools. The total cost of the project is \$37,918. The sponsor requested \$21,600 from HCP Tributary Funds. ***The Rock Island Committee approved funding for this project.*** The Committee appreciated the sponsor's responses to questions and complemented the sponsor on their diligence and desire to implement a cost-effective project.

### Cottonwood Bridge Removal Project

The Committees reviewed a Small Projects Program application from Chelan-Douglas Land Trust titled, *Cottonwood Bridge Removal Project*. The purpose of the project is to remove the steel and creosoted railroad ties that make up the Cottonwood Bridge on the Entiat River. Once the bridge is removed, the sponsor can remove the associated road and begin floodplain enhancement on the Cottonwood property. The total cost of the project is \$95,000. The sponsor requested \$21,000 from HCP Tributary Funds. The Committees declined the opportunity to fund the project because the project did not include the removal of the bridge abutments. The Committees recommended that the sponsor resubmit a larger project that includes the removal of the abutments. The project could be a phased approach if the sponsor includes a timeline showing when each phase of the project will be completed.

Following the meeting, Chelan-Douglas Land Trust provided the following response to the Committees' comments. "*The reason the abutments are not being removed at the same time as the railroad ties and steel is due to 3 interrelated reasons: (1) due to the deterioration of the bridge, it is essential to remove it this summer, before additional high water, ice, freezing and thawing that would result in complete failure, (2) abutment removal would involve in-water work requiring additional permitting and (3) the abutments will be removed as part of a larger project, probably in 2020, to remove the fill for the bridge approaches on both sides, fill added for "streets" within the Cottonwood property, and enhancement of side channels*

through Cottonwood – all of which will involve the appropriate time, equipment and permitting. These factors all led to the conclusion that the goal for this work season should be limited to removal of the ties and steel, and “pulling back” the abutment so that it does not come apart in the river.” After evaluating the response, *the Rocky Reach Tributary Committee approved funding for this project.*

## VII. General Salmon Habitat Program Proposals

The Committees received four General Salmon Habitat Program proposals. Before reviewing the proposals and consistent with the Committees’ Operating Procedures, members of the Committees identified potential conflicts of interest. Kate Terrell recused herself from voting on the *Piscine Passage Design for Brush and Minnow Creeks Project.*

### M2 WDFW Flow Connection Project

The Methow Salmon Recovery Foundation is the sponsor of the M2 WDFW Flow Connection Project. The purpose of this project is to reconnect 3.7 acres of floodplain habitat and wetlands by removing a flood levee located at RM 46.8 on the Methow River. The total cost of the project is \$78,828. The sponsor requested \$11,824 from HCP Tributary Funds. *The Wells Committee approved funding for this project.*

The Committee noticed in the proposal that the sponsor expects the side channel to connect at flows above 6,000 cfs; however, Figure 1 in the proposal indicates that the channel will be connected at flows near 8,000 cfs. The Committee prefers the channel to connect at flows closer to 6,000 cfs.

### M2 Mid-Sugar Acquisition Project

The Methow Salmon Recovery Foundation is the sponsor of the M2 Mid-Sugar Acquisition Project. The purpose of this project is to acquire 17.3 acres of riparian and floodplain habitat including about 1,300 feet of stream bank and 550 feet of side channel near RM 42.2 on the Methow River. The acquisition will allow for future restoration actions including side channel and floodplain reconnection and riparian enhancement. The total cost of the project is \$291,268. The sponsor requested \$43,690 from HCP Tributary Funds. *The Wells Committee approved funding for this project.*

### Piscine Passage Design for Brush and Minnow Creeks Project

Cascade Columbia Fisheries Enhancement Group is the sponsor of the Piscine Passage Design for Brush and Minnow Creeks Project. The purpose of this project is to produce designs and submit permits for projects that will restore fish passage and connectivity within Minnow and Brush creeks, tributaries to the Chiwawa River. The total cost of the project is \$162,500. The sponsor requested \$52,500 from HCP Tributary Funds. *The Tributary Committees elected not to fund this project.*

The Committees are not interested in the Brush Creek project, because of the low biological benefit associated with it. On the other hand, the Committees see more value in restoring connectivity on Minnow Creek. Given the level of funding available from the USFWS and the possibility of receiving funding from SRFB, the Committees believe the project will receive adequate funding without the need for Plan Species Account funds. In the event the Minnow Creek project does not receive adequate funding, the sponsor can resubmit an application to the Committees. The resubmittal must include the status of the roads in Minnow Creek.

### Methow Basin Barrier and Diversion Assessment Project

Cascade Columbia Fisheries Enhancement Group is the sponsor of the Methow Basin Barrier and Diversion Assessment Project. The purpose of this project is to complete a comprehensive and standardized fish barrier and diversion inventory in the Methow River basin and to prioritize barrier sites for restoration. The total cost of the project is \$206,650. The sponsor requested \$40,000 from HCP Tributary Funds. *The Wells Committee approved funding for this project.*

The Committee understands that the sponsor will use a combination of prioritization methods developed by WDFW and the RTT. As a requirement of the Committee’s funding contribution to this project, the Committee will need to review and approve the “final” approach used to prioritize fish passage barriers.

**Summary of Review of 2017 General Salmon Habitat Program Projects.**

| Project Name                                       | Sponsor <sup>1</sup> | Total Cost       | Request from T.C. | T.C. Contribution <sup>2</sup> |
|--|----------------------|------------------|-------------------|--------------------------------|
| M2 WDFW Flow Connection                            | MSRF                 | \$78,828         | \$11,824          | W: \$11,824                    |
| M2 Mid-Sugar Acquisition                           | MSRF                 | \$291,268        | \$43,690          | W: \$43,690                    |
| Piscine Passage Design for Brush and Minnow Creeks | CCFEG                | \$162,500        | \$52,500          | \$0                            |
| Methow Basin Barrier and Diversion Assessment      | CCFEG                | \$206,650        | \$40,000          | W: \$40,000                    |
| <b>Total:</b>                                      |                      | <b>\$739,246</b> | <b>\$148,014</b>  | <b>\$95,514</b>                |

<sup>1</sup> CCFEG = Cascade Columbia Fisheries Enhancement Group; MSRF = Methow Salmon Recovery Foundation.

<sup>2</sup> RI = Rock Island Plan Species Account; RR = Rocky Reach Plan Species Account; W = Wells Plan Species Account.

**VIII. Information Updates**

The following information updates were provided during the meeting.

1. Approved Payment Requests in June and July:

Rock Island Plan Species Account:

- \$47.50 to Clifton Larson Allen for Rock Island financial administration in June 2017.
- \$855.94 to Chelan County PUD for project coordination and administration during the first and second quarters of 2017.
- \$11,487.26 to Trout Unlimited for the MVID Instream Flow Project.

Rocky Reach Plan Species Account:

- \$47.50 to Clifton Larson Allen for Rocky Reach financial administration in June 2017.
- \$911.16 to Chelan County PUD for project coordination and administration during the first and second quarters of 2017.
- \$3,442.78 to Trout Unlimited for work on the Clear Creek Fish Passage and Instream Flow Enhancement Project.

Wells Plan Species Account:

- \$661.84 to Chelan County PUD for project coordination and administration during the second quarter of 2017.

2. Tracy Hillman said the Independent Scientific Advisory Board (ISAB) will be in Wenatchee on 19-21 July for presentations and site visits as part of their evaluation of Upper Columbia Spring Chinook. The Council has prepared a draft agenda for the ISAB visit.
3. Tracy Hillman and Becky Gallaher shared the updated logos for the Tributary Committees. The Committees approved the following logo:

4. Becky Gallaher reported that she received a request from Cascade Columbia Fisheries Enhancement Group asking the Wells Tributary Committee if CCFEG could use the Committee's piezometers for an assessment project in the Methow River basin. The Wells Committee approved the request, but asked that the sponsor let the Committee know how long they need the piezometers, where exactly they will use them, and for what project. Kate Terrell said she will provide Becky with a release form that is used by the USFWS when they lend equipment to project sponsors.
5. Tracy Hillman asked the Committees if they have decided on which completed project they would like to visit in 2017. Given schedules and interest, it is unlikely members will have time to visit completed projects in 2017. Chris Fisher said by August he will have information on the annual tour of projects in Canada.

## **IX. Next Steps**

If necessary, the next meeting of the Tributary Committees will be on Thursday, 10 August 2017 at Grant PUD in Wenatchee.

Meeting notes submitted by Tracy Hillman ([tracy.hillman@bioanalysts.net](mailto:tracy.hillman@bioanalysts.net)).

## Wells, Rocky Reach, and Rock Island HCP Tributary Committees Notes 9 November 2017

---

**Members Present:** Jeremy Cram (WDFW), Chris Fisher (Colville Tribes), Steve Hays (Chelan PUD), Tom Kahler (Douglas PUD), Kate Terrell (USFWS), Justin Yeager (NOAA Fisheries), and Tracy Hillman (Committees Chair).

**Members Absent:** Lee Carlson (Yakama Nation)<sup>1</sup>

**Others Present:** Becky Gallaher (Tributary Project Coordinator), Brandon Rogers (Yakama Nation), Jeff Osborn (Chelan PUD), Catherine Willard (Chelan PUD), and Scott Hopkins (Chelan PUD).

---

The Wells, Rocky Reach, and Rock Island Hydroelectric Projects Habitat Conservation Plans Tributary Committees met at Grant PUD in Wenatchee, Washington, on Thursday, 9 November 2017 from 9:30 am to 12:05 pm.

### **I. Review and Adopt Agenda**

Tracy Hillman welcomed everyone to the meeting and the Committees adopted the proposed agenda with additional agenda items. The Committees reviewed two Small Projects Program applications they received from the Methow Salmon Recovery Foundation.

### **II. Review and Approval of Meeting Minutes**

The Committees reviewed and approved the 13 July 2017 meeting notes.

### **III. Monthly Update on Ongoing Projects**

Becky Gallaher gave an update on funded projects. Most are progressing well or had no salient activity in the past month.

- MVID Instream Flow Improvement Project – The project sponsor (Trout Unlimited; TU) completed the remaining punch-list items and will submit their final report by the end of the month.
- Clear Creek Fish Passage and Instream Flow Project – The sponsor (TU) met with the project engineers to discuss bids and to examine the potential for cost savings through project design modifications. They found little room for cost savings by modifying structural and civil/plumbing plans. Any changes here would result in reduced functionality, quality, lifespan, or overall project value. Electrical modifications are currently being considered. For example, the current design calls for a robust, multi-function operator interface, which offers remote control capability with numerous checks and alarms. Switching to a simple control-panel interface could save several

---

<sup>1</sup> Lee provided votes on decision items following the meeting.

thousand dollars. The electrical engineer is evaluating cost savings and effort/cost. The sponsor will send the project out for bid later this year or early next.

- Barkley Irrigation – Under Pressure Project – The sponsor (TU) continues to work on the joint diversion redesign and gravity portion of the system. They have also been working on finalizing the water rights change, completing environmental compliance, securing easements, and seeking funding and general coordination with the districts.
- Similkameen RM 3.8 Project – This project is complete. The sponsor (Okanogan Conservation District; OCD) submitted the final report, which was uploaded to the extranet site.
- White River Floodplain (RM 3.4) Connection Project – This project is complete. The sponsor (Cascade Columbia Fisheries Enhancement Group; CCFEG) will submit a final report soon.
- Icicle Boulder Field Project – The sponsor (TU) dug test pits to evaluate subsurface material. The information collected is being evaluated and a report of findings should be available in November. The cultural resource survey was completed in October and that report is expected in November. Tracy Hillman stated that the Committees may receive a proposal asking for funds to install a fish screen in the Icicle Diversion. The irrigation district has stated they may not allow the Icicle Boulder Field Project to move forward unless their diversion is screened.
- Peshastin Creek RM 10.5 PIT-Tag Detection Site Project – The sponsor (WDFW) will submit the second-year monitoring report on 31 December 2017.
- Permitting Nutrient Enhancement Project – The sponsor (CCFEG) reported there was no new activity.
- Burns-Garrity Design Project – The sponsor (CCFEG) met recently with the “new” private landowners. The new landowners support a design for a perennial channel. The sponsor will work with WDFW and the other private landowner to select a preferred concept and then they will move forward with design. *Following the meeting, the sponsor noted that the proposed channel will be a flow-through channel connected upstream and downstream with the river.*
- Beaver Fever Project – The sponsor (TU) is communicating with private landowners and the Forest Service hoping to get interest and insight about the potential for BDA work in lower Potato Creek.
- Wenatchee Sleepy Hollow Floodplain Acquisition Project – The sponsor (Chelan-Douglas Land Trust; CDLT) reported that Larry Rees is scheduled to complete the appraisal by the end of the year.
- Poison Canyon Restoration Project – The sponsor (Chelan County Natural Resources Department; CCNRD) indicated that they awarded the construction contract to Wildfire Home Protection. All but three structures have been built. The sponsor provided photos.
- Cottonwood Bridge Removal Project – This project is complete. The sponsor (CDLT) submitted the final report, which was uploaded to the extranet site.
- M2 Mid-Sugar Acquisition Project – The sponsor (Methow Salmon Recovery Foundation; MSRF) reported that Larry Rees initiated the appraisal on 27 October. Reclamation confirmed that a project budget is being processed for prioritization of project design alternatives for 2018/2019.

#### IV. Small Projects Program Applications

##### Frazer Creek – Lazy K Property Appraisal Project

The Committees reviewed a Small Projects Program application from MSRF titled, *Frazer Creek – Lazy K Property Appraisal Project*. The purpose of the project is to appraise the value of a 20-acre parcel along Frazer Creek in the Methow River basin. Acquiring the property would allow stream restoration in a site where the 2017 flood plugged a culvert causing the stream to cut deep gullies through the property. The cost of the project is \$1,421.40, which covers coordination with the landowner and appraiser, and billing and administration work. The Committees would pay for the appraiser. After careful consideration, the Committees elected not to fund the appraisal. Most of the property does not boarder the stream and restoring this site would have little biological benefit.

##### Upper Beaver Creek – Anderson Property Appraisal Project

The Committees reviewed a Small Projects Program application from MSRF titled, *Upper Beaver Creek – Anderson Property Appraisal Project*. The purpose of the project is to appraise the value of a 1.6-acre parcel along Beaver Creek in the Methow River basin. Acquiring the property would allow stream restoration in a site where the 2017 flood avulsed through the Anderson property and damaged the County road. The cost of the project is \$1,421.40, which covers coordination with the landowner and appraiser, and billing and administration work. The Committees would pay for the appraiser. The Committees were unable to make a final decision on the project and asked for additional information. They said before they can make a final decision on the appraisal, they would like to know if the County intends to relocate the road away from the channel. They also need information on the status of the channel upstream and downstream from the property, and what measures adjacent landowners are taking, or have taken, to minimize future damage to the Anderson parcel.

Following the meeting, MSRF provided additional information on the proposed project. After carefully reviewing the proposal and the additional information, the Committees elected not to fund the appraisal. The Committees are uncomfortable acquiring the property without a comprehensive review of the vulnerability of the road from the stream.

#### V. Chelan River Restoration Presentation

Steve Hays gave a presentation on the Chelan River Restoration project, which was funded by Chelan PUD (see Attachment 1). He began by describing riverine conditions before hydro development in the Chelan River, and then talked about the first two Chelan Licenses. He followed that by describing the most recent relicensing process, objectives, and agreement. He then walked through the restoration process, showing the evolution of the river during the restoration process.

With the completion of the restoration work, Steve said Chelan PUD has implemented a robust monitoring program to evaluate the success of the work. He said they conduct spawning surveys for summer/fall Chinook, coho salmon, and steelhead; conduct studies to evaluate powerhouse operations on intragravel dissolved oxygen levels in redds; evaluate egg-emergence success for Chinook and steelhead; conduct snorkel surveys in designated reaches; conduct macroinvertebrate population studies; conduct water temperature monitoring and modeling; and monitor TDG, DO, pH, and turbidity. He provided results from monitoring efforts and concluded that the restoration work is providing high quality habitat for salmonids, including cutthroat trout. He added that riparian vegetation is growing rapidly, and salmonids are spawning successfully within the habitat channel and tailrace. He ended by stating, "I'm not complaining."

#### VI. Effectiveness of Enhancement Projects Presentation

Tracy Hillman gave a presentation on the effectiveness of tributary habitat enhancement projects (see Attachment 2). He stated that he and his coauthors (Phil Roni and Jen O'Neal) prepared a report for BPA

that addressed six policy-level questions (the report was made available to the Committee members). These questions were identified by the region and answers to them will help guide the next FCRPS BiOp. In order to answer the questions, Tracy and his coauthors reviewed well over 1,000 published and unpublished papers. Of those papers, 617 met their criteria for relevance. Tracy shared the number of papers associated with different categories of enhancement actions and the countries in which the studies were conducted. He also identified the intensively monitored watersheds located throughout the Pacific Northwest.

Although the purpose of the paper was to answer the six policy-level questions, Tracy's presentation focused on what works and why. He identified six characteristics of successful projects and identified reasons why good intension fail. He referred to some of the failures as "Myths of Restoration." He concluded by providing eight recommendations.

## **VII. Information Updates**

The following information updates were provided during the meeting.

### 1. Approved Payment Requests from August to November:

#### Rock Island Plan Species Account:

- \$162.50 to Clifton Larson Allen for Rock Island financial administration in July 2017.
- \$2,135.41 to Cascade Columbia Fisheries Enhancement Group for the Permitting Nutrient Enhancement Project.
- \$1,891.75 to Trout Unlimited for the MVID Instream Flow Improvement Project.
- \$125.00 to Clifton Larson Allen for Rock Island financial administration in August 2017.
- \$117.50 to Clifton Larson Allen for Rock Island financial administration in September 2017.
- \$556.41 to Chelan County PUD for project coordination and administration during the third quarter of 2017.
- \$2,190.97 to Trout Unlimited for the Beaver Fever – Restoring Ecosystem Function Project.
- \$1,827.95 to Trout Unlimited for the MVID Instream Flow Improvement Project.
- \$162.50 to Clifton Larson Allen for Rock Island financial administration in October 2017.
- \$6,828.79 to Cascade Columbia Fisheries Enhancement Group for the White River Floodplain Connection Project.
- \$1,000.00 to the Upper Columbia Salmon Recovery Board for the Upper Columbia Science Conference.

#### Rocky Reach Plan Species Account:

- \$162.50 to Clifton Larson Allen for Rocky Reach financial administration in July 2017.
- \$4,080.73 to Okanogan Conservation District for the Similkameen RM 3.8 Rehabilitation Project.

- \$1,191.16 to Okanogan Conservation District for the Similkameen RM 3.8 Rehabilitation Project.
- \$125.00 to Clifton Larson Allen for Rocky Reach financial administration in August 2017.
- \$117.50 to Clifton Larson Allen for Rocky Reach financial administration in September 2017.
- \$417.05 to Chelan County PUD for project coordination and administration during the third quarter of 2017.
- \$11,000.00 to Chelan-Douglas Land Trust for the Cottonwood Bridge Removal Project.
- \$2,614.51 to Okanogan Conservation District for the Similkameen RM 3.8 Rehabilitation Project (withholding 10% until final report is received).
- \$162.50 to Clifton Larson Allen for Rocky Reach financial administration in October 2017.
- \$10,000.00 to Chelan-Douglas Land Trust for the Cottonwood Bridge Removal Project.
- \$290.50 to Okanogan Conservation District for the Similkameen RM 3.8 Rehabilitation Project (this was the 10% that was withheld from the final invoice).
- \$1,000.00 to the Upper Columbia Salmon Recovery Board for the Upper Columbia Science Conference.

Wells Plan Species Account:

- \$195.03 to Chelan County PUD for project coordination and administration during the third quarter of 2017.
  - \$376.94 to Trout Unlimited for the MVID Instream Flow Improvement Project.
  - \$2,192.00 to Douglas County PUD for Wells Administration.
  - \$1,000.00 to the Upper Columbia Salmon Recovery Board for the Upper Columbia Science Conference.
2. Tracy Hillman reminded the Committees of the email that Steve Kolk (BOR) sent the Committees in late September providing an update on the Middle Entiat Restoration Project. In his email, Steve asked if the Committees would like him to attend a future meeting and provide additional updates. The Committees indicated that at this time there is no need for Steve to provide an update in person. Email updates will suffice.
  3. Tracy Hillman reminded the Committees that the Upper Columbia Science Conference, which is hosted by the Upper Columbia Salmon Recovery Board, will be on 24 and 25 January 2018 in Wenatchee. In October, each Committee agreed to donate \$1,000.00 to the Conference. Funding will come from administrative expenses (not to exceed \$80,000 per year per account) under the Plan Species Accounts. This level of sponsorship identifies the Committees as “Gold Sponsors.”
  4. Tracy Hillman said the Rocky Reach Tributary Committee approved a budget amendment and scope change for the Clear Creek Fish Passage and Instream Flow Enhancement Project in August. In early August, the sponsor (Trout Unlimited) asked to add activities related to water/electrical lines and treatment building to the deliverables. Specific activities included clearing/grubbing, trenching, piping, electrical, plumbing/mechanical, building construction,

moving chlorine injection and backup power equipment to a new location, inspections, and final approvals. In addition, the sponsor asked for an additional \$77,174.40 to complete the project. Although the Rocky Reach Tributary Committee approved the scope change and budget amendment, which increased the total contribution from the Committee to \$146,674.40, the Committee let the sponsor know they are growing increasingly concerned with the planning, management, and implementation of this project. This was the fifth amendment to this project. The Committee trusts that the sponsor will do a better job of planning and managing similar future projects.

5. Chris Fisher asked if the Committees would be interested in reviewing a proposal to fund the monitoring of discharge in select tributaries in the Methow River basin. Chris said the tributaries include Early Winters, Eight-Mile, Gold, Little Bridge, and Libby creeks. In the past, the Rocky Reach Tributary Committee approved funding for a similar monitoring effort in the Okanogan Basin. Members indicated they would review a proposal to monitor discharge, but they would need to know how the work will lead to habitat enhancement projects.
6. Chris Fisher said the Okanogan Nation Alliance is planning wetland construction in the parcel recently acquired with the help of Rock Island Plan Species Account funds. They are also doing floodplain construction near the Town of Oliver.

### **VIII. Next Steps**

The next meeting of the Tributary Committees will be on Thursday, 11 January 2018 at Grant PUD in Wenatchee.

Meeting notes submitted by Tracy Hillman ([tracy.hillman@bioanalysts.net](mailto:tracy.hillman@bioanalysts.net)).

Note.—Gage not read Sundays (except June 15) and a few other days; discharge interpolated. Discharge October 17-22, when gage was not read, estimated at 300 second-feet. Low discharge March 10 due to backing of water in lake while bridge was being repaired. Decrease in discharge August 26 due to inserting fishboards to raise the lake surface for navigation.

Looking downstream on site of proposed tail race, 12/15/26

## PRE-CHELAN HYDRO CONDITION

## FIRST TWO CHELAN LICENSES

- ❖ Lake Chelan Hydroelectric Project Had No Provision for Minimum Flows – River Dry from Lake Chelan Dam to Chelan Falls 9 Months of the Year 1926 – 2009
- ❖ Lake Storage Managed Only For Recreation, Power Generation and Flood Control
- ❖ 1980s Relicense Focused On Parks, Lake Fisheries and Wildlife
- ❖ Restoration of Chelan River Flows and Habitat Not In Terms and Conditions in 1980s

# RELICENSING OBJECTIVES

- ❖ FERC Relicense Negotiations Included Minimum Flow Regime and Fish Habitat Enhancements for Anadromous Fish Spawning and Rearing
- ❖ Habitat Modeling Estimated Possible 2.8 Acres of Chinook and 2.2 Acres of Steelhead Spawning Habitat in Scattered Pockets at 650 cfs Flow
- ❖ Existing Tailrace/Columbia River Spawning Habitat 2.8 Acres for Chinook and 2.2 Acres for Steelhead
- ❖ Summer Chinook Salmon Had Established Spawning Population on Alluvial Fan at Chelan Falls Beginning in 1980s – Demonstrating Feasibility of Adding Habitat
- ❖ Upper Three Reaches Managed for Resident Fish – Goal for Population of 200 Cutoffthroat Trout, the Native Salmonid
- ❖ Habitat Modeling Estimated Flows of 80 cfs – 160 cfs Yielded Most Acres of Habitat
- ❖ Main Limiting Factor Summer Water Temperatures > 24 Degrees C

## REACH 4 - 2004

## RELICENSING AGREEMENT

- ❖ Minimum Flow of 80 cfs Released from Dam, with May 15 – July 15 Minimum of 200 cfs in Average Runoff Years and 320 cfs in High Runoff Years
- ❖ Create Approximately 2 Acres of New Spawning and Rearing Habitat in Reach 4
- ❖ Fill Portion of Tailrace To Increase Chinook Spawning Habitat and Improve Existing Tailrace Spawning Habitat
- ❖ Create Sinuous Habitat Channel with Five Pool/Riffle Components – Boulder and Wood Structure Features for Rearing and Steelhead Spawning Cover
- ❖ Use Pumped Flows to Provide Habitat Channel Spawning Depths Velocities: March 15 – May 15 for Steelhead, October 15 – November 30 for Chinook
- ❖ Operate Powerhouse As Necessary to Maintain Favorable Spawning and Incubation Conditions, Including Intra-gravel DO in Tailrace
- ❖ Investigate Water Temperature Dynamics, Model Studies to Evaluate Potential Temperature Reduction Measures, and Riparian Feasibility Study in Reach 1 for Cutthroat Population

# LET'S BUILD IT

Chelan River, Reach 4 and Tailrace  
New Stream Channel Construction  
Aerial Showing Redds  
November 5, 2008

# COMPLETED PROJECT

## LOW LEVEL OUTLET

# REACH 1 – THEN AND NOW

Chelan River before construction, 10/22/25

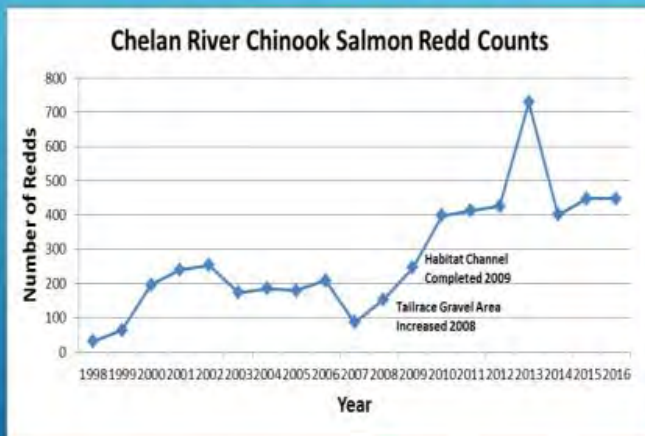

# RESULTS

# M&E INCLUDES

- ❖ Spawning Surveys for Summer Chinook and Coho in Fall, Steelhead in Spring
- ❖ Studies to Determine Powerhouse Operations Necessary to Maintain Intra-Gravel DO  $\geq$  6.0 mg/l in Tailrace Redds
- ❖ Snorkel Surveys Reach 4 and Reach 1
- ❖ Egg – Emergence Survival Studies for Chinook and Steelhead
- ❖ Macroinvertebrate Population Studies
- ❖ Water Temperature Monitoring and Model Study
- ❖ Water Quality Assessment for TDG, DO, pH, Turbidity

# CHINOOK SPAWNING SURVEYS

# CHELAN RIVER IS WARM

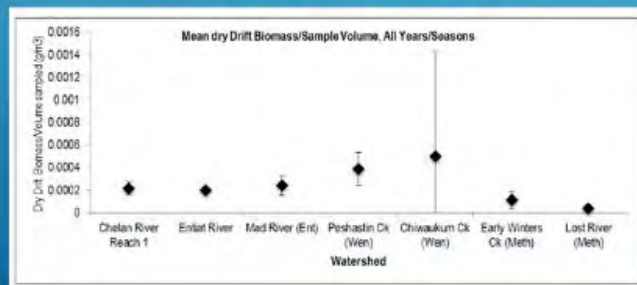

# TEMPERATURE MODEL FINDINGS

- ❖ Hyporheic Zone Parameters Had Most Influence on Model Calibration
- ❖ High Degree of Hyporheic Exchange – 30% of Flow Fraction
- ❖ Daily Maximum Temperature Could Be Reduced by Up to 2 Degrees C if Flow Increased from 80 cfs to 500 cfs
- ❖ However, Daily Minimum Temperature Would Increase by the Same Amount and Hyporheic Influence Could be Reduced
- ❖ Mature Riparian Vegetation Only Reduce Maximum Temperature by 0.1 Degrees C

# MACROINVERTEBRATE STUDIES

- ❖ Benthic and Drift Samples had Limited Species Richness – Similar to Upstream Above Dam Samples
- ❖ Some Drift Samples in Tailrace and Habitat Channel Had High Abundance of Lake Species – Cladocerans and Copepods
- ❖ Dominant Taxa Were Chironomidae, Baetis and Orthocladinae
- ❖ Drift Abundance in Reach 1 Similar to CHaMP Data for Local Streams

## CUTTHROAT DON'T LOOK STARVED

Cutthroat Trout stocked in Reach 1 on 3/24/15 and recaptured 6/24/15 (photo by Graham Simon, WDFW)

## I'M NOT COMPLAINING

QUESTIONS?

## Attachment 2

### Presentation by Tracy Hillman on Effectiveness of Tributary Habitat Enhancement Projects

## Purpose

### Respond to six, policy-level questions:

- What are the effects of habitat actions on habitat conditions?
- Which actions are most effective in producing desired habitat conditions for salmonids?
- How do salmonids respond to changes in habitat conditions?
- What are the effects of individual actions on fish at the site, reach, and watershed scales?
- Are benefits sustained over time?
- Which actions provide the greatest benefit to fish?

2

## Approach

Conducted a comprehensive review of published and unpublished literature (reviewed 617 papers).

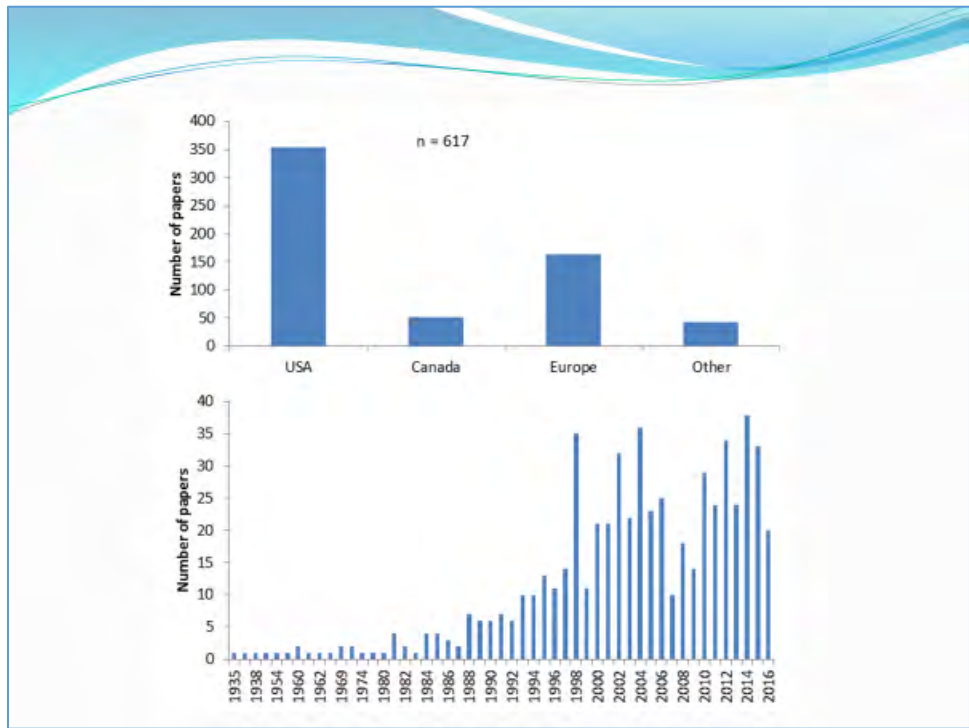

Criteria for relevance:

- Paper must describe results from monitoring and evaluation of enhancement actions.
- Paper must provide quantitative information on physical and biological response to enhancement.

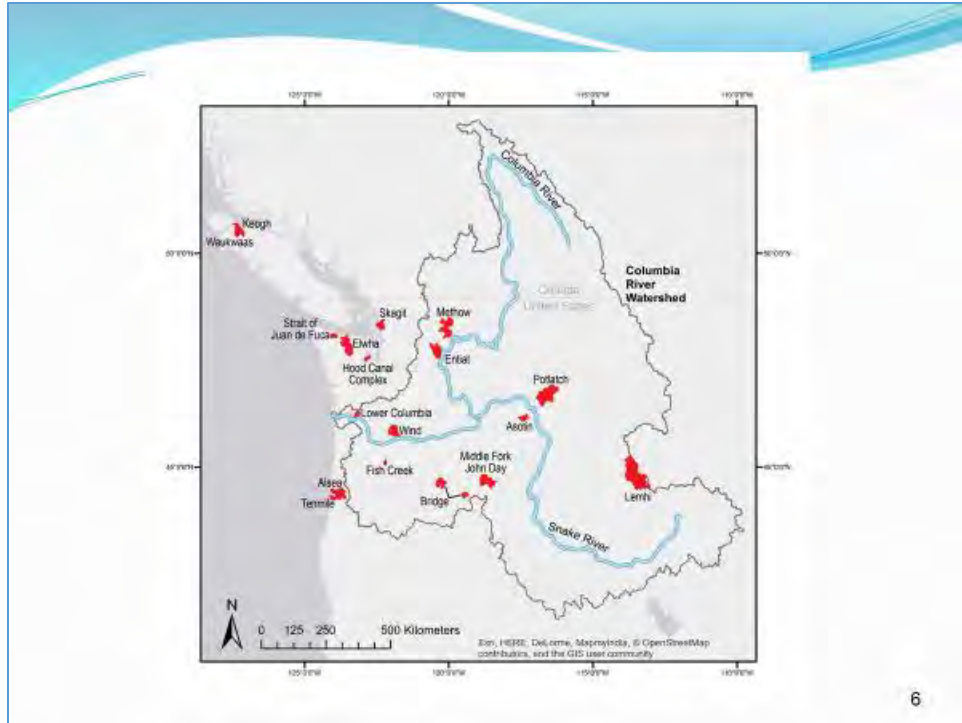

Compiled an annotated bibliography of all papers reviewed and summarized results for eight categories of enhancement.

3

| PROJECT CATEGORY               | SUBCATEGORY                                 | NUMBER OF STUDIES |

| Acquisition and Protection     | Land acquisition, lease, or easement        | 1                 |

6

## What Works and Why?

**Implementing the *right action* in the *right place* at the *right time*!**

### **Right Action:**

- Actions that remove or minimize threats causing limiting factors.
- Actions that address the factors affecting the limiting life stage.

### **Right Place:**

- Actions that improve or are not affected by degraded upstream process.
- Actions that treat a large percentage of the degraded habitat (20%).

### **Right Time:**

- Actions that are sequenced appropriately.

7

## Characteristics of Successful Enhancement Work:

- Understanding the habitat requirements of the target species and their life-history characteristics.
- Assessments that identify enhancement opportunities and provide a clear understanding of the problems and limiting life-stage and habitats.
- Implementation plans that prioritize locations for enhancement and prioritize actions (sequencing).

8

## Characteristics of Successful Enhancement Work:

- Extensive coordination among stakeholders, landowners, funding and monitoring entities, and implementers.
- Success is directly related to the size or magnitude of the treatment.
- Incorporation of effectiveness monitoring within an adaptive management framework.

9

## Why Do Good Intensions Fail?

- **Pristine Fantasy** – Assuming we can achieve some pre-development condition or single endpoint.
- **Field of Dreams** – Focus solely on the physico-chemical conditions.
- **Copy-Cat Approach** – Over use of a method that is not sufficiently validated.
- **Fast Forward** – Belief we can accelerate ecosystem structure and function.

10

## Why Do Good Intensions Fail?

- **Command and Control** – Illusion that we can control nature (focus on treating symptoms).
- **Cornucopian Belief** – Technology will solve the problem.
- **Ecological Trap** – When good animals love bad habitat.
- **Perceptual Trap** – When good animals avoid good habitat.

11

## Recommendations

- Protect high-quality habitat.
- Focus on removing or reducing the threats or key limiting factors that degrade habitat conditions.
- Address and work within natural watershed processes.
- Screen water-withdrawal structures to reduce entrainment.

12

## Recommendations

- Reconnect spawning and rearing areas.
- Instream structures should be used in concert with actions that improve watershed processes.
- Nutrient enrichment projects should be considered experimental.
- Extensive coordination among all parties.

Appendix E  
Statement of Agreement for Habitat  
Conservation Plan Coordinating  
Committees

---

## FINAL

### Rocky Reach and Rock Island Habitat Conservation Plans Coordinating Committees

#### Statement of Agreement

#### Designation of Juvenile Coho in Phase III (Standard Achieved) at the Rock Island and Rocky Reach Projects

(March 30, 2017)

#### Agreement Statement

The Rock Island and Rocky Reach HCP Coordinating Committees (CC) have reviewed PIT-tag based estimates of juvenile coho passage survival compared with PIT-tag based yearling Chinook passage survival in the Columbia River hydropower system, prepared by J. Skalski and R. Townsend (2017). The CC agrees that comparison of PIT-tag based juvenile coho survival and yearling Chinook survival using juveniles released in the Methow sub-basin upstream of the Rocky Reach Project over seven consecutive migration years (2010-2016) demonstrates that juvenile coho survive hydropower system passage similar to yearling Chinook. Because juvenile coho and yearling Chinook passage survival is comparably similar, and because Chelan PUD has measured direct passage survival of yearling Chinook through Rocky Reach ( $\hat{S} = 92.72$ ) and Rock Island ( $\hat{S} = 93.75$ ) Projects in HCP acoustic tag survival studies, the CC also agrees that juvenile coho survival can be estimated using Chelan PUD's yearling Chinook acoustic tag survival estimates and coho PIT-tag based survival estimates. Yearling Chinook are in Phase III (Standard Achieved) at both Rock Island and Rocky Reach Projects. The CC acknowledges that based on the estimated juvenile coho Project survivals of 93.98% at Rock Island and 92.94% at Rocky Reach (Skalski and Townsend 2017), the CC agrees to move juvenile coho at both Projects from Phase III Standard Achieved Interim-Value to designation of Phase III Standard Achieved, with 93% survival at both Projects.

#### Background

The Rocky Reach and Rock Island HCP Coordinating Committees reviewed and approved an SOA on June 26, 2007 and agreed that (1) an interim coho juvenile survival value of 93% would be assumed and (2) juvenile coho survival studies would not be performed unless there was compelling information that demonstrated hydro project operations were having an impact greater than seven percent mortality on coho. As approved, juvenile coho were designated as Phase III (Standard Achieved – Interim Value) for the Rocky Reach and Rock Island projects.

#### Comparison of Juvenile Coho and Yearling Chinook PIT-tag Survival Estimates Through the Mid-Columbia

PIT-tag based estimates of survival for hatchery released juvenile coho and hatchery released

yearling Chinook through the Mid-Columbia can be used to evaluate how juvenile coho survive relative to yearling Chinook. Skalski and Townsend (2017) analyzed PIT-tagged juvenile coho and PIT-tagged yearling Chinook released from Winthrop National Fish Hatchery, Methow Hatchery and all Methow Sub-basin acclimation sites to estimate juvenile passage survival from Rocky Reach tailrace to McNary tailrace, and survival from McNary to John Day tailrace, 2010 through 2016 (Table 1).

Table 1. Cormack-Jolly-Seber PIT tag survival estimates of juvenile coho salmon and yearling Chinook salmon from Rocky Reach (RRH) to McNary (MCN) and McNary to John Day (JD) for pooled releases from the Winthrop National Fish Hatchery, Methow Hatchery, and Methow sub-basin final acclimation sites.

| Year | Release Sizes<br>Coho/Chinook | PIT Survival<br>Coho/Chinook<br>RRH to MCN | $\hat{S}$<br>SE<br>Coho/Chinook | PIT Survival<br>Coho/Chinook<br>MCN to JD | $\hat{S}$<br>SE<br>Coho/Chinook |
|------|-------------------------------|--|---------------------------------|---|---------------------------------|
| 2010 | 11,859 / 25,806               | 88.15% / 76.17%                            | (0.0915)/ (0.0421)              | 96.73%/ 100.1%                            | (0.1570)/ (0.1228)              |
| 2011 | 20,873 / 28,117               | 66.55% / 62.65%                            | (0.0411)/ (0.0314)              | 120.3%/ 97.11%                            | (0.1778)/ (0.1022)              |
| 2012 | 17,891 / 29,569               | 67.78% / 72.07%                            | (0.0362)/ (0.0336)              | 84.39%/ 78.38%                            | (0.0742)/ (0.0549)              |

| 2014 | 23,489 / 22,475               | 72.60%/ 75.39%                             | (0.0436)/ (0.0565)              | 87.25%/ 93.0%                             | (0.0822)/ (0.1255)              |
| 2015 | 24,233 / 31,913               | 75.18%/ 71.08%                             | (0.0863)/ (0.0422)              | 91.69%/ 80.44%                            | (0.2036)/ (0.0837)              |
| 2016 | 17,885 / 31,884               | 67.73% / 76.09%                            | (0.0223)/ (0.0252)              | 98.66%/79.70%                             | (0.0828)/ (0.0502)              |

(Source: Skalski and Townsend 2017)

The PIT-tag survival estimates for juvenile coho and yearling Chinook were generated for fish migrating in the same river reaches in the same years, Rocky Reach to McNary and McNary to John Day, 2010 to 2016 (Skalski and Townsend 2017). Comparison of Rocky Reach to McNary reach survival estimates suggest juvenile coho salmon and yearling Chinook have the most comparable survivals with a survival ratio near 1.0000. In six of seven years of comparison, reach survival ratios for juvenile coho to yearling Chinook were not significantly different between the two species and the seven year weighted mean reach survival ratio was not significantly different (weighted mean=0.9549; SE=0.0307; P=0.1921) (Table 2).

Table 2. Ratios of multiple-project (hydro system) reach survivals for the above Rocky Reach release groups of juvenile coho and yearling Chinook salmon, (2010–2016). Numbers in bold indicate survival ratios that are significantly different from 1 ( $P < 0.05$ ).

| Species Ratio    | Year | Rocky Reach to  |               | McNary to       |              |
|------------------|------|-----------------|---------------|-----------------|--------------|
|                  |      | McNary          | $P (\neq 1)$  | John Day        | $P (\neq 1)$ |
| Coho/Yrl Chinook | 2010 | 1.1573 (0.1361) | 0.2478        | 0.9602 (0.1949) | 0.8382       |
|                  | 2011 | 1.0623 (0.0845) | 0.4612        | 1.2392 (0.2248) | 0.2873       |

(Source: Skalski and Townsend 2017)

*Projection of Coho Salmon Project Survival Using Acoustic Tag/PIT Tag Survival Estimates*

A ratio estimator was used to project coho salmon acoustic-tag passage survival based on PIT-tag data on juvenile coho salmon, and PIT-tag and acoustic-tag data on yearling Chinook salmon. Using PIT-tag releases, reach survivals from Rocky Reach tailrace (detections in the Rocky Reach bypass) to McNary tailrace were estimated for coho and yearling Chinook salmon for the years 2010–2016 (Table 1). In addition, acoustic-tag investigations were performed on yearling Chinook salmon at Rocky Reach (i.e., 2010, 2011) and Rock Island (i.e., 2007, 2008, and 2010) as part of the HCPs’ survival compliance testing. Assuming the PIT-tag studies and acoustic-tag studies are each reliably estimating the same quantities, ratios of reach survivals for juvenile coho and yearling Chinook salmon should be the same whether they were estimated using acoustic or PIT tags.

Table 3: PIT-tag reach survival estimates from Rocky Reach tailrace to McNary tailrace ( $\hat{S}_{RR-MCN}^{PIT}$ ),  $\frac{1}{4}$ -root survival ( $\hat{S}^{1/4}$ ), and coho-to-Chinook-salmon survival ratios through the four Mid-Columbia projects ( $\hat{R}$ ). Standard error in parentheses.

| Year           | $\hat{S}_{RR-MCN}^{PIT}$ |         | $\hat{S}^{1/4}$ |         | $\hat{R}_{Coho/Chin}^{PIT}$ |
|----------------|--------------------------|---------|-----------------|---------|-----------------------------|
|                | Coho                     | Chinook | Coho            | Chinook |                             |
| 2010           | 0.8815                   | 0.7615  | 0.9690          | 0.9342  | 1.037                       |
| 2011           | 0.6655                   | 0.6265  | 0.9032          | 0.8897  | 1.015                       |
| 2012           | 0.6778                   | 0.7207  | 0.9074          | 0.9214  | 0.985                       |
| 2013           | 0.8334                   | 0.8215  | 0.9554          | 0.9520  | 1.004                       |
| 2014           | 0.7260                   | 0.7539  | 0.9231          | 0.9318  | 0.991                       |
| 2015           | 0.7518                   | 0.7108  | 0.9312          | 0.9182  | 1.014                       |
| 2016           | 0.6773                   | 0.7609  | 0.9072          | 0.9340  | 0.971                       |
| <i>Average</i> |                          |         |                 |         | <b>1.0024</b><br>(0.0084)   |

(Source: Skalski and Townsend 2017)

The value of  $\hat{R} = \mathbf{1.0024}$  in Table 3 above was used to project average direct-measured yearling Chinook salmon acoustic tag passage survival at the Rocky Reach Project of  $\hat{S}_{\text{ChinACO}} = 0.9272$  into a coho salmon project passage survival estimate, where

$$\begin{aligned}\hat{S}_{\text{CohoACO}} &= \hat{R}_{\text{Coho/Chin}}^{\text{PIT}} \cdot \hat{S}_{\text{ChinACO}} \\ &= 1.0024(0.9272) \\ &= \mathbf{0.9294} \ (\widehat{\text{SE}} = 0.0081).\end{aligned}$$

The same coho-to-Chinook-salmon survival ratio of  $\hat{R} = \mathbf{1.0024}$  was used to project average direct-measured yearling acoustic tag passage survival at the Rock Island Project of  $\hat{S}_{\text{ChinACO}} = 0.9375$  into a coho salmon project passage survival estimate, where

$$\begin{aligned}\hat{S}_{\text{CohoACO}} &= \hat{R}_{\text{Coho/Chin}}^{\text{PIT}} \cdot \hat{S}_{\text{ChinACO}} \\ &= 1.0024(0.9375) \\ &= \mathbf{0.9398} \ (\widehat{\text{SE}} = 0.0233).\end{aligned}$$

Appendix F  
Statements of Agreement for Habitat  
Conservation Plan Hatchery Committees

---

**Rocky Reach and Rock Island HCP Hatchery Committees  
Statement of Agreement**

**Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD  
Hatchery Programs, dated March 13, 2017**

*(Chelan PUD, NMFS, USFWS, WDFW, YN, and CCT approved on March 13, 2017)*

**Statement**

The Rocky Reach and Rock Island Habitat Conservation Plans (HCP) Hatchery Committees (HC) approve the Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 13, 2017. Any future alterations of the schedule will require HCP Hatchery Committees approval.

**Background**

Chelan PUD's HCPs specify the need to update the hatchery monitoring and evaluation (M&E) plan every five years and to comprehensively review the hatchery program every 10 years utilizing new information from the M&E program. The National Marine Fisheries Service Section 10(A)(1)(a) and 10(A)(1)(b) Endangered Species Act permits for Chelan PUD's hatchery programs and the *Monitoring and Evaluation Plan for PUD Hatchery Programs* also contain reporting requirements for hatchery M&E information. To date, these reporting requirements have not aligned, which has resulted in a disjointed review and input cycle to inform updates to M&E plans, recalculation of hatchery production, evaluation of M&E objectives, status of meeting permit requirements, and adaptive management actions. The document, Monitoring and Evaluation Reporting Schedule for the Douglas PUD, Grant PUD and Chelan PUD Hatchery Programs, dated March 13, 2017, optimizes the sequence of hatchery M&E reporting and is the new reporting schedule for hatchery M&E information.

**Rocky Reach and Rock Island HCP Hatchery Committees**  
**FINAL Statement of Agreement**  
**Regarding District's Coho Obligation**  
**November 15th, 2017**

*Approved as follows: CCT approved via email on November 14, 2017, and Chelan PUD, WDFW, USFWS, NMFS, and YN approved on November 15, 2017.*

**Statement**

The Rocky Reach and Rock Island HCP Hatchery Committees (hereafter "Committees") agree that Chelan PUD shall provide coho compensation for the Methow River and Wenatchee River sub-basins at a rate equivalent to 7.0% at each project to meet Chelan PUD's No Net Impact hatchery obligations for brood years 2017 to 2021 (release years 2019 to 2023); therefore, 7.0% will be used as the coho hatchery compensation rate until the next scheduled hatchery compensation recalculation (2023). Methodology described in the SOA Regarding the 2013 No Net Impact Recalculation Methodology (dated July 20<sup>th</sup>, 2011) will be used to calculate hatchery compensation levels for coho.

**Background**

On June 20, 2007, the Committees agreed to implement coho hatchery compensation as detailed in Section 8.4.3.a of the Rocky Reach and Rock Island HCPs and agreed that the District shall begin providing hatchery compensation no later than October 1, 2007. On March 28, 2017, the Rocky Reach and Rock Island Coordinating Committees agreed to use Chelan PUD's yearling Chinook acoustic tag survival estimates and coho PIT-tag based survival estimates to estimate juvenile coho survival of 93.98% at Rock Island and 92.94% at Rocky Reach (Skalski and Townsend 2017) which culminated in a 93% survival value at both projects.

**Calculations for the Methow Sub-basin Coho Reintroduction Project**

Compensation for **hatchery-origin smolts** will be determined by multiplying the Program's annual release targets from the Methow sub-basin coho reintroduction project by the unavoidable project mortality (1-(0.93 x 0.93)) for Rocky Reach and Rock Island.

Compensation for **natural-origin smolts** produced is determined by:

- Mean NOR<sup>1</sup> to Rocky Reach (return years 2008 to 2011 and 2013 to 2015) = 43
- Mean NOR in absence of project mortality:  $43/0.9300 = 46$
- Adult equivalents to meet NNI:  $46-43=3$
- Mean 8-year SAR (release years 2008-2015 Methow sub-basin hatchery program) = 0.59%
- Compensation for natural-origin smolts:  $3/0.0059 = 508$  smolts

**Calculations for the Wenatchee Sub-basin Coho Reintroduction Project**

Compensation for **hatchery-origin smolts** will be determined by multiplying the Program's annual release targets from the Wenatchee sub-basin coho reintroduction project by the unavoidable project mortality (1-0.93) for Rock Island.

Compensation for **natural-origin smolts** is determined by:

- Mean NOR to Rock Island (return years 2007-2016) = 529
- Mean NOR in absence of project mortality:  $529/0.9300 = 569$
- Adult equivalents to meet NNI:  $569-529 = 40$
- Mean 10 year SAR<sup>2</sup> (release years 2006-2015 Wenatchee sub-basin hatchery program) = 0.75%
- Compensation for natural-origin smolts:  $40/0.0075 = 5,333$  smolts

<sup>1</sup>Natural-origin return=NOR

<sup>2</sup>SAR=releases from the Wenatchee hatchery programs and returns to Priest Rapids Dam (versus Rock Island Dam due to historic variable PIT tag detection efficiency at the adult ladders).

December 30, 2016

## Abstract

This report provides information on Chelan PUD's Northern Pikeminnow (*Ptychocheilus oregonensis*) control programs for 2016. This program entails the use of deck and boat fishermen (USDA), long liners (Columbia Research), the East Wenatchee Rotary Club Pikeminnow Derby, as well as several miscellaneous efforts throughout the year.

Northern Pikeminnow are one of the most abundant predators of juvenile steelhead and salmonids (*Oncorhynchus spp.*) in the Columbia River. In 1998, the American Fisheries Society (AFS) formally changed the common name of this fish from Northern Squawfish to Northern Pikeminnow. Pikeminnow may concentrate in hydroelectric project tailraces during the late spring and summer months, concurrent with the juvenile salmonid migrations. The Public Utility District No. 1 of Chelan County (District) initiated a pikeminnow removal program in 1994 at Rocky Reach dam and extended the program to include Rock Island in 1995. Since 1996, the District has contracted annually with the United States Department of Agriculture Wildlife Services (USDA) to carry out this program. In addition to the USDA program, Chelan PUD conducted a pilot study using set-lines in 2005 under contract with Columbia Research. The objective of the set-line program was to remove pikeminnow from over-wintering habitats before the start of out-migration of salmonid smolts. The District also provides funding for the annual Pikeminnow Derby sponsored by the East Wenatchee Rotary Club. This year marked the 24th consecutive year for the annual derby and the 21st consecutive year that the District has provided funding for the event.

In 2016, a total of 91,522 pikeminnow were removed from Rocky Reach and Rock Island reservoirs (60,327 by USDA, 27,472 by Columbia Research, 2,347 during the Pikeminnow Derby, and 1,376 by miscellaneous projects).

## **Introduction**

Northern Pikeminnow (*Ptychocheilus oregonensis*) are native to the Columbia River. Burley and Poe (1994) identified pikeminnow as the most abundant predator on out-migrating juvenile steelhead and salmonids (*Oncorhynchus spp.*) in the mid-Columbia River between Priest Rapids and Chief Joseph dams. They also concluded that the highest abundance of pikeminnow concentrate in the tailrace areas. Loch et al (1994) reported that the highest consumption of juvenile salmonids takes place within the tailraces of dams and those pikeminnow densities in these areas increase during the late spring and summer. Pikeminnow are believed to become highly piscivorous on juvenile salmonids at approximately 280 mm (11 inches) and their predation rate on juvenile salmonids increase significantly as their size and age increases (Peterson, 2001).

In an effort to reduce predation on juvenile salmonids, the District implemented a pikeminnow removal program (Program) in 1994 in the Rocky Reach project area and in 1995 the program was expanded to include the Rock Island project area. From 1996 to present time, the District has contracted with the United States Department of Agriculture, Wildlife Services (USDA) to employ anglers to fish for pikeminnow during the summer months from the District's dams and reservoirs. The program has continued to focus on increasing fishing effort, increasing pikeminnow catch totals, and evaluating catch data to characterize attributes of the pikeminnow populations in the reservoirs. As a result, the USDA fish for a longer duration and with multiple boats. From 2005 to current, the District has contracted Columbia Research to fish for pikeminnow within the District's reservoirs with set-lines in an effort to remove pikeminnow from deeper over-wintering areas. Chelan PUD has also provided funding for the annual Pikeminnow Derby sponsored by the East Wenatchee Rotary Club. This year marked the 21st consecutive year that the District has partnered with the Rotary Club.

## **Program Objectives**

The objectives for the 2016 pikeminnow removal program were three-fold:

- 1) Reduce the number of pikeminnow in the Rocky Reach and Rock Island tailraces and reservoirs in order to reduce predation on juvenile anadromous salmon and steelhead smolts.
- 2) Continue to evaluate the efficiency of angling methods and the timing of seasonal fish movement to improve the efficiency and harvest.
- 3) Continue to evaluate current and historic catch statistics characterize effects of the removal program on pikeminnow populations in Rocky Reach and Rock Island reservoirs.

## **Methods and Materials**

### **USDA**

Since 1996, the District has contracted the USDA to conduct pikeminnow fishing from Rocky Reach and Rock Island projects. The USDA employs approximately 17 anglers to fish during the summer months. Crews consist of four 3-person boat crews, one 3-person crew at Rocky Reach dam, and one 2-person crew at Rock Island dam. Boat crews fished for 23 weeks from 25 April to 28 September. Deck crews fished for 16 weeks from 25 April to 12 August.

Each angler is outfitted with two fishing rods and reels, assorted tackle, tackle box, small ice chest (for keeping bait cool), fillet knife (for cutting bait), pliers, line clippers, personal floatation device, hard hat, 5 gallon bucket, and data sheets to record weekly catch. Each crew also carries a District radio or cell phone for communication. For more detail description of equipment used by anglers, please refer to West (2001).

Anglers fish a variety of locations within the tailraces and reservoirs in search of the most productive fish locations. Early in the fishing season when catch rates are low, anglers move in search of “hot spots”. Later in the season when flows reside, water temperatures increase, and when anglers become more familiar with pikeminnow holding areas and feeding activity, the anglers are able to concentrate their efforts in established locations.

Each crew leader is in charge of recording specific information. Data is collected weekly from each crew including; total number of pikeminnow caught, total number of hours fished, fishing locations, number of non-target fish captured, and the dates that were fished. Twice a week anglers are required to measure fork length on all pikeminnow in order to evaluate the size distribution. Upon capture, pikeminnow are measured, euthanized, and their carcasses are returned to the river. All non-target species are released immediately back into the reservoir.

### **Columbia Research**

Set-lines are the primary fishing technique used by Columbia Research to capture and remove pikeminnow. Set-lines are long weighted nylon lines with buoys attached at each end. The weighted rope allows the set-line to sink and remain on the bottom of the reservoir where pikeminnow tend to congregate during the winter months. Approximately 120 small hooks are attached to each line. Each hook is tied to a leader that contains a small float, which allows the hook to float slightly off the bottom substrate. An 8-pound test leader allows non-target species to break free from the set-line upon capture.

Each day, between 15 and 20 set-lines are deployed and allowed to fish for 24 hours. Deployment of set-lines occurs in the Rocky Reach and Rock Island reservoirs and varies in depth between 10 feet to 150 feet. Once set-lines are retrieved and non-target species are released, pikeminnow are measured (fork length) and turned into the District for rendering. Columbia Research provides the District with specific information including; the number of pikeminnow caught on each set-line, fork length (mm), depth and location of each set-line, and set-line time. They also provide the District with any incidental species encountered during set-line retrieval.

### **East Wenatchee Rotary Club**

The East Wenatchee Rotary Club takes place during the last week in June. During this two-day event, sportsmen fish Rocky Reach and Rock Island reservoirs for pikeminnow. After each day, the anglers submit their fish for count and total weight. Prizes are awarded to individuals who catch the most pikeminnow by weight. Daily prizes are awarded for the largest fish and the most fish as well.

### **Chelan County PUD #1**

In past years, the District has either contracted or operated a pikeminnow trapping project using modified lamprey traps. Traps were very effective during peak pikeminnow migration season. However, trap efficiency is significantly decreased during seasons of above average adult Sockeye Salmon runs. The last year traps were used was in 2010. For an overview on trap configurations, please refer to Mallas and Stevenson, 2008. For past catch data, please refer to Keller et. al., 2010.

## **Program Contracts and Compensation**

### **USDA**

The USDA receives compensation on an hourly basis for labor through an annual contract. The contract is typically less than 7 months in duration, from May through mid-October. In 2016, the contract payout was \$402,710.00. USDA rod and reel fishing activities for the tailrace and boat crews takes place 5 days a week for 8 hours each day.

### **Columbia Research**

In 2016, Columbia Research received \$3.00 for each fish between 127 mm and 227 mm and \$7.25 for each fish great than 227 mm in fork length. Columbia Research received no compensation for fish measuring less than 127 mm. Columbia Research anglers fish 7 days a week, for up to 15 hours a day during the contract period. In 2016, Columbia Research conducted set-line fishing in the Rocky Reach and Rock Island reservoirs in two distinct seasons. In the spring Columbia fished from April into July, and in the fall from October into November. The total contract payout was \$179,906.75.

### **East Wenatchee Rotary Club**

The District contracts with the East Wenatchee Rotary Club to hold the annual Pikeminnow Derby. In 2016, this contract was \$20,000 with specific requirements for anglers to fish in Rocky Reach and Rock Island reservoirs only.

## **Results**

### **USDA**

Since 2003, the USDA has removed 607,514 pikeminnow from the Rocky Reach and Rock Island projects. In 2016, USDA crews removed 60,327 pikeminnow from May through mid-October. (Table 1).

**Table 1. Total pikeminnow removed from Rocky Reach and Rock Island projects by USDA from May through October 2003 to 2016.**

| <b>Year</b>  | <b>USDA</b>    |

| 2016         | 60,327         |
| <b>Total</b> | <b>607,514</b> |

***Pikeminnow Size Distribution***

The USDA submitted length measurements to the District weekly. Fish lengths are recorded into size categories 10 mm in length. A total of 25,000 pikeminnow were measured in 2016. Of the pikeminnow measured, 21,431 were less than or equal to 250 mm, and 3,569 were greater than 250 mm (Table 2).

**Table 2. Size and number of pikeminnow captured by USDA that were measured from the Rocky Reach and Rock Island reservoirs in 2016.**

| <b>Size (mm)</b> | <b>USDA</b> |
|------------------|-------------|
| 100-110          | 594         |
| 111-120          | 1,039       |

| 581-590 | 0   |
| 591-600 | 2   |

The overall mean fork length of pikeminnow removed from both Rocky Reach and Rock Island in 2016 was 183 mm. The mean length for Rocky Reach and Rocky Island were 177 mm and 233 mm respectively. Overall mean lengths have been generally decreasing over time and mean lengths in 2016 were the lowest since measurements began in 2003 (Table 3).

**Table 3. The mean fork length (mm) of pikeminnow removed during USDA fishing at Rocky Reach and Rock Island projects, 2003 to 2016.**

| Year | Rocky Reach Mean Length (mm) | Rock Island Mean Length (mm) | Overall Mean Length (mm) |

| 2016 | 177                          | 233                          | 183                      |

***Pikeminnow Catch Rates***

In 2003, 2004, and 2005 the angler hours were reported as fishing day (8 hours). From 2006 through 2016, anglers fishing from the dam reported their time as “angling hours” while boat anglers reported fishing time as boat hours”. Angling hours were just that – defined as the number of hours the tailrace crews spent fishing. Boat hours are defined as the number of hours the boat was in the water. It does not include the time required to launch or load the boat, refuel, or purchasing equipment. The catch per angler hour (CPAH) increased every year through 2008. The CPAH then began to decrease through 2012 before it began to generally increase again to 5.8 in 2016 (Table 4).

**Table 4. The overall rod and reel CPAH for USDA pikeminnow anglers from May to October, 2003 to 2016.**

| Year | Angler Hours | Fish Captured | CPAH |
|------|--------------|---------------|------|
| 2003 | 6,857.00     | 19,754        | 2.9  |
| 2004 | 11,676.00    | 36,145        | 3.1  |
| 2005 | 10,849.00    | 39,818        | 3.7  |
| 2006 | 9,159.50     | 40,747        | 4.4  |
| 2007 | 9,513.50     | 46,240        | 4.9  |

### **Cost Benefit Analysis**

Expenditures for the USDA portion of the pikeminnow predator program have fluctuated since the initial start of the contract in 1996. Since 2013, the cost per fish has been near or below \$7.00 with the exceptions of years 2011 through 2014 when prices reached a peak in 2012 at \$9.85 per fish (Table 5).

**Table 5. Cost of USDA pikeminnow program and the cost per fish breakdown from 2003 to 2016.**

| Year | Cost of Program | Fish Captured | Cost per fish |
|------|-----------------|---------------|---------------|
| 2003 | \$135,709.98    | 19,754        | \$6.87        |
| 2004 | \$237,834.10    | 36,145        | \$6.58        |
| 2005 | \$255,233.38    | 39,818        | \$6.41        |
| 2006 | \$263,225.62    | 40,747        | \$6.46        |
| 2007 | \$253,395.20    | 46,240        | \$5.48        |
| 2008 | \$264,752.24    | 42,158        | \$6.28        |
| 2009 | \$327,164.50    | 50,333        | \$6.50        |
| 2010 | \$332,425.08    | 47,354        | \$7.02        |
| 2011 | \$342,533.41    | 36,401        | \$9.41        |
| 2012 | \$355,685.00    | 36,118        | \$9.85        |
| 2013 | \$360,780.96    | 47,563        | \$7.59        |
| 2014 | \$373,112.00    | 44,826        | \$8.32        |
| 2015 | \$397,619.00    | 59,730        | \$6.66        |
| 2016 | \$402,710.00    | 60,327        | \$6.68        |

### **Non-Target Fish Species**

Rod and reel angling is one preferred pikeminnow removal method because baits can be tailored to exploit primarily pikeminnow and is the least harmful to non-target species. Non target species caught in 2016 included; chiselmouth (*Acrocheilus alutaceus*), peamouth (*Mylocheilus caurinus*), large scale and bridgelip suckers (*Catostomus spp.*), mottled sculpin (*Cottus bairdii*), bass (*Micropterus dolomieu*), mountain whitefish (*Prosopium williamsoni*), walleye (*Sander vitreum*), yellow perch (*Perca flavescens*), white sturgeon (*Acipenser transmontanus*), carp (*Cyprinus carpio*), adult and juvenile salmon, and adult steelhead and resident rainbow trout (*Oncorhynchus mykiss*). In 2016, all non-target fish were released unharmed back to the river.

### **Columbia Research**

Columbia Research has removed 320,865 pikeminnow from Rocky Reach and Rock Island reservoirs from 2005-2016. In 2016, set-lines run by Columbia Research produced 27,472 pikeminnow (Table 6).

**Table 6. Total pikeminnow removed from Rocky Reach and Rock Island projects by Columbia Research from 2005 to 2016.**

| <b>Year</b>  | <b>Columbia Research</b> |
|--------------|--------------------------|
| 2005         | 19,337                   |
| 2006         | 22,418                   |
| 2007         | 21,301                   |
| 2008         | 21,472                   |

| 2010         | 31,620                   |
| 2011         | 32,846                   |
| 2012         | 29,526                   |
| 2013         | 29,310                   |
| 2014         | 27,090                   |
| 2015         | 26,790                   |
| 2016         | 27,472                   |
| <b>Total</b> | <b>320,865</b>           |

### ***Pikeminnow Size Distribution***

Columbia Research submitted length measurements to the District for all pikeminnow captured. Fish lengths are recorded into size categories 10 mm in length. Of the pikeminnow measured, 11,780 were less than or equal to 250 mm, and 15,692 were greater than 250 mm (Table 7).

**Table 7. Size and number of pikeminnow captured by Columbia Research in Rocky Reach and Rock Island reservoirs in 2016.**

| <b>Size (mm)</b> | <b>Columbia Research</b> |
|------------------|--------------------------|
| 100-110          | 0                        |
| 111-120          | 0                        |
| 121-130          | 0                        |
| 131-140          | 406                      |
| 141-150          | 417                      |
| 151-160          | 367                      |
| 161-170          | 361                      |
| 171-180          | 416                      |
| 181-190          | 343                      |
| 191-200          | 443                      |
| 201-210          | 388                      |

| 441-450 | 18    |
| 451-460 | 10    |
| 461-470 | 12    |
| 471-480 | 13    |
| 481-490 | 17    |
| 491-500 | 19    |
| 501-510 | 17    |
| 511-520 | 5     |
| 521-530 | 1     |
| 531-540 | 20    |
| 541-550 | 0     |

Because the set-line program is an incentive based contract and that the main objective is to target deep over wintering habitats, Columbia Research is required to measure every pikeminnow captured. Both of these factors contribute to Columbia Research producing larger mean lengths compared to other District pikeminnow capture projects. In 2016, the average mean fork lengths in the Rocky Reach reservoir and Rock Island reservoir were 260 mm and 252 mm respectively. The overall 2016 mean fork length was 258 mm. The overall mean fork length for Columbia Research has been trending downwards with the largest mean fork length (282 mm) in 2005 and the smallest mean fork length in 2016 (Table 8).

**Table 8. The mean fork length of pikeminnow removed by Columbia Research set-line fishing at Rocky Reach and Rock Island projects, 2005 to 2016.**

| Year | Rocky Reach Mean Length (mm) | Rock Island Mean Length (mm) | Overall Mean Length (mm) |
|------|------------------------------|------------------------------|--------------------------|
| 2005 | N/A                          | N/A                          | 282                      |
| 2006 | N/A                          | N/A                          | 281                      |
| 2007 | 269                          | 294                          | 281                      |
| 2008 | 269                          | 268                          | 269                      |
| 2009 | 274                          | 272                          | 274                      |
| 2010 | 267                          | 256                          | 261                      |
| 2011 | 258                          | 270                          | 261                      |
| 2012 | 293                          | 288                          | 275                      |
| 2013 | 268                          | 273                          | 270                      |
| 2014 | 262                          | 274                          | 268                      |
| 2015 | 268                          | 276                          | 270                      |
| 2016 | 260                          | 252                          | 258                      |

***Pikeminnow Catch Rates***

In 2016, Columbia Research removed 27,472 pikeminnow during 61,920 hours of set-line effort. This equates to 7,430,400 hook hours as each set line has 120 hooks. The overall catch per unit effort (CPUE) was 0.37 for 2016. The District calculates CPUE as the number of pikeminnow captured per 100 hook hours. In general, the CPUE for Columbia Research has remained pretty constant. The last two years have produced the highest CPUE's at 0.42 and 0.37 (Table 9).

**Table 9. Annual catch per unit effort (CPUE) for Columbia Research in Rocky Reach and Rock Island reservoirs, 2008 to 2016.**

| Year | Total Hook Hours | Fish Captured | CPUE* |
|------|------------------|---------------|-------|
| 2008 | 6,624,000        | 21,472        | 0.32  |
| 2009 | 10,980,000       | 31,683        | 0.29  |
| 2010 | 8,517,600        | 31,620        | 0.37  |
| 2011 | 10,332,000       | 32,846        | 0.32  |
| 2012 | 9,388,800        | 29,526        | 0.31  |
| 2013 | 9,129,600        | 29,310        | 0.32  |
| 2014 | 8,643,600        | 27,090        | 0.31  |
| 2015 | 6,402,240        | 26,790        | 0.42  |
| 2016 | 7,430,400        | 27,472        | 0.37  |

\*CPUE is calculated as the number of pikeminnow per 100 hook hours.

### ***Cost Benefit Analysis***

Columbia Research is compensated on a per-fish basis. Fish captured between 127 mm and 227 mm were compensated at a lower rate than fish captured that measured greater than 227 mm in length. These two size categories are considered “Under” and “Over” the 227 mm delineation. In 2005, Columbia Research received \$2.75 or \$5.50 per fish depending on size. In 2006, compensation rate increased to \$3.00 and \$6.00 respectively. In 2007, the compensation rate increased to \$3.00 and \$6.25 depending on fish size. From 2008 to 2011, Columbia Research received \$3.00 or \$6.50 per fish. For years 2012 and 2013 the compensation rate increased to \$3.00 and \$6.75 respectively. From 2014 to 2016 the compensation rate has been \$3.00 for fish 127 mm to 227 mm and \$7.25 for fish greater than 227 mm in length. No compensation was awarded for any fish measuring less than 127 mm. For the District’s total annual compensation to Columbia Research for their pikeminnow efforts and the equivalent annual cost per fish refer to Table 10.

**Table 10. Cost of Columbia Research set-line program in Rocky Reach and Rock Island and the cost per fish breakdown from 2005 to 2016.**

| <b>Year</b> | <b>Cost of Program</b> | <b>Fish Captured</b> | <b>Cost per fish</b> |
|-------------|------------------------|----------------------|----------------------|
| 2005        | \$99,726.00            | 19,337               | \$5.16               |
| 2006        | \$125,000.00           | 22,418               | \$5.58               |
| 2007        | \$124,998.75           | 21,301               | \$5.87               |
| 2008        | \$124,997.50           | 21,472               | \$5.82               |
| 2009        | \$174,999.50           | 31,683               | \$5.52               |
| 2010        | \$174,999.50           | 31,620               | \$5.53               |
| 2011        | \$180,250.50           | 32,846               | \$5.49               |
| 2012        | \$180,000.00           | 29,526               | \$6.10               |
| 2013        | \$179,988.75           | 29,310               | \$6.14               |
| 2014        | \$179,742.50           | 27,090               | \$6.64               |
| 2015        | \$179,998.50           | 26,790               | \$6.72               |
| 2016        | \$179,906.75           | 27,472               | \$6.55               |

\*CPUE is calculated as the number of pikeminnow per 100 hook hours.

### ***Non-Target Fish Species***

The non-target fish species caught by Columbia Research included chiselmouth, peamouth, large scale and bridgelip suckers, mottled sculpin, mountain whitefish, white sturgeon, and burbot (*Lota lota*). In 2016, no adult or juvenile salmon or steelhead were captured. All non-target fish were released unharmed back into the river.

### **East Wenatchee Rotary Club**

The East Wenatchee Rotary Club Annual Pikeminnow Derby has captured 60,415 pikeminnow in 42 days of total fishing since 1996. In 2016, the annual derby produced 2,347 pikeminnow over the 2-day event. There were 98 tickets sold (82 adults and 16 youth). Of the participants, 76 people turned in fish (68 adults and 8 youths). Participation and total number of pikeminnow captured were both down in 2016 (Table 11).

**Table 11. Total pikeminnow removed from Rocky Reach and Rock Island reservoirs during the annual Pikeminnow Derby from 1996 to 2016.**

| <b>Year</b>  | <b>Pikeminnow Captured</b> |
|--------------|----------------------------|
| 1996         | 1,800                      |
| 1997         | 2,240                      |
| 1998         | 1,847                      |
| 1999         | 2,294                      |
| 2000         | 1,370                      |
| 2001         | 1,601                      |
| 2002         | 2,783                      |
| 2003         | 2,568                      |
| 2004         | 2,943                      |
| 2005         | 3,950                      |

### **Discussion**

#### **USDA**

The continued success of the USDA program is likely a result from a variety of factors. A key efficiency is credited to a core group of veteran anglers who return to work in the program each year, resulting in better catch rates overall. Experienced anglers are more productive, relying on their knowledge of pikeminnow holding areas in the reservoirs, effective baits, and presentation methods. While the USDA continues to catch similar numbers of pikeminnow each year, the overall average size has dropped considerably over the course of the program. This resulted in the lowest average size observed ever for the program in 2016. The start and duration of the USDA pikeminnow program is designed to coincide with the outmigration period of juvenile salmonids. Smolts arrive at Rocky Reach and Rock Island Dams in early April, and continue passing the dams through the end of August. Pikeminnow primarily ascend the adult fish ladders during mid-May through September. Peak ladder passage occurs in August at Rocky Reach and in mid-July at Rock Island. The highest catch rates for pikeminnow usually occur in July and August for Rocky Reach and Rock Island.

## Columbia Research

The objective for the Columbia Research set-line program was to remove large pikeminnow that congregate in deep over-wintering areas. Columbia Research has become very efficient at using set-lines. Because set-line angling is designed to capture fish that hold on or near the river bottom, targeting deep areas within the reservoir where pikeminnow congregate in colder months is effective. Pikeminnow likely move into deep pools where the daily water temperature remains more constant. A fish's metabolic rate decreases over winter periods, and hence it needs less food to survive (Sauter et. al, 1994). By presenting pikeminnow with food that they do not have to chase, they likely expend very little effort and energy to obtain the bait. The boat crew deployed 20 set-lines nearly every day at various depths. In 2016, all fish were caught at depths between the surface and 120 feet with most fish being caught between the surface and 90 feet.

Fishing with set-lines and at deeper depths has resulted in Columbia Research having a larger mean length than USDA over the years. From year to year there is some overlap but it can be seen that the two programs are targeting pikeminnow from different size classes (Figure 1). Also seen in Figure 1 is that the trend for both programs is a reduction in mean length over time. If capture rates can outpace the recruitment rate then this would result in a reduction in mean length over time. Columbia Research's mean length has steadily declined despite the fact they are targeting larger fish for a higher payout. It is predicted that the programs will reach a point where capture rates will off-set the recruitment rates and mean lengths will start to level off.

Figure 1. Mean fork lengths (mm) for pikeminnow captured by Columbia Research and the USDA from 2003 to 2016.

### East Wenatchee Rotary Derby

The Pikeminnow Derby is nearing its 25<sup>th</sup> annual event in a few years and marks the District's longest effort toward reduction in pikeminnow numbers. While numbers in the past have been higher, this year's effort was impacted by poor weather on the second fishing day. The derby is only a two-day event and can be influenced heavily by weather. Since the limiting factor is the number of anglers on the river, additional efforts should be put into increasing the number of anglers participating. This was addressed in 2015 by doubling the prize contribution by the District from \$10,000 to \$20,000.

### Chelan County PUD (miscellaneous)

In past years the District has conducted pikeminnow ladder trapping efforts in both Rocky Reach and Rock Island fish ladders. These efforts were abandoned in the 2011 season due to the increased bycatch of adult Sockeye Salmon. With the increased run sizes of Sockeye Salmon and the overall success of the District's other pikeminnow programs, the District abandoned the ladder trapping completely in 2012.

In 2016, there were 1,376 pikeminnow caught in miscellaneous instances. Some of these miscellaneous captures included bycatch at facilities, fish ladder outage rescues, bycatch during miscellaneous studies, and a few targeted angling efforts by District employees. These various events accounted for 1.5% of the total pikeminnow catch in 2016. An overall visual of the District's different pikeminnow programs can be seen in Figure 2.

Figure 2. Breakdown of pikeminnow contributions from Chelan County PUD's different pikeminnow programs from 2010 to 2016.

## **Project Recommendations**

### **USDA**

Several factors, including USDA angler skills, reservoir knowledge, increased efforts, and overall program duration combined to make the 2016 the most successful pikeminnow effort to date for the USDA. The USDA anglers continue to maintain excellent pikeminnow catch rates by documenting fish movements and holding locations. We expect that overall catch may increase as anglers continue to learn where pikeminnow reside during the summer and fall months. However, if the program has started to outpace the recruitment efforts, then we may start to see a decrease in total capture numbers. If possible, the District should continue to utilize USDA anglers with experience and knowledge of the reservoirs and who are familiar and adept at the angling techniques used in the program.

### **Columbia Research**

We recommend continuing the set-line program at the 2016 funding and effort level. This program is productive because it compensates on a per fish basis, with no equipment, fuel, or administrative costs. The current recommendation is to continue to start the program in February and continue through November to take advantage of favorable CPUE documented during past fishing efforts in November.

### **East Wenatchee Rotary Derby**

The District should continue to fund the East Wenatchee Rotary Club Pikeminnow Derby at its current funding level. The derby removes a large number of fish in a short time frame of two days. This likely provides an immediate within-year benefit to juvenile survival in the reservoirs. Since 1996 the derby has removed 60,415 pikeminnow in just 42 days of effort. In order to increase overall angler turn out the District should increase efforts to advertise the derby. The increased advertising along with the contribution increase from \$10,000 to \$20,000 in 2015 should help encourage higher participation. The Rotary Club should continue to host the event concurrent with the peak smolt migrations through Rocky Reach and Rock Island Reservoirs.

Appendix H  
2017 Wenatchee Steelhead Release Plan  
(Brood Year 2016)

---

## Memorandum

**Date:** March 3, 2017

**To:** Rock Island and Rocky Reach HCP Hatchery Committees

**From:** Catherine Willard (CPUD), Scott Hopkins (CPUD), Chris Moran (WDFW), and McLain Johnson (WDFW)

**Re:** 2017 Wenatchee Steelhead Release Plan (Brood Year 2016)

---

### Background

Chelan PUD is required to produce 247,300 steelhead smolts for release into the Wenatchee River Basin in 2017 as part of the Rock Island and Rocky Reach HCP requirements. As of February approximately 267,035 Wenatchee summer steelhead (142,224 HxH and 124,811 WxW) are on station at the Facility.

Beginning in winter 2011 the Chelan PUD Wenatchee River steelhead program was relocated to the Chiwawa Acclimation Facility (“Facility”) (Figure 1) following significant upgrades to accommodate tributary based overwinter acclimation for the Wenatchee steelhead program. Steelhead are transferred from Eastbank Hatchery to the Facility in November and released in April through May. The Facility consists of three, in line circular, dual-drain tanks within an enclosed building and are operated on a partial water reuse system (RAS). The two outer tanks hold steelhead during rearing and the center tank is used solely for receiving fish that are allowed to move from the outer tanks to the center tank during release. Fish are not provided the opportunity to move to the center tank until gates are removed (typically April 20<sup>th</sup>). When the center tank contains a pre-determined number of fish for a release, fish are loaded into a hatchery truck and truck-planted at one of five release locations. This “screening” method has been used to differentiate between apparent active migrants (fish that move from the outer tanks to the center tank) from apparent non-active migrants (fish that do not move from the outer tank to the center tank).

In addition to the circular vessels, there are three traditional flow-through raceways (RCY) located outside. The smaller of the three, Raceway Three (RCY3), is used to rear steelhead when it is not needed for rearing “high ELISA” spring Chinook juveniles. Raceways One (RCY1) and Two (RCY2) are located adjacent to each other. The wall between the two raceways contains a gated opening that when removed, allows fish to move between the raceways. In addition to removing the gate, the water is lowered in the receiving pond (typically April 20<sup>th</sup>) to establish a directional flow that apparent active migrant fish may cue to. Similar to

the RAS vessels, this set-up allows for a screening method that attempts to differentiate between apparent active- and apparent non-active migrants. When RCY1 contains the pre-determined number of fish suitable for release, fish are loaded into a transport truck and truck-planted at one of five release locations. Historically, this screening method has been termed a volitional release but is currently termed a screening method as this more accurately describes the end result of the action.

### 2017 Release Strategy Objectives

- Evaluate best hatchery management practices for hatchery releases to optimize homing fidelity, minimize residualism, maximize out-migration survival, and minimize negative ecological interactions (Draft NMFS Wenatchee River Steelhead Section 10 Permit).
- Assess hatchery release practices to inform development of a residualism baseline for the Wenatchee steelhead program consistent with the Draft NMFS Wenatchee River Steelhead Section 10 Permit DRAFT Steelhead Residual Management Plan.
- Utilize data collected from the 2017 Wenatchee River Steelhead release to assess applicable monitoring and evaluation objectives (i.e., Objectives 4 and 6) for the Wenatchee River summer steelhead hatchery program (Hillman et al. 2013).

### Methods

The 2017 release strategy will evaluate the effectiveness of the screening method, and the role of rearing vessel (RAS versus RCY) and brood origin on fish performance (e.g., juvenile survival and adult returns). The 2017 release plan methodology will consist only of screened releases; release years 2015 and 2016 evaluated screened and non-screened releases. Additionally, 2,500 PIT tags will be applied to non-movers remaining in RCY2 at the end of the screened release period to increase the PIT sample size of non-movers to better understand their post release performance. As with previous years, the release numbers and locations identified in Table 1 are proportionally based on the spawning distributions in the respective streams.

- Cormack-Jolly-Seber survival probabilities to MCN will be calculated for each release group using recaptures of PIT-tagged fish.
- The percentage of PIT-tagged fish detected in the Wenatchee sub-basin after July 1 of the year of release will be calculated to estimate potential residualism for each release group.

### Release Timing

In an effort to more closely align hatchery steelhead releases with the peak outmigration period for wild steelhead and potentially increase smolt to smolt survival, all fish located at the Facility will be released by May 8<sup>th</sup>; fish acclimated at Blackbird Island Pond will be allowed to voluntarily move out of the pond through the end of June (after which time the pond outlet will be closed as in years past).

### Release Location

Release locations in 2017 will be the same as the previous two years.

### Pre-release Monitoring and Evaluation

Throughout acclimation and release, established sampling, transfer and release protocols will be followed (Hillman et al. 2013). Additionally, to gain an additional year of data for the RAS reared steelhead that are screened, assessment of smolt index and precocial maturation will be conducted via non-lethal sampling from the two screened RAS vessels (n=200 movers; n= 200 non-movers).

Table 1. Steelhead release numbers and locations, 2017.

| Vessel | Origin <sup>1</sup> | Estimated Number Released <sup>2</sup> | Estimated # PIT-tagged | Destination  | rkm  | Movers or Non-movers |
|--------|---------------------|--|------------------------|--------------|------|----------------------|
| RAS3   | WxW                 | 11,971 <sup>3</sup>                    | 2,375                  | Nason        | 7.0  | Movers               |

# 2017 Rocky Reach Juvenile Fish Bypass System Operations Plan

## Final Plan

Prepared By:

Lance Keller  
&  
Scott Hopkins

Public Utility District No. 1 of Chelan County  
P.O. Box 1231  
327 North Wenatchee Avenue  
Wenatchee, Washington 98801

March 2017

## Introduction

The Public Utility District of Chelan County (District) constructed and installed a permanent fish bypass system (FBS) in 2002/2003. The bypass system is designed to guide juvenile salmon and steelhead away from turbine intakes at Rocky Reach Dam. The system consists of one surface collector entrance (SC) and the intake screen (IS) system in turbine units 1 and 2. Please refer to Mosey (2004) for a detailed description of the bypass production system.

Studies and data collection at the Rocky Reach FBS fall under one of two general categories “Standard Operations” or “Special Operations” for bypass evaluations. Activities and data collection under standard operations include day to day sampling of run-of-river (ROR) fish to evaluate run timing, species composition, and fish condition after passage. Special operations may include additional sampling time to supply fish for marked fish releases.

## 2017 Evaluation Requirements

Run-of-river fish collected at the Juvenile Sampling Facility (JSF) to evaluate and provide fish for the following:

1. Run timing of target species:
  - a. Provide standardized juvenile capture rate data to supplement Program RealTime (UW) run-timing predictions
  - b. Guide decisions about initiating summer fish spill
  
2. Fish species composition:
  - a. Guide decisions about starting or stopping spill
    - i. Currently summer fish spill occurs at Rocky Reach (9% of the daily average river flow).
  
3. Origin of fish stock:
  - a. Fin clips/marks
  
4. Interrogate for tags:
  - a. PIT tags
  - b. Acoustic tags (sutures)
  
5. Fish condition:
  - a. Ensure that the bypass system remains safe for migrating juvenile salmon and steelhead by evaluating:
    - i. Descale: 20% or more scale loss on either side
    - ii. Injury: Scratches, bruises, or hemorrhages
    - iii. Mortality: Any fish dead on arrival to sampling facility

## 2017 Study Methods

For more information about the study methods please refer to Mosey (2004).

### **Standard Operations:**

1. Sampling Periods (1 April to 31 August):
  - a. Monday through Sunday
  - b. Collections Times
    - i. 30 minute maximum (**or**)
      - i. 0800-0830
      - ii. 0900-0930
      - iii. 1000-1030
      - iv. 1100-1130
    - ii. Target number of fish
      - i. 350 spring species
      - ii. 125 summer species
2. Fish Length:
  - a. Up to 100 fish of each species will be measured for fork length (mm).
3. Fish Condition:
  - a. All fish of each species are examined for condition:
    - i. Descale
    - ii. Injury
    - iii. Mortality
4. Species Composition:
  - a. ROR fish collected are enumerated by species
  - b. Collect data for Program RealTime to determine start and end of spill
  - c. Currently summer fish spill occurs at Rocky Reach
5. Origin of fish stocks and identification of marked individuals:
  - a. PIT tags
  - b. Fin clips

**Special Operations:**

1. Marked Fish Releases (Prior 1 April):
  - a. Prior to the 1 April system start-up, hatchery yearling Chinook will be used for marked fish releases to determine if the JFBS is causing descale, injury, or mortality.
    - i. Releases will be conducted with hatchery summer chinook prior to the 1 April start date to determine if the JFBS is working properly and to help isolate potential sources of descale, injury, and mortality.
    - ii. Fish (n = 100/release) of varying sizes will be randomly selected from hatchery chinook. Only those with no scale loss or injury will be marked.
    - iii. Marked fish will be systematically released at locations upstream of the sampling screen in the bypass system and into both intake screens in units C1 and C2.
    - iv. If potential problems are identified, resolve problems by 1 April system start-up.

2. Marked Fish Releases (1 April to 31 August):
- a. A phased approach will be used to evaluate the descaling rate, injury rate, and mortality rate of fish passing through the bypass system. We developed a sampling protocol and threshold percentages (Table 1) for descale, injury and mortality that will trigger study phases.
  - b. Identify “ambient” rates of descale, injury and mortality.
  - c. Once the ambient rate is estimated and if further sampling shows descale problems continuing at 5%, (3% for injury, 2% for mortality) *above* ambient level for three consecutive samples.
    - i. If variable rates of descale, injury or mortality do occur between species, then collection of yearling chinook, sockeye, or steelhead may be necessary for marked releases.
    - ii. Fish (n = 100/release) of varying sizes will be randomly selected at the juvenile facility and only those migrants with no scale loss or injury will be marked.
    - iii. Marked fish will be systematically released at locations upstream of the sampling screen in the bypass system until the problem area is isolated.
  - d. Identify circumstances when we would refer to the HCP Coordinating Committee.
  - e. The District will consult with the Coordinating Committee if any abnormal fish conditions (within values outlined in Table 1) are observed in the sample population.

Table 1. Flow diagram of phased approach and threshold values for conducting marked-fish releases in the juvenile bypass system at Rocky Reach Dam (*Skalski and Townsend 2003*)

|                  | Phase 1                                  |                 | Phase 2                                   |              | Phase 3   |               | Phase 4  |
|------------------|--|-----------------|---|--------------|---|---------------|--|

A\* = Ambient percentage

3. Collection of Bull Trout:
  - a. Document:
    - i. Fork Length and weight measurements
    - ii. Condition (descale, injury, or mortality)
    - iii. Interrogate for PIT tags
    - iv. Examine for fin clips/marks
  - b. Allow to recover, then release

### Daily Protocol for Fish Collection

#### **Standard Operations:**

1. Deploy sampling screen at beginning of each hour (0800, 0900, 1000, 1100 hours).
2. Use direct enumeration to count fish entering the sampling facility
3. Collect for 30 minutes **or** until approximately 350 spring migrants/125 summer migrants have been collected, whichever comes first. **RETRACT SCREEN IF 200 TO 300 FISH ARE COLLECTED IN FIRST TWO MINUTES.**
4. Retract screen when time period or target number of fish has been reached.
5. Determine species composition of all collected fish in the hourly sample.
6. Scan/examine each fish for PIT tags, fin clips, and acoustic tags.
7. Evaluate fish length (first 100 fish per species) and condition (all fish).
8. If needed, collect and hold fish for marked releases (Special Operations).
9. Return to step 1 for next sample period. After the 1100 hour sample, go to step 11.
10. See Special Operations (if applicable).
11. Allow anesthetized fish (examined for species composition and fish condition) to recover in the facility's holding tank for at least 1.5 hours.

#### **Special Operations:**

1. If fish are collected for marked fish releases, verify that the required number of target species has been set aside from the four sample periods.
2. If the required number of fish are not collected by the 1100 hour sample period, deploy the sampling screen and repeat steps 2 and 4 under standard operations.
3. Scan/check all anesthetized fish for PIT and acoustic tags.
4. Collect and hold fish at the facility for transport and/or marking (marked fish releases).
5. Determine species composition for any remaining anesthetized fish and scan for PIT tags.
6. After fish have been collected to meet study needs, estimate the number of fish remaining in the raceway (by species to the extent practical), record the number, and immediately release the fish back into the bypass pipe.
7. Return to step 11 under Standard Operations.

#### **Contingencies:**

1. If, after start-up of the bypass system, we encounter any unforeseen problem(s) with fish collection, we will immediately consult with the HCP Coordinating Committee on how to correct the problem(s).
2. If we accumulate many fish during a collection period (e.g. just after a hatchery release), we will only handle/sample the number of fish needed to satisfy the study requirements and then immediately release the remaining fish back into the bypass pipe.

**Diversion Screen and Trashrack Cleaning (Units 1 and 2):**

During the last week of March, the trashracks in front of Units 1 and 2 (six intakes total) will be cleaned by divers and clammed to remove any dislodged debris. The trash rack cleaning will be repeated as differentials increase across the racks due to debris load. A mid-season cleaning will be scheduled in June. Starting 1 April, the vertical barrier and diversion screens (IS system) will be cleaned one to two times per week or as needed with an automated screen cleaner. Careful observation of trash build up will also be monitored and the screens will be cleaned on a more regular basis if warranted. Frequency of the cleanings may increase depending on debris load during spring run-off and aquatic plant load in the summer. The District will log each screen cleaning, and in the event of high descaling/injury in a single sample, the vertical barrier and diversion screens will be inspected prior to releasing marked fish.

Discussion

The 2017 biological studies at Rocky Reach will encompass the following: 1) a continuing evaluation of the juvenile bypass system, and 2) a daily sampling program to monitor fish passage for run timing. Representatives of various research agencies and the HCP Coordinating Committee will be consulted about the development of detailed study plans and protocols. A time line showing important activities and deadlines for these activities has been developed and is presented in Table 2.

**Table 2. Tasks and deadlines for the Rocky Reach 2017 biological evaluations.**

**Glossary of Abbreviations, Acronyms, and Terms  
For the 2016 Report**

- Acoustic Tag. A surgically implanted device that offers an efficient means of remotely tracking fish in three dimensions with sub-meter resolution.
- BC Bypass Conduit. Fish transportation pipe that includes all fish conveyance structures (pipe, flumes, channels, and outfall) downstream of the ring-follower gates on the forebay wall to the discharge point in the tailrace.
- Diversion Screen. The inclined section of the intake screen system, extending from the bottom of the VBS used to divert fish from water entering the turbine intake.
- FBE Fish Bypass Efficiency. The percentage of fish passing the project through the fish bypass system (surface collector and screens).
- FPE Fish Passage Efficiency. The percentage of fish passing the project through non-turbine routes.
- IS Intake screen. The combined diversion screen and vertical barrier screen system installed in a turbine intake to divert fish from the flow entering the turbine.
- ISS Intake Screen System. Screens (diversion and vertical barrier) and associated screen cleaner, bulkheads, closures, roof seals, weir boxes, slide gates, and controls which are found within the turbine intakes of units 1 and 2.
- JFBS Juvenile Fish Bypass System. The overall fish bypass system consisting of the surface collector and the intake screen system.
- JSF Juvenile Sampling Facility. A structure that includes conduits, channels, a raceway, pumping equipment and systems used for fish monitoring and sampling activities.
- PIT Passive Integrated Transponder. Small radio frequency tags with unique identification codes that are injected into fish for identification at specific monitoring locations after releases.
- ROR Run of River. Used in reference to actively outmigrating smolts that are captured at the JSF.
- SC Surface Collector. A structure positioned in the forebay to collect juvenile salmon and steelhead from surface flows, before the flows dive and enter a turbine intake. The

structure includes components such as an entrance, dewatering screens, weir box, and transportation channel.

VBS Vertical Barrier Screen. The vertical section of the intake screen.

### Summary

The District constructed and installed a permanent bypass system from September 2002 to March 2003. The system consists of one surface collector (SC) and the intake screen system (ISS) in turbine units 1 and 2. Flow through the current SC entrance is designed for 6 kcfs. For additional information referring to the construction and configuration of the juvenile fish bypass system, please refer to the *Biological Evaluation of the Rocky Reach Juvenile Fish Bypass System 2005* (Schoolcraft and Mosey 2006).

Multiple studies were conducted during the 2016 biological evaluation. The first priority and primary goal was to assure that the system was safe for fish prior to and during the juvenile outmigration. Marked fish releases with hatchery spring Chinook yearlings were conducted in late March to verify that the system was working properly and to locate any areas where descale, injury, and mortality might occur. The District's goal was to find and immediately repair any problems prior to the 1 April start date. Ongoing sampling at the juvenile sampling facility (JSF) occurred throughout the outmigration to: 1) assure that the system remained safe for migrating juveniles and 2) provide standardized juvenile fish capture rate data to supplement Program RealTime's (University of Washington) run-timing predictions at Rocky Reach. The bypass capture rate, along with Program RealTime and species composition data, guided decisions about initiating 2016 operations for the timing of summer fish spill.

A total of 63,062 fish were collected during the 2016 sampling season; 56,288 fish were collected in the spring (1 April to 6 June) and 6,774 fish were collected in the summer (7 June to 31 August). The season-wide species composition for 2016 is as follows: 25.1% yearling chinook, 13.0% subyearling chinook, 1.0% steelhead, 58.8% sockeye, and 2.1% coho.

The Season-wide estimates for all species in 2016 for descale, injury and mortality are as follows: descale (0.16%), injury (0.13%) and mortality (0.01%). None of the three metrics, (descale, injury, mortality) exceeded the critical thresholds over three consecutive days of sampling, and no marked fish releases through the bypass system were required during bypass operations in 2016.

## Introduction

In 2016, the Rocky Reach juvenile fish bypass system (JFBS) began operation on 1 April. The Chelan County Public Utility District (District) used the JSF for monitoring the physical condition of fish and species composition. The District also used the facility to evaluate seasonal run timing for target species. For additional history and developmental test of the juvenile fish bypass system, please refer to Schoolcraft and Mosey (2006).

Juvenile salmonids were routinely sampled to determine run timing and to visually examine fish for any descale, injury, and mortality. Species that were monitored on a daily basis during the 2016 out-migration for species composition and species condition included yearling and subyearling chinook salmon, steelhead trout (*O. mykiss*), sockeye salmon (*O. nerka*) and coho salmon (*O. kisutch*).

Major objectives for the 2016 biological evaluations were:

- ◆ to examine the daily species composition of fish using the JFBS
- ◆ to use bypass capture rate data, along with Program RealTime and species composition data to guide decisions about initiating 2016 operations for the timing of summer fish spill (Mosey, 2016), and
- ◆ to evaluate the physical condition of fish using the JFBS.

## Materials and Methods

### Guidance Equipment

#### *Surface Collector (SC)*

The SC is located in the cul-de-sac of Rocky Reach Dam, adjacent to the forebay wall and generating units 1, 2, and 3. The SC consists of three major subparts: entrance, dewatering and passage channels, and pump station (Figures 1 and 2). These components were designed to meet specific hydraulic performance criteria which provided for collection of outmigrating juvenile fish. For more detail about SC configuration and operations, please refer to Schoolcraft and Mosey (2006).

#### *Intake Screen System (ISS) – Units 1 & 2*

The ISS encompasses the intake screens in Generating Units 1 and 2 (Figure 3). This system is designed to guide fish that have been drawn into the intakes up into the gate well slot for collection. For more detail about ISS configuration and operations, please refer to Schoolcraft and Mosey (2006).

Debris accumulations on the diversion and Vertical Barrier Screens (VBS) were monitored by measuring head loss across the screens and by visual observations with an underwater camera. The screens in Units 1 and 2 were cleaned by an automated screen cleaner system.

### Juvenile Fish Bypass System Operations

SC and ISS operations for the JFBS began on 1 April and continued through 31 August 2016.

#### *Sampling Protocol*

Sampling at the juvenile collection facility began on 1 April 2016. Juvenile salmonids were primarily collected during four 30 minute periods each day (7 days/week). In previous years, during afternoon and late-night collections (outside of the aforementioned periods), the juvenile facility was routinely monitored to avoid collecting and holding more fish than necessary for daily acoustic tagging and releases. The length of time needed to collect adequate numbers of fish for District studies varied depending on the number of spring migrants in the river. The collection and sampling schedules conformed to the schedules developed for acoustic tag evaluations and descale and injury evaluations. Please refer to Schoolcraft and Mosey (2006) to review the procedure for handling and sampling fish at the juvenile facility. In 2016, no collections were performed outside of the primary collection period (0800 to 1100 hours).

#### *Species Composition*

The primary collection period was used as the index to estimate daily run timing for each species. Sampling occurred seven days a week, April through August.

#### *Run-of-River Fish Condition Evaluations*

Fish that entered the JFBS were routinely monitored for descale, injury, and mortality from 1 April to 31 August. Please refer to Pacific States Marine Fisheries Commission (2003) for classification of descale and injury guidelines. Fish condition evaluations were conducted by trained surface collector personnel to maintain consistency in interpretations. A maximum of approximately 100 fish of each species of interest were examined from each day's primary collection period.

#### *Marked Fish Condition Evaluations*

To determine if the JFBS was causing descale, injury, or mortality prior to system start-up on 1 April, hatchery fish were marked with either a right or left ventral fin clip and released into the bypass system at established release sites. Only fish with no previous descale or injury were used in these evaluations. Upon recapture, marked fish were re-examined and levels of descale, injury, and mortality were summarized using the same guidelines and procedures as described above for ROR condition evaluations.

The four locations for marked fish releases in 2016 included: 1) the SC north channel upstream from trashrack, 2) the SC south channel upstream of trashrack, 3) Unit C1, and 4) Unit C-2. Releases were conducted with hatchery spring chinook prior to the 1 April start date to determine if the JFBS was working properly and to help isolate potential sources of descale, injury, and mortality. Routine marked fish releases were not done after initial evaluations and were not resumed because the percentage of descale, injury or mortality never exceeded the levels established in the 2004 Rocky Reach study plan for the biological evaluation (Mosey et al. 2004).

## Results

### Hydraulic Conditions

#### *Juvenile Fish Bypass System (JFBS) Flows*

The 24-hr average entrance flows for the SC (both channels) and ISS weir box flows (combined flow for the 12 weirs) are presented in Appendix A along with river temperatures. Actual SC entrance flow at the North Channel averaged 2,960.7 cfs and flow at the south channel averaged 3,050.1cfs; ISS collection flow averaged 102.8 cfs from 1 April to 31 August.

### Juvenile Fish Bypass System (JFBS) Sampling

#### *Overview of 2016 JFBS Operations*

The SC and ISS operated throughout the season, except when they were temporarily shut down for repairs or debris removal. Unit 1 and 2 intake screens were cleaned with an automated screen cleaner. The units were not shut down while the intake screens were cleaned, however a reduction in load (12.5 kcfs to 7.0 kcfs) was necessary to move the screen cleaner across the screens. As the amount of debris increased with spring runoff and growth of milfoil, frequency of cleaning was adjusted accordingly to keep up with the influx of debris. The JFBS was monitored 24-hours/7-days a week for debris build-up on the SC trash racks, SC dewatering screens and turbine unit intake screens. Racks, screens, gates and pipes were cleaned daily as needed by District bypass attendants. When high differentials were observed at the trashracks in units 1 and 2, an outage period of 5 to 6 hours was usually required for divers to manually remove debris from the trashracks in both units.

#### *Species Composition*

A total of 63,062 fish were collected during the 2016 sampling season; 56,288 fish were collected in the spring (1 April to 6 June) and 6,774 fish were collected in the summer (7 June to 31 August). The season-wide species composition for 2016 was as follows: 25.1% yearling chinook, 13.0% subyearling chinook, 1.0% steelhead, 58.8% sockeye, and 2.1% coho (Figure 4). For the entire 2016 outmigration, the collection of fish from the JFBS for the biological evaluation took approximately 266 hours. Species composition of smolts in daily samples is summarized for the spring and summer study periods in Appendix B. In general, chinook yearlings and sockeye were the predominant species captured during April into early June. Steelhead and coho migrated through Rocky Reach Dam in early April through late May. Chinook subyearlings were the dominant species collected in June through the end of August comprising 99.0% of the daily totals during the summer months. Proportions of adipose-clipped salmonids sampled at Rocky Reach Dam (2003-2016) are summarized in Table 1, and daily adipose-clipped rates can be found in appendix B.

**Table 1. Proportions of adipose-clipped juvenile salmonids sampled at the Rocky Reach JSF from 2003-2016.**

| <b>Percent of Adipose-Clipped Fish Sampled</b> |                          |                             |                  |                |             |

During the spring migration, salmonid species were the primary species captured. During the summer migration, other ‘resident’ fishes were captured, including chiselmouth minnows (*Acrocheilus alutaceus*), peamouth minnows (*Mylocheilus caurinus*), northern pikeminnows (*Ptychocheilus oregonensis*), mountain whitefish (*Prosopium williamsoni*), redbelt shiners (*Richardsonius balteatus*), sticklebacks (*Gasterosteus aculeatus*) sucker species (*Catostomas sp.*), rainbow trout (*Oncorhynchus mykiss*), kokanee (*Oncorhynchus nerka*), and bluegill (*Lepomis macrochirus*).

Other resident fish of special interest include juvenile and adult pacific lamprey (*Entosphenus tridentatus*) and bull trout (*Salvelinus confluentus*). During 2016, a total of 3 juvenile pacific lamprey (3 migratory, 0 non-migratory) and 1 juvenile bull trout were collected. Five adult pacific lamprey were collected in 2016 and were released upstream at Lincoln Rock Park. Any of these fish that were exposed to anesthesia were allowed to recover for 2 hours before being released back into the bypass (Appendix C).

#### *Run-of-River Fish Condition Evaluations*

Chinook yearlings and subyearlings, steelhead, sockeye, and coho were collected at the juvenile facility from the JFBS and routinely inspected for descale, injury and mortality. The results from daily samples are reported in Appendix D. The District, with guidance from the Habitat Conservation Plan Coordinating Committee (HCPCC), set descale, injury, and mortality critical threshold levels at 5%, 3% and 2%, respectively. For more information about the threshold levels for fish condition, please refer to Schoolcraft and Mosey (2006). Descale estimates remained

below 0.2% in 2016. Figure 5 compares the season-wide descale percentage for all species from 2007 to 2016.

Injury is characterized by lacerations or bruises occurring to any part of the head or body. These types of injuries as well as severe descaling can lead to mortality. In 2016 the season-wide injury (Figure 6) estimates for the bypass system remained below 0.2%.

Mortalities collected during the spring and summer sampling were categorized as being *river*, *facility*, *sample*, or *research* mortalities. A *river* mortality is any fish “long-dead” on arrival in the raceway and defined by body characteristics such as pale or blotchy coloration and soft body condition. A *facility* mortality is classified as any fish recently dead, or near death upon arrival in the raceway, and exhibits fresh descale or injury. A *sample* mortality is any fish that dies as a result of the sampling activity itself. A *research* mortality is any fish that dies as a result of transferring and/or holding fish in research holding tanks for the purpose of further study or evaluation. In 2016, the percent mortality (Figure 7), estimate was below 0.01%. The results from daily samples are reported in Appendix D. Proportions of descale, injury and mortality of salmonids sampled at Rocky Reach Dam (2008-2016) are summarized in Table 2.

**Table 2. Comparison of descale, injury and mortality rates at the Rocky Reach JSF Years 2008 through 2016.**

| Descale %          |       |       |       |       |       |       |       |       |       |

*Marked Fish Condition Evaluations*

Fish recovered from marked fish releases (prior to bypass operation on 1 April) were examined for descale, injury, and mortality associated with passage through the JFBS. Results from individual test groups are summarized in Appendix E. On March 24, 2016, the District conducted four marked fish releases. Of the initial 396 fish released, 384 were recaptured. All of the recaptured fish were examined for descale, injury, and mortality. Of the 384 recaptured fish, two showed signs of descale (1 from the SC North Channel and 1 from the Unit 2 release). No recaptured fish exhibited any observable injury and no mortalities occurred in any of the releases. Fish appeared healthy and energetic.

## Discussion

### Juvenile Fish Bypass System Species Composition and Observations

Species composition of smolts migrating through Rocky Reach Dam in 2016 varied somewhat from that observed in 2015. Sockeye comprised the largest percentage of smolts sampled in the JFBS, with the percentage increasing from last year (58.8% of the total composition in 2016 compared with 30.6% in 2015). Meanwhile yearling chinook decreased to 25.1% in 2016 compared to 32.9% in 2015, while subyearling chinook decreased from 26.5% to 13.0% in 2016. Steelhead also decreased from 4.9% to 1.0% in 2016. The proportion of coho decreased from 5.1% to 2.1% in 2016. There was a slight increase in the percentage of adipose-clipped Chinook yearlings from 2015 to 2016, 91.6% to 91.8% respectively, while subyearling Chinook increased from 30.5% to 34.7% respectively. Steelhead smolts decreased from 68.5% proportion of adipose-clipped smolts in 2015 to 34.7% in 2016. The proportion of adipose-clipped sockeye decreased slightly from 0.02% in 2015 to 0.01% in 2016, and coho decreased from 1.2% in 2015 to 0.3% in 2016.

Season-wide estimates of descale, injury, and mortality for all species combined was 0.16%, 0.13%, and 0.01% respectively. At no time during the 2016 spring and summer sampling months did fish condition reach critical threshold levels triggering marked fish releases. This is important to note as during the winter of 2009-2010, the flow-spreaders above the weir box were replaced with fiberglass flow-spreaders that housed 2 PIT tag antennas each. In the seventh year of bypass operation with the new flow-spreaders, descale, injury, and mortality levels for all species continues to be low and comparable to levels observed with the original flow spreaders installed.

Observed incidence of predations marks on smolts utilizing the JFBS in 2016 was 0.3%.

### **Conclusions from the 2016 Evaluations**

- ◆ Flow spreaders with PIT antennas continue to be fish-friendly
- ◆ Season-wide estimates of descale, injury and mortality did not exceed 0.2% for all species during the fourteenth year of operation of the permanent bypass system.

### **2017 Bypass Operations and Survival Studies**

In 2017, the District will not be conducting a survival study at Rocky Reach, as Phase 3 Standards Achieved has been reached for all planned spring migrants. The District will continue to evaluate seasonal run-timing, species composition, and physical condition of ROR fish at the JSF in 2017.

## **Acknowledgements**

Several District employees assisted in the implementation of the 2016 evaluations. Alene Underwood, Todd West, and Thad Mosey provided logistical and administrative help. Chris Nystrom and the bypass operators oversaw day to day operation of the JFBS. CM mechanics and wiremen performed critical maintenance and repairs. Fish and Wildlife personnel assisting with the 2016 Rocky Reach evaluations included: Dennis Litchfield, Dave Beardsley, Todd Jackson, Josh Boyd, Nathan Clark, Chris VanWey, and Paul Edwards.

## Appendix K

# 2017 Fish Spill Plan Rock Island and Rocky Reach Dams

---

**2017 Fish Spill Plan**

**Rock Island and Rocky Reach Dams**

**Public Utility District No. 1 of Chelan County**

Prepared By:

Thad Mosey  
Fisheries Biologist

Public Utility District No. 1 of Chelan County  
Wenatchee, Washington

**Final**  
March 28, 2017

## **Introduction and Summary**

In 2017, Public Utility No. 1 of Chelan County (Chelan PUD) will implement spill operations for fish passage at the Rock Island and Rocky Reach and projects. Spill timing and spill percentages are specified by the anadromous Habitat Conservation Plans (HCP) for each respective project. Chelan PUD conducted juvenile project survival studies from 2002 through 2011 at Rocky Reach and Rock Island under varying spill levels in order to achieve HCP survival standards. The Rock Island Project completed multiple survival studies over a nine year period (17 total studies) for spring migrating Plan Species (yearling Chinook, steelhead, sockeye), first using a 20 percent spill level, then a 10 percent spill level. Rock Island will continue to spill 10 percent of day average flow during the spring outmigration period through at least year 2020. Rocky Reach completed its suite of HCP survival studies for spring migrating Plan Species in 2011 (14 studies), under spill and no-spill operation at the dam. HCP juvenile survival standards were achieved for species tested with a no spill operation (yearling Chinook, steelhead, sockeye). Project spill levels are summarized in Tables 2 and 4 of this plan. Chelan PUD holds valid Incidental Take Statements (ITS) from National Oceanic and Atmospheric Administration Fisheries (NOAA) and the United States Fish and Wildlife Service (USFWS) for HCP fish spill operations at Rocky Reach and Rock Island dams.

For the 2017 juvenile outmigration, Chelan PUD will operate the Rocky Reach juvenile fish bypass system (JFBS) starting 1 April for the spring juvenile outmigration of yearling Chinook, steelhead, and sockeye. Spring spill at Rocky Reach Dam will consist of hydraulic spill for reservoir control only. HCP Project survival standards were achieved with bypass-only operations. During the subyearling Chinook outmigration in 2017, Rocky Reach will spill 9 percent of day average river flow for a duration covering 95 percent of subyearling outmigration past the dam.

At Rock Island Dam in 2017, Chelan PUD will operate the Project with a 10 percent day-average spill level for the spring outmigration period. Rock Island has also completed HCP spring Plan Species survival testing for all Plan Species with a 10 percent spill level at the dam and has achieved juvenile survival standards for yearling Chinook, steelhead and sockeye and combined adult-juvenile survival for all three species.

During the summer period in 2017, Rock Island Dam will spill 20 percent of the day-average river flow for the outmigration of subyearling (summer) Chinook. Spill is the primary means of juvenile salmon and steelhead passage at Rock Island per Section 5.4.1(a) of the Rock Island HCP. Spring and summer spill will cover 95 percent of the juvenile fish outmigration for yearling/subyearling Chinook, steelhead, and sockeye in 2017.

### **Rocky Reach Juvenile Fish Bypass Operations**

Rocky Reach will operate its JFBS continuously through the spring outmigration period, beginning 1 April 2017. Daily index sampling (for steelhead, yearling Chinook, and sockeye) will be performed at the bypass sampling facility to estimate the outmigration percentiles for each species through the spring period. During “index sampling” each day, a total of four 30-minute samples (Table 1) will be taken beginning at the top of each hour, 0800 to 1100 hours. Spring spill for fish passage is not required at Rocky Reach in addition to the JFBS operation, but periods of forced spill may occur under high river flows. Some level of forced spill (river flow above 201 kcfs turbine capacity) normally occurs at Rocky Reach in the spring. Over the past 20 years, forced spill has occurred approximately 28 percent of all hours, April through June.

Sampling protocols at the Rocky Reach bypass system in 2017 will remain consistent with those used in 2004-2016. Daily sampling in spring and summer periods (Monday through Sunday) will use four 30-minute “index periods” at 0800, 0900, 1000, and 1100 hours (Table 1). The sample target for each 30-minute sample will be 350 smolts during the spring period (yearling Chinook, steelhead, and sockeye combined), and 125 smolts for summer period (subyearling Chinook). If the number of fish collected in the bypass sampling raceway is estimated to reach the maximum number prior to completion of the 30-minute sample, the sampling screen will be retracted from the bypass conduit, and the number of fish collected in the shortened sample period will be proportionately expanded to the entire 30-minute period.

Table 1. Index sampling times at the Rocky Reach juvenile fish bypass and the number of smolts per sample. Sample times and sample targets have remained consistent since 2004.

| Time        | Sample Duration | Number of Smolts          | Day of Week   |
|-------------|-----------------|---------------------------|---------------|
| 08:00-08:30 | 30 minutes*     | 350 (spring) 125 (summer) | Monday-Sunday |
| 09:00-09:30 | 30 minutes*     | 350 (spring) 125 (summer) | Monday-Sunday |
| 10:00-10:30 | 30 minutes*     | 350 (spring) 125 (summer) | Monday-Sunday |
| 11:00-11:30 | 30 minutes*     | 350 (spring) 125 (summer) | Monday-Sunday |

\*Sample duration may be less than 30 minutes if smolt numbers are met prior to full 30 minute sample time

### Rocky Reach 2017 Summer Spill Operations

Rocky Reach Dam will spill 9 percent of the estimated day average river flow for the subyearling Chinook outmigration (Table 2). Spill will commence in late May to early June upon arrival of subyearling Chinook smolts in the Rocky Reach bypass samples. Juvenile run-timing information at Rocky Reach will be used to estimate subyearling Chinook passage percentiles (from the University of Washington’s Program RealTime run forecaster) and guide spill operations to cover 95 percent of the summer outmigration. Actual subyearling counts in combination with juvenile passage estimates from the University of Washington’s Program RealTime run forecaster will determine start and stop dates for the summer spill program.

The HCP guidelines for starting and ending summer spill at Rocky Reach are as follows:

1. Summer spill will start at midnight no later than the day on which the estimated 1-percentile passage point is reached, as indicated by Program RealTime run-forecast model. Subyearling Chinook will be defined as any Chinook having a fork length from 76 to 150 mm.
2. Summer spill season will generally end no later than 15 August, but not until subyearling index counts from the juvenile bypass sampling facility are 0.3 percent or less of the cumulative run for three out of any five consecutive days (same protocol used 2004-2016) and Program RealTime is estimating that the 95<sup>th</sup> percentile passage point has been reached. In addition, spill operations must cover at least 95% of the subyearling outmigration

### Diel Spill Shaping at Rocky Reach and Rock Island Dams

Daily spill volumes will be shaped within each 24-hour period at Rocky Reach Dam during the summer spill period, and at Rock Island Dam during both spring and summer spill periods (Tables 2 and 4).

Spill-shaping attempts to optimize spill water volume to maximize spill passage effectiveness for smolts. The diel spill shape functions to provide either higher or lower spill volume during periods of either higher or lower fish passage. Spill-shaping is based on the observed diel (24-hour) passage distributions of smolts at each project during spring and summer (Steig et al. 2009, Steig et al. 2010, Skalski et al. 2008, Skalski et al. 2010, Skalski et al. 2011, Skalski et al. 2012). The different spill percentages and time blocks are shaped such that the summation of water volume from all time blocks within the day equals the volume of water that would have been spilled under a constant, unshaped spill level (i.e. spill at 9 percent day-average river flow at Rocky Reach with no shaping). The hourly spill shape in 2017 will remain consistent with previous years, 2004-2016. Spill gates 2 through 8 will be used to meet daily spill percentage targets.

Table 2. Fish spill percentages and spill shape for the Rocky Reach spill program, 2017.

| Project     | Season  | Daily Spill Average | Within-Day Spill Levels | Duration (# of hours each day) | Hourly Blocks of Spill | Spill Shape % |
|-------------|---------|---------------------|-------------------------|--------------------------------|------------------------|---------------|
| Rocky Reach | Spring  | none                | --                      | --                             | --                     | --            |
| Rocky Reach | Summer* | 9%                  | Med                     | 1                              | 0000-0100              | 9.0           |
|             |         |                     | Low                     | 6                              | 0100-0700              | 6.0           |
|             |         |                     | Med                     | 2                              | 0700-0900              | 9.0           |
|             |         |                     | High                    | 6                              | 0900-1500              | 12.0          |

\*Spill for subyearling Chinook

### 2017 Run-Timing Predictions

Chelan PUD contracts with the University of Washington (UW) to provide run-timing predictions and year-end observed values for spring and summer out-migrating percentiles for salmon and steelhead. UW's Program RealTime run-time forecasting model is used for this purpose. Program Real-Time provides daily forecasts and cumulative passage percentiles for steelhead, yearling/subyearling Chinook and sockeye at both Rocky Reach and Rock Island dams. This program enables Chelan PUD to better predict the time when a selected percentage of these species will arrive, and when a given percentage of any stock has passed. The program utilizes daily fish counts from the Rocky Reach bypass sampling facility and the juvenile fish bypass trap at Rock Island Dam. Estimates of passage percentiles are generated with the model's forecast error and are displayed with the daily predictions at:

<http://www.cbr.washington.edu/crisprt/>

## Historic Run Timing

Estimated mean passage dates (first percentile to the 95<sup>th</sup> percentile) for each species at Rocky Reach and Rock Island dams are summarized in Table 3. Run-timing dates are estimated from daily index sample counts at the Rocky Reach JFBS (2004-2016), and from the Rock Island bypass trap, (2002-2016). At Rocky Reach Dam, the subyearling Chinook run generally begins the first week of June, with the one-percentile passage date on 31 May (mean date for years 2004-2016). Rocky Reach subyearling passage reaches the 95<sup>th</sup> percentile, on average, around 7 August (2004-2016, range: 21 July to 24 August).

Rock Island Dam juvenile salmon and steelhead sampling from the Smolt Monitoring Program (SMP; 2002-2016) indicates that the first percentile (one-percent passage) mean passage date for combined spring migrants (yearling Chinook, steelhead, and sockeye) occurs around 18 April (Table 3). The latest spring spill start date for Rock Island Dam per the HCP is 17 April. The summer outmigration of subyearling Chinook smolts at Rock Island Dam generally begins in early June (although fry are encountered earlier), and on average, reaches the 95<sup>th</sup> percentile passage point around 7 August (range: 22 July to 19 August, 2002-2016).

Table 3. Spill percentages, bypass operation dates, and mean passage percentile dates (2002-2016) for the 1<sup>st</sup> and 95<sup>th</sup> percentile passage points for HCP spring and summer outmigrants at Rocky Reach and Rock Island dams.

### **Rock Island 2017 Spring Spill Operations**

In 2017, Rock Island Dam will spill 10 percent of the estimated day average river flow starting no later than 17 April and will end spill after 95 percent of spring outmigrants have passed the dam (usually the first week of June), with spill being provided for at least 95% of the spring species outmigration. Spill volume will be shaped to maximize spill efficiency (Table 4). Chelan PUD personnel will operate the Rock Island bypass trap, an upper Columbia SMP site, continuously from 1 April through 31 August (seven days per week) to provide daily smolt counts. Index counts will provide the basis to determine the start and end of the spring and summer outmigration periods. The HCP guidelines to start and end the spring spill program at Rock Island Dam are as follows:

1. The Rock Island spring spill program will begin when the daily smolt passage index count exceeds 400 fish for more than 3 days (this corresponds to the approximately 5 percent passage date), or no later than 17-April, as outlined in Section 5.4.1. (a) of the Rock Island HCP.
2. Rock Island spring spill will end 1) following completion of the spring outmigration (95 percent passage point), and 2) when subyearling (summer) Chinook have arrived at the Project.

Operators will utilize the following spill gate sequence to meet daily spill percentage targets: 32, 31, 30, 1, 26, 16, 18, 24, 29, 17, 19, 20, 22, 25, 7, and 8.

### **Rock Island 2017 Summer Spill Operations**

Rock Island will spill 20 percent of the estimated daily average river flow for a duration covering 95 percent of the summer outmigration of subyearling Chinook. Daily smolt counts from the Rock Island bypass trap will inform decisions on when to start and stop spill. The HCP guidelines to start and stop summer spill at Rock Island Dam are outlined as follows:

1. Rock Island summer spill in 2017 will begin immediately after completion of the spring spill. The summer spill level will be 20 percent of day average flow, shaped to increase spill efficiency. Spill will continue for a duration covering 95 percent of the subyearling Chinook outmigration.
2. Summer spill will generally end no later than 15 August, or when subyearling Chinook counts from the Rock Island trap are 0.3 percent or less of the cumulative run total for

three out of any five consecutive days, and UW's Program RealTime is estimating 95 percent run completion (same protocol used in 2004-2016).

Operators will utilize the following spill gate sequence to meet daily spill percentage targets: 32, 31, 30, 1, 26, 16, 18, 24, 29, 17, 19, 20, 22, 25, 7, and 8.

\*Spring spill for yearling Chinook, steelhead, and sockeye; \*\*summer spill for subyearling Chinook.

### Spill Program Communication

Chelan PUD's HCP representative will notify the HCPCC not less than once per week when fish passage numbers indicate that specific triggers for starting or stopping spill are likely to occur in the immediate future. Chelan PUD will notify the HCPCC regarding any unforeseen issues that pertain to the spill program as the season progresses. Communications with the HCPCC on spill information will generally be made by email, pre-scheduled conference calls, and HCPCC monthly meetings.

## Executive Summary

On February 19, 2009, the Federal Energy Regulatory Commission (FERC) issued a new operating license for the Rocky Reach Hydroelectric Project (Rocky Reach Project or Project) which is owned and operated by the Public Utility District No. 1 of Chelan County (Chelan PUD). Pursuant to the requirements of the Federal Power Act (FPA), the FERC adopted in its entirety, the conditions identified within the 401 Water Quality Certification (401 Certification; Ecology 2006) issued on March 17, 2006 by the Washington Department of Ecology (Ecology) pursuant to Section 401 of the CWA (Order 3155).

Section 5.4(1)(d) of the 401 Certification requires a “Determination of Compliance” in the fifth year of the effective date of the Rocky Reach Project License which requires Chelan PUD to prepare a report summarizing the results of all Total Dissolved Gas (TDG) studies performed to date, and describing whether compliance with the numeric criteria had been attained (Ecology 2006). On January 30, 2015, Chelan PUD submitted to the Washington Department of Ecology (Ecology) a Final TDG: Step One, Year Five Compliance Report (Chelan PUD 2015) in accordance with the 401 Certification and Rocky Reach Project License. On July 15, 2015, Ecology issued a letter of determination (Ecology 2015) stating that the Rocky Reach Project “approaches but does not quite achieve full compliance with the applicable numeric criteria for TDG.” However, Ecology also determined that despite not achieving full compliance, aquatic life is not adversely affected.

Section 5.4(1)(e)(2) of the 401 Certification states that if Ecology determines that aquatic life has not been adversely affected by TDG resulting from ongoing Project operations, Chelan PUD shall consult with Ecology and the Rocky Reach Fish Forum (RRFF) to determine if any additional reasonable and feasible measures may exist to meet the TDG standards. If Chelan PUD concludes that no other additional reasonable and feasible measures exist to reduce TDG, Chelan PUD may petition Ecology to modify the standards as detailed in Section 5.4(1)(f-g).

This TDG Abatement Alternatives Analysis (TDG AAA) has been developed consistent with Section 5.4(1)(e)(2) of the 401 Certification (Ecology 2006). It is based upon both historic and the most current regional and site-specific TDG information regarding potential operational and structural abatement measures. It serves as the basis for consultation to determine if any additional reasonable and feasible measures may exist to meet the TDG standards for the Rocky Reach Project.

This analysis compiled all relevant site-specific and regional information regarding both operational and structural TDG abatement alternatives. Results of the literature review indicated that numerous TDG abatement measures had already been compiled and evaluated for their potential as reasonable and feasible TDG reduction alternatives for the Rocky Reach Project (MWH 2003; Schneider and Wilhelms 2005). Remaining potential alternatives identified from results of these assessments formed the basis for a multi-disciplinary review regarding potential operational, coordination, financial, regulatory, and environmental implementation concerns and whether additional alternatives should be included.

Results suggest that all of the alternatives evaluated would likely produce some level of TDG benefit. However, a number of concerns regarding the uncertainty around impacts to generation, environmental resources, and the feasibility of operational implementation were identified. In addition, both of the structural measures identified would likely require significant capital costs to implement with reoccurring operations and maintenance (O&M) costs. Any further evaluation of any of the alternatives in the future will require detailed site-specific assessment and in some cases require additional physical, hydraulic and financial evaluations to more accurately scope the TDG benefit relative to the overall implementation cost. Furthermore, previous site specific TDG assessments have noted that the current spillway infrastructure already have the unintended impact of moderating TDG exchange. Structures such as the nappe deflector, continuous baffle, and high stilling basin end sill provide sufficient energy dissipation over the short length of the stilling basin. The combination of efficient energy dissipation in a shallow stilling basin with an end sill that produces a surface oriented jet entering the adjoining tailwater channel result in TDG pressures that are similar to projects with retrofitted TDG abatement structures (Schneider and Wilhelms 2005).

Existing spillway infrastructure appears to already provide TDG benefits and coupled with the high cost, nominal TDG benefits, and implementation uncertainties and significant additional information needs of adding structural alternatives evaluated during this analysis, it may be more appropriate to continue exploring, in consultation with Ecology, the Rocky Reach Fish Forum (RRFF), and the Habitat Conservation Plan Coordinating Committee (HCP CC), operational alternatives such as a flattened spill configuration. This would allow for a more incremental approach to evaluating TDG benefits versus costs and other potential impacts including to aquatic resources.

## 1.0 INTRODUCTION

On February 19, 2009, the Federal Energy Regulatory Commission (FERC) issued a new operating license for the Rocky Reach Hydroelectric Project (Rocky Reach Project or Project) which is owned and operated by the Public Utility District No. 1 of Chelan County (Chelan PUD). Pursuant to the requirements of the Federal Power Act (FPA), the FERC adopted in its entirety, the conditions identified within the 401 Water Quality Certification (401 Certification; Ecology 2006) issued on March 17, 2006 by the Washington Department of Ecology (Ecology) pursuant to Section 401 of the CWA (Order 3155).

Section 5.4(1)(d) of the 401 Certification requires a “Determination of Compliance” in the fifth year of the effective date of the Rocky Reach Project License which requires Chelan PUD to prepare a report summarizing the results of all Total Dissolved Gas (TDG) studies performed to date, and describing whether compliance with the numeric criteria had been attained (Ecology 2006). On January 30, 2015, Chelan PUD submitted to the Washington Department of Ecology (Ecology) a Final TDG: Step One, Year Five Compliance Report (Chelan PUD 2015) in accordance with the 401 Certification and Rocky Reach Project License. On July 15, 2015, Ecology issued a letter of determination (Ecology 2015) stating that the Rocky Reach Project “approaches but does not quite achieve full compliance with the applicable numeric criteria for TDG.” However, Ecology also determined that despite not achieving full compliance, aquatic life is not adversely affected. Ecology also recommended that measures currently in affect to reduce TDG as identified in the Rocky Reach Water Quality Management Plan should be continued.

Section 5.4(1)(e)(2) of the 401 Certification states that if Ecology determines that aquatic life has not been adversely affected by TDG resulting from ongoing Project operations, Chelan PUD shall consult with Ecology and the Rocky Reach Fish Forum (RRFF) to determine if any additional reasonable and feasible measures may exist to meet the TDG standards. If Chelan PUD concludes that no other additional reasonable and feasible measures exist to reduce TDG, Chelan PUD may petition Ecology to modify the standards as detailed in Section 5.4(1)(f-g).

This TDG Abatement Alternatives Analysis (TDG AAA) has been developed consistent with the relevant requirements identified in the Rocky Reach Project 401 Certification (Ecology 2006) as discussed above. It is based upon both historic and the most current regional and site-specific TDG information regarding potential operational and structural abatement measures. It serves as the basis for consultation to determine if any additional reasonable and feasible measures may exist to meet the TDG standards for the Rocky Reach Project. In Section 2.0 the TDG AAA provides background information on the Rocky Reach Project and associated facilities; operations (including fish spill) at the Project and relevant regional coordination agreements; and applicable TDG standards. Also in this section, TDG management within the mid-Columbia River system relative to Rocky Reach Dam and historic and current Rocky Reach Project TDG activities are also described. Section 3.0 details the methods for identifying and evaluating TDG abatement alternatives. Section 4.0 summarizes the analysis of both operational and structural TDG abatement alternatives and Section 5.0 provides summary conclusions and next steps for TDG management at the Rocky Reach Project.

## 2.0 BACKGROUND

### 2.1 Rocky Reach Project Overview

The Rocky Reach Project is located at approximately river mile (RM) 474 on the mainstem Columbia River in Chelan County, Washington, approximately seven miles upstream of the city of Wenatchee, Washington (Figure 1). It is the eighth dam upstream from the mouth and is a run-of-river hydroelectric project with limited ability to modify river flows. Rocky Reach Dam is located approximately 43 RMs downstream of the Wells Hydroelectric Project, owned and operated by Public Utility District No. 1 of Douglas County; and 21 miles upstream from the Rock Island Hydroelectric Project, owned and operated by Chelan PUD. The Project has an allowable forebay fluctuation of four feet, with minimum forebay elevation of 703 and maximum of 707 feet above mean sea level (msl) for normal operation (710 under special flood control operation). However, in consideration of system reliability for the regional electric grid, the Project rarely allows the forebay elevation to drop below 704 feet. The forebay elevation is usually maintained between 706 and 707 feet. Tailwater elevation is determined primarily by Project discharge, which is managed under the 1997 Agreement for the Hourly Coordination Agreement (HCA), as described later in this Section. On a daily basis, minimum and maximum discharge is related to the fluctuation in flows released from upstream federal dams, the Grand Coulee Project and Chief Joseph Project (Chelan PUD 2006).

The Rocky Reach Reservoir is 43 miles long and the surface area of the reservoir is approximately 8,235 acres at a flow of 100,000 cfs and forebay elevation of 707 feet. The gross storage capacity of the reservoir at 100,000 cfs is 387,500 acre-feet. The volume of water that the reservoir can contain between the minimum and maximum forebay elevation is 36,400 acre-feet. This storage is useable for capturing or augmenting flow on an hourly basis. If inflow to the Project ceased, the reservoir's useable storage would be sufficient only to run the plant for about two hours. The Chelan and Entiat rivers are tributaries of the Columbia River within the Rocky Reach Reservoir (Chelan PUD 2006).

The inflow to the Project is primarily determined by operations of the Federal Columbia River Power System (FCRPS), which is composed of the federal dams and the accompanying electrical system on the Columbia and Snake rivers in Oregon, Washington, and Idaho. The dams are operated by U.S. Bureau of Reclamation (USBOR) and the U.S. Army Corps of Engineers (USACE), and generate hydropower that is marketed by the Bonneville Power Administration (BPA). The FCRPS is managed for a number of objectives, the primary being flood control, power production, protection of fish resources, recreation, and irrigation. In general, the FCRPS is operated to fill upstream storage reservoirs in June, then provide augmented flows for fish passage and power production through the summer. The FCRPS drafts storage reservoirs to meet power demand and salmon spawning requirements through the fall and winter. Depending on snow accumulations and runoff forecasts, during the spring the reservoirs may be further drafted for flood control and to meet flow targets for downstream juvenile salmon migration periods. FCRPS operations from late May to July focus on managing reservoir levels to meet June refill targets and to be full at the end of July. The FCRPS manages for these objectives using storage releases that pass through the Grand Coulee and

Chief Joseph projects and adjusting for inflow from tributary streams above (the Okanogan, Methow and Entiat rivers) and below (Wenatchee and Snake rivers) the Rocky Reach Project. The FCRPS water management determines the daily, weekly and monthly average flows through the Rocky Reach Project (Chelan PUD 2006).

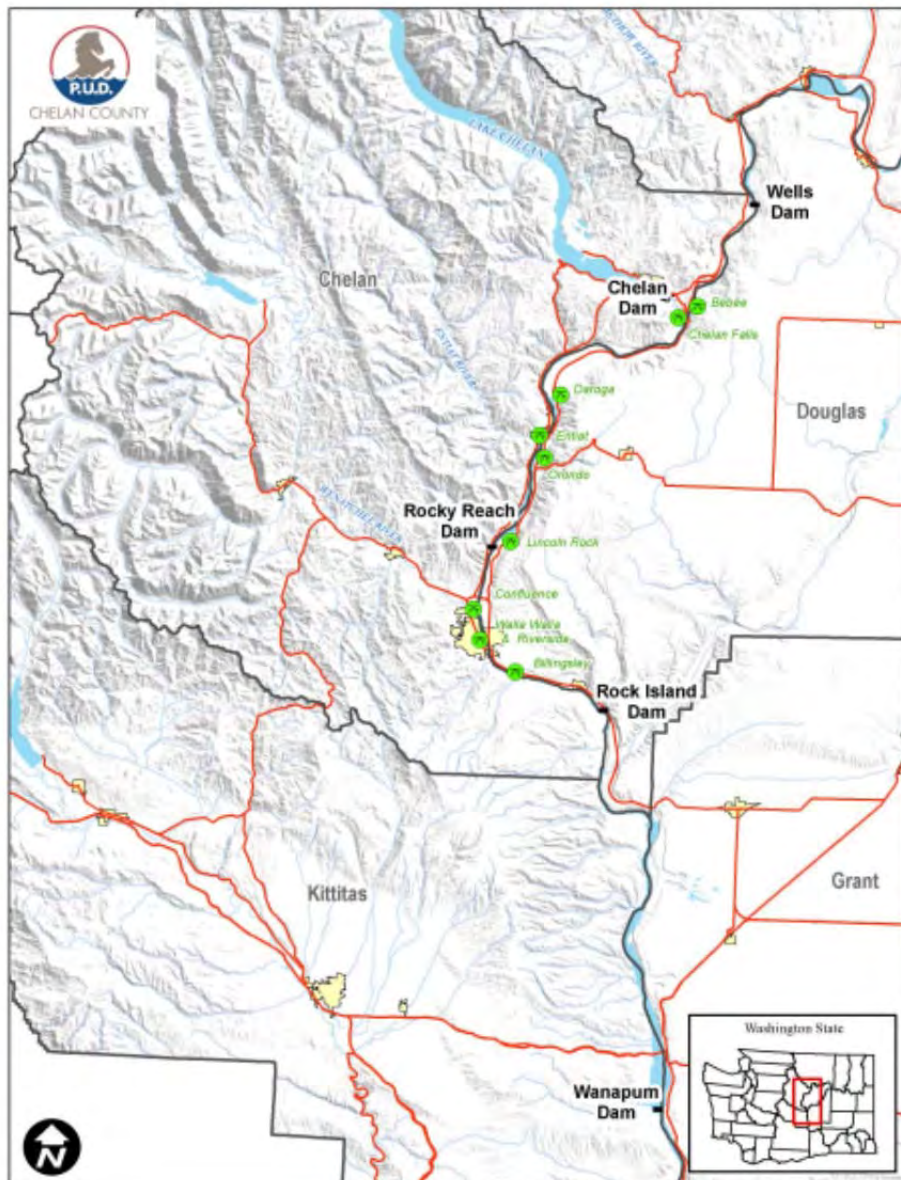

Figure 1. Rocky Reach Hydroelectric Project in Central Washington.

## 2.2 Rocky Reach Dam

Rocky Reach Dam consists of a concrete-gravity structure approximately 130 feet high and about 2,847 feet long (Figure 2). The dam comprises, from left (east) abutment to right (west) abutment, the east abutment blocks, spillway, center dam, powerhouse, and forebay wall. Fish

passage facilities are included in the dam, passing through several of the other structures. Key components of the dam related to TDG management include the spillway and its' operations, powerhouse, and fish passage facilities. These elements are described in more detail below.

**Figure 2. Rocky Reach Dam.**

### **2.2.1 Spillway**

The dam includes a gated spillway that allows regulation of flows and headwater levels in the Rocky Reach Reservoir (Figure 3). The spillway structure is oriented roughly perpendicular to the flow of the river. The spillway section consists of twelve 50-foot-wide bays separated by 10-foot-wide piers. The crest of the ogee spillway section is at elevation 650 feet. Flow through each bay is controlled by a 58-foot-high radial gate. Each gate is operated by a stationary hoist and is equipped for remote operation from the control room in the Project powerhouse.

The spillway capacity is periodically reviewed pursuant to FERC regulations (18 CFR 12.35). The Periodic Safety Inspection Report submitted to the FERC in 1997 found the spillway to have adequate capacity to pass the probable maximum flood (PMF) with a peak flow of 1,260,000 cfs and headwater elevation of 718.3 feet. This elevation would be above deck level, but below the top of the parapet wall (Chelan PUD 2004).

**Figure 3. Rocky Reach Project spillways.**

#### 2.2.1.1 Spillway Operations

The standard Project spill configuration (for fish) uses gates 2 through 8 with a minimum discharge per spill bay of about four thousand cubic feet per second (kcfs). The standard spill configuration was designed to create a crown-shaped pattern of turbulent flow below the spillway with decreasing velocities leading toward the upstream migrating adult fishway entrances.

This spill pattern provides favorable guidance conditions for adult migrant salmon and steelhead. This spill configuration and alternate patterns were tested and it was determined this pattern was as good as, if not better than, the alternate patterns for upmigrating salmonids (Schneider and Wilhelms 2005). The same pattern is used for juvenile downstream migrating fish passage spill. During spill operations, whether for juvenile fish passage, TDG management, or for other purposes, the gates are operated via a computer automated system that follows the spill pattern (Chelan PUD 2016).

Note that although the above referenced crown-shaped pattern may be as good as, if not better, than tested alternate patterns for upstream migrating adult salmonids, it may not be ideal for TDG. According to Section 5.4(1)(b)(6) of the 401 Certification, Chelan PUD shall study

alternative spillway operations using any of gates 2 through 12 (refer to Section 2.5.2.9 below for more information on additional evaluation activities).

In general, there are seven scenarios that may result in spill at Rocky Reach Dam. With the exception of the juvenile salmon Fish Spill scenario, to reduce negative impacts of all other spill scenarios, Chelan PUD has completed a TDG Operational Plan that can be implemented, as needed. The TDG Operational Plan is attached to annual the Gas Abatement Plan (GAP). Chelan PUD anticipates implementation of the TDG Operational Plan to be an operational function, requiring no structural modification to the Project (Chelan PUD 2016).

### Fish Spill

Voluntary spill for fish is a generally ineffective method of bypassing downstream migrating juvenile salmon and steelhead away from the turbines at Rocky Reach Dam (Steig et. al., 1997) and, consequently, is not considered a solution for the long-term fish passage program under the Anadromous Fish Habitat Conservation Plan (HCP). To minimize or eliminate the need for fish-spill, Chelan PUD has focused efforts to increase the fish passage efficiency and survival through the juvenile bypass system (JBS).

The JBS continues to be the most efficient and safe non-turbine route for downstream migrating juvenile fish passage at the Project. The JBS does not require spill for its operation.

#### *Spring Fish Spill Operations*

Operating the JBS exclusively, Chelan PUD has been able to meet the HCP survival standards for the three spring migrants (spring/yearling Chinook, steelhead, and sockeye). Chelan PUD will continue operating the JBS exclusively, with no voluntary spill during the spring (typically from April to late May/early June) which significantly reduced TDG from the pre-fish bypass condition of 15 percent to 25 percent spill of the day average river flow in April and May (Chelan PUD 2013)

#### *Summer Fish Spill Operations*

In 2016, summer spill at Rocky Reach for subyearling Chinook was nine percent of day average flow. Commencement of summer spill has been determined using run-timing information at Rocky Reach Dam via the JBS. Summer spill generally begins in early June and ends in mid-August when 95 percent of the migration of subyearling Chinook has passed the Project.

Due to tag technology limitations and uncertainties regarding their life history (outmigration behavior) no survival studies for subyearling Chinook have been conducted since 2004, nor are any planned within the next three years (Chelan PUD 2016).

### Flow in Excess of Hydraulic Capacity

The minimal storage and limited hydraulic capacity of the Project occasionally force Chelan PUD to spill water past the Project. This spill is required to maintain headwater elevations within the limits set by the Project's FERC license (707 feet), to prevent overtopping of the

Project, and to maintain optimum operational conditions. When spilling for fish or due to excess inflow or generation, the spillway is operated using gate settings that have been shown to limit TDG production and meet fish passage requirements (Schneider and Wilhelms 2005).

#### Plant Load Rejection Spill

This type of spill occurs when the plant is forced off line by an electrical fault, which trips breakers, or any activity forcing the units off line. This is an emergency situation and generally requires emergency spill. When the units cannot pass flow, the flow must be passed by other means, such as spill, to avoid overtopping the dam (Chelan PUD 2016).

#### Immediate Replacement Spill

Immediate replacement spill is used to manage TDG levels throughout the Columbia River basin. The Technical Management Team which includes the National Marine Fisheries Service (NMFS), USACE, and BPA, manages this spill. Immediate replacement spill occurs when TDG levels are significantly higher in one river reach than they are in another reach. To balance the TDG levels throughout the basin, spill is reduced and generation increased in the reach with high TDG levels and the energy is transferred to reaches with lower TDG levels where spill is increased. The result is higher generation in the reaches with high TDG levels, increased spill in reaches with lower TDG levels, and equal distribution of TDG levels throughout the basin (Chelan PUD 2016).

#### Maintenance Spill

Maintenance spill is utilized for any maintenance activity that requires spill to assess the routine operation of individual spillways and turbine units. These activities include forebay debris flushing, checking gate operation, gate maintenance, and all other maintenance that would require spill. The FERC requires that all spillway gates be operated once per year. This operation requires a minimal amount of spill for a short duration annually and is generally accomplished in conjunction with fish passage spill operations (Chelan PUD 2016).

#### Error in Communication Spill

Error in communication with the USACE Columbia River Basin Water Management Division, including computer malfunctions or human error in transmitting proper data, can contribute to spill. Hourly coordination between hydroelectric projects on the river minimizes this type of spill, but it does occur occasionally (Chelan PUD 2016).

#### Reduced Generation Spill

Reduced electric demand on the system can, at times, result in the need to spill water at run-of the river projects such as Rocky Reach. Hourly coordination between hydroelectric projects on the river can minimize this type of spill, but it does occur (Chelan PUD 2016).

### **2.2.2 Powerhouse**

The powerhouse is an indoor-type, approximately 1,088 feet long by 206 feet wide and 218 feet high. It includes eleven generating units and a service bay. Each unit is housed in an independent block of reinforced concrete 86 feet wide by 206 feet long (parallel to the flow). Units 1 through 7 were part of the original Project construction completed in 1961. At the time of original construction, spaces were prepared for Units 8 through 11, which were added in 1971. Units 1 through 7 generators are each rated at 111,150 kilowatt (kW), but these units are turbine limited to 140,000 hp or 105,000 kW. Units 8 through 11 generators are each rated at 125,400 kW for an installed capacity for the 11 units of 1,236.6 megawatts (MW). In 1995 through 2003, all the turbine runners were replaced with new more fish-friendly and efficient turbine runners. In 2002, FERC revised the installed Project capacity to 1,237.4 MW with the authorization of a micro-turbine. Operation of the Project is automated and can be controlled locally by full-time operators in the Project control room or remotely from Chelan PUD's dispatch center in Wenatchee (Chelan PUD 2004).

Maintenance and servicing of the equipment in the powerhouse is facilitated by two overhead, traveling-bridge cranes. These cranes have a capacity of 250 tons, with an auxiliary hook capacity of 25 tons. The cranes are powered by electric motors and operated using remote radio controls (Chelan PUD 2004).

Each generating unit has three intake openings. Intakes for the units are equipped with two sets of slots, the upstream slot is typically used for trashracks and the downstream slot is used for placement of headgates when a unit needs to be de-watered. Trashracks and headgates are handled using the intake deck gantry crane. This crane has a capacity of 150 tons with an auxiliary hook capacity of 10 tons. In addition, a high-speed 45-ton hoist is available which can be suspended from the gantry crane's main hooks (Chelan PUD 2004).

Draft tubes for the units are equipped with slots for placement of bulkhead gates used to de-water the units. Draft tube bulkhead gates are handled using the draft tube deck gantry crane. This crane has a capacity of 60 tons, with an auxiliary hook capacity of 6 tons (Chelan PUD 2004).

The powerhouse service bay is a concrete structure forming the corner between the forebay wall and Unit 1 of the powerhouse. The service bay is a rectangular structure approximately 170 feet long and 142 feet wide. The short dimension of the structure is parallel with the upstream face of the powerhouse. The service bay is a combination of mass and reinforced concrete construction. The headworks, foundation mat, and soil and water retaining sections of the structure are constructed of mass concrete. The walls, floor slabs, beams, and columns are constructed of heavily reinforced concrete (Chelan PUD 2004).

### **2.2.3 Fish Passage Facilities**

Facilities for passage of adult anadromous fish moving upstream to spawn are an integral part of the Project. A single fishway with three entrances provides for upstream migration. Entrances to the fishway are between spillway bays 8 and 9, at the center dam, and at the powerhouse service bay. Fish using any of these entrances follow passages to the center dam,

and then along the downstream side of the powerhouse to a fish ladder along the forebay wall. Just before reaching the Rocky Reach Hydroelectric Project reservoir, the fish ladder passes through a fish counting station, which is part of the visitor facilities near the right abutment. Attraction water for the fishway passages is provided from the tailrace by three hydraulic turbine-driven pumps with a capacity of 3,500 cfs. The adult fish passage facilities are monitored and controlled from a dedicated control room on the draft tube deck near the middle of the powerhouse (Chelan PUD 2004).

The JBS was constructed at the Rocky Reach Project in 2002-2003 to provide for safer, more efficient passage of downstream-migrating fish. The JBS design is based on testing conducted from 1985 through 2002. The system consists of a forebay surface collector, intake screens on two generating units, a large-diameter bypass conduit to convey downstream-migrating fish past the dam, and a sampling facility (Chelan PUD 2004).

The surface collector is located adjacent to the forebay wall and generating units 1, 2 and 3. It includes two channels, each 20-feet wide extending to a bottom elevation of 650 feet. In addition to the surface collector, Units 1 and 2 are equipped with intake screens that collect fish from the intake area. Fish from both the surface collector and intake screens are delivered to the bypass conduit. The bypass conduit is a pipe up to 9 feet in diameter, routed along the downstream side of the powerhouse and spillway, through the sampling facility, to an outfall point approximately 1,700 feet downstream of the dam and 450 feet from the east bank (Chelan PUD 2004).

Juvenile fish are collected and examined, as necessary, at the sampling facility on the east bank downstream of the spillway. Chelan PUD's fish and wildlife crew collects species composition and fish condition data. Fish are also collected for ongoing survival and behavioral studies at Rocky Reach and Rock Island project dams (Chelan PUD 2004).

## **2.3 Project Operations for Power and Fish Resource Protection**

### **2.3.1 Overview of Project Flow Regulation and Generation**

The amount of flow that enters the Rocky Reach Project is regulated by releases from the federal Grand Coulee Project, which essentially dictates the flowage curve for all downstream projects on the Columbia River hydropower system. Seasonal demand for hydroelectric generation is governed by the Pacific Northwest Coordination Agreement (PNCA);<sup>1</sup> however, non-power constraints such as flood control operations and the FCRPS Biological Opinion also dictate flow releases from the Grand Coulee Project. In the mid-Columbia, five non-federal hydroelectric projects (Wells, Rocky Reach, Rock Island, Wanapum and Priest Rapids projects) cooperate with each other and with the federal projects immediately upstream (Grand Coulee and Chief Joseph projects) through the HCA to efficiently manage these releases to meet power demand and non-power operations for fish protection under the Hanford Reach Agreement. The HCA is set up to meet the daily demands of power load peaking while maintaining reservoir

---

<sup>1</sup> Coulee Project releases are governed by the PNCA. All generating utilities in the Northwest, with the exception of Idaho Power Company, are parties to the PNCA. The PNCA, in conjunction with the Canadian Treaty of 1964, provides a plan for optimizing water releases to meet power and non-power requirements on a seasonal basis.

levels as stable and full as possible. These seven projects are the primary source for electricity load regulation for the entire Northwest (Chelan PUD 2006).

Hydropower is a unique energy resource because of its ability to start and stop with relative ease compared to other energy sources, such as coal or natural gas, which require hours or days to bring additional capacity online to meet increased demand. If generation and load requirements do not match, the electrical system becomes unstable. Load regulation is the ability to adjust generation as often as every four seconds so that at every moment in time, the generation of the interconnected electrical system matches the load requirements being placed upon it by customer demand. The BPA uses the Grand Coulee and Chief Joseph projects as its primary tools to align supply with demand signals, while all major Northwest investor-owned and some public power utilities have shares of the generation output of the five mid-Columbia non-federal projects. These projects are used for load regulation because of their abilities to regulate river flows on a daily or hourly basis (Grand Coulee and Chief Joseph) or, in the case of the Rocky Reach Project, for a unique ability to adjust to changes in power demand on a real-time basis (Chelan PUD 2006).

Operation of the Rocky Reach Project is completely automated, including decisions to start, stop and adjust the output of the 11 generating units to achieve maximum efficiency. The automated functions are backed up with around-the-clock on-duty plant operators who monitor operations and can over-ride computer control if needed. When a generation request is transmitted from the central computer to the Rocky Reach Project's on-site computers, the most efficient way to meet the request is determined and implemented. Units 1 through 11 are adjustable blade Kaplan units and are efficient over a wide range of operating conditions. During the downstream juvenile salmon migration, operations are adjusted to assure that turbine units 1-2, which support the JBS, are operating at all times and other units near the JBS are operated in preference to turbines further from the bypass entrance (Chelan PUD 2006).

Spillway releases to pass water in excess of turbine capability or load requirements, or for fish passage, are also controlled by computer. When the headwater level exceeds operator-set maximum points, gates are automatically opened to pass the excess flow. During fish passage operations, the sequence and amounts of gate opening can also be adjusted to maximize the effectiveness of the water being spilled for fish passage. During high water years, the Project operates at a higher plant factor and is more often subject to spill to pass flows in excess of plant turbine capacity. A higher plant factor implies that the Project is able to operate at or near full load for longer periods of time without drafting the storage from the reservoir. As flows increase, tailwater effects reduce plant capacity due to higher tailwater levels and lower available gross head. Under lower water supply conditions, the number of hours that the plant can sustain operations at or near peak load diminishes (Chelan PUD 2006).

While the Rocky Reach Project has little control over river flow, operations do have some immediate impact on control of hourly fluctuations in reservoir level and discharge. The Rocky Reach Project is managed in accordance with the resource optimization framework set up through the HCA (Chelan PUD 2006). The history and purpose of the HCA is described below.

### 2.3.1.1 Mid-Columbia Hourly Coordination Agreement

The HCA was first signed in 1974 as a one-year agreement. It was then renewed in a series of longer-term agreements. The current agreement was signed in 1997 and extends until June 30, 2017. The HCA is signed by the project owners (Chelan PUD, Douglas PUD, Grant PUD, USACE, and the USBOR), as well as all purchasers and participants of the projects, including the BPA. The HCA sets forth terms for operating the five non-federal mid-Columbia hydroelectric projects and two upstream federal projects, Grand Coulee and Chief Joseph, in a coordinated manner through the “middle” stretch of the Columbia River (Chelan PUD 2006).

The objectives of the HCA are to: (1) coordinate the hydraulic operation of the projects to optimize the amount of energy from the available water consistent with the needs to both (i) adjust the total actual generation to match the total requested generation, and (ii) operate within all parties’ power and non-power requirements; (2) provide flexibility and ease of scheduling generation for the projects through centralized coordinated scheduling and to provide flexibility in scheduling project generation; and (3) to minimize unnecessary project generation changes, including unit starts and stops to the extent this objective is consistent with the other objectives of the HCA (Chelan PUD 2006).

Under the HCA, the system’s federal and non-federal hydroelectric projects cooperate to efficiently manage Grand Coulee Project flow releases in order to meet the daily demands of power load peaking while maintaining reservoir levels as stable and full as possible. The operating strategy under the HCA includes specific algorithms related to reservoirs for power production, spill prevention, and downstream reservoir refill. In general, spill is avoided unless necessary for fish survival, since it wastes energy. To prevent spill, the total system of projects attempts to meet load by drafting from the project on the system that results in the least head loss. Spill is reduced or prevented where possible, by drafting a project downstream of the point of spill and reducing discharge above the point of spill, if it is anticipated that the drafting project’s reservoir can refill within a prescribed time interval. Additional generation produced by the downstream draft is intended to reduce the coordinated request upstream of the point of spill, thereby reducing the inflow to the project being forced to spill. The net effect of this operation is to reduce involuntary spill, where hourly inflow to a project could exceed the hydraulic capacity of the powerhouse, thus forcing the project to spill water. This minimization of spill is desirable from a water quality standpoint, in that it minimizes the occurrence of elevated levels of TDG to only years with high flows and to voluntary spill provided to improve fish survival (Chelan PUD 2006).

Each project on the system generates the most power when a release from Grand Coulee Project moves into its reservoir. The Project receiving the flow of water moving through the system generates at the highest plant factor necessary to provide as much power as possible, regardless of whether that particular project’s customers are making the request at that time. All power requests and non-power requirements are collected and tracked by a computer at Grant PUD’s headquarters (Ephrata, Washington) which serves as “Central” to the operation. This computer optimizes movement of water to maximize generation while keeping the reservoirs as full as possible. Participants in the HCA make requests for power from the central system in real time. The computer assigns each project a desired generation level so that all load

requests are satisfied in a manner that optimizes the combined operational efficiency of all of the participating projects. This means that a power purchaser with an agreement with the Rocky Reach Project may actually be receiving power generated at Priest Rapids Project at a certain time of the day. The situation may be reversed when it is more efficient to a Grant PUD's purchaser to receive power generated at the Rocky Reach Project. The programming for the computer has evolved through many years of refinements and is intended to achieve the highest overall level of efficiency for the participating projects (Chelan PUD 2006).

The HCA reduces water level fluctuations that would otherwise occur in both the reservoirs and tailraces of projects, because the higher efficiency is achieved by keeping the reservoirs as full as possible. Most of the mid-Columbia reservoirs have some backwatering (encroachment) effect on the tailrace of the project upstream, and the backwatering also reduces the magnitude of water level fluctuations in the tailwater that result from changes in plant discharge. In the absence of the HCA, the tailwater levels at each plant would fluctuate based on discharge of inflows originating from the Grand Coulee Project, potentially exacerbated by additional fluctuation as individual projects drafted and refilled their useable storage while meeting load requests that are not synchronized with the flow of water through the mid-Columbia River. The HCA prevents compounding effects and actually reduces water level fluctuations by dampening the effect of daily swings in flow releases from Grand Coulee Project (Chelan PUD 2006).

While the HCA allows participants to take advantage of these resource efficiencies in real time, it also ensures that each participant receives such power benefits in accordance with its rights to the generating assets. The computer keeps accounting records that recognize the varying generation obligations of each participating project. The computer's accounting programming permits the shifting in time of actual generation from one project to another by means of "coordinated exchange." As a result, each project generates when and at the level that is most efficient, and the contractual obligations of each project are met in the most cost-efficient manner possible. A paper account tracks when a project is generating less or more power than it needs to fill its obligations. In any 24-hour period, each project will have generated more than its customers require at certain times of the day and less than its customers require at other times of the day. Over approximately a 24-hour period, there is essentially no discrepancy between a single project's actual generation under the HCA and the customer demand it has worked to fulfill (Chelan PUD 2006).

#### 2.3.1.2 Role of Rocky Reach and other Mid-Columbia Projects in Meeting Regional Energy Requirements

Federal hydropower projects throughout the Columbia and especially the Snake River system are subject to many operational restrictions intended to protect fish resources. These restrictions have prevented some projects from fluctuating power generation significantly in order to meet local and regional power demand. In response, the BPA relies almost entirely on the ability of the mid Columbia projects to respond to demand through regional load following outlined in the HCA. Essentially, the seven mid-Columbia projects perform all of the load regulation for the Northwest electrical system. The operational restrictions placed on Grant PUD projects through the Hanford Reach Agreement shifts the burden of meeting local and regional load following demand even more heavily onto the Rocky Reach and Wells projects.

The main role of the Rocky Reach Project in the HCA is to utilize ramping (change in generation output) to meet the burden of regional load following. However, despite the system's heavy reliance on Rocky Reach's ramping capability, the Project manages to perform this role with the second smallest amount of useable reservoir storage in the Mid-Columbia power system and a maximum reservoir fluctuation of only four feet.

The Rocky Reach Project is fulfilling its appropriate role under the HCA from the perspective of both fish and power obligations. It follows load in a manner that cannot be duplicated by the Wanapum and Priest Rapid projects (due to Hanford Reach Agreement considerations), thereby allowing those projects to manage their reservoirs in order to meet obligations for fish. If Rocky Reach were similarly restricted in operation, there would be implications for the entire Northwest electricity market, which would demand replacement power. This could be problematic in other environmental respects, given the amount and likely sources of replacement power. Hydro units are able to adjust to meet load much more quickly than thermal (gas, oil, coal, or nuclear) systems, and much more efficiently. Hydropower units can start and stop quickly, matching load demands on a four-second basis and reducing the need for significant reserves. If the load regulating ability of the mid-Columbia was lost due to restrictions, new generating facilities would need to come online to replace the hydropower system's ability to respond to electrical demand on a four-second basis. In order to replace this kind of flexible resource in a manner that would provide sufficient reserves for immediate response to regional load, as much as 2,000 megawatts of additional thermal generation would be required. These plants would be operated much more inefficiently, have negative air quality impacts and increase greenhouse gas emissions (Chelan PUD 2006).

### **2.3.2 Current Operations**

Chelan PUD operates the reservoir with a normal maximum headwater elevation of 707 feet. The minimum allowable headwater level is 703, but drafting of headwater below 705 feet is infrequent (less than 2 percent of the time). Although the Project has a total useable storage of 36,400 acre-feet between headwater 707 and 703 feet, not all the storage is used, except in an emergency. Standard procedure is to not reduce forebay elevation below 704 feet because the bottom foot of storage is needed in reserve to maintain stability in the power grid. The reservoir's total useable storage is sufficient to run the plant for about two hours (at average flows) without additional inflows. In normal operations, this storage can be used to increase outflow over the inflow by about 10,000 cfs over a full day.

During a normal water year, the plant operates at a plant factor of 55 percent (average flows are only sufficient to operate at 55 percent of the Project's maximum generating capacity). During high water years, the Project operates at a higher plant factor but is also more often subject to spill to pass flows in excess of plant turbine capacity. When operating at a higher plant factor, the Project is able to operate at or near full load for longer periods of time without drafting the storage from the reservoir. Under lower water supply conditions, the number of hours that the plant can sustain operations at or near peak load diminishes (Chelan PUD 2006).

### **2.3.3 Hanford Reach Fall Chinook Protection Program**

Chelan PUD has participated since 1988 in flow management operations for the protection of fall Chinook salmon that spawn in the Hanford Reach of the Columbia River. These joint operations were originally specified in the Vernita Bar Agreement, which provided protective operations from the beginning of spawning activity (late October) through incubation until the end of the emergence period (late April to early May). The Vernita Bar Agreement was scheduled to expire in 2005, concurrent with the expiration of Grant PUD's License for the Priest Rapids Project (Chelan PUD 2006).

Research in the late 1990s found that flow fluctuations in the Hanford Reach can also adversely affect survival of fall Chinook fry during the first few weeks after emergence. Due to the extensive areas of backwater channels and shallow gravel bars in the Hanford Reach, changes in river elevation associated with daily and weekly flow fluctuations can cause fish to be stranded in areas where they are exposed to mortality from dewatering, or heat stress and predation in shallow pools that become isolated from the main river channel. To address these issues, Chelan PUD has voluntarily cooperated with Grant PUD, BPA and Douglas PUD to enable Grant PUD to operate the Priest Rapids Project to reduce flow fluctuations. These voluntary operations, initiated in 1999, included research covering alternative operating methods that resulted in development of a long-term operating plan that has replaced and improved upon the Vernita Bar Agreement (Chelan PUD 2006).

The new agreement, the Hanford Reach Agreement, has been executed by most of the original parties to the Vernita Bar Agreement. In addition to Chelan PUD, this new agreement includes the following parties; Grant PUD, BPA, Douglas PUD, WDFW, NMFS, and the Colville Confederated Tribe. The new agreement includes operations for the protection of fall Chinook salmon from the beginning of spawning through the early rearing period when Chinook fry are susceptible to stranding. The new agreement requires the same actions from Chelan PUD as the original Vernita Bar Agreement, but includes the additional time period that extends from April into June. This includes supporting Grant PUD's operations through the HCA and providing up to one foot of draft from the reservoir (Chelan PUD 2006).

### **2.3.4 Anadromous Fish Agreement and Habitat Conservation Plan**

A 50-year agreement regarding protection of anadromous salmon and steelhead at the Project has been incorporated into the Project's License. The Project has special operations and facilities that are used to meet the survival objectives of the HCP, which are 93 percent survival for juveniles passing the Project and 91 percent combined survival of juvenile and adult salmon and steelhead passing the Project. Operations for the Project under the HCP use the JBS, installed in 2003, as the primary method for safely passing juvenile salmonids. Under the HCP, Chelan PUD continuously operates the JBS system from April 1 to August 31 each year. The spillway is also used, when needed to supplement the JBS, to provide a safe passage route. Spill levels are set by the HCP CC based on the results of past survival studies. Due to the performance of the JBS in passing yearling Chinook, sockeye, and steelhead, spill is not currently needed to meet survival standards for these species. Spills will continue to be used for passing subyearling Chinook salmon until such time that the JBS or other tools for improving

fish survival have met the survival standards. Spill, when required, is provided over a time period that encompasses 95 percent of each species' downstream migration. Spill levels in 2016 were 9 percent of the estimated daily average flow for subyearling Chinook (Chelan PUD 2016). After completion of survival studies, spill will supplement the JBS as necessary to achieve the survival standards. Spill is managed to reduce adverse effects on water quality and meet water quality standards for TDG (Chelan PUD 2006).

In 2020, as part of an HCP "check in", Chelan PUD is required to conduct a juvenile survival study at Rock Island Dam using representative species to confirm that past juvenile survival results for yearling Chinook, sockeye, and steelhead are still being upheld. A similar type of study is currently scheduled at Rocky Reach Dam in 2021 (L. Keller, personal communication).

## **2.4 TDG Criteria and Regulatory Framework**

Chapter 173-201A of the WAC defines the water quality standards (WQS) for the surface waters of Washington State. Under the WQS, TDG shall not exceed 110 percent at any point of measurement in any state water body. However, the standards exempt dam operators from this TDG standard when the river flow exceeds the seven-day, 10-year-frequency flood (7Q10). The 7Q10 flow is the highest calculated flow of a running seven consecutive day average, using the daily average flows that may be seen in a 10-year period. The 7Q10 total river flow for the Rocky Reach Project was calculated following methods from the United States Geological Survey (USGS) Bulletin 17B, "Guidelines for Determining Flood Flow Frequency" and determined the value to be 252,000 cfs (Ecology et. al. 2004).

In addition to allowances for natural flood flows, the TDG numeric criterion (110 percent) may be adjusted to aid fish passage over hydroelectric dams when consistent with an Ecology-approved GAP per WAC 173-201A-200(1)(f)(ii)). The increased levels of spill resulting in elevated TDG levels are authorized by Ecology to allow salmonid smolts a non-turbine downstream passage route that is less harmful to fish populations than caused by turbine fish passage. This TDG exemption provided by Ecology is based on a risk analysis study (NMFS 2000). The GAP must be accompanied by fisheries management and physical and biological monitoring plans and is approved on a per application basis for juvenile fish passage at dams on the Columbia and Snake rivers. This TDG exemption comprises three separate standards to be met by dam operators.

1. TDG shall not exceed 125 percent as a maximum one-hour average in the tailrace of a dam;
2. TDG shall not exceed 120 percent in the tailrace of a dam as measured as an average of the 12 highest consecutive hourly readings in any 24-hour period (12-C High); and
3. TDG shall not exceed 115 percent in the forebay of the next dam downstream as measured as the 12-C High.

Each year, the Rocky Reach Project operates under this TDG exemption during its fish spill season (generally April to August) per an Ecology-approved GAP. Outside of the fish spill

season, Rocky Reach Dam is required to adhere to the general TDG WQS numeric criterion of 110 percent.

#### **2.4.1 Designated and Beneficial Uses**

It is important to note that in addition to numeric criteria, WQS standards contain narrative criteria and an anti-degradation policy that requires that beneficial and designated and existing water uses be “maintained and protected” 40 CFR § 131.12(a), WAC 173-201A-070(1), 40 CFR §§ 131.6, .12(a), WAC 173-201A-030. Among those uses that must be protected are fish and wildlife, recreation and industrial (including hydropower) 40 CFR § 131.10(a). The fundamental purpose of numeric criteria is to protect beneficial and designated uses, i.e., “states must adopt those water quality criteria that protect the designated use.” 40 CFR § 131.11(a). Thus, numeric criteria exist to support the beneficial and designated uses, not as ends in themselves, and not as something to be achieved regardless of the consequences for beneficial and designated uses (Chelan PUD 2006).

The Washington State Pollution Control Hearings Board (PCHB) recognized this in a decision upholding Ecology’s 401 certification for the Lake Chelan Hydroelectric Project. In rejecting the notion that numeric criteria should be pursued even when the result would harm beneficial and designated uses, the PCHB stated that “the primary aim of the § 401 certification ... is to meet water quality standards *by complying with the intent and the substance of the standard rather than its numeric form.*” PCHB No. 03-075, Final Order, at 15. (emphasis added).

The example above illustrates the need to assure overall compliance with the intent and substance of the WQS, rather than seeking to achieve mechanical compliance with the numeric criteria, regardless of the consequences for beneficial and designated uses. Ecology’s Determination of Compliance Letter (2015) has stated that despite the Rocky Reach Project not achieving full compliance with the TDG numeric criteria, the aquatic life designated use has not been adversely affected. Furthermore, as Chelan PUD proceeds with TDG management at the Rocky Reach Project, Section 5.4(1)(d) of the Project’s 401 Certification states that probable and possible impacts to fish species must be considered in the evaluation of any additional “reasonable and feasible” TDG abatement methods. The concept of achieving a balance between achieving mechanical compliance with the numeric criteria while also considering the potential impacts for beneficial and designated uses (e.g., aquatic life, recreation, etc.) serves as the basic framework for a risk based assessment that will be implemented to evaluate potential TDG abatement alternatives for the Rocky Reach Project (see Section 3.0 and 4.0 below).

#### **2.4.2 TDG in the Mid-Columbia River System**

##### **2.4.2.1 Mid-Columbia River Non-Federal Projects**

As mentioned previously, the mid-Columbia HCA is an agreement focused on coordinating the power operations of the seven mid-Columbia projects toward meeting daily load requirements through the assignment of "coordinated generation" through Central. Five of these mid-Columbia River projects (from upstream to downstream – Wells, Rocky Reach, Rock Island, Wanapum and Priest Rapids dams) are operated by public utilities (i.e., Douglas, Chelan and

Grant counties) under FERC licenses and all are located downstream of the two mid-Columbia River federal projects discussed below. Each project in the system has preferred operating criteria depending upon generation requests and environmental conditions and requirements. The preferred forebay elevation at each non-federal project is a combination of power demand, discharge from upstream projects and maximum and minimum elevations located within each projects respective FERC license. Central River Control is used to maintain preset reservoir levels in order to meet load requirements and prevent involuntary spill, which has the potential to produce TDG. These preset reservoir levels are maintained at each project through management of a positive or negative “bias” which assigns a project more or less generation depending on whether the reservoir elevation should be increased or decreased in order to maximize system benefits and minimize involuntary spill and resultant TDG. The agreement allows for intermittent trade-offs of maximum benefits at individual dams to spread benefits throughout the system in a coordinated fashion while meeting environmental, recreational, and power generation requirements (Kiefer 2009).

#### 2.4.2.2 Mid-Columbia River Federal Projects

Chief Joseph Dam is part of the FCRPS, which comprises 29 dams. It is located 30 miles upstream from the Wells Dam and 52 miles downstream of Grand Coulee Dam and operates as a run-of-river hydropower project, fluctuating less than six feet in elevation over a normal year in Lake Rufus Woods (the reservoir behind Chief Joseph Dam). Chief Joseph Dam has no upstream fish passage and is considered the furthest upstream point of anadromous fish distribution in the Columbia River basin. Water discharge from Chief Joseph Dam is generally dispatched by the BPA for the production of electricity and by the USACE for flood control purposes (USACE 2000a).

Grand Coulee Dam, also part of the FCRPS, is operated by the USBOR, and is located at Grand Coulee, Washington. Grand Coulee was completed with 18 generating units in 1942, prior to Chief Joseph Dam, and impounded what is now called Lake Roosevelt. The Project is authorized by Congress for uses associated with flood control, power production, and irrigation. The reservoir is managed by the USACE to reducing flooding downstream in the spring and to enhance electric generation in the fall and winter. Complete refill of Grand Coulee is normally targeted for June 30 each year and then dropped near elevation 1280 feet or higher by the end of September (full pool elevation is 1290 feet). Fall draft is limited to elevation 1265 feet by December 31 to ensure an 85 percent confidence of refill to the flood control rule curve on the planning date of April 10 per the supplemental Biological Opinion (BO; NMFS 1998) and to be consistent with previous operations and studies conducted during Endangered Species Act (ESA) consultations (USACE 2000a).

The greatest water quality concern related to Chief Joseph and Grand Coulee dams is TDG levels in both Rufus Woods Reservoir and the Columbia River below the Chief Joseph Dam. Due to the height of the spillway and the configuration of the stilling basin at Grand Coulee Dam, TDG levels can easily exceed 110 percent. This problem is most acute during the spring and summer when both Grand Coulee and Chief Joseph dams are spilling water due to high runoff or the anticipation of freshet conditions causing drafting at Grand Coulee in anticipation of

capturing snowmelt entering the Project, and insufficient power demand does not allow all inflow to pass through generating units (USACE 2000a).

In 2004, Ecology, the Spokane Tribes of Indians, and the U.S Environmental Protection Agency (EPA) developed a total maximum daily load (TMDL) report for TDG in the mid-Columbia and Lake Roosevelt (Pickett et al. 2004). The document indicates that compliance in the Chief Joseph Dam tailrace is carried out by Ecology, the Colville Confederated Tribe and EPA. Ecology's standards differ between Phase I and Phase II of implementation of the TMDL with Phase I having identical WA State WQS TDG criteria during fish passage periods and Phase II being 73 mm of Hg (or 110 percent) in the tailrace of Chief Joseph up to the mouth of the Okanogan River (Pickett et al. 2004). In addition, TDG standards in the tailrace of Chief Joseph Dam are enforced by the Colville Confederated Tribes, whereby standards are 110 percent as measured at any time of year along the reservation boundary, including the Chief Joseph tailrace, and as an instantaneous measurement (Pickett et al. 2004; Colville Tribe 2010).

To address the issue of spill and resultant TDG production, the USACE and USBOR identified a preferred alternative of installing flow deflectors at Chief Joseph Dam combined with joint operations at Grand Coulee Dam (USACE 2000a). The joint operating policy, aimed at more effective management of TDG supersaturation at Grand Coulee and Chief Joseph dams, can limit TDG producing operations (i.e., spilling out of regulating outlets) and increase generation at Grand Coulee thereby providing additional spill capabilities at Chief Joseph Dam without increasing TDG for a comparable level of flow and spill.

#### 2.4.2.3 Federal Gas Abatement and Spill Priority

In response to Reasonable and Prudent Alternative (RPA) 136 in the NMFS 2000 BO, construction of the spillway flow deflectors was initiated in 2005 at Chief Joseph Dam (BPA et al. 2010). Although Chief Joseph Dam does not have fish passage, during Phase I testing of the TMDL implementation (2004-2010), the project was operated under the higher TDG load allocation criteria normally reserved for projects with beneficial fish passage via spill (i.e., similar to fish passage TDG exemptions issued annually at non-federal mid-Columbia River dams). The purposes for the Phase I TMDL load allocation tests were: (1) to evaluate whether the joint operations of Grand Coulee and Chief Joseph dams could produce less TDG; and (2) to authorize TDG in excess of the standard during the Phase I spill deflector construction and testing at Chief Joseph Dam. Testing of Chief Joseph Dam spill deflectors was completed in 2009 (BPA et al. 2010).

Since the completion of spill deflectors at Chief Joseph Dam in 2009, there has been a marked shift in federal spill operations resulting in a significant increase in the amount of spill at Grand Coulee and Chief Joseph dams. This increase in spill has resulted in a dramatic increase in the volume of water supersaturated with TDG entering the non-federal project reach of the mid-Columbia River. A primary factor for increased spill has been the significant development of new wind generation in the region resulting from renewable portfolio standards and federal production tax credits, investment tax credits, and Renewable Energy Credits. Currently, 5,100 MW of wind generation are connected to BPA's transmission system and this is expected to

grow another 3-4,000 MW by 2025<sup>2</sup>. Wind generation usually occurs at night or in the spring when the generation is not needed. However, the power grid requires that system load and generation be balanced at all times. System imbalances can result in system frequency shifts that damage electronic equipment or cause system protection devices to trip. Federal regulations require system operators to maintain system frequency at 60 hertz (Hz) at all times. Hydropower is one of the best generation sources for managing system frequency and load/generation imbalance due to wind (e.g., wind integration or dynamic capacity). However, curtailing hydroelectric power generation to facilitate the integration of wind into the electric grid often results in increased spill.

Contrary to the trends observed recently, the joint operations of Chief Joseph and Grand Coulee reservoirs and installation of flow deflectors at Chief Joseph Dam were originally intended to reduce TDG levels within the mid-Columbia River. This is recognized in the 2008 BO for the FCRPS (NMFS 2008), in the Environmental Assessment (EA) and Finding of No Significant Impact for the flow deflectors (USACE 2000b), and in the FCRPS TDG TMDL (Ecology et al. 2004).

If operations at Chief Joseph Dam continues to increase spill and increase the volume of water supersaturated with TDG entering the non-federal reach of the mid-Columbia River at greater frequencies, the mid-Columbia River PUD projects will have a more difficult time meeting state WQS due to increased TDG exceedances of incoming waters.

## **2.5 Rocky Reach Project TDG Activities**

Chelan PUD has been spilling water for downstream fish passage at the Rocky Reach Project since 1976. Spill is a tool used for improving survival of anadromous salmonids during their downstream migration and is part of the “tool box” being implemented to meet HCP survival standards. Spill can also occur when high stream flows exceed the hydraulic capacity of the powerhouse or, occasionally, when energy demand is low and river flows are high. In the Columbia River basin, a regional effort has been undertaken to monitor and control TDG and its biological effects. Chelan PUD has participated in that regional effort since 1982 (Chelan PUD 2006).

Since 1982, Chelan PUD has monitored TDG at the Rocky Reach Project. Since that time, TDG management has evolved based upon information gathered from numerous evaluations, continued refinements in monitoring, and improved coordination. These activities have resulted in a better understanding of TDG production dynamics and the identification of potential alternatives to further improve TDG management at the Project.

### **2.5.1 Relicensing Studies**

#### **2.5.1.1 TDG Analysis 1997-2000**

Early in the Rocky Reach Project relicensing process, Chelan PUD funded a review of TDG monitoring and project operations data for the years 1997-2000. This study (Parametrix 2000)

---

<sup>2</sup> Available at <https://www.bpa.gov/Projects/Initiatives/Wind/Pages/default.aspx>.

examined the relationships between incoming levels of TDG, total flow, spill volumes and spillgate configurations at Rocky Reach Dam, and the levels of TDG recorded at the downstream monitoring site and at the forebay of Rock Island Dam. The analysis of monitoring data determined that spill at the Rocky Reach Project has a lower TDG entrainment effect than is observed at most other Columbia River projects. During the years of 1998-2000, TDG levels increased only slightly during the spill period (1-3 percent of saturation on average, range –5 percent to +15 percent). Average TDG levels during 1998-2000 remained below 110 percent of saturation, although point measurements ranged from 100 percent to 120 percent of saturation. These conditions occurred with total river flows ranging from less than 100,000 cfs to about 275,000 cfs. Increases in TDG levels were only slightly greater at higher river flows (Parametrix 2000).

The analysis determined that the TDG level below the Rocky Reach Project is more influenced by the TDG level arriving at the Project than by the level of spill at the Project, confirming earlier observations from annual reports between 1996 and 1998 (Chelan PUD 2005). However, the incoming TDG concentrations to the forebay of the Project tended to be higher with higher water flow, lending to higher concentrations at monitoring locations downstream.

The analysis also indicated that different types of spill operations can affect the entrainment of air and the resultant TDG level. Study results suggested that configurations using a greater number of gates tend to minimize the increase in TDG from the forebay to the tailrace but could not identify a precise relationship between configuration and decreases in TDG due to confounding effects such as the TDG levels of incoming water and the varying degree of mixing of powerhouse and spillway flows at the downstream sampling location (Parametrix 2000). The analysis also determined that TDG levels dissipate somewhat when traveling through the Reservoir, with more reduction in TDG at lower flows than higher flows (Parametrix 2000).

#### 2.5.1.2 Near Field Effects Study

In 2002, a study of near-field effects of specific spillgate and powerhouse operations on TDG levels was conducted by the USACE (2003). The objective of the study was to improve the understanding of how different gate settings affect the level of TDG produced for specific volumes of spill. For near-field effects, TDG measurements are made in close proximity to Project structures which avoids the compounding effects of TDG levels of incoming water and variability associated with mixing spill and powerhouse flows as noted in the Parametrix (2000) study. TDG measurements were taken at an array of near-field locations upstream and downstream of Rocky Reach Dam during the week of April 26 to May 3, 2002.

A number of different spillgate configurations were tested to determine how best to manage spill operations to limit TDG levels. The spillway flow ranged from 10.6-61.0 kcfs during the study. In addition, two different modes of powerhouse loading were tested by concentrating discharge through either the south or north end of the powerhouse. The normal (standard) spill pattern uses a variable number of spillgates, three spillgates (4, 6 and 8) for total spill volumes below 20,000 cfs, increasing the number of spillgates as needed up to 7 spillgates (2 through 8) for spill volumes above 50,000 cfs. The standard spill pattern was developed to create tailwater conditions generally conducive to upstream salmon passage (a V-shaped margin of aerated

water leading to upstream fishway entrances). Discharge through individual spillgates ranged from about 4,000 to 10,000 cfs for total spillway flows of about 10 to 60 kcfs, but discharge was not evenly distributed through the spillgates. Alternative spillgate configurations included spreading spill evenly over seven spillgates, evenly over 11 spillgates, and concentrating spill into three different locations on the spillway (2 to 5, 5 to 8 and 9 to 12).

The study concluded that spillway operations at the Rocky Reach Project increased average TDG level in the Columbia River below the spillway by 1.8 to 8.6 percent over levels arriving at the Project. However, this study was conducted when the TDG level in the forebay was below 110 percent, which is rarely the case during the fish migration season. Thus, the increase in TDG level was greater than typically occurs during the fish migration season. Because TDG levels in the forebay were low, there was little opportunity to study the degassing effect of the Project's spillway, which can occur when forebay TDG levels exceed 120 percent (Chelan PUD 2006).

The standard spill pattern and a uniform pattern using spillgates 2 through 12 had the lowest TDG of the spillgate configurations tested. The uniform spill pattern (spillgates 2 through 12) produced slightly less TDG than the standard pattern for total spill levels of about 50,000 cfs. However, the powerhouse discharge was significantly higher during tests under the standard spill pattern, and mixing of powerhouse flow may have prevented observation of a greater difference between these spillgate configurations at the lower spill levels (Chelan PUD 2006).

The entrainment of powerhouse flows, mixing with spillway discharge, influenced TDG levels. Increases in powerhouse discharge while spill discharge was held constant resulted in a decrease in the maximum TDG level, which is likely due to mixing of powerhouse flow with the spillway flow. Although the mixing effect reduces the maximum TDG level measured, the entrainment of powerhouse flows into the highly aerated spill discharge results in a greater total volume of flow having elevated TDG levels (Chelan PUD 2006).

In addition to the analysis of different spill patterns, the study evaluated whether the existing fixed monitoring sites (forebay and downstream monitoring site) accurately represents the TDG levels in the river. The forebay monitoring site did represent TDG levels in the Columbia River arriving at the Project. The downstream site was found to underestimate the average TDG level across the river channel at that location by about 1 percent. Transects conducted during yearly monitoring find the downstream site is typically within 1 to 2 percent of the highest TDG level across this transect location (Chelan PUD 2006).

The USACE compared the TDG exchange (gas sorbing into and out of water) of the Rocky Reach spillway to other Columbia River hydroelectric projects. They concluded that TDG exchange at the Rocky Reach Project is similar to TDG exchange at Lower Granite Dam, which has been equipped with gas abatement technology (spill flow deflectors). The TDG level at Rocky Reach, using the standard spill pattern, reached 120 percent in the tailrace, at a spillway discharge of 62,700 cfs (131 percent of a 7Q10 flow if the powerhouse is running at full capacity). However, the Lower Granite Dam powerhouse hydraulic capacity is much lower in relationship to the 7Q10 flow for the Snake River, thus during high flow years the spill level at

Lower Granite Dam will cause much higher TDG levels than will occur at Rocky Reach Dam in high flow years.

At many federal projects on the Columbia River, a predictive model, SYSTDG, is one of the tools used to manage spill and prevent exceedances. The standard spill pattern TDG regression was tested with the SYSTDG model to evaluate its applicability to spill management at the Rocky Reach Project. SYSTDG predicted the TDG exchange at Rocky Reach Dam as a function of the forebay, background TDG level and Rocky Reach Project operations. High forebay TDG pressures reduce the allowable spillway discharge to avoid leading to excessive TDG at the fixed monitoring sites downstream of the dam. A review of historic records of TDG levels indicated that the 115 percent criterion for the forebay of Rock Island Dam, rather than the 120 percent criterion for the tailrace monitoring station, will be the location where exceedances are most likely to occur. This is particularly true when the TDG level arriving at the Rocky Reach forebay is high. The predictive error of the SYSTDG model was within a TDG level 0.3 percent over 90 percent of the study period (April 26-May 3, 2002). The SYSTDG model could be used as an additional tool to manage spill and prevent exceedances downstream from the Project.

#### 2.5.1.3 2003 Gas Abatement Techniques Investigation

MWH was retained by Chelan PUD to investigate alternatives for TDG abatement at Rocky Reach Dam spillway. The primary purpose of the study was to develop an up-to-date bibliography on TDG abatement techniques, from existing information identify all possible gas abatement alternatives, and evaluate the most probable solutions to reduce TDG supersaturation levels downstream of Rocky Reach Dam. These alternatives were to help Chelan PUD meet state and federal TDG standards below Rocky Reach Dam, especially during the high flow season (MWH 2003).

Several steps were performed to accomplish the objectives of this study including: (1) acquisition of site-specific relevant data, information on the TDG measurements, drawings of Rocky Reach Dam, and reports; (2) interviews with key TDG abatement researchers from both the USACE and NMFS; (3) a bibliography was assembled based on references obtained from interviews and the Corps' Dissolved Gas Abatement Study report and (4) a literature review was performed and references reviewed to assess the applicability of previously studied solutions to the Rocky Reach Dam TDG issues (MWH 2003).

The study concluded that the most robust TDG data source was associated with USACE projects on the Columbia River and found that of the four characteristics most critical to TDG entrainment (i.e., spillway crest elevation, stilling basin elevation, minimum operating pool and normal tailwater depth) Rocky Reach Dam was most similar to three USACE projects but only in two characteristics. These projects were The Dalles (spillway crest elevation and stilling basin elevation), Ice Harbor (spillway crest elevation and minimum operating pool) and Lower Granite (minimum operating pool and normal tailwater depth) dams (MWH 2003).

The study identified and evaluated possible operational and structural solutions to mitigate TDG at Rocky Reach Dam. Operational solutions evaluated included maximizing powerhouse flows

and spilling from the full suite of spill gates (i.e., 2 through 12). There were eighteen structural solutions evaluated that included spillway deflectors, submerged outlets, submerged outlets with deflectors, baffled spillway, side channel spillway, side channel stepped spillway, adding spillbays, raising the stilling basin, raising the stilling basin with deflectors, raising the tailrace, raising the tailrace with deflectors, new spillway gates, conversion of turbines to sluices containing throttling gates, rebuilding the powerhouse to allow for a hydrocombine design (spilling over units), V-shaped spillway, adding generation capacity, divider wall between powerhouse and spillway, and removing nappe deflectors (MWH 2003). Each alternative was evaluated against a set of criteria (8) that included TDG performance, effects to upstream and downstream fish passage, maintaining design spillway discharge, generation impacts, public use of the river, effects to operation and maintenance, and capital cost.

Results of the study indicated that both operational alternatives should be explored further. Maximizing powerhouse flows requires that the fish spill requirements be decreased and the reduced flows be passed through the powerhouse. Note however that periods of highest spill have typically occurred in the spring when flows are high and energy demand is low. The second alternative, optimizing spill from gates 2 through 12, also showed promise based on TDG measurements taken in two operational trials in spring of 2002. These data indicated that by altering the standard spill pattern, a decrease in saturation of up to 7 percent might be achieved during maximum fish spill of 62,500 cfs. Since there is only a small amount of data for this alternative, further data should be gathered (MWH 2003) especially since the original spill pattern is implemented to support upstream adult fish migration.

With regards to structural alternatives, the study concluded that most alternatives were either very expensive, exposed downstream migration fish to injury, had low TDG benefit to cost or a combination of the above. The study determined that in addition to the two operational alternatives, structural alternatives recommended for further investigation included flow deflectors, raising the stilling basin, raising the stilling basin with flow deflectors, raising the tailrace, raising the tailrace with deflectors, and removing existing nappe deflectors on spill bays (MWH 2003).

#### 2.5.1.4 2005 USACE Operational and Structural TDG Assessment

Chelan PUD hired researchers from the USACE Engineer Research and Development Center (ERDC) to further evaluate the alternatives recommended for further evaluation by MWH (2003). In addition to the eight alternatives identified from the previous study, researchers included consideration of an entrainment cutoff wall to partition powerhouse flows from spillway flows (Schneider and Wilhelms 2005).

The analysis of the nine TDG management alternatives was based upon direct observations of TDG exchange characteristics at Rocky Reach Dam and at other projects with a wide range of TDG management attributes. In addition to a review of physical data, the theoretical basis for TDG gas transfer and best engineering judgment was employed to develop the assessment.

The assessment concluded that the most reliable method to not impact the TDG loading in the Columbia River at Rocky Reach Dam would be to reduce or eliminate spill. However, as noted

earlier, high spill in the Columbia River basin often coincides with periods of high spring flows, wind generation, and low energy demand. As such, maximizing generation during a period when demand is low or eliminating spill entirely is likely not a realistic solution in the mid-Columbia; rather managing expected spill through coordination and better developed operational approaches may be a more promising approach. Furthermore, the current operating regime at the Project includes consideration for maximizing flows to reduce spill while operating for peak efficiency. With regard to uniform spill patterns on bays 2 through 12, the study concluded that additional field tests would be required to further quantify the TDG exchange benefits.

Most of the structural alternatives were identified to exhibit limited potential to effectively manage TDG saturation at Rocky Reach Dam primarily because of the relatively low rates of TDG exchange associated with current spill operations. The limited channel width of the Columbia River required the spillway and stilling basin at Rocky Reach Dam to take on a unique design aimed at efficiently dissipating the energy contained in spill over a short distance. The spillway and stilling basin include hydraulic structures like the nappe deflector, continuous baffle, and high stilling basin end sill that provides sufficient energy dissipation over the short length of the stilling basin. These hydraulic structures have the unintended impact of moderating the TDG exchange characteristics at Rocky Reach Dam. The combination of efficient energy dissipation in a shallow stilling basin with an end sill that produces a surface oriented jet entering the adjoining tailwater channel result in TDG pressures that are similar to projects with retrofitted TDG abatement structures (Schneider and Wilhelms 2005). Due to these unique characteristics, the assessment found that current TDG exchange performance at Rocky Reach Dam is comparable and in some cases superior to projects with spillway flow deflectors. Other alternatives evaluated such as raising the stilling basin elevation, raising the tailwater channel, and removing nappe deflectors were judged to provide minimal benefits to manage TDG saturation (Schneider and Wilhelms 2005).

Structural measures which were identified as having potential to further manage TDG saturation at Rocky Reach Dam were the entrainment cutoff wall and spillway flow deflectors in combination with a raised tailwater channel. The entrainment of powerhouse flow was estimated from the results of the 2002 near-field TDG exchange study and used to estimate the TDG benefits associated with an entrainment cutoff wall. The reduction to the average TDG saturation in the Columbia River below the Project was estimated to range up to 2.6 percent saturation when compared to current conditions. This alternative would have little influence on the maximum TDG saturation attained in spill but would reduce the TDG loading to the Columbia River and on TDG levels delivered to downstream projects. The amount of TDG abatement is smaller during voluntary spill conditions and goes to zero as the spill become small (Schneider and Wilhelms 2005).

The TDG exchange properties at Ice Harbor Dam have consistently exhibited the lowest TDG exchange properties of dams actively spilling for fish passage in the Columbia River Basin. The combination of spillway flow deflectors and a shallow tailwater channel has been identified as the cause for the low rates of TDG exchange. If the spillway, stilling basin, and adjoining tailwater channel at Rocky Reach Dam were rebuilt to resemble the conditions at Ice Harbor

Dam, an improvement to TDG management could be achieved. However, the benefits of TDG reduction were estimated to range up to 2.7 percent saturation or similar to the impacts attributed to an entrainment cutoff wall (Schneider and Wilhelms 2005).

Lastly, the study noted that further evaluation of the small suite of identified operational and structural TDG management alternatives must also consider the impacts to other beneficial uses of the river prior to further consideration for adoption. This recommendation is consistent with the requirements of the FERC Project License and Ecology's 401 Certification in addition to the discussion summarized in Section 2.4.1 above.

## **2.5.2 Post-relicensing TDG Compliance Activities**

Since filing the Rocky Reach Project Final License Application on June 30, 2004 (and receipt of a new operating license on February 19, 2009), Chelan PUD has continued to implement activities toward improving TDG management within the Rocky Reach Project. Many of the TDG Protection, Mitigation and Enhancement activities are summarized in the Rocky Reach Project Water Quality Management Plan (Chelan PUD 2005) and are described below.

### **2.5.2.1 Spill Testing 2011-2012**

Chelan PUD conducted a study to identify differences in TDG levels produced using four spill gate configurations (Parametrix 2013). The four spill gate configurations included Fish Spill (standard gate configuration for adult fish guidance using gates 2-8), TDG Spill, Shallow Arc Spill, and Flattened Spill. The latter three configurations used gates 2-9 and gates 11-12 in 2011 (gate 10 inoperable due to maintenance), and gates 2-10 and gate 12 in 2012 (gate 11 inoperable due to maintenance). Each configuration was tested under routine operating conditions to provide a record of TDG levels produced as a means to guide future spill gate operations. Data was obtained for spill periods of 2011 and 2012 for the forebay and downstream monitoring locations.

Results indicated that the Fish Spill configuration tended to increase TDG downstream from the dam and produced the highest TDG levels of the four configurations tested. The TDG Spill, Shallow Arc Spill, and Flattened Spill configurations tended to produce small reductions in TDG levels from the forebay to the downstream monitoring station. Given the similar number of gates used between these three spill gate configurations, the differences between configurations was not always clear or consistent. However, the Flattened Spill configuration tended to produce more consistent and slightly greater reductions in downstream TDG levels, than the other configurations (Parametrix 2013).

The basic difference between Fish Spill and the other configurations is the number of gates used to discharge a given amount of flow. Fish Spill used only seven gates, while the other configurations employed ten gates each. Spreading spill over a greater number of gates generally tends to minimize the production of TDG levels downstream (Parametrix 2013).

### **2.5.2.2 GAP and TDG Annual Reporting**

Consistent with years prior to the completion of relicensing, Chelan PUD continues to submit and operate under an Ecology-approved GAP to support downstream juvenile fish passage.

Chelan PUD coordinates the development of the GAP each year with the HCP CC and RRF using the best available information to minimize TDG while maximizing the benefits of spill for ESA-listed anadromous salmonids. Reporting of the Project's TDG management activities is submitted annually to the FERC and Ecology.

#### 2.5.2.3 TDG Monitoring

Chelan PUD maintains two fixed monitoring stations at Rocky Reach Dam to monitor TDG levels annually from April through August in the forebay and tailrace for the term of the License and any subsequent annual licenses, or until such monitoring is no longer required by Ecology, whichever occurs sooner. The monitoring point for TDG in the tailrace has been moved to near the JBS outfall. TDG is monitored hourly from April through August at these two stations and data is posted on a daily basis to Chelan PUD's web page and various web-accessible databases used by Ecology and regional fish management agencies. In addition to the two Rocky Reach Dam TDG monitoring locations, TDG data is also collected in the Rock Island Dam forebay occurs to support GAP requirements.

#### 2.5.2.4 Operation Plan for Fish Passage Spill Management

Chelan PUD manages voluntary spill levels provided for fish passage in real time in an effort to continue meeting TDG numeric criteria, using an Operational Plan for TDG, while meeting the HCP survival objectives. An Operational Plan is filed each year as part of the Project's GAP.

Under the Operational Plan for TDG, the Project's operations personnel monitor TDG levels hourly. If the previous six-hour average TDG level in the tailrace at the JBS outfall is at or above 120 percent, or the instantaneous TDG level is at or above 125 percent, the voluntary spill volume will be reduced by 3 kcfs, or as necessary to achieve an instantaneous TDG level below 120 percent. The new spill volume will be monitored for an hour. If the next six-hour average TDG level is not less than 120 percent, the spill will be reduced by another 2 kcfs and monitored for an hour. The cycle continues, with the spill reduced by 2 kcfs until the average TDG level of the previous six-hour period is less than 120 percent and remains at less than 120 percent through the next full hour. If the instantaneous TDG drops below 118 percent for one full hour, the spill will be increased by 2 kcfs and monitored. The objective is to maintain as much of the spill level scheduled for fish passage operations as possible, without exceeding the tailrace TDG numeric criteria. In 2016, voluntary spill at Rocky Reach was implemented only for subyearling Chinook and consisted of nine percent of the daily average flow.

If the TDG level in the forebay of Rock Island Dam exceeds 115 percent, Rock Island operations personnel notify Rocky Reach operations personnel immediately. If the TDG level in the Rock Island forebay is greater than 115 percent and the TDG level in the forebay of Rocky Reach is less than 115 percent, the voluntary spill volume at Rocky Reach will be reduced by 3 kcfs for two hours. If, after two hours of reduced spill, the Rock Island forebay TDG levels are still above 115 percent, the spill will be reduced another 2 kcfs. If, subsequently, the instantaneous TDG level in the forebay of Rock Island is less than 113 percent, spill will be increased to the level necessary to comply with the TDG level of 115 percent. Since the TDG level in the Rock Island forebay is affected by mixing of powerhouse flows with spillway flows at

the Rocky Reach Project, Rocky Reach operations personnel may develop additional protocols to adjust spill levels based on changes in powerhouse flow levels.

#### 2.5.2.5 Minimizing Voluntary Fish Passage Spill

Chelan PUD minimizes voluntary spill by implementing the HCP Agreement to meet survival objectives, using measures other than spill, such as the JBS, as much as practicable. Minimizing the use of spill to meet survival objectives reduces TDG levels caused by the Project. Reducing the use of voluntary spill is the most effective way to reduce TDG levels, as evidenced by the low TDG levels observed in 2004. As noted in Section 2.5.2.4, Chelan PUD provides Ecology with an Operations Plan for use of voluntary fish passage spill each year.

#### 2.5.2.6 Minimization of Spill Due to Maintenance

Chelan PUD minimizes spill, to the extent practicable, by scheduling maintenance based on predicted flows. The objective throughout the year is to maintain adequate hydraulic capacity to pass expected inflows through the powerhouse. The Project rarely spills for lack of hydraulic capacity. The continued improvement in maintenance planning to assure turbine unit availability during high flow periods is the most effective action that can be taken to prevent unplanned spill and meet the TDG numeric criteria.

#### 2.5.2.7 Avoidance of Spill Past Unloaded Units

Chelan PUD avoids spill by continuing to participate in the HCA, or any successive agreements to which Chelan PUD may be a party, to the extent it reduces TDG, and manage its operations in an effort to minimize spill past unloaded turbine units caused by imbalances between upstream flow releases and projected power demand. Continued improvement in the efficient operation of the coordinated system is an ongoing priority for Chelan PUD. This effort will continue to reduce the already very low incidence of involuntary spill, resulting in a reduction in TDG. Spill past unloaded units is infrequent and usually the result of problems with coordination of load requests and movement of water through the coordinated system. Improvements in the computer program that implements the HCA, as well as the changes to the allocation of the costs resulting from this type of spill reduce the incidence of spill past unloaded units (Chelan PUD 2006).

#### 2.5.2.8 Maximizing Powerhouse Discharge

Chelan PUD operates the powerhouse at maximum hydraulic capacity when necessary to maintain compliance with TDG criteria. At flows near the 7Q10 level and with one turbine out of service for maintenance, the 120 percent TDG criterion could be slightly exceeded. When operated under peak efficiency, turbines C1 through C7 will each pass up to 17,150 cfs of water and turbines C8 through C11 will each pass up to 21,200 cfs of water, for a total powerhouse hydraulic capacity of 204,000 cfs. The turbine flows can be increased to a total plant hydraulic capacity of 212,000 cfs for several hours, if necessary to control TDG loading. To do so would bring the Project into compliance at the tailrace for all flows under the 7Q10 flow. During the rare events where flows exceed normal powerhouse capacity during the non-fish spill period, this same operation could be used in addition to management of active storage to avoid spill. Chelan PUD regulates forebay levels, using active storage (the 36,400 acre-feet of storage

between minimum and maximum forebay levels allowed by the FERC license) to minimize spill events to the extent practicable under the HCA (Chelan PUD 2006).

#### 2.5.2.9 Spill from Gates 2 Through 12

In 2002, limited testing was conducted of a spill configuration using gates 2 through 12. That testing indicated some potential to use that spill operation configuration to reduce TDG levels during high spill volumes (USACE 2003). The findings from the limited number of test conditions indicated a potential reduction in average TDG levels of up to 2 percent (Schneider and Wilhelms 2005). Researchers recommended consideration of future additional testing of a spread spill configuration to evaluate its potential TDG management benefits at the Project.

As discussed in Section 2.5.2.1 above, Chelan PUD, in 2011 and 2012, studied alternative spillway flow distribution patterns, in order to evaluate the potential to reduce total dissolved gas TDG levels, particularly during high spill levels (above 50 kcfs). Generally, all of the three alternative spill patterns studied resulted in lower TDG levels than the standard spill pattern. Of the three alternative patterns, the flat spill pattern (flow distributed evenly between spillway gates) had a slightly better TDG performance than the other two alternative patterns. Chelan PUD presented these findings to Ecology, the RRFF and Habitat Conservation Plan Coordinating Committee (HCP CC; Chelan PUD 2016).

During the winter of 2016, computer programming of gates 9-12 for automated use occurred so that an operational configuration using spill gates 2 through 12 could be tested and ready late 2016 and early 2017, prior to the start of the 2017 fish-spill season. Currently, it is anticipated that the gate configuration, if successful in reducing TDG, would only be used during the non-fish spill season. Chelan PUD plans to operate the new spill configuration as a pilot or test spill and further evaluate the results for a designated period of time. If upon operating under the new spill configuration, data show that optimal results are not occurring as previously evaluated, Chelan PUD shall implement adaptive management in coordination with the RRFF and HCP CC. If operation under the new spill configuration provides significant reduction in TDG, Chelan PUD will incorporate the spill configuration into its regular operations during the non-fish spill season (Chelan PUD 2016). Additionally, Chelan PUD could consult with the RRFF and HCP CC to evaluate whether a flattened spill configuration should also be considered during the fish spill season to manage TDG.

#### 2.5.2.10 Monitoring of Aquatic Life for Gas Bubble Trauma

Gas bubble trauma (GBT) monitoring is not conducted on an annual basis at Rocky Reach Dam. However, Section 5.4(1)(c) of the Rocky Reach Project 401 Certification (Ecology, 2006) requires Chelan PUD to develop and implement a plan to study GBT below Rocky Reach Dam. On April 21, 2014, Chelan PUD received a letter from Ecology postponing the GBT monitoring until such a time as is determined to be appropriate by Ecology (Ecology 2014). Ecology is currently evaluating the need for future GBT studies below Rocky Reach Dam.

Currently, Chelan PUD, in conjunction with the Fish Passage Center (FPC) Smolt Monitoring Program, continues to conduct gas bubble trauma (GBT) monitoring at the Rock Island Bypass Trap. Random samples of 100 fish composed of spring Chinook, steelhead and subyearling

Chinook may be examined two days per week during the fish spill season (April 1 to August 31). Examinations for GBT symptoms follow a standardized FPC protocol (FPC 2009). The results of this monitoring effort are included in the GAP annual report each year.

#### 2.5.2.11 Regional Participation

Chelan PUD continues to participate in coordination with other Columbia River operators and regulators to address regional water quality issues, including sharing the results from water quality monitoring in the Rocky Reach Project.

## **3.0 METHODS**

### **3.1 Study Objective**

Ecology (2015) has determined that the Rocky Reach Project is currently not in full compliance with the TDG numeric criteria but that it also does not adversely affect aquatic life. The objective of this TDG AAA, as identified in the Project License and 401 Certification, is to prepare a report that evaluates what measures, both operational and structural, may be “reasonable and feasible” to implement to further reduce TDG production at the Project including an assessment of the probable and possible impacts of each measure to fish species (Chelan PUD 2004).

### **3.2 Alternatives Identification**

Several steps were implemented to achieve the objectives of the evaluation. First, site specific TDG information was acquired and reviewed for relevance. These data, studies, and compliance reports represent over a decade of TDG activities at the Rocky Reach Project and were comprised of TDG compliance monitoring, relicensing field and modeling activities, and post-license issuance compliance activities (Section 2.5). In addition to site-specific information, TDG assessments from facilities in the mid-Columbia River and greater Columbia and Snake River basins (i.e., local and regional) were also evaluated or considered if identified as relevant and applicable to the Rocky Reach Project.

As summarized above, the most relevant source of information available was associated with numerous site-specific studies conducted during or after the Project’s relicensing process and the USACE Phase I and II Dissolved Gas Abatement Studies (DGAS) for the Columbia River Fish Mitigation Program. TDG abatement measures identified and analyzed in these assessments have already been compiled and evaluated for their potential as reasonable and feasible TDG reduction alternatives for the Rocky Reach Project (MWH 2003; Schneider and Wilhelms 2005). Although completed over a decade ago, the suite of alternatives evaluated and the final set of potential alternatives recommended for further consideration as part of these site-specific evaluations remain the state-of-the-science in TDG management and in general, represent a comprehensive set of potential alternatives available to address TDG management in the region. As such, the results and conclusions of these assessments served as the starting point for this analysis.

A suite of operational and structural alternatives were identified from the existing information presented above. Each alternative was evaluated with respect to engineering, operations, power management, and environmental resources. The review included potential operational, coordination, financial, regulatory, and environmental implementation concerns and whether additional alternatives should be included. Each alternative was evaluated against a set of criteria that included:

1. Potential TDG benefits;
2. Capital cost;
3. O&M cost;
4. Feasibility of operational implementation;
5. Implications for generation;
6. Implications to environmental resources; and
7. Implications to public use

Section 4.0 below provides a summary of this alternatives analysis.

## **4.0 ANALYSIS**

### **4.1 Operational Alternatives**

Operational alternatives are typically the simplest to implement. They require less capital costs however their annual operating costs can be significant. Operational measures are generally constrained by a number of factors including power-generating requirements, existing coordination agreements, and voluntary spill for the downstream passage of juvenile salmonids as well as upstream migrating adults. In addition to the two operational alternatives (maximizing powerhouse flows and optimizing spill from gates 2 through 12) identified by Schneider and Wilhelms (2005), several other alternatives were identified in the evaluation process and are also discussed below.

#### **4.1.1 Maximize Powerhouse Flows**

Currently water passes through the spillway of Rocky Reach Dam for the following reasons: 1) excess flows at the Project to meet load/demand 2) observed flows above maximum generation of 212 kcfs and/or 3) requirements to provide fish bypass flows for outmigrating anadromous salmonids. In all three of these scenarios spilled water has the potential to increase TDG. In scenarios 1 and 3, if spill can be redirected to the powerhouse to maximize generation, then TDG loading from spill can be prevented.

At the Rocky Reach Project, the use of this operational alternative is constrained by fish spill requirements. The Rocky Reach HCP serves as the foundation for anadromous salmonid management at the Rocky Reach Project. All measures proposed in the HCP are intended to minimize and mitigate impacts to Plan species which include Upper Columbia River steelhead, yearling spring Chinook, and subyearling summer/fall Chinook; sockeye, and coho salmon. The Rocky Reach HCP provides for optional tools Chelan PUD may implement to aid in juvenile fish passage at the Project, including spill and the use of the JBS (Chelan PUD 2016). At this time,

survival standards (i.e., Phase III) have been met for all spring migrants (spring/yearling Chinook, steelhead and sockeye) at Rocky Reach Dam while operating the JBS exclusively. However, summer spill is still required for subyearling Chinook and in 2016, was equal to nine percent of daily average flow. Summer spill generally begins in early June and ends in mid-August when 95 percent of the migration of subyearling Chinook has passed the Project.

Another constraint upon diverting spillway flows to the powerhouse to maximize generation is coordination with upstream operations of federal facilities. FCRPS BO requirements have resulted in limitations to the load-following capability of much of the federal power system resulting in an apparent shift of load-following to Grand Coulee and Chief Joseph, which tends to increase flow fluctuations and decrease flow predictability in the mid-Columbia River existing coordination agreements.

Powerhouse hydraulic capacity also limits the potential benefit of this alternative. The 7Q10 flow at Rocky Reach Dam is 252 kcfs and the powerhouse capacity is approximately 212 kcfs for short periods of time and with all ten units in service. Even at maximum generation, approximately 40 kcfs of spill may need to be managed to meet TDG water quality requirements. Furthermore, time periods when flows are high and compliance with TDG criteria are a concern are often coupled with periods of low electricity demand. This scenario may restrict the potential for maximizing generation at a single project in a coordinated system.

Maximizing powerhouse flows likely has potential TDG benefits and low capital cost. Positive impacts to generation and negligible impacts to public use are also anticipated. However, the magnitude of TDG benefits remains uncertain given the potential for increased powerhouse flows to mix with spillway flows (depending upon operational regimes) and as noted above, the constraints of implementing this option within a coordinated system. Furthermore, in the absence of a detailed approach for maximizing powerhouse flows, costs associated with operation and maintenance of this alternative are unknown. Lastly, putting more water through turbines could have an adverse effect to downstream migrating juvenile fish. No impacts to upstream migrating adults are anticipated. Although maximizing powerhouse flows remains a viable option, it is likely one of several approaches best utilized in combination for managing spill.

#### **4.1.2 Optimizing Spill From Gates 2 Through 12**

As discussed in Section 2.2.1.1, the standard Project spill configuration uses gates 2 through 8 with a minimum discharge per spill bay of about 4 kcfs. This configuration was designed to create a crown-shaped pattern of turbulent flow below the spillway with decreasing velocities leading toward the upstream adult fishway entrances and provides favorable guidance conditions for adult migrant salmon and steelhead. Testing of this spill configuration and alternate patterns determined this pattern was as good as, if not better than, the alternate patterns for upmigrating salmonids (Schneider and Wilhelms 2005). The same pattern is used for juvenile downstream migrating fish passage spill. Currently, during spill operations, whether for juvenile fish passage, TDG management, or for other purposes, the gates are operated via a computer automated system that follows the spill pattern (Chelan PUD 2016).

Note that although the above referenced spill configuration may be as good as, if not better, than tested alternate patterns for upmigrating salmonids, it may not be ideal for TDG. During relicensing, TDG studies indicated that a uniform spill pattern (using gates 2 through 12) produced slightly less TDG than the standard pattern for total spill levels of about 50 kcfs (USACE 2003). Additional analysis supported this observation based upon a small number of operational trials that indicated a flat or uniform pattern optimizing spill from gates 2 through 12 might decrease TDG saturation up to 7 percent during maximum fish spill of 62.5 kcfs (MWH 2003). A common recommendation of relicensing studies identified the need for additional field tests of the uniform spill pattern to better quantify TDG exchange benefits (Schneider and Wilhelms 2005). This recommendation is also reflected in Section 5.4(1)(b)(6) of the Project 401 Certification (Ecology 2006).

Chelan PUD studied alternative spillway operations using gates 2 through 12 in 2011 and 2012 (Parametrix 2013) with promising results for flattened spill patterns versus the current fish spill configuration. In 2015, Chelan PUD, through coordination with the HCP CC, requested the ability to use the flattened spill configuration during the non-fish spill season. The HCP CC approved and in the winter of 2016, computer programming of gates 9-12 for automated use was completed. Chelan PUD will begin testing the flattened spill pattern late 2016.

Preliminary spill testing indicates that optimizing spill from gates 2 through 12 has the potential to reduce TDG production at the Project. Operation and maintenance efforts to implement a more flattened spill shape when necessary are likely negligible and there would be no capital costs associated with this alternative. Since no structural alterations would be considered, the spillway would maintain its ability to pass the spillway design flow and power generation and public use would likely remain unaffected. Downstream passage of juvenile salmonids would also likely remain similar to the current condition. The primary concern with maximizing the use of spillway bays during the fish spill season is the potential impact to upstream adult passage at the Project since a wider band of spillway flows could create flow patterns that make locating upstream fishway entrances difficult for migrating adult salmonids. This alternative is promising but may require additional study to better understand TDG production dynamics at different flows and under different spill operational scenarios to identify an operation(s) that reduces TDG. Identified operations could be utilized during the non-fish spill season and if there is interest in utilization during the fish spill season, additional evaluations to determine whether there are adverse effects to upstream adult migration are recommended.

#### **4.1.3 Scheduling Project Maintenance**

Scheduling outages for project maintenance may be affected by a number of factors including the type of outage (i.e., major versus minor, unexpected versus annual maintenance) and associated duration, electricity demand and prices, overall system reserve or shortfall, river flows, and environmental requirements during the maintenance period. Generating unit maintenance is typically scheduled during the “shoulder” months when power demands are lower or when lower river flows are anticipated. Re-evaluating the factors under which project maintenance and associated unit outages are scheduled to consider seasonal peaks in TDG production as a primary consideration may be an option for improving TDG management.

As noted in Section 2.5.2.6, Chelan PUD minimizes spill, to the extent practicable, by scheduling maintenance based on predicted flows. The objective throughout the year is to maintain adequate hydraulic capacity to pass expected inflows through the powerhouse. The Project rarely spills for lack of hydraulic capacity. The continued improvement in maintenance planning to assure turbine unit availability during high flow periods is the most effective action that can be taken to prevent unplanned spill and meet the TDG numeric criteria.

In general, scheduled maintenance events at Rocky Reach Dam already consider environmental and resource requirements including upstream and downstream protection of anadromous salmonids and would not change operations and maintenance. The duration of major maintenance projects such as unit rebuilds may result in unavoidable unit outages during typical peak spill periods (i.e., spring). It is likely that any changes in prioritization of factors used to determine maintenance schedules would result in minimal benefits to TDG performance while generating unit reliability and availability could be jeopardized.

#### **4.1.4 Modification of Existing Agreements**

The Rocky Reach Project is operated under a number of agreements (coordinated and uncoordinated) that affect current operations (e.g. HCP, HCA, etc.). Evaluating existing agreements to identify potential modifications that would facilitate improved TDG management could be an option. However, any potential changes to existing agreements would require renegotiations with signatory parties. In the case of the HCA, such discussions would require the participation and approval of a number of federal and mid-Columbia PUD entities and power purchasers. Furthermore, the HCA requires that the power and non-power constraints of the individual projects be recognized in the coordination process. As such, stable and predictable river flows that would support TDG management are already an objective of this agreement.

In general, renegotiating existing agreements would be a complex and timely process with considerable financial implications. Any updated agreement would also need to consider implications for existing resource protection (i.e., ESA, public use) and regulatory compliance (i.e., FERC license) requirements. Given that existing agreements already aim to maximize generation and minimize spill on a system-wide basis, prioritizing TDG performance at a single project would likely result in a net decrease in overall protection of aquatic life designated uses and at considerable cost (e.g., compensation for replacement spill requests, system-wide effects, ESA and FERC implications, etc.; Douglas PUD 2014).

#### **4.1.5 Gas Abatement Spill**

Gas Abatement Spill is used to manage TDG levels throughout the Columbia River Basin. The Technical Management Team (including NMFS, USACE, and BPA) implements and manages this spill. Gas Abatement Spill is requested from dam operators from a reach of the river where TDG levels are high. A trade of power generation for spill is made between operators, providing power generation in a section of river with high TDG and trading an equivalent amount of spill from a project where TDG is low (Douglas PUD 2014). Gas Abatement Spill options or other agreements to trade power generation for spill could result in potential TDG benefits. In addition to the potential for an increase in operations and maintenance costs and constraints (due to coordination of an abatement program), potential impacts to environmental resources,

maintenance of spillway design flows, and generation cannot be determined at this time since no specific agreement or operation schedule is currently in place.

## **4.2 Structural Alternatives**

At many federal hydroelectric facilities on the Columbia River, substantial effort has been devoted to investigating structural alternatives for TDG reduction (MWH 2003). During the relicensing of the Rocky Reach Project, Chelan PUD contracted with the ERDC researchers who led many of the key studies on TDG management alternatives of the federal system, and these studies provide the basis for this investigation of structural alternatives. As noted above, relicensing studies began by evaluating 18 different structural TDG management alternatives for Rocky Reach Dam. However, results of the various studies indicated that many of the alternatives were either very expensive to implement, exposed downstream migrating fish to injury, had a low TDG benefit relative to cost or a combination of the above (MWH 2003). Researchers also found that most structural alternatives identified exhibit limited potential to effectively manage TDG saturation at Rocky Reach Dam primarily because of the relatively low rates of TDG exchange associated with current spill operations (Schneider and Wilhelms 2005). Results of the ERDC analyses concluded that only two structural alternatives have the potential to further manage TDG saturation at Rocky Reach Dam: the entrainment cutoff wall and spillway flow deflectors in combination with a raised tailwater channel (Schneider and Wilhelms 2005). These two alternatives comprise the structural alternatives analysis below. Factors considered in the analysis include TDG benefits, generation impacts, potential resource impacts (e.g., fish and aquatic, recreation, etc.), engineering feasibility, and capital and O&M cost. It is assumed that any structural alternative would require Chelan PUD to submit a license amendment application to FERC for approval.

### **4.2.1 Entrainment Cutoff Wall**

Rocky Reach Dam is unusual in that the powerhouse and spillway are constructed in a right-angle arrangement that provides opposing discharges. With the powerhouse and spillway arranged at approximately 90 degrees to each other, there is the potential for the spillway discharge to mix with the powerhouse discharge prior to the entrained air reaching the surface. An interaction of this nature generally produces increases in the TDG levels. Such an interaction results in both the loss of the dilution factor provided by most powerhouse discharges and an actual increase in the TDG levels of the powerhouse water. This interaction of the two flows appears to be most likely to occur with spill from the right side (looking downstream) of the spillway and turbine discharge from the higher numbered units (Units 8-11; Parametrix 2013).

Equations were developed by ERDC (Schneider and Wilhelms 2005) to estimate the reduction in TDG loading provided by a property designed entrainment cutoff wall. The TDG level measured below the spillway at the JBS monitoring location will not change with the implementation of an entrainment wall because the TDG level of spilled water is not affected; rather the entrainment wall could reduce the amount of powerhouse discharge that gets drawn into the spillway discharge, thus reducing the average TDG loading across the entire river channel downstream of the tailrace. The entrainment of powerhouse flow was estimated from the results of the 2002 near-field TDG exchange study and used to estimate the TDG benefits

associated with an entrainment cutoff wall. The reduction to the average TDG saturation in the Columbia River below the Project was estimated to range up to 2.6 percent saturation when compared to current conditions. This alternative would have little influence on the maximum TDG saturation attained in spill but would reduce the TDG loading to the Columbia River and on TDG levels delivered to downstream projects (Schneider and Wilhelms 2005).

The capital cost to design, permit, and construct an entrainment cutoff wall would be significant and would require extensive modification to the Project's structures, thus several years of design and model testing would be required before it could be approved and implemented. The TDG benefit relative to the cost appears to be low, especially since estimates of reduction noted above would likely not achieve full compliance with the TDG WQS. This option, if implemented, would also alter the flow characteristics of the tailrace in a manner that could adversely affect adult and juvenile salmonid passage and survival (Chelan PUD 2006). As such, additional consultation would be required with appropriate workgroups and agencies (e.g., RRF, HCP CC, NMFS, USFWS, etc.) to ensure the protection of aquatic resources. There would also be additional O&M costs associated with a new structure, although they would likely be low once an entrainment cutoff wall is constructed. However, if impacts to adult and juvenile salmonid passage and survival were identified and resulted in operational constraints, these costs could be significant.

#### **4.2.2 Spillway Flow Deflectors in Combination with a Raised Tailwater Channel**

Spillway flow deflectors are concrete lips built on the lower part of the spillway and have been one of the primary methods used for TDG management at dams on the lower Snake and Columbia River (USACE 2002). Spillway flow deflectors have been installed at Bonneville, John Day and McNary dams on the lower Columbia River and at Wanapum and Chief Joseph dams on the mid-Columbia River. Spillway flow deflectors have also been installed at Ice Harbor, lower Monumental, Little Goose, and lower Granite dams on the lower Snake River. Flow deflectors direct the spill in a horizontal direction to flow across the surface of the tailrace so that it does not travel deep in the water column allowing entrained air to re-enter the atmosphere at the water's surface. Encouraging near-surface flow also prevents entrained air from reaching a depth at which gas is more readily dissolved, thereby decreasing TDG levels relative to water that plunges to depth (MWH 2003). Important factors to consider for spillway flow deflectors include deflector elevation relative to operating tailrace elevation, depth of the stilling basin, and downstream passage requirements for anadromous salmonids.

Several predictive models were developed during the DGAS program (Schneider and Wilhelms 1998a; Schneider and Wilhelms 1998b) to estimate the effects of a raised tailrace channel on TDG exchange at Columbia and Snake River projects. The TDG estimates were based on the application of theoretical and conceptual models of the gas exchange processes, an analysis of historical data, application of an empirical relationship based on near-field measurements, and an analysis of degassing in the tailrace region. Model results suggest that a rapid and substantial desorption of supersaturated dissolved gas takes place in the tailwater channel immediately downstream of the stilling basin. As the entrained air bubbles are transported downstream, they rise above the compensation depth in the tailwater channel and air bubbles strip dissolved gas from the water column (Schneider and Wilhelms 2005).

Based upon the two methods described above, this alternative could reduce TDG levels at Rocky Reach Dam by redirecting spill horizontally along the tailrace surface (avoid plunging) and promoting TDG degassing (re-entry of entrained air to the atmosphere) at the water surface. Any portion of spill flow that plunges (and entrain air) would enter a reconstructed tailwater area that would be shallower. The reduction in the plunging depth of aerated flow would promote the stripping of TDG (Schneider and Wilhelms 2005).

ERDC used the TDG exchange relationship developed for Ice Harbor Dam to estimate the TDG level in spillway flows for Rocky Reach Dam. Calculations (at 7Q10 flow with one turbine out of service) indicate that this alternative would reduce TDG in spill by 4.0 to  $4.2 \pm 1.2$  percent. There remains considerable uncertainty in the estimates of TDG exchange associated with this alternative as applied to Rocky Reach Dam. The interaction of both the continuous baffles and the stilling basin end sill will interfere with the deflected surface jet and may alter the trajectory and TDG exchange properties of this alternative (Chelan PUD 2006).

This option would only be needed during high flows and would only be effective if the deflectors are designed to function under high tailwater surface elevations. Under normal and low tailwater elevations, studies of fish survival at Ice Harbor Dam and other dams have shown that spill deflectors may decrease the survival of juvenile salmon passing through the spillway. Most of the spill at the Project is voluntary spill for fish passage, which occurs when flow is below 200 kcfs. Spillway deflectors would only be needed to abate TDG when flows approach the 252 kcfs level, but would affect fish survival during any spill, including voluntary fish passage spill. Thus, the need to protect downstream migrating salmonids may preclude implementation of this option (Chelan PUD 2006).

Similar to the entrainment cutoff wall, the capital cost to design, permit, and construct this structural alternative would be significant and would require extensive modification to the Project's structures. Further consideration would require additional site-specific hydraulic and physical modeling studies to assess the deflector design and interactions with existing spillway infrastructure; the type, amount and location of tailrace fill; and the potential performance of the alternative. The TDG benefit, although estimated to be higher than the entrainment cutoff wall, remains uncertain and is still low relative to the cost implementation. Additional consultation would be required with appropriate workgroups and agencies (e.g., RRFF, HCP CC, NMFS, USFWS, etc.) to ensure the protection of aquatic resources, primarily ESA-listed salmonids given the potential survival impacts of spill deflectors to juvenile salmonids. There would be additional O&M costs although these would likely be low once constructed. Flow patterns in the tailrace would also be likely to change under this alternative and this could impact adult salmonid passage. Consultation and with fish management agencies would be required to evaluate impacts and this could result in operational constraints or other mitigation or protection measures. These costs could be significant but cannot be characterized at this time.

Other factors requiring evaluation include whether coffer damming would be required during construction; impacts to public use (i.e., boating) below the dam as turbulence would likely be carried further downstream; erosion; and backwater impacts resulting in reduced head and power revenue impacts.

## 4.3 Alternatives Evaluation

In the following section, an evaluation summary is presented in which each of the preceding alternatives is evaluated against a set of criteria.

### 4.3.1 Evaluation Criteria

Using the MWH (2003) report as a basis, the following evaluation criteria (listed below) and scoring metrics were developed for each alternative presented in Section 4.2.

For TDG Reduction (i.e., evaluation criterion 1 below), scoring metrics ranged from 1 to 2. A score of 1 was defined as remaining the same as at present condition and a score of 2 was defined as improvement over present conditions. For all other criteria below (i.e., criteria 2-8), scoring metrics ranged from 1 to 4. A score of 1 was defined as less desirable than present conditions; a score of 2 was defined as the same as at present conditions; a score of 3 was defined as more desirable than present conditions; and a score of 4 was defined as unknown at this time.

1. TDG Reduction: the potential for the alternative to reduce TDG below current levels;
2. Downstream Fish Passage: the potential for the alternative to impact downstream fish passage at the dam including mortality and injury;
3. Upstream Fish Passage: the potential for the alternative to impact upstream fish passage at the dam including disorientation resulting in passage delays;
4. Maintaining Design Spillway Discharge: how does the project affect the ability of the spillway to pass the spillway design flood?;
5. Generation Impacts: the potential for the alternative to impact the ability to generate electricity;
6. Public Use: the potential for the alternative to affect public use of the river;
7. O&M: the potential for the alternative to impact operations and maintenance. This includes both limitation on operational flexibility and O&M cost; and
8. Capital Cost: Four cost categories in 1,000s of dollars were identified and include \$0 (no capital cost), <\$20,000, \$20,000-\$60,000, and >\$60,000. It includes the cost of design, engineering, construction, administration, and interest incurred during construction. Most costs were computed by adjusting final costs of alternatives in various studies done at USACE projects (MWH 2003). Note that the entrainment wall estimate is an approximate cost developed by HDR. The accuracy of these estimates is less than that of a feasibility level assessment and it is recommended that a more thorough design analysis be conducted to provide more accurate costs prior to considering implementation.

The evaluation is presented in Table 1.

**Table 1. Evaluation summary of total dissolved gas reduction alternatives at Rocky Reach Dam.**

| Alternative   | TDG Benefit | D/S Passage | U/S Passage | Maintain Spillway Design | Generation Impacts | Public Use | O&M | Capital Cost (\$1,000) | Comments  |
|---|-------------|-------------|-------------|--------------------------|--------------------|------------|-----|------------------------|---|
| Maximize Powerhouse Flows   | 2           | 1           | 2           | 2                        | 3                  | 2          | 4   | \$0                    | Mid-Columbia is under HCA and maximizing generation at single project may be infeasible. Impacts to downstream migrating juvenile fish.   |
| Optimizing Spill from Gates 2 through 12                          | 2           | 2           | 4           | 2                        | 2                  | 2          | 2   | \$0                    | Preliminary results indicate a TDG benefit. Highest potential for TDG benefit without additional impacts to aquatic resources.  |
| Scheduling Project Maintenance                                    | 2           | 2           | 2           | 2                        | 1                  | 2          | 1   | \$0                    | TDG benefit likely minimal with unknown costs and likely increase in O&M.   |
| Modification of Agreements  | 2           | 4           | 4           | 4                        | 4                  | 4          | 1   | \$0                    | Given multi-party agreements in place, renegotiation likely complex. Prioritizing TDG at one project would likely result in overall net decrease in resource protection and generation however scope of impact unknown. |
| Gas Abatement Spill   | 2           | 4           | 4           | 4                        | 4                  | 4          | 1   | \$0                    | In the absence of more specifics on a spill program, impacts to most resources are unknown.   |
| Entrainment Cutoff Wall   | 2           | 1           | 1           | 2                        | 4                  | 2          | 1   | \$20,000-\$60,000      | Significant capital cost and low TDG benefit.   |
| Spillway Deflectors in combination with Raised Tailrace Elevation | 2           | 1           | 1           | 2                        | 4                  | 1          | 1   | \$20,000-\$60,000      | Spillway Deflector: Interaction of existing Project infrastructure with deflector. D/S passage concerns.<br><br>Raised Tailrace Elevation: Concerns include resource protection, public use and generation impacts.     |

## 5.0 CONCLUSIONS

This TDG Abatement Alternatives Analysis (TDG AAA) has been developed consistent with Section 5.4(1)(e)(2) of the Rocky Reach Project 401 Certification (Ecology 2006). It is based upon both historic and the most current regional and site-specific TDG information regarding potential operational and structural abatement measures. It serves as the basis for consultation to determine if any additional reasonable and feasible measures may exist to meet the TDG standards for the Rocky Reach Project.

This analysis compiled all relevant site-specific and regional information regarding both operational and structural TDG abatement alternatives. Results of the literature review indicated that the most significant source of TDG abatement alternatives information originated from two sources, 1) Site specific studies conducted by Chelan PUD during and after the Rocky Reach Project FERC relicensing process; and 2) the USACE DGAS program and that these alternatives were compiled in a report by MWH (2003). Numerous TDG abatement measures identified and analyzed in these assessments had already been compiled and evaluated for their potential as reasonable and feasible TDG reduction alternatives for the Rocky Reach Project (MWH 2003; Schneider and Wilhelms 2005). Although completed over a decade ago, the suite of alternatives evaluated and the final set of potential alternatives recommended for further consideration as part of these site-specific evaluations remain the state-of-the-science in TDG management and in general, represent a comprehensive set of potential alternatives available to address TDG management in the region. Potential alternatives identified from results of these assessments formed the basis for a multi-disciplinary review regarding potential operational, coordination, financial, regulatory, and environmental implementation concerns and whether additional alternatives should be included.

Results suggest that all of the alternatives evaluated would likely produce some level of TDG benefit. However, a number of concerns regarding the uncertainty around impacts to generation, environmental resources, and the feasibility of operational implementation were identified. In addition, both of the structural measures would likely require significant capital costs to implement with reoccurring O&M costs. Any further evaluation of any of the alternatives in the future will require detailed site-specific assessment and in some cases require additional physical, hydraulic and financial evaluations to more accurately scope the TDG benefit relative to the overall implementation cost. Furthermore, previous site specific TDG assessments have noted that the current spillway infrastructure already have the unintended impact of moderating TDG exchange. Structures such as the nappe deflector, continuous baffle, and high stilling basin end sill provide sufficient energy dissipation over the short length of the stilling basin. The combination of efficient energy dissipation in a shallow stilling basin with an end sill that produces a surface oriented jet entering the adjoining tailwater channel result in TDG pressures that are similar to projects with retrofitted TDG abatement structures (Schneider and Wilhelms 2005).

Existing spillway infrastructure appears to already provide TDG benefits and coupled with the high cost, nominal TDG benefits, and implementation uncertainties of adding structural alternatives evaluated during this analysis, it may be more appropriate to continue exploring, in

consultation with Ecology, the RRFF and the HCP CC, operational alternatives such as a flattened spill configuration. This would allow for a more incremental approach to evaluating TDG benefits versus costs and other potential impacts including to aquatic resources.

Subject: **DRAFT UPPER COLUMBIA RIVER 2017 BY SALMON AND 2018 BY STEELHEAD HATCHERY PROGRAM MANAGEMENT PLAN AND ASSOCIATED PROTOCOLS FOR BROODSTOCK COLLECTION, REARING/RELEASE, AND MANAGEMENT OF ADULT RETURNS**

The attached protocol was developed for hatchery programs rearing spring Chinook salmon, summer Chinook salmon and summer steelhead associated with the mid-Columbia HCPs; spring Chinook salmon, summer Chinook salmon and steelhead programs associated with the 2008 Biological Opinion for the Priest Rapids Hydroelectric Project (FERC No. 2114); and fall Chinook salmon consistent with Grant County Public Utility District and Federal mitigation obligations associated with Priest Rapids and John Day dams (ACOE funded), respectively. These programs are funded by Chelan, Douglas, Grant County Public Utility Districts (PUDs), and ACOE and are operated by the Washington Department of Fish and Wildlife (WDFW), with the exception of the Omak Creek/Okanogan Basin steelhead broodstock collection, and acclimation/release of Omak Creek steelhead which is implemented by the Confederated Tribes of the Colville Reservation (CTCR).

This protocol is intended to be a guide for 2017 collection of salmon (2017BY) and steelhead (2018BY) broodstocks in the Methow, Okanogan, Wenatchee, and Columbia River basins. It is consistent with previously defined program objectives such as program operational intent (i.e., conservation and/or harvest augmentation), mitigation production levels (e.g., HCPs and Priest Rapids Salmon and Steelhead Settlement Agreement), changes to programs as approved by the HCP-HC and PRCC-HSC, and to comply with ESA permit provisions, USFWS consultation requirements.

Notable in this year's protocols are:

- Continuing for 2017, no age-2 or 3 males will be incorporated into spring or summer Chinook programs unless necessary to maintain effective population size (minimum female to male ratio of 1:0.75; conservation programs only).
- Use of ultrasonography to determine the sex of each fish retained for brood to ensure achieving the appropriate number of females for program production (does not include Priest Rapids Hatchery).

- Utilization of genetic sampling/assessment to differentiate Twisp River and Methow River Basin natural-origin spring Chinook adults collected at Wells Dam, and CWT interrogation during spawning of hatchery spring Chinook collected at the Twisp Weir and Methow FH to differentiate Twisp and Methow Composite hatchery fish for discrete management of Twisp and Methow Composite production components for the GPUD, CPUD and DPUD programs.
- Collection of only hatchery adult steelhead at Wells Dam/Hatchery for the Lower Methow safety-net (WFH/MFH), and Wells Hatchery Okanogan and mainstem Columbia safety-net programs.
- Collection of spring Chinook for the Nason Creek and Chiwawa programs using combination of Tumwater Dam and the Chiwawa Weir.
- Targeted collection of 100% of the Wenatchee summer Chinook and Wenatchee hatchery origin steelhead broodstock at Dryden Dam to reduce the number of activities that may contribute to delays in fish passage at Tumwater Dam (some adult collections at Tumwater may be necessary if sufficient adults cannot be acquired at Dryden Dam).
- Targeted collection of 100% of the natural origin steelhead broodstock at Tumwater Dam.
- Collection of summer Chinook broodstock from the Chelan Falls Canal Trap (CFCT), sufficient to meet the entire Chelan Falls yearling program of 576K. Summer Chinook collections at Entiat Hatchery may be used to support the Chelan Falls program if broodstock collection efforts at the CFCT fall short.
- Collection of surplus hatchery origin steelhead from the Twisp Weir (up to 25% of the required broodstock) to produce the 100K Methow safety-net on-station-released smolts (up to 17 adults). The remainder of the broodstock (51) will be WNFH returns collected at WNFH (or by angling/trapping for WNFH program) and/or Methow Hatchery and surplus to the WNFH program needs. Collection of Wells stock may be used if WNFH and Twisp returns are insufficient. The collection of adults will occur in spring of 2018.
- Summer Chinook collections at Wells Dam to support the CJH program may occur if CCT broodstock collection efforts fail to achieve broodstock collection objectives.
- Collection of ad-clipped only (no wire) spring Chinook adults (or possibly eggs identified through CWTs from ad-clipped +CWT CJH segregated returns) may occur from facilities in the Methow basin and/or Wells Dam. These alternative collection locations will only be used if CCT and USFWS broodstock collection efforts fail to achieve broodstock collection objectives for the CJH segregated program, or if conditions (e.g., spill at CJD, ladder/trap efficiency) appear uncondusive to efficient collection of broodstock.

Collection will run concurrent with spring Chinook broodstock collection for Methow Hatchery.

- Collection from the Wells Hatchery volunteer channel of Wells summer Chinook to support the YN, Yakima River summer Chinook program.
- Targeted collection of 1,000 adipose present, non-coded wire tagged fall Chinook from the PRD OLAFT.
- Targeted collection of about 400 adipose present, non-coded wire tagged fall Chinook using hook and line efforts in the Hanford Reach.

These protocols may be adjusted in-season, based on actual run monitoring at mainstem dams and/or other sampling locations. Additional adaptive management actions as they relate to broodstock objectives may be implemented as determined by the HCP-HC or PRCC-HSC and within the boundaries of applicable permits.

Also included in the 2017 Broodstock Collection Protocols are:

**Appendix G:** DRAFT Hatchery Production Management Plan

## **Methow River Basin**

### *Spring Chinook*

Inclusion of natural-origin fish in the broodstock will be prioritized for the aggregate conservation program in the Methow Basin. Collections of natural-origin fish will not exceed 33% of the Methow Composite (i.e., non-Twisp) and Twisp natural-origin run escapement consistent with take provisions in Section 10 (a)(1)(A) Permits 18925 and 20533.

Hatchery-origin spring Chinook, if needed, will be collected in numbers excess to program production requirements to facilitate BKD management, comply with ESA Section 10 permit take provisions, and to meet programmed production shortfalls with natural origin fish. Based on historical Methow FH spring Chinook ELISA levels above 0.12, any hatchery origin spring Chinook broodstock collection will include hatchery origin spring Chinook in excess to broodstock requirements by approximately 33.3% (based upon the most recent 5-year mean

ELISA results for the Methow/Chewuch program; 11.8% for the Twisp program). For purposes of BKD management and to comply with maximum production levels and other take provisions specified in ESA Section 10 permits 18925 and 20533, culling will include the destruction of eggs from hatchery-origin females with ELISA levels greater than 0.12 and/or that number of hatchery origin eggs required to maintain production at 223,765 yearling smolts. Culling of eggs from natural-origin females will not occur unless their ELISA levels are determined by WDFW Fish Health to be a substantial risk to the program. Progeny of natural-origin females, with ELISA levels greater than 0.12, may be differentially tagged for evaluation purposes. Annual monitoring and evaluation of the prevalence and level of BKD and the efficacy of culling returning hatchery- and natural-origin spring Chinook will continue and will be reported in the annual monitoring and evaluation report for this program.

WDFW genetic assessment of natural-origin Methow spring Chinook (Small et al. 2007) indicated that Twisp natural-origin spring Chinook can be distinguished, via genetic analysis, from non-Twisp spring Chinook with a high degree of certainty. The Wells HCP Hatchery Committee accepted that Twisp-origin fish could be genetically assigned with sufficient confidence and that natural origin collections can occur at Wells Dam. Scale samples and non-lethal tissue samples (fin clips) for genetic/stock analysis will be obtained from adipose-present, non-CWT, non-ventral-clipped spring Chinook (suspected natural-origin spring Chinook) collected at Wells Dam, and origins assigned based on genetic analysis. Natural-origin fish retained for broodstock will be PIT tagged (pelvic girdle) for cross-referencing tissue samples/genetic analyses. Tissue samples will be preserved and sent to the WDFW genetics lab in Olympia Washington for genetic/stock analysis. Spring Chinook collected from Wells will be held until genetic analysis results are received (unless adult holding is not yet available due to the Wells modernization project, in which case fish will be held at Methow FH pending results), then transferred to and retained at Methow Hatchery and spawned for each program depending on results of DNA analysis. Brood collection of NORs at Wells will be based upon assignment of Twisp NORs to the Twisp program and non-Twisp NORs being used to support Methow and Chewuch River releases. Spring Chinook collected at Methow Hatchery will be held at MFH until genetic analysis results are received and then handled accordingly.

The number of natural-origin Twisp and Methow Composite (non-Twisp) spring Chinook retained will be dependent upon the number of natural-origin adults returning and the collection objective limiting extraction to no greater than 33% of the natural-origin spring Chinook return to the Methow Basin. Natural origin fish not assigning to the Twisp or Methow Composite will be released back into the Columbia River.

Weekly estimates of the passage of Wells Dam by natural-origin spring Chinook will be provided through stock-assessment and broodstock-collection activities. This information will facilitate in-season adjustments to collection composition so that extraction of natural-origin spring Chinook remains no more than 33%. Trapping at the Winthrop NFH will be included, if needed, in the event of broodstock shortfalls.

Pre-season run-escapement of Methow-origin spring Chinook to Wells Dam during 2017 is estimated at 3,265 spring Chinook, including 2,292 hatchery and 973 natural origin spring Chinook (Table 1 and Table 2). In-season estimates of natural-origin spring Chinook will be

adjusted proportional to the estimated returns to Wells Dam at weekly intervals and may result in adjustments to the broodstock collection targets presented in this document.

The following broodstock collection protocol was developed based on BKD management strategies, projected return for BY 2017 Methow Basin spring Chinook at Wells Dam (Table 1 and Table 2), and assumptions listed in Appendix A.

The 2017 aggregate Methow spring Chinook broodstock collection will target up to 122 adult spring Chinook (18 Twisp, 104 Methow; Table 3). Based on the pre-season run forecast, Twisp fish are expected to represent about 5% of the CWT tagged hatchery adults and 18% of the natural origin spring Chinook passing above Wells Dam (Tables 1 and 2). Based on this proportional contribution and a collection objective to limit extraction to no greater than 33% of the age-4 and age-5 natural-origin spawning escapement to the Twisp, the 2017 Twisp origin broodstock collection will total 18 wild fish, representing 100% of the broodstock necessary to meet Twisp program production of 30,000 smolts. Methow Composite fish are expected to represent about 42% of the CWT tagged hatchery adults and 82% of the natural origin spring Chinook passing above Wells Dam (Tables 1 and 2). Based on this proportional contribution and a collection objective to limit extraction to no greater than 33% of the age-4 and age-5 natural-origin recruits, the 2017 aggregate Methow broodstock collection will total 104 natural origin spring Chinook. Broodstock collected for the aggregate Methow programs represents 100% of the broodstock necessary to meet the Methow programs production of 223,765 smolts. The Twisp River releases will be limited to releasing progeny of broodstock identified as wild Twisp and or known Twisp hatchery origin fish, per ESA Permit 18925. The MetComp releases will include progeny of broodstock identified as wild non-Twisp origin (or known Methow Composite hatchery origin if needed to meet shortfalls in the production goal) fish. Age-3 males (“jacks”) will not be collected for broodstock.

Table 1. Brood year 2012-2014 age class-at-return projection for wild spring Chinook above Wells Dam, 2017.

| Brood year                   | Age-at-return      |                           |             |            |           |            |                  |              |            |            |            |                  |

Trapping at Wells Dam will occur at the East and West ladder traps beginning on May 1, or at such time as the first spring Chinook are observed passing Wells Dam, and continue through June 30, 2017 (collection quotas will be prioritized for the May 1-June 20 time frame). Spring Chinook broodstock collection and stock assessment sampling activities authorized through the 2017 Douglas PUD Hatchery M&E Implementation Plan will utilize a combination of trapping on the East and West ladders as per the detailed descriptions of the modified trapping operations

for spring Chinook collection in Appendix D (pages 38 and 39). Natural origin spring Chinook will be retained from the run, consistent with spring Chinook run timing at Wells Dam (weekly collection quota). Collection goals will be developed by Wells M&E staff to identify the most appropriate spatial and temporal approach to achieving the overall brood target. All natural origin spring Chinook collected at Wells Dam for broodstock will initially be held at Wells FH (or immediately transferred to Methow FH taking into account the status of adult holding during the modernization project) pending genetic results and then transferred to Methow FH. Fish collected at MFH will remain at MFH or be transferred to WNFH.

Collection of ad-clipped only (no wire) spring Chinook adults (or possibly eggs identified through CWTs from ad-clipped +CWT CJH segregated returns) may occur from facilities in the Methow basin and/or Wells Dam. These alternative collection locations will only be used if CCT and USFWS broodstock collection efforts fail to achieve broodstock collection objectives for the CJH segregated program, or if conditions (e.g., spill at CJD, ladder/trap efficiency) appear uncondusive to efficient collection of broodstock. Collection will run concurrent with spring Chinook broodstock collection for Methow Hatchery.

Trapping at the Twisp Weir for spring Chinook may begin May 1 or at such time as spring Chinook are observed passing Wells Dam and may continue through August 23. The trap may be operated up to seven days per week/16 hours per day (provided it is manned during active trapping).

However, trapping at the Methow Outfall trap may continue beyond the Twisp Weir operations as needed to meet basin wide PNI/pHOS objectives. Pending development of an adult management plan for spring Chinook in the Methow basin, hatchery-origin adults captured at the Methow Outfall (surplus to the Methow Hatchery program) will be: 1) used for adult out-planting to increase natural production (see Appendix for approved plan) and secondarily 2) transferred to the WNFH for incorporation into WNFH brood, or removed as surplus as supported by the HGMP's of both facilities.

### Steelhead

Douglas PUD and Grant PUD steelhead mitigation programs above Wells Dam utilize adult broodstock collections from multiple sources and locations such as at Wells Dam, Twisp Weir, Methow Hatchery volunteer trap, WNFH volunteer traps, Omak Weir, Wild horse Creek box trap and angling in the Methow River and Okanogan River (Table 5). Generally incubation/rearing occur for the Methow safety net, Okanogan, and Columbia River release at Wells Fish Hatchery (FH) with incubation/early rearing at Methow Hatchery for the DPUD conservation program. Broodstock for the conservation programs (USFWS and DPUD) is achieved via hook-and-line in the Methow Basin and the Twisp Weir (as needed), respectively (these programs are under program design review and may composite the broodstock). Broodstock for the Methow safety net program is achieved primarily through returns to WNFH (including hook and line-caught HOR steelhead) and surplus fish removed at Methow Hatchery and the Twisp Weir.

Specific program brood sources are structured as follows:

*Twisp River – Conservation Releases*

Due to the recent increased concern for inbreeding depression risk (Ryman-Laikre) for the Twisp program as a result of low  $N_e$  and other confounding issues, the design of Twisp program is currently under review.

The HC and JFP are working to redefine the scope and nature of the 2017 brood and future Twisp program. Parties will complete this task no later than October 1 (or sooner) of the current year such that an approved plan can be implemented and in a manner that does not unnecessarily delay consultation on the Methow steelhead HGMPs.

*Wells Hatchery – Methow River Release*

The Wells Hatchery Methow River release (Methow safety net program) uses locally collected hatchery origin broodstock representative of the Twisp and WNFH conservation programs and as needed, the Methow safety-net program. Adults are collected in concert with adult management activities at the Twisp Weir, Methow Hatchery, WNFH, and through hatchery fish intercepted during natural-origin brood hook-and-line collection for the USWFS Winthrop conservation program. As a backup to potential collection shortfalls in the Methow safety-net program and as a result of uncertainties in spring collection efficiencies, a portion of the Methow program will be augmented with collection of hatchery origin adults (30) occurring in the fall at Wells Dam. These fall-collected fish will be considered surplus to any spring-collected Methow, and eggs and/or fry from these surplus broodstock may be utilized for other programs in the upper Columbia. At least through the 2017 releases, fish are released from the Methow Hatchery, but may be released at other locations in the lower Methow once the HC approves a plan for such releases.

*Wells Hatchery-Columbia River Release*

The Wells Hatchery Columbia River releases will use returns to Wells Hatchery and may be augmented with adult returns to the Methow Hatchery and Winthrop NFH if needed to fulfill the program. To ensure the safety-net programs (Methow and Okanogan) have broodstock, a portion of the broodstock requirement (60 adults) will be collected at Wells Dam in the fall of 2017, and held at Wells Hatchery (Table 5). These fall-collected fish will be considered surplus to the spring-collected Methow and Okanogan broodstock, and eggs and/or fry from these surplus broodstock may be utilized for other programs in the upper Columbia. Fish are released to the Columbia River, immediately downstream of Wells Dam.

*Winthrop NFH – Methow River Release*

The USFWS Methow River release will primarily use natural-origin fish collected through hook-and-line collection efforts in the Methow River each spring. In the event NO collection falls short of the target, WNFH hatchery-origin returns will be prioritized, followed by safety-net

hatchery returns. Transfer of adult and/or gametes/eggs between program will be carefully choreographed to ensure fish are being utilized in the most efficient and effective manner. Fish may be released throughout the Methow basin.

### *Okanogan River releases*

The Okanogan River uses a combination of natural and hatchery-origin adults collected in Omak Creek and elsewhere in the Okanogan Basin through CCT collection efforts. As a backup to potential collection shortfalls in the Okanogan, a portion of the Okanogan program may be augmented with Okanogan locally-adapted hatchery-origin adults identified at spawning from 30 back up adults collected in the fall at Wells Dam. If needed to supplement spring collections, only fish with positive CWT for Okanogan origin will be used for this safety net aspect of the program. These fall-collected fish will be considered surplus to any spring-collected Okanogan broodstock, and eggs and/or fry from these surplus broodstock will be utilized for other programs in the upper Columbia. Surplus fish will be surplussed at the earliest time when overages are apparent.

Steelhead programs located upstream of Wells Dam and at Wells Hatchery are presented in Table 4.

Table 4. 2018 brood year Steelhead Programs at Wells Hatchery and Upstream of Wells Dam

| Program                        | Hatchery                           | Owner         | Release Location                                 | Release Target                  | Broodstock Collection Locations  |
|--------------------------------|------------------------------------|---------------|--|---------------------------------|--|
| DPUD Conservation <sup>2</sup> | TBD                                | Douglas PUD   | TBD  | 48,000 (S <sub>1</sub> )        | TBD  |
| Methow Safety-Net              | Wells Hatchery                     | Douglas PUD   | Methow Hatchery                                  | 100,000                         | HxH: Twisp Weir (up to 25%) + WNFH Hatchery (75%) or WNFH 1 <sup>st</sup> , MFH 2 <sup>nd</sup> to make up balance |
| Mainstem Columbia Safety-Net   | Wells Hatchery                     | Douglas PUD   | Wells Hatchery                                   | 160,000                         | HxH: Wells FH/Dam returns (1 <sup>st</sup> option); Methow FH/WNFH (2 <sup>nd</sup> option)                        |
| WNFH Conservation Program      | WNFH                               | USFWS         | WNFH or other locations as determined by the JFP | Up to 200,000 (S <sub>2</sub> ) | Maximize use of NOR, up to 55 pair captured by hook and line in the Methow River and Spring Creek Weir.            |
| Okanogan <sup>1</sup>          | Wells Hatchery/<br>St. Mary's Pond | Grant PUD/CCT | Okanogan tributaries                             | 100,000 <sup>1</sup>            | Okanogan Basin, Wells Dam  |

<sup>1</sup> CCT received approval for the Okanogan steelhead HGMP as part of their Tribal Resource Management Plan in February, 2017. Omak Creek and Wells Fish Hatchery are no longer separate hatchery programs. Up to 58 broodstock (NOB or HOB) may be collected from throughout the Okanogan basin (or Wells Dam if necessary) to meet the 100k program.

<sup>2</sup> The DPUD Twisp conservation program is currently under re-development after detection of inbreeding depression risk. The HC and JFP have committed to developing an approved plan in sufficient time for implementation and such that is doesn't negatively affect the consultations for Methow steelhead HGMPs.

The following broodstock collection protocol was developed based on mitigation program production objectives (Table 6), biological assumptions (Appendix A), and the probability that sufficient adult steelhead will return in 2017/2018 to meet production objectives absent a preseason forecast at the present time.

For the 2018 brood steelhead programs operating above Wells Dam, a total of 350 adults (152 natural origin and 198 hatchery origin adults) are estimated to be needed to fulfill the respective mitigation obligations (Table 6). To support these obligations and to ensure sufficient backup adults are on hand in the event tributary based collection efforts fall short of targets, trapping at Wells Dam and/or Wells FH will selectively retain up to 257 hatchery origin steelhead (west [and east, as necessary] ladder and volunteer trap collection; Table 5). As a note, all potential broodstock will be scanned for PIT tags at collection and PIT tagged fish will be returned to the river to meet their monitoring objective. Any adult determined to have been part of the Yakama Nations kelt reconditioning program will be released in the vicinity it was collected.

#### *Twisp Conservation Program (DPUD)*

Due to the increased concern for inbreeding depression risk (Ryman-Laikre) for the Twisp program as a result of low  $N_e$  and other confounding issues, the design of the Twisp program is currently under review.

The HC and JFP are working to redefine the scope and nature of the 2017 brood and future Twisp program. Parties will complete this task no later than October 1 (or sooner) of the current year such that an approved plan can be implemented and in a manner that does not unnecessarily delay consultation on the Methow steelhead HGMPs.

#### *Methow Safety Net Program*

Up to 14 surplus hatchery-origin Twisp-stock steelhead (to meet up to 25% of the 100K Methow Safety-Net release) will be targeted at the Twisp Weir and moved to Wells Hatchery for spawning. No less than 46 hatchery adults will be targeted at WNFH and through angling efforts, and if needed/available, Methow Hatchery volunteer traps to meet the balance of the program needs (Table 6). Up to 30 hatchery origin Wells stock collected and held at the Wells Hatchery will be used as a final option if broodstock collection at the Twisp Weir, and WNFH and MH traps/collection efforts are unsuccessful (Table 5). If needed, WNFH HO fish identified through PIT tag detections, collected at the MFH outfall may be transferred to WNFH for use in the Spawning Channel Evaluation Project rather than retained for broodstock. Coordination between USFWS and WDFW hatchery staff will occur during the season to determine prioritization.

#### *Methow Conservation Program (USFWS)*

Approximately 110 natural origin adults (55 pair) will be targeted for retention through hook-and-line collection efforts in the Methow River (Table 6). In the event of a shortage, excess hatchery steelhead from the Twisp Weir and volunteer returns to the WNFH (including angle-caught fish) will be utilized as needed to augment WNFH broodstock. Should there be

inadequate surplus steelhead from these sources, excess hatchery steelhead (presumed Methow Safety-Net origin) captured at the Methow Hatchery volunteer trap will be used to fulfill the program. Natural-Origin females will be live-spawned and reconditioned.

### *Okanogan Hatchery/Endemic Program*

Up to 58 adult steelhead will be targeted in the Okanogan Basin, including up to 100% natural-origin adults (dependent on run size and within the 33% natural origin extraction rate) (Table 5). Additionally, up to 30 hatchery adult steelhead will be targeted at Wells Dam/Hatchery as a back-up collection contingency due to unknown broodstock collection efficiencies in the Okanogan River Basin (Table 5).

Table 5. Broodstock collection locations, number, and origin by program.

| Program                     | Number of Adults <sup>1</sup> |                   | Primary collection location                  | Number of backup adults <sup>2</sup> | Backup collection location(s)       | Total adult collection <sup>1</sup> |                |
|-----------------------------|-------------------------------|-------------------|--|--------------------------------------|-------------------------------------|-------------------------------------|----------------|
|                             | Hatchery                      | Wild              |  |                                      |                                     | Hatchery                            | Wild           |

<sup>1</sup> Assumes a 1:1 sex ratio (see table 6). Natural origin females will be live spawned and reconditioned.

<sup>2</sup> All backup broodstock are hatchery origin adults.

<sup>3</sup> May include hatchery origin adults collected via the USFWS hook and line efforts for natural origin fish in the Methow River and adult returns to WNFH.

<sup>4</sup> May also include excess hatchery origin adults collected via angling and at Methow FH and the Twisp Weir.

<sup>5</sup> Spring collection of hatchery origin steelhead as needed to meet program shortfall for the Okanogan Program.

<sup>6</sup> Dependent upon number of NOR broodstock collected in the Okanogan Basin, age structure and fecundity to achieve sufficient brood for a 100k smolt program for the Okanogan.

<sup>7</sup> Depending upon NOR abundance and trapping efficiency

Table 6. Number of broodstock needed to produce approximately 608,000 smolts for the above Wells Dam 2018 brood summer steelhead programs. Includes primary collection location(s) and mating strategy. *Broodstock totals do not include additional fish that may be collected at other locations as a backup for shortfalls from primary collection sources.*

| Program                          | Production target/request | Number of Adults |                | Total                  | Collection location              | Mating protocol      |

<sup>1</sup>Mainstem Columbia releases at Wells Dam. Target HxH parental adults as the hatchery component.

<sup>2</sup>Methow hatchery release of HxH fish produced from either adults returning from the Winthrop conservation program, adults trapped at MFH, and/or surplus hatchery adults from the Twisp weir.

<sup>3</sup>CCT intends to achieve greater than 0.5 pNOB in both 2017 and 2018, but the actual number will be dependent upon run size and trap efficiency, per the HGMP. Numbers of hatchery and wild males and females in this table should not be taken as the goal or limit for any collection effort, as it could be up to 100% pNOB or pHOB.

<sup>4</sup> Up to an additional 30 hatchery adults will be collected at Wells FH as a fall back to shortfalls in collections for the Methow safety net.

<sup>5</sup> Up to an additional 30 hatchery origin adults will be collected at Wells Dam as backup to potential shortfalls in Okanogan Basin collection efforts.

<sup>6</sup> Collection priority: 1) hook and line, 2) adult returns to WNFH, 3) excess adult returns to Methow Hatchery.

<sup>7</sup> A 1:1 mating protocol will be used for all HxH/HxW crosses within the Okanogan. The Okanogan locally-adapted natural stock (WxW) will utilize a minimum 2x2 factorial mating to minimize potential negative effects associated with a small effective population size.

Overall collection for the PUD programs will be 294 fish (a combination of program specific and back-up adults; Table 5) and limited to no more than 33% of the entire run and/or 33% of the natural origin return. Hatchery and natural origin collections will be consistent with run-timing of hatchery and natural origin steelhead at Wells Dam and the Twisp Weir. Trapping at the Wells Dam ladders will occur between 01 August and 31 October, up to three days per week, and up to 16 hours per day, as required to meet broodstock objectives. Trapping will be concurrent with summer Chinook broodstocking efforts through 15 September on the west ladder (Appendix D). Operational criteria and dates for the Twisp Weir are still under construction.

Adult return composition including number, origin, age structure, and sex ratio will be assessed in-season at Priest Rapids and Wells dams. Broodstock collection adjustments may be made based on in-season monitoring and evaluation. If collection of adults from the east ladder trap is necessary, access will be coordinated with staff at Wells Dam due to the rotor rewind project.

### Surplus UCR Juvenile Steelhead Management

In the event excess juvenile are produced from the over-collection efforts to support the Methow safety net and /or Okanogan programs which rely on spring adult collections, the parties agree that distribution of juveniles will follow the following priority matrix:

1. Used to support shortfalls in the WNFH production obligation provided fish health and/or marking requirements for the program can be met.
2. Used to support any shortfalls in the Wells Columbia River release provided fish health and/or marking requirements for the program can be met.
3. Used to support shortfalls in the Ringold SHD program provided fish health and/or marking requirements for the program can be met.
4. Out-planted to landlocked lakes within Okanogan County and/or Colville Reservation provided fish health requirements can be met or provided stocking allotments are not exceeded (as determined by WDFW, YN and CCT fishery managers, as applicable).

In addition, surplus fish, including broodstock, will be distributed at the earliest possible life-stage (e.g., prespawm adults, eyed-egg, fry) per WDFW policy.

### Summer/fall Chinook

The summer/fall Chinook mitigation program in the Methow River utilizes adult broodstock collections at Wells Dam and incubation/rearing at Eastbank Fish Hatchery. The total production level target is 200,000 summer/fall Chinook smolts for acclimation and release from the Carlton Acclimation Facility.

The TAC 2017 Columbia River UCR summer Chinook return projection to the Columbia River (Appendix D) and BY 2012, 2013, and 2014 spawn escapement to tributaries above Wells Dam indicate sufficient summer Chinook will return past Wells Dam to achieve full broodstock collection for supplementation programs above Wells Dam. The following broodstock collection protocol for the Methow summer Chinook program was developed based on initial run expectations of summer Chinook to the Columbia River, program objectives, and program assumptions (Appendix A).

For 2017, up to 118 natural-origin summer Chinook at Wells Dam west (and east, if necessary) ladder(s), including 59 females for the Methow summer Chinook program (Table 7). Collection will be proportional to return timing between 01 July and 15 September. Summer Chinook stock assessment will run concurrent with summer Chinook broodstock collection at the west ladder trap. Trapping may occur up to 3-days/week, 16 hours/day (48 cumulative hours per week). Age-3 males (“jacks”) will not be collected for broodstock.

Should use of Wells Dam be needed to meet any shortfalls in broodstock for summer/fall

Chinook programs occurring in the Okanogan Basin, the CCT will notify the HCP-HC and Wells HCP Coordinating Committee/PRCC-HSC and coordinate with Douglas PUD, Grant PUD, and WDFW to facilitate additional broodstock collection effort. Summer Chinook broodstock collection efforts at Wells Dam, should they be required to meet CJH program objectives, will be conducted concurrent with broodstock collection efforts for the Methow summer Chinook program and or steelhead collection efforts for steelhead programs above Wells Dam. If the probability of achieving the broodstock goal is reduced based on passage at the west ladder or actual natural-origin escapement levels, broodstock collections may be expanded to the east ladder trap and/or origin composition will be adjusted to meet the broodstock collection objective. If collection of adults from the east ladder trap is necessary, access will be coordinated with staff at Wells Dam due to the rotor rewind project.

Table 7. Number of broodstock needed for Grant PUDs Methow summer Chinook production obligation of 200,000 smolts, collection location, and mating strategy.

| Program      | Production target | Number of Adults |            | Total      | Collection location | Mating protocol |
|--------------|-------------------|------------------|------------|------------|---------------------|-----------------|
|              |                   | Hatchery         | Wild       |            |                     |                 |
| Methow       | 200,000           |                  | 59F/59M    | <b>118</b> | Wells Dam           | 1:1             |
| <b>Total</b> | <b>200,000</b>    |                  | <b>118</b> | <b>118</b> |                     |                 |

**Rearing** – Early rearing growth will be modulated for a targeted size at release of approximately 18 fpp. Beginning on or about February 1, fish will be fed to satiation to maximize spring growth regardless of end size.

**Release** - The summer Chinook salmon acclimated at the Carlton Acclimation Facility will be forced released using the following criteria.

- all fish will be released during darkness (e.g., 9:00 PM or later),
- all fish will be released when Columbia River and Methow River flows are predicted to be satisfactory,
- all fish will be released no later than May 7 regardless of flow conditions,
- attempts will be made to have a steady release of fish to reduce collisions on the PIT antenna array.

Satisfactory flows in the Columbia occur when spilling flows are started and flows in the Methow River are satisfactory when flows are high and turbid. Releases will not occur until satisfactory flows in the Columbia occur, but could occur if Methow River flows are not satisfactory due to insufficient snow pack.

## Columbia River Mainstem below Wells Dam

### Summer/fall Chinook

Collection at the Wells FH volunteer channel will be used to collect the broodstock necessary for the Wells FH yearling (320,000) and sub-yearling (484,000) programs.

Because of CCT concerns about sufficient natural origin fish reaching spawning grounds and to ensure sufficient NOR's being available to meet the CCT summer Chinook program, incorporation of natural origin fish for the Wells program or programs with broodstock originating from the Wells volunteer channel, will be limited to fish collected in the Wells volunteer channel. The following broodstock collection protocol was developed based on mitigation objectives and program assumptions (Appendix A).

WDFW will target 494 run-at-large summer Chinook from the volunteer ladder trap at Wells Fish Hatchery outfall for the Wells sub-yearling and yearling programs, and up to 178 for the YN 275K-350K green egg request for the Yakima summer Chinook program (Table 8). Due to fish health concerns associated with the volunteer collection site (warming Columbia River water during late August), the volunteer collection will begin July 1 and terminate by August 31.

For 2017, broodstock collection for the Chelan Falls summer Chinook program will be prioritized at the Chelan Falls Canal Trap (CFCT) which was successfully piloted in 2016, beginning July 1 through September 15. Collection efforts in the EBO in 2015 and 2016 were insufficient to meet the adult requirements for the Chelan Falls program necessitating development of alternate collection locations/strategies. If shortfalls in adult needs are expected and the number of females needed to meet program has not been reached by August 15<sup>th</sup>, the HCP HC will discuss whether broodstock collection may default to surplus summer Chinook from the Entiat NFH or other HCP approved location to make up the difference. The 2017 broodstock target for the Chelan Falls program is 358 adults (Table 8). The total production level supported by this collection is up to 576,000 yearlings for the Chelan Falls program.

Table 8. Number of broodstock needed for the combined Chelan and Douglas PUD Columbia River below Wells summer Chinook production obligations of 1,380,000 smolts, collection location, and mating strategy. Also includes broodstock necessary for outside programs that rely on adult collection at Well Hatchery in 2017.

| Program         | Production target    | Number of Adults <sup>2</sup> |      | Total        | Collection location   | Mating protocol |

|                 |                      | Hatchery                      | Wild |              |                       |                 |
| Wells 1+        | 320,000              | 94F/94M                       |      | <b>188</b>   | Wells VC <sup>3</sup> | 1:1             |
| Wells 0+        | 484,000              | 153F/153M                     |      | <b>306</b>   | Wells VC <sup>3</sup> | 1:1             |
| Chelan Falls 1+ | 576,000              | 179F/179M                     |      | <b>358</b>   | CFCT <sup>4</sup>     | 1:1             |
| Yakama Nation   | 350,000 <sup>1</sup> | 89F/89M                       |      | <b>178</b>   | Wells VC <sup>3</sup> | NA              |
| <b>Total</b>    | <b>1,730,000</b>     | <b>515F/515M</b>              |      | <b>1,030</b> |                       |                 |

<sup>1</sup> The YN request is for between 275K and 350K green eggs to support the Yakima River summer Chinook program.

<sup>2</sup> The number of adults collected for these programs may indirectly incorporate natural origin fish; however, because they are volunteers, the

number is likely to be less than 10% of the total.

<sup>3</sup> Wells Hatchery volunteer channel trap.

## Wenatchee River Basin

In 2017 the Eastbank Fish Hatchery (FH) is expecting to rear spring Chinook salmon for the Chiwawa River and Nason Creek acclimation facilities located on the Chiwawa River and Nason Creek. The program production level target for the Chiwawa program (Chelan PUD obligation) in 2017 is 144,026 smolts, and based upon the biological assumptions (Appendix A) will require a total broodstock collection of about 74 natural origin spring Chinook (Table 10). The spring Chinook production obligation for Grant PUD in the Wenatchee Basin is 223,670 smolts (125,000 conservation and 98,670 safety net) and based upon the biological assumptions (Appendix A) will require a total broodstock collection of 142 adults (70 natural origin and 72 hatchery origin; Table 10).

Pre-season run-escapement of Wenatchee spring Chinook to Tumwater Dam during 2017 is estimated at 5,410 spring Chinook, including 4,637 hatchery and 773 natural origin spring Chinook (does not include age-3 males; Table 9). In-season estimates of natural-origin spring Chinook to Tumwater Dam will be provided through stock-assessment and broodstock-collection activities. This information will facilitate in-season adjustments to collection composition so that extraction of natural-origin spring Chinook remains no more than 33%.

Table 9. Age-4 and age-5 class return projection for wild and hatchery spring Chinook to Tumwater Dam during 2017.

|---------------------|----------------|----------------------|------------|------------------------|-----------------|-----|
| Nason<br>Safety net | 98,670         | 34F/34M <sup>3</sup> | 0          | <b>68</b>              | Tumwater<br>Dam | 1:1 |
| <b>Total</b>        | <b>367,969</b> | <b>104</b>           | <b>144</b> | <b>255<sup>2</sup></b> |                 |     |

<sup>1</sup> Includes 36 hatchery origin adults (represents ~50% of the adult target) to ensure the Chiwawa production goal is met if insufficient NO adults are collected).

<sup>2</sup> Includes ~10% additional NO fish for the Nason program to account for fish that may assign back to the White River spawning aggregate. No more than 70 NO fish will be retained for spawning.

<sup>3</sup> Chiwawa hatchery fish will only be collected to satisfy the Nason Cr. safety net program if in-season estimates of returning Nason conservation fish fall short of expectations.

<sup>4</sup> Collection of NO fish at Tumwater for the Chiwawa program will include previously PIT tagged adults (NO juveniles PIT tagged at the Chiwawa smolt trap).

### *Chiwawa River Conservation Program Broodstocking:*

- Based upon estimates of returning previously PIT tagged NO fish to Tumwater Dam (Table 11), approximately 30 previously PIT-tagged NO spring Chinook from the Chiwawa River could be collected at TWD between June 1 and July 15, concurrent with Nason Creek brood stocking, adult management, RM&E, and the RRS Study.
- The balance of adults needed to meet the Chiwawa Conservation program (up to ~74 total or ~37 females) would be collected at the Chiwawa Weir.
  - Weir operations would be on a 24 hour up/24 hour down schedule from about June 1 through August 15 (not to exceed 15 cumulative trapping days). Timing of trap operation would be based on NO fish passage at TWD and would use estimated travel times (derived from PIT tags) to the lower Chiwawa PIT tag antenna array.
  - In the absence of adequate redd count data (i.e. until 2018) to calculate the 10% threshold, if after 15-days of weir operation, 67 bull trout encounters, or 15 August, the NO broodstock target is not reached, the balance of the mitigation obligation will be met through hatchery fish already retained for the Chiwawa program at TWD.
  - Over five years, the average number of bull trout captured during weir operation shall not exceed 70 individuals per year. Additionally, no more than 10 percent of the estimated mean number of adult bull trout in the Chiwawa Basin (using up to a rolling five year average derived from expanded redd counts) may be encountered during broodstock collection without concurrence from the USFWS. Sufficient redd data to calculate a full five year average is expected to be available as early as 2018.
  - To ensure the production target is met for the Chiwawa program, in the event that insufficient NO adults are collected for the conservation program, HO adults (presently estimated at 50% of the total broodstock requirement, however may be adjusted up or down depending on the run) would be collected at TWD to make up the shortfall (see Table 10) between June 1 and July 15.
  - Historic and in-season data for NO spring Chinook timing to the lower Chiwawa array from TWD will be used to determine optimal dates for collection.

- Any bull trout that are caught at the Chiwawa trap will be immediately removed and released at a site ~10KM upstream of the weir to prevent fallback/impingement and to mitigate for potential delay. Handling and transport will be conducted by WDFW hatchery staff.
- If a bull trout is killed during trapping, despite implementing conservation measures, trapping activities will cease and not continue until additional measures to minimize risks to bull trout can be discussed with the USFWS.

Table 11. PIT tagged natural origin adults to Tumwater Dam for the most recent 5-years (2012-2016) with conversion rates from Bonneville Dam.

| Return year | Detections at Bonneville Dam |         | Detections at Tumwater Dam |                 |         |                 |
|-------------|------------------------------|---------|----------------------------|-----------------|---------|-----------------|
|             | Nason                        | Chiwawa | Nason                      | Conversion rate | Chiwawa | Conversion rate |
| 2012        | 7                            | 60      | 5                          | 0.714           | 52      | 0.867           |
| 2013        | 2                            | 29      | 2                          | 1.000           | 22      | 0.759           |

| 2015        | 9                            | 42      | 6                          | 0.667           | 28      | 0.667           |
| 2016        | 8                            | 34      | 8                          | 1.000           | 24      | 0.706           |
| Mean        | 6.4                          | 46.2    | 4.4                        | 0.710           | 31.0    | 0.688           |
| Geomean     | 5.7                          | 44.0    | 3.4                        | 0.603           | 29.5    | 0.671           |

*Nason Creek Conservation Program Broodstocking:*

- Up to ~77 NO spring Chinook (to allow for up to 10 percent of White River NO fish estimated to be encountered at Tumwater Dam MSA; Table 10) would be collected at TWD between June 1 and July 15.
  - Only 70 NO adults (35 females) will be retained to produce the 125K Nason Conservation program.
  - Collection of additional HO fish may occur in the event NO collection/retention falls short of expectation.
  - Brood stock collection would run concurrent with adult management, RM&E, and the Spring Chinook Relative Reproductive Success Study. The GAPS microsatellite panel and existing GAPS plus WDFW spring Chinook Wenatchee baseline will be used for genotyping and GSI analyses similar to methods used in 2013.
- Decision Rules:
  - Any fish that assigns to the White River with greater than 90% surety will be released in the White River.

- Unassigned fish (individuals that can't be assigned to the Wenatchee Population or Leavenworth NFH), will be released upstream of Tumwater Dam.
- In the event more fish assign to Nason or Chiwawa than are needed to meet the conservation program, the excess with the lowest assignment probabilities will be returned to the river upstream of Tumwater Dam.

*Nason Creek Safety Net Program Broodstocking:*

- Up to ~68 HO spring Chinook adults (from safety net program – identified by snout wire + body wire) would be targeted at TWD (Table 10) between June 1 and July 15, concurrent with NO brood stock collection, adult management, RM&E, and the Spring Chinook Relative Reproductive Success (RRS) Study.

*Nason Creek spring Chinook Rearing/Release Strategy:*

**Rearing** – Early rearing growth will be modulated for a targeted size at release of approximately 18 fpp. Beginning on or about February 1, fish will be fed to satiation to maximize spring growth regardless of end size.

**Release** - Spring Chinook salmon acclimated at the Nason Creek Acclimation Facility will be forced released using the following criteria.

- all fish will be released during darkness (e.g., 9:00 PM or later),
- all fish will be released when Columbia River and Nason Creek flows/conditions are predicted to be satisfactory,
- all fish will be released no later than May 7 regardless of flow conditions,
- attempts will be made to have a steady release of fish to reduce collisions on the PIT antenna array.

Satisfactory flows in the Columbia occur when spilling flows are started and flows in Nason Creek are satisfactory when flows are high and turbid. Releases will not occur until satisfactory flows in the Columbia occur, but could occur if Nason Creek flows are not satisfactory due to insufficient snow pack.

*Steelhead*

The steelhead mitigation program in the Wenatchee Basin uses broodstock collected at Dryden and Tumwater dams located on the Wenatchee River. Per ESA section 10 Permit 1395

provisions, broodstock collection will target adults necessary to meet a natural origin – conservation (WxW) oriented program, not to exceed 33% of the natural origin steelhead return to the Wenatchee Basin and a hatchery origin (HxH) – safety net program. The conservation and safety net programs each make up approximately half of the 247,300 production obligation. Based on these limitations and the assumptions listed in Appendix A, the following broodstock collection protocol was developed:

WDFW will retain a total of 140 mixed origin steelhead for broodstock for a smolt release objective of 247,300 smolts (Table 12). The 70 hatchery origin adults will be targeted at Dryden Dam and if necessary Tumwater dam. The 70 natural origin adults will be targeted for collection at Tumwater Dam. Collection will be proportional to return timing between 01 July and 14 November. Collection may also occur between 15 November and 5 December at both traps, concurrent with the Yakama Nation coho broodstock collection activities. Only adipose present coded wire tagged hatchery fish (or previously PIT tagged WxW hatchery progeny) will be retained for the safety net program. Adult return composition including number, origin, age structure, and sex ratio will be assessed in-season at Priest Rapids and at Dryden Dam. In-season broodstock collection adjustments may be made based on this monitoring and evaluation. To better ensure achieving the appropriate females equivalents for program production, the collection will include the use of ultrasonography to determine the sex of each fish retained for broodstock.

In the event steelhead collections fall substantially behind schedule, WDFW may initiate/coordinate adult steelhead collection in the mainstem Wenatchee River by hook and line. In addition to trapping and hook and line collection efforts, Tumwater and Dryden dams may be operated between February and early April the subsequent spring to supplement broodstock numbers if the fall trapping effort provides fewer than the required number of adults.

Table 12. Number of broodstock needed for the combined 2018 BY Wenatchee summer steelhead production obligation of 247,300 smolts, collection location, and mating strategy.

| Program                             | Production target | Number of Adults |           | Total      | Collection location                           | Mating protocol |
|-------------------------------------|-------------------|------------------|-----------|------------|---|-----------------|
|                                     |                   | Hatchery         | Wild      |            |   |                 |
| Wenatchee Conservation <sup>1</sup> | 123,650           | 0                | 35F/35M   | 70         | TWD <sup>3</sup> /Dryden LBT-RBT <sup>4</sup> | 2x2 factorial   |
| Wenatchee Safety net <sup>2</sup>   | 123,650           | 35F/35M          | 0         | 70         | Dryden LBT-RBT <sup>4</sup> /TWD <sup>4</sup> | 1:1             |
| <b>Total</b>                        | <b>247,300</b>    | <b>70</b>        | <b>70</b> | <b>140</b> |   |                 |

<sup>1</sup> Broodstock collection for the conservation program will occur primarily at Tumwater Dam and will only fall back to Dryden Dam trapping facilities if a shortfall is expected.

<sup>2</sup> Broodstock collection for the safety net program will occur primarily at the Dryden Dam trapping facilities to minimize activities at TWD that could increase unintended delays on non-target fish. Collection at Tumwater Dam will only occur if shortfalls in broodstock are expected at Dryden Dam.

<sup>3</sup> TWD=Tumwater Dam.

<sup>4</sup> Dryden LBT-RBT= Dryden Dam left and right bank trapping facilities.

### *Summer/fall Chinook*

Summer/fall Chinook mitigation programs in the Wenatchee River Basin utilize adult broodstock collections at Dryden and Tumwater dams, incubation/rearing at Eastbank Fish Hatchery (FH) and

acclimation/release from the Dryden Acclimation Pond. The total production level target for BY 2017 is 500,001 smolts (181,816 GCPUD mitigation and 318,185 CCPUD mitigation).

The TAC 2017 Columbia River UCR summer Chinook return projection to the Columbia River (Appendix D) and BY 2012, 2013 and 2014 spawner escapement to the Wenatchee River indicate sufficient summer Chinook will return to the Wenatchee River to achieve full broodstock collection for the Wenatchee River summer Chinook supplementation program. Review of recent summer/fall Chinook run-timing past Dryden and Tumwater dam indicates that previous broodstock collection activities have omitted the early returning summer/fall Chinook, primarily due to limitations imposed by ESA Section 10 Permit 1347 to minimize impacts to listed spring Chinook. In an effort to incorporate broodstock that better represent the summer/fall Chinook run timing in the Wenatchee Basin, the broodstock collection will front-load the collection to account for the disproportionate collection timing. Approximately 43% of the summer/fall Chinook destined for the upper Basin (above Tumwater Dam) occurs prior to the end of the first week of July; therefore, the collection will provide 43% of the objective by the end of the first week of July. Weekly collection after the first week of July will be consistent with run timing of summer/fall Chinook during the remainder of the trapping period. With concurrence from NMFS, summer Chinook collections at Dryden Dam may begin up to one week earlier. Based on these limitations and the assumptions listed in Appendix A, the following broodstock collection protocol was developed:

WDFW will retain up to 262 natural-origin, summer Chinook at Dryden and/or Tumwater dams, including 131 females (Table 13). To better ensure achieving the appropriate females for program production, the collection will implement the draft Production Management Plan, including ultrasonography to determine the sex of each fish retained for broodstock. Trapping at Dryden Dam may begin 27 June and terminate no later than 15 September and operate up to 7-days/week, 24-hours/day. Trapping at Tumwater Dam if needed may begin 15 July and terminate no later than 15 September and operate up to 48 hours per week for broodstock related activities.

Table 13. Number of broodstock needed for the combined 2017 BY Chelan and Grant PUD Wenatchee summer Chinook production obligations of 500,001 smolts, collection location, and mating strategy.

| Program      | Production target | Number of Adults |                  | Total      | Collection location                           | Mating protocol |

### Priest Rapids Fall Chinook

Collection of fall Chinook broodstock at Priest Rapids Hatchery (PRH) will generally begin in early September and continue through about mid-November. Juvenile release objectives specific to Grant PUD (5,599,504 sub-yearlings), and Federal (1,700,000 sub-yearlings at PRH + 3,500,000 smolts at Ringold Springs Hatchery – collection of broodstock for the federal programs are conditional upon having contracts in place with the ACOE), mitigation commitments. Biological assumptions are detailed in Appendix A. For the Ringold Springs production, adult collection, holding, spawning and incubation occurs at PRH until the eyed-egg stage. Eyed eggs are transferred to Bonneville Hatchery until they are transferred for spring acclimation and release at Ringold Springs.

For 2017 up to 1,000 adipose present, non-coded wire tagged (high proportion of natural origin) fall Chinook adults will be targeted at the OLAFT). Additional NO adults targeted as a continued pilot evaluation through hook-and-line angling efforts in the Hanford Reach to increase the proportion of natural origin adults in the broodstock to meet integration of the hatchery program will also be incorporated into the program. It is estimated that approximately 400 adults may be collected through the hook-and-line efforts. Close coordination between broodstock collections at the volunteer channel, the OLAFT and through hook-and-line efforts in the Hanford Reach will need to occur so over collection is minimized. Fish surplus to production needs will be culled at the earliest possible life-stage (e.g, brood collected, brood spawned, eggs). Presumed NOR's collected and spawned from either hook-and-line caught broodstock or OLAFT collections will be prioritized for PRH programs (i.e. OLAFT and Hanford Reach angler caught fish will be externally marked, held in a separate pond from volunteer collected fish, spawned first each week, and to the extent possible segregated and reserved for the GPUD program).

Grant PUD staff will work closely with WDFW hatchery and M&E staff to maintain separation of gametes/progeny of OLAFT and angling collected adults at spawning and through incubation/early rearing.

Based upon the biological assumptions in Appendix A, an estimated 4,219 females will need to be collected (3,536 spawned) to meet the 10,799,054 smolts required to meet the current three up-river bright (URB) programs which rely on adults collected at the Priest Rapids Hatchery volunteer channel trap, hook-and-line efforts on the Hanford Reach, and/or the Priest Rapids Dam off ladder trap (OLAFT; Table 14).

To increase the probability of incorporating a higher percentage of NOR's from the volunteer channel, adipose present, non-CWT males and females will be prioritized for retention and males older than 3 will be prioritized. In addition, preliminary information suggests that the pNORs is higher in the later part of the trapping period than the earlier period. As data become available, the PRCC-HSC may choose, in-season, to retain a disproportionately high number of broodstock from the latter half of the returns to the volunteer trap.

### Implementation Assumptions

- 1) Broodstock may be collected at any or all of the following locations/means: the PRD off ladder trap (OLAFT – operated 4-days per week/8 hrs/day to collect up to 1,000 presumed NOR's), hook-and-line angling (ABC) in the Hanford Reach (actual numbers collected are uncertain but will contribute to the overall brood program and pNOB), and the Priest Rapids Hatchery volunteer channel trap.
- 2) Assumptions used to determine egg/adult needs is based upon current program performance metrics.
- 3) Broodstock retained from the volunteer channel will exclude to the degree possible, age-2 and 3 males (using length at age; i.e. retain males  $\geq 75$  cm) to address genetic risks/concerns of younger age-at-maturity males producing offspring which return at a younger age (decreased age-at-maturity) and also decrease the probability of using hatchery origin fish in the broodstock that are skewed towards earlier ages at maturity.
- 4) Only adipose present, non-CWT males and females will be retained for broodstock from volunteer channel collected broodstock unless a shortage is expected.
- 5) Only progeny of adipose present, non-wired fish encountered through hook-and-line angling and at the OLAFT will be prioritized for retention into the program.
- 6) Broodstock collected from the OLAFT and by hook-and-line will exclude age-2 and to the degree possible age-3 fish (<75 cm) to minimize genetic risks/concerns of younger age-at-maturity males producing offspring which return at a younger age (decreased age-at-maturity) and to ensure the highest proportion of NOR's in the collection (e.g. collection of 1 in 5 age-3 fish for broodstock from the OLAFT).
- 7) All gametes of fish spawned from hook-and-line broodstocking efforts and/or OLAFT collections will be incorporated into the PRH based programs.
- 8) Real time otolith reading and an alternative mating strategy will be implemented in 2017 similar to 2015 and 2016 unless the PRCC-HSC agrees that the PNI objective in 2017 can be met without implementing 1x4 matings. Otoliths from males from the OLAFT and ABC collections will be collected during the peak spawning week and read prior to spawning. If the male is natural origin, then it will be spawned with 4 females, otherwise it will be spawned with two females or the milt discarded if it is a known hatchery male and there are sufficient numbers of unknown males available for spawning.
- 9) All eggs or juveniles leaving PRH (including surplus) will have a unique otolith mark so that returning adults can be identified. Exceptions to this could occur if there are guarantees of a suitable mark/tag from a receiving hatchery.

- 10) Natural origin broodstock collection at the volunteer trap will be prioritized for the GPUD program by collecting fish when the probability of encountering natural origin fish is highest and balancing run-time representation.

| <b>Total</b>           | <b>3,596F/1,881M</b><br>(5,477; 84.0%) | <b>592F/454M</b><br>(1,046; 16.0%) | <b>6,523</b> |                     |                 |

<sup>1</sup> As of brood year 2009, Priest Rapids Hatchery is taking sufficient eggs to meet the 3,500,000 sub-yearling smolt release at Ringold-Meseberg Hatchery funded by the ACOE – late incubation of this program occurs at Bonneville.

<sup>2</sup> Estimated number of fall Chinook females and males to be acquired from the OLAFT in 2017. F/M ratios were derived through run at large data. Estimates of H/W were derived through otolith results.

<sup>3</sup> ABC fish are adults collected from hook and line collection efforts on the Hanford Reach. Estimates of F/M were derived through 2012-2014 spawn numbers. Estimates of and H/W were derived through otolith results from 2012 and 2014.

<sup>1</sup> Release of fish at the Goat Wall Pond remote acclimation site operated by the YN is conditional upon HC and HSC approval.

<sup>2</sup> Externally marking of this group is presently funded by WDFW. Marking of this 1M fish is contingent on *US v. Oregon* Policy Committee approval for 2017.

<sup>3</sup> Presently all CWT's are applied to the snout.

<sup>4</sup> The Okanogan SPC program derives its juveniles from a 200K transfer of Methow SPC from WNFH as part of a reintroduction effort. Fish are released into the Okanogan Basin.

<sup>5</sup> The Chief Joe Hatchery SPC program presently receives surplus adults from the Leavenworth NFH. Juveniles are released on station from CJH.

<sup>6</sup> Total Okanogan release not to exceed 100K + 10%.

<sup>7</sup> PIT number s to each release site are estimated and not actual.

<sup>8</sup> The Okanogan steelhead HGMP and NOAA's BiOp for the TRMP state that WxW progeny will receive a unique internal tag (CWT or PIT) and/or receive an alternative fin clip. At this time, CCT does not intend to use an alternative fin clip until/unless a high proportion of the released fish have WxW parents and there is an acceptable survival risk/benefit of the alternative fin clip.

<sup>9</sup> Total PIT tag release in the Okanogan 20,000

<sup>10</sup> Beginning with the 2017 brood, adult returns from the Nason conservation program will be utilized to meet the Nason safety net program and will receive a supplemental body tag (blank wire either at the base of the adipose or the caudal peduncle) in addition to the adipose clip.

<sup>11</sup> With the recent detection inbreeding depression effects in the Twisp conservation program, parties are currently working on developing a new plan for the program. Once developed and agreed to, this table will be updated to reflect any changes.

DRAFT

## Appendix C

### Return Year Adult Management Plans

At a gross scale, adult management plans will include all actions that *may* be taken within the current run year to address surplus hatchery fish (if any). At the time of submission for this document, spring Chinook will probably be the only group where a reasonable pre-season forecast may be available to lay out what the expected surplus is, how many can be expected to be removed through each action, etc. Preseason forecasts for steelhead will be available in September.

#### *Wenatchee Spring Chinook*

Pre-season estimates for age-4 and age-5 adults project a total of 5,410 (773 natural origin [14.3%] and 4,637 hatchery origin [85.7%]) spring Chinook back to Tumwater Dam in the Wenatchee Basin. Approximately 3,827 Chiwawa and 1,491 Nason spring Chinook are to reach Tumwater Dam in 2017, of which about 681 (12.8%) and 4,637 fish (87.2%) are expected to be natural and hatchery origin spring Chinook, respectively. The balance of about 92 natural origin spring Chinook expected back are destined to the remaining spawning aggregates (Table 1). In-season assessment of the magnitude and origin composition of the spring Chinook return above Tumwater Dam will be used to provide in-season adjustments to hatchery/wild composition and total broodstock collection, consistent with ESA Section 10 Permits 18118 and 18121.

Table 1. Age-4 and age-5 class return projection for wild and hatchery spring Chinook to Tumwater Dam during 2017.

<sup>1</sup> Reflects NOR estimates to Tumwater Dam and has not been adjusted for pre-spawn mortality.

<sup>2</sup> Wenatchee Basin to Tumwater Dam total includes NORs to the White, Little Wenatchee, and Chiwawa rivers and Nason Creek.

Absent conservation fisheries or adult removal at Tumwater Dam (TWD), the expected number of age-4 and age-5 Hatchery Origin Returns (HOR) for the upper Wenatchee River Basin as a whole is estimated to be approximately six times the expected number of Natural Origin Returns (NORs; 6.3 times the number of NOR's in the Chiwawa River and 8.6 times the number of NOR's in Nason Creek). The combined HO and NO returns will represent about 4.2 times the number of adults needed to meet the interim Chiwawa run escapement to TWD of 900 fish indicating a disproportionate number of hatchery origin spring Chinook will be on the spawning

grounds in the fall of 2017 (Table 2). The combined HO and NO returns will represent about 3 times the number of adults needed to meet the interim Nason run escapement to TWD of 500 fish indicating a disproportionate number of hatchery origin spring Chinook will be on the spawning grounds in the fall of 2017 (Table 3).

### Additional Adult Management

2017 adult management actions are intended to provide for near 100% removal of age-3 hatchery males (jacks), and unknown hatchery origin adults (ad-/cwt-) and up to about 93% of the age-4 and age-5 hatchery origin adults (about 1,717 males and 1,288 females according to current models, Table 2). In addition, approximately 68 HO and 144 NO adults will be removed between TWD and the Chiwawa Weir and retained for broodstock to support meeting the combined Grant and Chelan PUD Wenatchee spring Chinook obligation, the balance will be surplus at TWD and used for tribal and/or food bank disbursements or nutrient enhancement projects.

Table 2. Run escapement and spawning escapement of Chiwawa River hatchery and natural origin fish to Tumwater Dam and the Chiwawa River in 2017.

| Expected pHOS                   |                 |          |                     |                       |                                    | <b>0.25</b>            |

<sup>1</sup> Wild broodstock needs of 74 wild NO fish (37 females/37 males) for the Chiwawa conservation program have already been accounted for in this total as well as pre-spawn mortality.

<sup>2</sup> Adjusted for pre-spawn mortality.

<sup>3</sup> Does not include age-3 hatchery males "jacks" removed during adult management activities at TWD or through a conservation fishery.

<sup>4</sup> Age-4 and age-5 fish only. Gender proportions were made based upon a 5-year average sex ratio for hatchery and wild fish of the same age class.

<sup>5</sup> This should result in approximately 301 redds in the Chiwawa Basin under the assumption that each female produces only one redd.

<sup>6</sup> Estimated survival from Tumwater to spawn.

|------------------|-------------|

<sup>1</sup> Wild broodstock needs of 70 wild NO fish (35 females/35 males) for the Nason conservation program have already been accounted for in this total as well as pre-spawn mortality.

<sup>2</sup> Adjusted for pre-spawn mortality and HO broodstock needs of 68 fish (34 females/34 males).

<sup>3</sup> Does not include age-3 hatchery males “jacks” removed during adult management activities at TWD or through a conservation fishery.

<sup>4</sup> Age-4 and age-5 fish only. Gender proportions were made based upon a 5-year average sex ratio for hatchery and wild fish of the same age class.

<sup>5</sup> This should result in approximately 206 redds in Nason Creek under the assumption that each female produces only one redd.

<sup>6</sup> Estimated survival from Tumwater to spawn.

### ***Wenatchee Summer Steelhead***

Depending on the outcome of preseason and in-season estimates of hatchery and natural origin steelhead to the Wenatchee Basin during the annual run cycle monitoring at the Priest Rapids Dam Off Ladder Trap (OLAFT), removal of surplus adult steelhead may occur at Tumwater Dam or in combination with a conservation fishery.

A more detailed run forecast will be available in September 2017. Adult management plans will be finalized then and appended to this document.

### ***Methow Spring Chinook***

Pre-season estimates project a total of 3,265 (973 natural origin [29.8%] and 2,292 hatchery origin [70.2%]) spring Chinook back to Methow Basin. Of the 2,292 hatchery returns, about 748 are estimated to be from the conservation program with the balance of 1,544 from the WNFH safety net program (Table 5).

Table 5. Brood year 2012-2014 age class and origin run escapement projection for UCR spring Chinook at Wells Dam, 2017.

| <b>Stock</b>                  | <b>Projected Escapement</b> |              |           |              |             |            |            |            |                     |              |            |              |

Some level of adult management will be required to limit the number of hatchery spring Chinook on the spawning grounds. Because a conservation fishery is not yet possible under current permit limitations, adult management will need to occur through operation of the volunteer channel traps located at both the Methow Hatchery (MH) and Winthrop NFH (WNFH).

Presently hatchery fish from MH are prioritized to: a) contribute to the supplementation of the natural populations (up to either the escapement objectives or PNI/pHOS goal), b) make up shortfalls in natural-origin brood for the MH conservation program, and c) to support the 400K safety-net program at WNFH. As such WNFH will operate volunteer hatchery ladder to support removal of excess safety-net and conservation fish (when needed) fish. MH will operate its volunteer trap and will provide surplus hatchery adults (in excess to the MH and conservation needs) to WNFH to support the safety-net program, to support removal of excess safety-net and conservation fish, or retain adults to facilitate testing translocation of conservation fish to under-seeded spawning areas as approved by the HCP HC and PRCC HSC. The translocation of conservation program adults will be prioritized over their use as broodstock for the safety net program as long as both programs can meet full production. The intention of adult translocation is to increase natural production which is the primary function of the Methow Hatchery.

Specific actions are as follows:

**Adult management actions will be used to support achieving hatchery production levels and escapement/sliding-scale PNI targets identified in the Methow Spring Chinook BiOp (2017) and Permits #18925, #18927 and #20533. Adult management removal targets identified in this document may be revised based on best available inseason run estimates.**

*Twisp River Spring Chinook:* spring Chinook in the Twisp River will be managed separately from the rest of the basin.

- a. Adipose-clipped fish encountered at the Twisp Weir will be removed (putative WNFH returns or strays from outside of the basin).
- b. Age-3 hatchery males will be removed and euthanized or transported to WNFH.
- c. Adult management will be performed to maintain pHOS  $\leq 0.50$ . pNOB will be  $>0.50$  and may be allowed to fluctuate between 0.50 and 1.0 in order to achieve a pHOS  $\leq 0.50$ .
- d. Wild fish will be collected as broodstock – up to ~18 individuals, but not to exceed 33% of the wild run. Hatchery fish may be collected as broodstock dependent on collection success of wild fish and provided that Twisp-program pNOB may not be less than 0.50.
- e. The Twisp Weir will be fished for the duration of the broodstock collection, only, in 2017. Adult management activities will be incidental to broodstock collection. Once broodstock collection is completed, the weir will be opened to fish passage to limit delay/trapping effects on bull trout. Tentatively, during broodstock collection, the weir will be fished from 6:00 AM to 9:00 PM on a daily basis. Deviation from this schedule may be implemented based on the run size and catch efficiency for broodstock.

*Methow River (MFH and WNFH) and Chewuch River Spring Chinook (MetComp):*

- a. Stock assessment will be performed at Wells Dam during the spring Chinook broodstock collection. This information on stock, hatchery:wild, and male:female composition in conjunction with fish counts at Wells Dam will be used to adjust in-season adult management targets.
- b. MetComp returns will be managed by removing volunteers at WNFH and Methow Hatchery using the outfall traps at these facilities.
  - i. All hatchery-origin age-3 males will be removed
    1. Gender identified by ultrasound.
  - ii. The Methow and Winthrop FH volunteer traps will be fished continuously (24 h per day/7 d per week) throughout the run and fish removed at least once daily (depending on specific facility limitations), or as often as needed when fish are present. Adjustments to the operation of the trapping facilities will be made based upon capture/extraction rates as well as bull trout encounters and take limitations.
  - iii. Trapping will cease at Methow Hatchery if:
    1. Removal of MFH and WNFH origin adults meets the targets established (in this document and as adjusted in-season), or
    2. If overall hatchery bull trout take is likely to be exceeded. However, in-season adjustment may be made to reduce the likelihood of bull trout encounters including, but not limited to: limiting 1) the time of day trap is fished, 2) hours per day fished, 3) days per week fished.
  - iv. Trapping will cease at Winthrop NFH if:
    1. Removal of WNFH and MFH origin adults meets the targets established (in this document and as adjusted in-season), or
    2. If overall hatchery bull trout take is likely to be exceeded. However, in-season adjustment may be made to reduce the likelihood of bull trout encounters including, but not limited to: limiting 1) the time of day trap is fished, 2) hours per day fished, 3) days per week fished.
  - v. All adipose clipped returns encountered at WNFH and MFH volunteer traps will be removed.
    1. Returns to WNFH will be retained at WNFH for broodstock (WNFH safety net and Okanogan 10(j) programs) or surplus.
    2. Returns to MFH will be transferred to WNFH for broodstock (WNFH safety net and Okanogan 10(j) programs) or surplus.
  - vi. Conservation program returns may also be transported to specific reaches of the Methow and/or Chewuch Rivers to meet the minimum spawning escapement objective or to experimentally augment spawner distribution (such an action will require an approved study or implementation plan by the HCP HC and PRCC HSC, and be permissible under current ESA permits).

Based on the preseason forecast for wild and hatchery spring Chinook to the Methow Basin, once NO broodstock requirements are fulfilled and accounting for an estimated prespawner mortality for NO fish of 50% (42% for HO fish), there will be approximately 426 NO spawners. Based upon the sliding PNI scale for NO run sizes >300 fish, the initial goal for 2017 will be to manage for a minimum spawning escapement of 548 spawners; to achieve this, an estimated 67.4% of the hatchery returns (1,862 HO fish) will need to be removed (Table 6). This will

result in approximately 122 hatchery origin spawners on the spawning grounds after accounting for prespawn mortality.

Table 6. Calculated targets and projected adult management results for Methow spring Chinook in 2017.

| Wild Spawning Escapement | pNOB <sup>2</sup> | pHOS  | PNI Target <sup>3</sup> | Allowable Hatchery Spawners | Hatchery surplus | Hatchery Broodstock (WNFH + 10j) | Proportion of Hatchery Fish to Remove | Total spawning escapement |
|--------------------------|-------------------|-------|-------------------------|-----------------------------|------------------|----------------------------------|---------------------------------------|---------------------------|
| 426 <sup>1</sup>         | 1.00              | 0.223 | 0.82                    | 122                         | 0 MH             | 472                              | 0.674 <sup>4</sup>                    | 548                       |
|                          |                   |       |                         |                             | 1,544 WNFH       |                                  |                                       |                           |
|                          |                   |       |                         | Adjusted for Pre-spawn loss | Total Surplus    |                                  |                                       |                           |
|                          |                   |       |                         | 290                         | 1,390            |                                  |                                       |                           |

<sup>1</sup> Adjusted for prespawn mortality. Includes about 78 NO fish expected to go into the Twisp River basin.

<sup>2</sup> pNOB of conservation program only.

<sup>3</sup> Based on 3-pop model and assumes a minimum of 75% conservation program adults for WNFH broodstock.

<sup>4</sup> Assumes a 90% conversion of hatchery fish to hatchery outfalls. Value includes hatchery adults needed to meet WNFH and Okanogan 10(j) production components.

In-season assessment of the magnitude and origin composition of the spring Chinook return above Wells Dam will be used to provide in-season adjustments to hatchery/wild composition and total broodstock collection, consistent with ESA Section 10 Permits 18925, 18927, and 20533.

### ***Methow Summer Steelhead***

Depending on the outcome of preseason and in-season estimates of hatchery and natural origin steelhead to the Methow Basin during the annual run cycle monitoring at the Priest Rapids Dam Off Ladder Trap (OLAFT), removal of surplus adult steelhead may occur at the Twisp Weir (primarily as an action related to the steelhead RSS to meet a 1:1 hatchery:wild spawning composition upstream of the weir), the Wells Hatchery Volunteer Channel, volunteer returns to the Methow Hatchery and Winthrop NFH, or in combination with a conservation fishery.

A more detailed run forecast will be available in September 2017. Adult management plans will be finalized then and appended to this document.

### ***Okanogan Summer Steelhead***

Depending on the outcome of preseason and in-season estimates of hatchery and natural origin steelhead to the Okanogan Basin during the annual run cycle monitoring at the Priest Rapids Dam Off Ladder Trap (OLAFT), removal of surplus adult steelhead may utilize a conservation fishery or in combination with removal through spring Okanogan tributary weir operations.

A more detailed run forecast will be available in September 2017. Adult management plans will be finalized then and appended to this document.

## Appendix D

### Site Specific Trapping Operation Plans

#### Tumwater Dam

For 2017, WDFW and Chelan PUD are proposing the following plan (a summary of activities by month for Tumwater Dam is summarized in Table 1):

- 1) **Real-time monitoring and trap operations:** Throughout all trapping activities described in this plan, the two PIT tag antennae arrays within the Tumwater Dam ladder (weir 15 and 18 see Appendix 2), will be monitored by WDFW and Chelan PUD and detections of previously PIT tagged fish will be evaluated to determine the median passage time of fish between first detection at weir 15 and last detection at weir 15 or weir 18. Median passage estimates will be updated with every 10 PIT-tagged fish encountering weir 15. If the median passage time is greater than 48 hours, trapping will cease and fish will be allowed to exit via the ladder (i.e., bypass the trap). If trapping has been stopped, PIT tag passage monitoring will continue and trapping will resume if and when the median passage time is less than 24 hours. In summary, real-time PIT tag monitoring will occur both when the trap is operational and when fish are bypassed. This will provide an opportunity to evaluate trapping effects versus baseline passage rates through the ladder for future operations.
- 2) **Improved Fish Handling Efficiency:** Several infrastructure improvements at Tumwater allow WDFW and other operators to cycle through sampled fish more quickly. These improvements consist of an additional holding tank and an improved conveyance system between the trap and holding tank. The facility improvements and additional staffing by WDFW (3 operators instead of 2) during peak spring Chinook and sockeye passage (i.e. June 1 and July 15), will ensure that the trapping denil is operated constantly allowing unimpeded passage through the trap. Historically, the trapping denil has been periodically shut down while fish were being processed.
- 3) **Enhanced effort for Tumwater trapping operations from June 1 and July 15:** The Tumwater trap will be operated in an active-manned trapping condition (the ladder bypass will not be used however, fish may still ascend the denil [steep pass] unimpeded). The trap will be checked a minimum of 1x per day. More frequent trap checks will be made as fish numbers increase. Between June 16 and July 15 the Tumwater trap will be actively manned 24 hours/day 7 days/week utilizing two- three person crews (two people will sample fish and the third will maintain operation of the steep pass so that it will not be closed to passage). This represents an additional person to keep the denil operating

constantly. If during this period staff are not available (due to logistical, funding, or other issues) to keep the denil operating continuously, the trap will be opened to allow for nighttime passage (this is in addition to passage required under a detected delay event).

- 4) **Enhanced effort and limited Tumwater trapping operations from July 16 to August 31:** The trap will be operated 3 days/week for up to 16 hours/day (not to exceed 48 hours per week) to support broodstock collection activities for summer Chinook and sockeye run composition sampling (CRITFC) and sockeye spawner escapement PIT tagging. Video enumeration and full passage will occur when trapping is not occurring.
- 5) **Planned Tumwater trapping operations from September 1 until mid-December:** The trap will return to a 24 hours/7days/week manned or unmanned active trapping for steelhead and Coho broodstock collection and adult steelhead management. During this time period bull trout are rare and spring Chinook are not present at Tumwater. For this trapping period, real-time monitoring will continue to be implemented.
- 6) **Operations at Tumwater from mid-December until about mid-February:** During this period the trapping facility is not operated due to having been winterized. Only video enumeration and full passage are available during this period.
- 7) **Planned Tumwater trapping operations from mid-February through May:** The trap will return to a 24 hours/7days/week manned or unmanned active trapping for adult steelhead management and spawner escapement tagging. Beginning on or about May 1, limited spring Chinook broodstocking, run comp sampling, etc. may also occur. For this trapping period, real-time monitoring will continue to be implemented.
- 8) **Limitation in staffing or other unforeseen problems:** If WDFW staff are not available to operate the trapping facility (according to this plan) for any reason, then full passage will be allowed (fish will be allowed to bypass the trap and exit the ladder directly), until staff are able to return.
- 9) **Unforeseen scenarios and in season observations:** If during the trapping period, observations from field staff warrant reconsideration of any part of the plan as described above, WDFW and Chelan PUD will alert the Hatchery Committee and work cooperatively with the Services to determine whether changes are needed to further minimize incidental take or otherwise ensure that take is maintained at the manner and extent previously approved by the Services

Table 1. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and reproductive success activities anticipated to be conducted at Tumwater Dam in 2017. Blue denotes steelhead, brown spring Chinook, orange sockeye, pink summer Chinook, and green Coho.

| Activity                                  | Month |           |     |     |       |         |        |           |           |     |           |           |

<sup>1</sup> Adult management of the 2017 brood will end in June 2017. However it is anticipated that adult management will occur for the 2018 brood beginning 1 September or earlier if conducted in conjunction with broodstock collection activities at Tumwater Dam for other species.

<sup>2</sup> Summer steelhead broodstock collection will be prioritized at Dryden Dam traps. However if broodstock objectives cannot be met at Dryden then trapping may occur at Tumwater concurrent with other activities.

<sup>3</sup> SHD spawner composition tagging at Tumwater Dam will run concurrent with SHD adult management and other (broodstock) activities at Tumwater Dam.

<sup>4</sup> The spring Chinook RSS will run from 1 May through about 15 July or at such time or at such time the sockeye return develops at Tumwater Dam.

<sup>5</sup> Spring Chinook run composition sampling will run concurrent with the RSS.

<sup>6</sup> Spring Chinook pHOS management will end in July consistent with the arrival of the sockeye return and run concurrent with RSS activities.

<sup>7</sup> Removal of unknown hatchery origin spring Chinook strays at Tumwater Dam will run concurrent with the RSS.

<sup>8</sup> Sockeye run composition sampling will occur at Tumwater Dam beginning no earlier than 15 July. Trapping at Tumwater Dam for run composition sampling will follow a 3d/week, 16hrs/d (48 hrs/week) trapping schedule consistent with permit 1347.

<sup>9</sup> Sockeye spawner escapement sampling will occur at Tumwater Dam beginning no earlier than 15 July. Trapping at Tumwater Dam for spawner escapement tagging will follow a 3d/week, 16hrs/d (48 hrs/week) trapping schedule consistent with permit 1347.

<sup>10</sup> Summer Chinook broodstock collection will be prioritized at Dryden Dam. However if broodstock objectives cannot be met at Dryden Dam then trapping may occur at Tumwater Dam. Trapping at Tumwater Dam for summer Chinook broodstock will follow a 3d/week 16hr/day (48 hrs/week) trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities.

<sup>11</sup> Coho trapping will be conducted at both Dryden and Tumwater Dams. Trapping at Tumwater Dam for Coho broodstock will follow a 3d/week 16hr/day (48 hrs/week) trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities. Collection is permitted through December 7 of each year but typically ceases by the end of November.

## Dryden Dam

For 2017, WDFW and Chelan PUD are proposing the following plan (a summary of activities by month for the right and left bank Dryden Dam traps is summarized in Table 2):

The Dryden Dam left and right bank trapping facilities will operate up to five days per week, 24 hours per day beginning July 1 and continue until as late as November 15. Both traps, if operated, will do so on concurrent days and will be checked and cleared every 24 hours, or

sooner if it appears that run contribution to the facilities exceeds reasonable limits for adult holding.

If daily river temperatures meet or exceed 21° C (69.8° F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

Table 2. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and/or reproductive success activities anticipated to be conducted at Dryden Dam trapping facilities in 2017. Blue denotes steelhead, pink summer Chinook, and green Coho.

| Activity                                  | Month |     |     |     |     |      |       |     |           |     |     |           |

| Coho BS collection <sup>4</sup>           |       |     |     |     |     |      |       |     | 1 Sep     |     |     | 30<br>Nov |

<sup>1</sup> Summer steelhead broodstock collection will be prioritized at Dryden Dam traps. However if broodstock objectives cannot be met at Dryden then trapping may occur at Tumwater concurrent with other activities.

<sup>2</sup> SHD spawner composition tagging at Dryden Dam will run concurrent with other (broodstock or M&E) activities at Dryden Dam.

<sup>3</sup> Summer Chinook broodstock collection will be prioritized at Dryden Dam. However if broodstock objectives cannot be met at Dryden Dam then trapping may occur at Tumwater Dam. Trapping at Dryden Dam for summer Chinook broodstock will follow an up to 5d/week 24hr/day trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities.

<sup>4</sup> Coho trapping will be conducted at both Dryden and Tumwater Dams. Trapping at Dryden Dam for Coho broodstock will follow an up to 5d/week 24hr/day trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities. Collection is permitted through December 7 of each year but typically ceases by the end of November.

### Wells Dam Ladder and Hatchery Volunteer Traps

For 2017, WDFW and Douglas PUD are proposing the following plan (A summary of activities by month for the Wells Dam East/West ladder and Wells FH volunteer traps is summarized in Table 3):

#### 1). East Ladder Trap:

The East ladder trap will only be operated as needed to meet broodstock collection objectives and other management activities if they cannot be adequately fulfilled through the West ladder and Wells FH volunteer trap operations or if construction activities on the hatchery modernization preclude use of either the West ladder or volunteer traps.

If the East ladder trap is used, it may begin as early as May 1 and, with two exceptions, will operate under a maximum 3-day per week/16 hours per day or 48 cumulative hours per week and will run concurrent with any trapping activities occurring at the West ladder trap. The first exception to the above is that for spring Chinook between May 1 and June 20, the trap may operate a maximum of 5-days per week (but no more than three consecutive days)/16 hours per day and will run concurrent with any trapping activities occurring at the West ladder trap. The second exception is for coho trapping after September 26. Anticipated trap operation is not expected to go beyond November 15.

For coho trapping, the East ladder trap may be operated, concurrent with the West ladder trap, 5 days per week/ 9 hours per day September 27 through October 9, and 7 days per week/16 hours per day beginning October 10. Trap operators will bypass Chinook, steelhead, and sockeye during coho trapping. Anticipated trap operation is not expected to go beyond November 15.

The CRITFC will also trap sockeye at Wells Dam for tagging and stock assessment. They have not yet submitted a specific request for trapping in 2017, but their preference in past years has been to use the East ladder, and to begin the last week of June and end the third week of August.

If daily river temperatures meet or exceed 21° C (69.8° F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

2). **West Ladder Trap:**

The West ladder may begin as early as May 1 for spring Chinook broodstock collection and, with two exceptions, will operate under a maximum 3-day per week/16 hours per day or 48 cumulative hours per week. The first exception to the above is that for spring Chinook between May 1 and June 20, the trap may operate under a maximum 5-days per week (but no more than three consecutive days)/16 hours per day and will run concurrent with any trapping activities occurring at the East ladder trap. The second exception is for coho trapping after September 26. Anticipated trap operation is not expected to go beyond November 15.

For coho trapping, the West ladder trap may be operated 5 days per week/ 9 hours per day September 27 through October 9, and 7 days per week/16 hours per day beginning October 10. Trap operators will bypass Chinook, steelhead, and sockeye during coho trapping. Anticipated trap operation is not expected to go beyond November 15.

The CRITFC will also trap sockeye at Wells Dam for tagging and stock assessment. They have not yet submitted a specific request for trapping in 2017, but their preference in past years has

been to use the East ladder, but they also use the West ladder in some years. CRITFC trapping generally begins the last week of June and end the third week of August.

If daily river temperatures meet or exceed 21° C (69.8° F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

3). **Wells FH Volunteer Trap:** The Wells FH volunteer trap may begin as early as July 1 for summer Chinook broodstock collection and operate through mid-June of the following year for steelhead broodstock collection and adult management if needed. The trap may operate up to seven days per week/24 hours per day to facilitate broodstock collection and adult management actions.

If daily river temperatures meet or exceed 21° C (69.8° F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

Table 3. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and/or reproductive success activities anticipated to be conducted at Wells Dam in 2017. Blue denotes steelhead, brown spring Chinook, pink summer Chinook, orange sockeye, and green Coho.

| Su. Chin BS collection <sup>7</sup>       |       |        |     |     |       |         | 1 Jul  |        | 15 Sep |     |        |        |
| Su. Chin Surplussing                      |       |        |     |     |       |         | 1 Jul  |        |        |     | 30 Oct |        |

<sup>1</sup> Summer steelhead broodstock collection will be prioritized at West ladder and volunteer traps. However if broodstock objectives cannot be met at either of those two locations then trapping may occur at the East ladder concurrent with other activities.

<sup>2</sup> SHD spawner composition tagging at Wells Dam will run concurrent with other (broodstock or M&E) activities at Wells Dam.

<sup>3</sup> Summer Chinook broodstock collection for the Methow (Carlton) program will be prioritized at the West ladder trap. However if broodstock objectives cannot be met at the West ladder then trapping may occur at the East ladder. Trapping at the west and/or East ladders for summer

Chinook broodstock will follow an up to 3d/week 16hr/day (48 cumulative hours) trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities.

<sup>4</sup> CRITFC trapping of sockeye for stock assessment and tagging typically begins the last week of June and extends through the third week of August, following an up to 3d/week 16hr/day (48 cumulative hours) coordinated with WDFW spring or summer Chinook and steelhead broodstock collection and stock assessment trapping, preferring to trap on the East ladder.

<sup>5</sup> Coho trapping may be conducted at both East and/or West ladders. Trapping at Wells Dam ladder traps for Coho broodstock will follow an up to 3d/week 16hr/day trapping schedule and may run concurrent with other broodstock collection, run sampling, or adult management activities. Trapping at the Wells Dam ladder will cease no later than November 15.

<sup>6</sup> Adult management of the 2017 brood will end in June 2017. However it is anticipated that adult management will occur for the 2018 brood beginning 1 September or earlier if conducted in conjunction with broodstock collection activities at the Wells Hatchery volunteer channel for other species.

<sup>7</sup> Summer Chinook broodstock collection for the Wells Hatchery programs will be prioritized at the Wells Hatchery volunteer trap. Trapping at the volunteer channel may occur up to 7 days per week, 24 hours per day and may include broodstock collection and/or adult management.

## Methow Hatchery Volunteer and Twisp Weir Traps

For 2017, WDFW and Douglas PUD propose the following plan (A summary of activities by month for Methow Hatchery volunteer trap and the Twisp Weir is summarized in Table 4):

Specific operation details for the Methow Hatchery volunteer trap and Twisp Weir are still being worked through. Once those details have been fleshed out more thoroughly, this section will be updated.

If daily river temperatures meet or exceed 21° C (69.8° F) trapping activities and fish handling will cease until temperatures drop below this threshold. This may require reducing trap operation to only nighttime hours with early morning traps checks to ensure the safety of the fish.

Table 4. Summary of broodstock collection, spawner escapement tagging, adult management, run composition sampling, and/or reproductive success activities anticipated to be conducted at Methow Hatchery and the Twisp Weir in 2017. Blue denotes steelhead and brown spring Chinook.

| Activity                           | Month |     |       |          |        |        |     |        |       |     |        |     |

<sup>1</sup> Specific details on how operation of the Methow Hatchery volunteer trap will work for SHD adult management are still being worked out at this time.

<sup>2</sup> Adult management for spring Chinook at the Methow Hatchery volunteer trap will run concurrent with broodstock collection.

<sup>3</sup> Specific details on how operation of the Twisp Weir will work for 2017 to include the steelhead RSS, broodstock collection, and adult management and spring Chinook broodstock collection and adult management is still being worked out at this time.

### Priest Rapids Dam Off-Ladder-Adult-Fish-Trap (OLAFT)

Table 5. Summary of broodstock collection, VSP monitoring, and/or run composition sampling activities anticipated to be conducted at the Priest Rapids Dam Off-Ladder-Adult-Fish-Trap (OLAFT) in 2017. Blue denotes steelhead, purple fall Chinook, and orange sockeye.

| Activity                              | Month |     |     |     |     |        |        |     |       |     |     |        |
|---------------------------------------|-------|-----|-----|-----|-----|--------|--------|-----|-------|-----|-----|--------|
|                                       | Jan   | Feb | Mar | Apr | May | June   | Jul    | Aug | Sep   | Oct | Nov | Dec    |
| SHD VSP Monitoring <sup>1</sup>       |       |     |     |     |     |        | 1 Jul  |     |       |     |     | 15 Nov |
| Fall Chin. BS collection <sup>2</sup> |       |     |     |     |     |        |        |     | 1 Sep |     |     | 15 Nov |
| Fall Chinook Run Comp. <sup>3</sup>   |       |     |     |     |     |        |        |     | 1 Sep |     |     | 15 Nov |
| Sockeye BS Collection <sup>4</sup>    |       |     |     |     |     | 22 Jun | 10 Jul |     |       |     |     |        |

<sup>1</sup> Steelhead VSP monitoring targets up to 15% of the annual return over Priest Rapids Dam. Presently that requires operation of the OLAFT up to 3 days/ week, 8 hours per day. The trap is opened to passage each night.

<sup>2</sup> To acquire the target 1,000 adipose present, non-CWT adult fall Chinook for broodstock, the OLAFT is operated up to 5 days per week, 8 hours per day. Three of the five days are concurrent with the SHD VSP monitoring. The trap is opened to passage each night.

<sup>3</sup> Fall Chinook run composition runs concurrent with SHD VSP monitoring and/or fall Chinook broodstock collection activities.

<sup>4</sup> Sockeye broodstock collection to support YN reintroduction efforts in the Yakima is based upon abundance based sliding scale. Depending on the strength of the return and allowable allocation, the trap may be operated up to 5 days per week, 8 hours per day beginning about 22 June and running through about 10 July. The trap is opened to passage each night.

## Appendix G

# DRAFT

## Hatchery Production Management Plan

The following management plan is intended to provide life-stage-appropriate management options for Upper Columbia River (UCR) PUD salmon and steelhead mitigation programs. Consistent, significant over-production or under-production risks the PUD's not meeting the production objectives required by FERC and overages in excess of 110% of program release goals violates the terms and conditions set forth for the implementation of programs under ESA and poses potentially significant ecological risks to natural origin salmon communities.

Under RCW 77.95.210 (Appendix A) as established by House Bill 1286, the Washington Department of Fish and Wildlife has limited latitude in disposing of salmon and steelhead eggs/fry/fish. While this RCW speaks more specifically to the sale of fish and/or eggs WDFW takes a broader application of this statute to include any surplus fish and/or eggs irrespective of being sold or transferred.

We propose implementing specific measures during the different life-history stages to both improve the accuracy of production levels and make adjustments if over-production occurs. These measures include (1) Improved Fecundity Estimates, (2) Adult Collection Adjustments, (3) Within-Hatchery Program Adjustments, and (4) Culling at the earliest life-stage.

### Improved Fecundity Estimates

- A) Develop broodstock collection protocols based upon the most recent 5-year mean in-hatchery performance values for female to spawn, fecundity, green egg to eye, and green egg to release.
- B) Use portable ultrasound units to confirm gender of broodstock collected (broodstock collection protocols assume a 1:1 male-to-female ratio). Ultrasonography, when used by properly trained staff will ensure the 1:1 assumption is met (or that the female equivalents needed to meet production objective are collected). Spawning matrices can be developed such that if broodstock for any given program are male limited sufficient gametes are available to spawn with the females.

### Adult Collection Adjustments

- C) Make in-season adjustments to adult collections based upon a fecundity-at-length regression model for each population/program and origin composition need (hatchery/wild). This method is intended to make in-season allowances for the age structure of the return (i.e. age-5 fish are larger and therefore more fecund than age-4 fish), but will also make allowances for age-4 fish that experienced more growth through better ocean conditions compared to an age-5 fish that reared in poorer ocean conditions.

### Within-Hatchery Program Adjustments

- D) At the eyed egg inventory (first trued inventory), after adjustments have been made for culling to meet BKD management objectives, the over production will be managed in one or more of the following actions as approved by the HCP-HC or PRCC-HSC:
- Voluntary cooperative salmon culture programs under the supervision of the department under chapter [77.100](#) RCW;
  - Regional fisheries enhancement group salmon culture programs under the supervision of the department under this chapter;
  - Salmon culture programs requested by lead entities and approved by the salmon funding recovery board under chapter [77.85](#) RCW;
  - Hatcheries of federally approved tribes in Washington to whom eggs are moved, not sold, under the interlocal cooperation act, chapter [39.34](#) RCW; and
  - Governmental hatcheries in Washington, Oregon, and Idaho; or
  - Culling for diseases such as BKD and IHN, consistent with the Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State; or
  - Distribution to approved organizations/projects for research.
- E) At tagging (second inventory correction) fish will be tagged up to 110% of production level at that life stage. If the balance of the population combined with the tagged population amounts to more than 110% of the total release number allowed by Section 10 permits then the excess will be distributed in one or more of the following actions as approved by the HCP-HC or PRCC-HSC:
- Voluntary cooperative salmon culture programs under the supervision of the department under chapter [77.100](#) RCW;
  - Regional fisheries enhancement group salmon culture programs under the supervision of the department under this chapter;
  - Salmon culture programs requested by lead entities and approved by the salmon recovery funding board under chapter [77.85](#) RCW;
  - Hatcheries of federally approved tribes in Washington to whom eggs are moved, not sold, under the interlocal cooperation act, chapter [39.34](#) RCW; and
  - Transfer to another resource manager program such as CCT, YN, or USFWS program;
  - Governmental hatcheries in Washington, Oregon, and Idaho;
  - Placement of fish into a resident fishery (lake) zone, provided disease risks are within acceptable guidelines; or
  - Culling for diseases such as BKD and IHN, consistent with the Salmonid Disease Control Policy of the Fisheries Co-managers of Washington State; or
  - Distribution to approved organizations/projects for research.
- F) In the event that a production overage occurs after the above actions have been implemented or considered, and deemed non-viable for fish health reasons in accordance with agency aquaculture disease control regulations (i.e. either a pathogen is detected in a population that may pose jeopardy to the remaining population or other programs if

retained or could introduce a pathogen to a watershed where it had not previously been detected) then culling of those fish may be considered.

All, provisions, distributions, or transfers shall be consistent with the department's egg transfer and aquaculture disease control regulations as now existing or hereafter amended. Prior to department determination that eggs of a salmon stock are surplus and available for sale, the department shall assess the productivity of each watershed that is suitable for receiving eggs.

## 1. INTRODUCTION

The Habitat Conservation Plan (HCP) specifies that a monitoring and evaluation plan will be developed for the hatchery program. The approach to monitoring the hatchery programs was guided by the *“Monitoring and Evaluation Plan for PUD Hatchery Programs: 2013 Update”* (Hillman et al. 2013) and the *“Conceptual Approach to Monitoring and Evaluating the Chelan County Public Utility District Programs”* (Murdoch and Peven 2005).

The purpose of this document is to define the tasks associated with the approved scope of work to implement Chelan PUD’s (CPUD’s) hatchery monitoring and evaluation (M&E) plan for 2018. Additionally, monitoring and evaluation activities for Lake Wenatchee sockeye in 2018 are included in this document. As monitoring tasks are completed in 2017 and are evaluated for their efficacy, methodologies to accomplish the tasks defined in the 2018 Implementation Plan may be modified [with Habitat Conservation Plan’s Hatchery Committee (HCP-HC) approval].

The work described in this plan has Endangered Species Act (ESA) coverage provided by NMFS Section 10(a)(1)(A) permits 18121 and 1395 and Section 10(a)(1)(B) permit 1347. All activities conducted under this Implementation Plan shall adhere to all terms and conditions as specified in the referenced permits. These permits allow for changes to monitoring or research protocols with the caveat that such modifications are approved by NMFS prior to implementing those changes. Terms and conditions relevant to monitoring and evaluating the hatchery programs have been used to inform the various measurements below and associated scopes of work with entities performing the work. A report summarizing compliance with the terms and conditions set forth under the above-references permits is required for submittal to NMFS; a copy of this completed report will be provided to the HCP HC.

The Implementation Plan includes all four components of the hatchery M&E Program including: (1) aquaculture monitoring; (2) juvenile monitoring; (3) adult monitoring; and (4) data, analysis and reporting. Under each component are study design elements that will be used to inform the overarching program components. Figure 1 illustrates the relationship of the components and study design elements used to address each component. Table 1 depicts which study design element is being performed by entity, and the associated objectives for each study design element as referred to in Hillman et al. 2013. For Lake Wenatchee sockeye salmon, the proposed M&E activities cover juvenile and adult life history stages and provide the data necessary to track or estimate viable salmonid population parameters (VSP) and is described in Section 6.0.

Figure 1. The four components of the hatchery monitoring and evaluation program and the study design elements within each component.

Table 1. Study design elements performed by entity, and the associated objectives for each study design element as referred to in Hillman et al. 2013.

<sup>1</sup> Monitoring questions relative to Objective 7 will be addressed at the next 10 year HCP check-in.

<sup>2</sup>CPUD crews will PIT tag in-hatchery fish.

<sup>3</sup>Biomark will PIT tag in-hatchery fish.

<sup>4</sup>In 2018, monitoring and evaluation for the Methow spring Chinook program is described in "Implementation of Comprehensive Monitoring and Evaluation of Wells Hatchery Complex Programs".

<sup>5</sup>Because the Chelan summer Chinook program is primarily an augmentation program, monitoring and evaluation efforts focus on straying, release characteristics, and harvest.

## 2. AQUACULTURE MONITORING

The aquaculture monitoring component is comprised of two basic elements: (1) stock assessment and broodstock collection at adult trapping locations and (2) in-hatchery monitoring including spawning, rearing, and release of juveniles. Data collected during these elements primarily support monitoring questions 5.1.1, 5.2.1, 8.1.1, 8.2.1, 8.3.1, 8.3.2, 8.4.1, 9.1.1, 9.2.1, 9.3.1 and 9.4.1, but also contribute data to monitoring questions 3.2.1, and 3.2.2 (Hillman et al. 2013). Table 2 below provides a summary of the variables to be measured in 2018 under the aquaculture monitoring component and what objective the measure(s) supports. The text that follows in this section further describes the activities.

Table 2. Monitoring and Evaluation Plan (Hillman et al. 2013) objectives and the associated measured variables for the aquaculture monitoring component.

| Objectives   | Measured Variables<br><i>(Applicable Study Component(s))</i>   |
|--|--|
| <p><u>Objective 3:</u><br/>Determine if the hatchery adult-to adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.</p> | <ul style="list-style-type: none"> <li>• Number of hatchery and naturally produced fish collected for broodstock<br/><i>(Broodstock Collection and Stock Assessment)</i></li> <li>• Number of broodstock used by brood year (hatchery and naturally produced fish)<br/><i>(Broodstock Collection and Stock Assessment)</i></li> </ul>  |
| <p><u>Objective 5:</u><br/>Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.</p>                    | <ul style="list-style-type: none"> <li>• Ages of hatchery and naturally produced fish sampled via PIT tags or stock assessment monitoring<br/><i>(Broodstock Collection and Stock Assessment)</i></li> <li>• Time (Julian date) of ripeness of hatchery and natural origin steelhead captured for broodstock<br/><i>(Broodstock Collection and Stock Assessment)</i></li> </ul>  |
| <p><u>Objective 8:</u><br/>Determine if hatchery programs have caused changes in phenotypic characteristics of the natural populations.</p>  | <ul style="list-style-type: none"> <li>• Size (length), gender, and total/salt age of broodstock<br/><i>(Broodstock Collection and Stock Assessment)</i> <ul style="list-style-type: none"> <li>• Assess age of fish<br/><i>(Broodstock Collection and Stock Assessment)</i></li> </ul> </li> <li>• Length, weight, and age (covariate) of hatchery and natural-origin broodstock after eggs have been removed<br/><i>(Broodstock Collection and Stock Assessment)</i> <ul style="list-style-type: none"> <li>• Number and weight of eggs<br/><i>(Broodstock Collection and Stock Assessment)</i></li> </ul> </li> </ul> |
| <p><u>Objective 9:</u><br/>Determine if hatchery fish were released at the programmed size and number.</p>   | <ul style="list-style-type: none"> <li>• Fork length and weights of random samples of hatchery juveniles at release<br/><i>(Release Monitoring)</i></li> <li>• Monthly individual lengths and weights of random samples of hatchery juveniles<br/><i>(In-Hatchery Monitoring)</i></li> <li>• Numbers of smolts released from the hatchery<br/><i>(Release Monitoring)</i></li> </ul>   |

## **2.1 Broodstock Collection and Stock Assessment**

Broodstock collection and stock assessment for Wenatchee summer steelhead, Wenatchee summer Chinook, Methow spring Chinook, Chelan Falls summer Chinook, and Chiwawa River spring Chinook, hatchery programs will, in most instances, occur concurrent to and consistent with the Broodstock Collection Protocol approved annually by the HCP-HC and relevant permits. Data collection during broodstock collection will be consistent with Murdoch and Peven (2005). A representative sample of fish trapped throughout the entire run, either collected for broodstock or released back to the river, will be sampled for origin, age, sex, size, and migration timing. Biological sampling of all fish trapped will include presence of internal (CWT or PIT) and external (VIE) tags or marks, scales, length, and sex (determined by ultrasound). PIT tags will be injected into all target species (Chinook and steelhead), whether collected for broodstock or released back to the river to monitor for potential fallbacks. All non-target species will be enumerated daily. Measures of central tendency and spread will be calculated and reported for each metric.

## **2.2 In-Hatchery Monitoring**

The in-hatchery monitoring component will begin when adult fish are collected and retained for broodstock and ends when juvenile fish are released. Life stage specific in-hatchery survival and growth rates, disease monitoring, and an estimate of the number of fish released will be collected and analyzed according to Murdoch and Peven (2005). Additional data to be collected includes individual lengths and weights of juveniles during monthly sampling, and the weight of gonadal mass and body of spawned broodstock. Measures of the central tendency and spread will be calculated and reported for each metric.

### *Fish Marking*

All of Chelan PUD's hatchery fish will be coded-wire tagged (CWT) and externally marked or marked as otherwise agreed to by the HCP HC. A comprehensive marking strategy will be developed by the HCP-HC and included as an Addendum to this Plan. The identification of these hatchery-produced fish is needed for a suite of adult metrics and may be used for adult management and/or fisheries as contemplated by the co-managers.

Using methods described in Keller and Murauskas (2012), hatchery fish will be PIT-tagged (Table 3) at Eastbank Hatchery approximately two to four weeks before the fish are transferred to acclimation ponds or in the spring prior to release. Additional PIT-tagging may occur for program specific studies/comparisons as approved by the HCP-HC. The data collected from the PIT-tags will assist in release monitoring, migration timing, juvenile survival, and smolt-to-adult survival. For all fish marking, quality control check will be performed during and immediately following tagging and prior to release.

Table 3. Chelan PUD’s hatchery program release goals and recommended number of fish PIT tagged.

| Program                     | Release goals                                    | Number of fish PIT tagged <sup>1</sup> | PIT tag rate (%) |
|-----------------------------|--|--|------------------|
| Chiwawa spring Chinook      | 144,026  | 10,000                                 | 6.9              |
| Wenatchee steelhead         | 247,300  | 20,000                                 | 8.0              |
| Wenatchee summer Chinook    | 318,816 (CPUD Program)<br>181,184 (GPUD Program) | 20,600                                 | 4.1              |
| Methow spring Chinook       | 60,156   | 5,000                                  | 8.3              |
| Chelan Falls summer Chinook | 576,000  | 10,000                                 | 1.7              |

<sup>1</sup> Additional PIT tagging may take place for Chelan PUD approved studies and/or comparisons.

### **2.3 Release Monitoring**

Hatchery fish will be released during smoltification in the spring, typically between 15 April and 1 June. Whenever possible, the exact release dates will coincide with environmental conditions that promote a rapid emigration that minimizes both the potential negative ecological interactions of hatchery fish with naturally produced fish and predation on hatchery fish by avian or other predators. The default release method will incorporate a volitional approach, as approved by the HCP HC, unless it can be demonstrated other approaches are better. The monitoring data collected for each stock are described below.

#### *Chiwawa and Methow Spring Chinook*

Pre-release sampling data will be conducted consistent with Murdoch and Peven (2005), including individual weights to the nearest 0.1 gram. Data collected will support monitoring questions 9.1, 9.2, 9.3 and 9.4 in the updated monitoring and evaluation plan (Hillman et al. 2013). PIT tag monitoring of spring Chinook released in the Chiwawa River will occur during the release period (April). Juvenile Chinook will pass through two 92-cm diameter PIT-tag antennas connected to Allflex 310 readers and Quantitative Sampling Technologies (QST) QuBE data logger. The release location and type (i.e., volitional, forced, or trucked) are recorded for each observation file created and uploaded to the PTAGIS database maintained by the Pacific States Marine Fisheries Commission after each year of release. PIT-tagged fish in each observation (release) file are assumed to represent untagged fish. Observation files contain the PIT tags associated with the original tag files and will be used for analysis (see Post-release Monitoring Section). The total number of fish released will be based on the population size at CWT tagging (100%), subtracting mortality enumerated by hatchery staff that occurred from tagging to release.

#### *Wenatchee Summer Steelhead–*

Pre-release sampling will be conducted consistent with Murdoch and Peven (2005), including individual weights to the nearest 0.1 gram. Data collected will support monitoring questions 9.1, 9.2, 9.3 and 9.4 in the updated monitoring and evaluation plan. Monitoring of steelhead released in the Wenatchee River sub-basin will occur during loading of fish into transport trucks, unless fish are released directly into the Chiwawa River. Steelhead will pass through a series of PIT-tag antennas, each connected to a data logger, thereby allowing the creation of a PIT-tag observation file for each truckload of steelhead consisting of unique tag records. The release location (stream and rkm), release type (volitional or forced), and hatchery group (HxH or WxW) will be recorded for each tag file created. PIT-tagged fish in each observation (release) file are assumed to represent untagged fish. However, because PIT-detection efficiency during loading will not be 100%, the number of fish in each truckload will be estimated using volumetric displacement. Observation files contain the PIT tags associated with the original tag files and will be used for analysis (see Post-release Monitoring Section). The total number of fish released will be based on the population size at CWT tagging (100%), subtracting mortality enumerated by hatchery staff that occurred from tagging to release.

#### *Wenatchee and Chelan Falls Summer Chinook*

Pre-release sampling will be conducted consistent with Murdoch and Peven (2005), including individual weights to the nearest 0.1 gram. Data collected will support monitoring questions 9.1, 9.2, 9.3 and 9.4 in the updated monitoring and evaluation plan. Should PIT tagging occur, a monitored release strategy consistent with other Chinook stocks (i.e., Chiwawa Spring Chinook) will be implemented. The total number of fish released will be based on the population size at CWT tagging (100%), subtracting mortality enumerated by hatchery staff that occurred from tagging to release.

### **2.4 Post-Release Monitoring and Survival Analysis**

Data will be collected during rearing, acclimation, release, and the emigration period that may prove valuable in explaining variability in adult survival (Murdoch and Peven 2005). Rearing densities have been reported to influence the survival of hatchery fish (Martin and Wertheimer 1989; Banks 1994) and may also be linked to disease prevalence during rearing (Banks 1994; Ogut and Reno 2004). Acclimation of hatchery fish before release has been found to increase survival and reduce stray rates when the duration of the acclimation period is sufficient (Clarke et al. 2010, 2012; Rosenberger et al. 2013). These metrics (i.e., rearing density and acclimation period) will be collected annually to determine their influence on fish survival.

PIT-tagged groups of hatchery fish will be used to estimate survival during their emigration. Variation in survival during the emigration period may also inform observed adult survival rates. Survival during emigration and travel will be estimated using interrogation or release files and the standard Cormack-Jolly-Seber (CJS) estimator. CJS estimates are termed apparent survival estimates because it is unknown whether fish suffered mortality (e.g., size or time of release) or simply failed to emigrate (i.e., residualized or were precocial males). In the latter case, the proportion of PIT-tagged fish detected in the Methow sub-basin, Wenatchee or Columbia rivers after the emigration period is complete may explain variation in smolt survival rates. The post-release performance of PIT-tag groups will be estimated and monitored annually, consistent

with methods in Murdoch and Peven (2005). Additionally, precocity of hatchery releases will be evaluated by examining the proportion of PIT tag releases detected in adult fish ladders and tributaries within the same year as release.

### 3. JUVENILE MONITORING

Data collected during these elements primarily support monitoring questions 2.1.1 and 2.2.1. and the monitoring objectives described in Table 4 (Hillman et al. 2013). Table 4 below provides a summary of the variables to be measured in 2018 under the juvenile monitoring component and what objective the measure supports. The text that follows in this section further describes the activities.

Table 4. Monitoring and Evaluation Plan (Hillman et al. 2013) objectives and the associated measured variables for the juvenile monitoring component.

| Objective   | Measured Variables<br><i>(Applicable Study Component(s))</i>  |
|---|---|
| <u>Objective 2:</u><br>Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks. | <ul style="list-style-type: none"> <li>Number of juveniles (smolts, parr [where appropriate], and emigrants)<br/><i>(Freshwater Productivity of Supplemented Stocks)</i></li> </ul> |

#### 3.1 Freshwater productivity of Supplemented Stocks

##### *Steelhead, Spring Chinook, and Summer Chinook*

The freshwater productivity of supplemented stocks in the Wenatchee sub-basin will be monitored using smolt traps in the Chiwawa River and the lower Wenatchee River consistent with historical trapping efforts. Additionally, a newly derived analytical method which uses PIT-tag mark-recapture data will be utilized that reduces bias and increases precision by including estimates of emigration during the winter non-trapping periods. Up to 3,000 parr will be PIT tagged in the Chiwawa River in the fall, based on the spatial distribution and abundance estimated during parr snorkel surveys, to generate estimates of migration during the non-trapping periods. A random sample of a minimum of 10 percent of fish per remote site will be held in a live box for 24 hours to evaluate tag loss and delayed mortality. Using PIT tagged parr detections at the lower Chiwawa PIT array during the non-trapping period, the total number of PIT-tagged parr that emigrated will be estimated, and then expanded by the tag rate.

Overwinter mortality of PIT-tagged parr is assumed to be the same as non-PIT-tagged parr. Overwinter survival estimates of Chiwawa River parr will be derived by estimating survival to the lower Wenatchee PIT tag array and analyses with the TribPit Survival software program and/or estimating survival of fall parr and spring smolts to McNary. PIT-tag mark-recapture trials conducted during the trapping period in the fall will also be used to estimate detection probabilities of the PIT-tag array at a given discharge level. Abundance and variance will be estimated using the same methods as those used in the smolt trap estimate. The estimated abundance and variance from each method and time period (trapping and non-trapping

periods) will be summed to estimate a total production estimate. Under the proposed methodology, unbiased estimates of abundance during the entire migration period will be generated with relatively high precision (PSE < 15%), which is consistent with NOAA Fisheries' recommendations (Crawford and Rumsey 2011). Historical estimates will be revised using the new estimation techniques.

Specific actions to monitor the freshwater productivity of supplemented spring Chinook salmon in the Methow sub-basin have yet to be determined. As these become available, the plan will be amended and presented to the HC by December.

### **3.2 Tributary Evaluations**

#### *Chiwawa River*

Snorkel surveys will be utilized to estimate parr abundance within the Chiwawa subwatershed during the summer. This approach has been used in the Chiwawa subwatershed since 1992. In parallel to addressing Objective 2, additional juvenile data can help to assess the habitat carrying capacity in each tributary. This information can add value to the overall M&E plans and help inform management decisions.

Sampling will follow a stratified random sampling design. Landscape classification will be used to stratify streams in the Chiwawa subwatershed that support juvenile Chinook salmon. In the Chiwawa subwatershed, WDFW found that classification "explained" most of the variability in fish numbers caused by geology, land type, valley bottom type, stream state condition, and habitat type (Hillman 2013). The same classification method was used to identify sections of the Little Wenatchee River (reference area) that corresponded to discrete reaches in the supplemented subwatersheds, but that had no release of hatchery Chinook. Consistent with previous efforts, habitat types within each land-class or reach will be identified and quantified annually. At least three units of each habitat type within each reach will be randomly selected for estimating densities of salmon and trout. Thus, overall sampling consists of a stratified- random sampling design, which increases the accuracy and precision of population estimates.

Densities of salmon and trout will be estimated in August and September by direct underwater observation within the randomly-selected habitat units. Underwater methods will follow those described by Thurow (1994), Dolloff et al. (1996), and O'Neal (2007). Habitat surface areas and volumes will be estimated during fish sampling. Numbers of fish counted will be adjusted for detection probabilities using the models published in Hillman et al. (1992). For each habitat type within a state type and reach stratum, the mean density of salmon and trout will be calculated as the ratio of mean numbers to mean area or volume sampled (Cochran 1977). Total numbers of fish will be estimated per habitat type within a state type and reach stratum as the product of mean density of fish in a given habitat type, times total area or volume of that habitat type within the stratum (Cochran 1977). Total numbers of fish within the supplemented subwatershed will be estimated as the sum of all population numbers per habitat type in state type/reach strata. Bootstrapping methods will be utilized to estimate variance and percent errors (based on 95% confidence interval) for total numbers of fish.

#### 4. ADULT MONITORING

The adult monitoring component is comprised of two basic elements: (1) estimating spawning escapement and (2) harvest monitoring. Data collected during these elements primarily support monitoring questions 1.1.1, 1.2.1, 2.1.1, 2.2.1, 3.2.1, 3.2.2, 4.1.1, 5.1.1, 5.2.1, 5.3.1, 5.3.2, 6.3.1, but also contribute data to monitoring questions 6.1.1, 6.2.1, 8.1.1, 8.2.1, 8.4.1, 10.1.1, 10.1.2, 10.1.3 and 10.1.4. Table 5 below provides a summary of the variables to be measured in 2018 under the adult monitoring component and what objective the measure(s) supports. The text that follows in this section further describes the activities.

Table 5. Monitoring and Evaluation Plan (Hillman et al. 2013) objectives and the associated measured variables for the adult monitoring component.

| Objective  | Measured Variables<br>(Applicable Study Component(s))   |
|--|---|
| <p><u>Objective 1:</u><br/>Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.</p> | <ul style="list-style-type: none"> <li>• Number of hatchery and naturally produced fish on spawning grounds<br/>(Spawning Escapement Estimates)</li> <li>• Number of hatchery and naturally produced fish taken for broodstock<br/>(Broodstock Collection and Stock Assessment)</li> <li>• Number of hatchery and naturally produced fish taken in harvest (if recruitment is to the Columbia)<br/>(Harvest Reporting)</li> </ul> |

#### **4.1 Spawning Escapement Estimates**

##### *Chelan Summer/Fall Chinook*

Chinook spawning ground surveys will be conducted in the Chelan River and (see Appendix A for survey reaches). Spawning ground surveys will be conducted via foot or raft beginning late September and continuing until spawning has ended (usually mid-November). Frequency of surveys will vary depending on method.

Summer Chinook carcass surveys will be conducted in the Chelan River beginning in September and ending in November consistent with methods described in Murdoch and Peven (2005). A representative sample (i.e., 20%) of spawners as determined by spawner abundance and distribution (typically 100% of the carcasses encountered in the Chelan River) will be sampled. Biological data will include collection of scale samples for age analysis, length measurements (POH and FKL), gender, egg voidance, and a check for tags or marks. DNA samples (five-hole punches from operculum) will be collected as needed to address different objectives. These data will be used to assess length-at-age, size-at-age, egg voidance, origin (hatchery or naturally produced), stray rates, and genetics. All carcass surveys will be conducted within the historical reaches.

##### *Wenatchee Steelhead*

The number of hatchery and naturally produced steelhead returning to the Wenatchee sub-basin will be estimated using a PIT tag mark recapture model. The estimated spawner abundance for the Wenatchee steelhead population will be a combination of PIT tag-based tributary and redd-based mainstem Wenatchee River estimates. Steelhead redd counts will be conducted weekly in all major spawning areas in the mainstem Wenatchee River (see Appendix A for survey reaches); minor spawning areas in the mainstem Wenatchee River will be surveyed once, based on the spawn timing in adjacent major spawning areas, to estimate redd abundance at peak spawning. The estimated total number of redds in the Wenatchee River mainstem will be expanded by the sex ratio of the population to estimate spawner abundance. Spawner abundance in tributaries of the Wenatchee River will be estimated using a PIT tag mark recapture model.

##### *Chiwawa Spring Chinook*

Chiwawa spring Chinook spawning escapement will be estimated based on the total number of redds found in each tributary (Murdoch et al. 2010) using methods described in Murdoch and Peven (2005). Weekly redd and carcass surveys will be conducted simultaneously from the first week of August through September (see Appendix A

for survey reaches). Redd-based estimates assume that each female constructs one redd, which WDFW has found to be appropriate for this population (Murdoch et al. 2009). The total number of redds in each reach will be estimated using methods described in Millar et al. (2012) and using the observer efficiency model currently under development by WDFW. Redd counts will be expanded and the number of hatchery and naturally produced fish will be estimated using methods in Murdoch et al. (2010). Carcasses encountered during surveys will be sampled according to methods outlined in Murdoch and Peven (2005). All CWTs (i.e., snout or adipose) from carcasses will be read and the data entered into the Regional Mark Processing Center database within one year of collection.

Additionally, all redds and female carcasses will be geo-referenced using hand-held GPS devices. Carcass recovery bias has been detected in the Chiwawa spring Chinook population (Murdoch et al. 2010) and if not corrected will bias estimates of hatchery and naturally produced fish on the spawning grounds. While it may be appropriate to correct for carcass recovery bias for some monitoring questions (e.g., 2.2), when comparisons to reference populations are made in monitoring questions 1.1 and 1.2, carcass bias will not be corrected because other monitoring programs have not corrected for a similar bias.

#### *Wenatchee Summer Chinook*

Wenatchee summer Chinook spawning ground counts will begin the first week in September and continue through the end of spawning in November (see Appendix A for survey reaches). Total census redd counts will be conducted by foot or raft depending on stream size, flow, and density of spawners within the stream reach (see Appendix A for survey reaches). All stream reaches will be surveyed once per week. Redd data will be collected using methods described in Murdoch and Peven (2005). The total number of redds in each reach will be estimated using methods described in Millar et al. (2012) and using the observer efficiency model currently under development by WDFW. Weekly ground-based census counts and the true number of redds (determined via intensive surveys) will be compared in order to generate observer efficiency. River characteristics (e.g., channel width, water depth, discharge, visibility, and habitat complexity), observer experience, and survey effort will be incorporated into a model to predict observer efficiency in all river reaches. Predicted redd generate observer efficiency for each river reach will be used to adjust ground-based redd counts to estimate the total reach redd count. Ground-based surveys will also be used to estimate redd life for each river reach. The estimated spawner abundance in the Wenatchee River and an associated level of precision will be calculated using the estimated total redd count for each reach, mean redd life, and the sex ratio of the population similar to methods described in Millar et al. (2012). Salmon carcass data collected during spawning ground surveys will be consistent with Murdoch and Peven (2005). All CWTs (i.e., snout or adipose) from carcasses will be sent to the WDFW lab in Olympia. The CWT lab will extract and read CWTs and submit all required information to RMIS within one year of collection.

#### **4.2 Harvest Reporting**

In years when the expected hatchery adult returns are in excess of the levels needed to meet the hatchery program goals (i.e., broodstock and/or escapement), surplus fish may be available for harvest. Harvesting or removal of surplus hatchery fish may have benefits to the natural populations by reducing potential negative ecological and genetic impacts (e.g., density dependent effects, loss of fitness, and loss of genetic variation). The contribution of hatchery fish to fisheries will be monitored using CWT recoveries on a brood-year basis supporting Objective 10.

To obtain the necessary data to determine if the harvest rates are meeting objectives, a statistically valid creel program will be designed and implemented for all sport and/or conservation fisheries in the Upper Columbia River to estimate harvest of hatchery fish from

both Chelan and Grant County PUD funded hatchery programs (Murdoch and Peven 2005). Information collected during creel surveys are an integral component to calculating the HRR (Objective 3), particularly given most CWT recoveries for PUD mitigation programs occur in the Upper Columbia River and its tributaries, with the exception of summer Chinook where most CWT recoveries occur in ocean fisheries. Because of considerable time lags in reporting of CWT's to the Regional Marking Information System (RMIS) database, it requires an ongoing query of recovery data until the number of estimated fish does not change.

## **5. DATA MANAGEMENT, ANALYSIS, AND REPORTING**

### ***5.1 Data Management***

A Microsoft Access database maintained by WDFW will contain all the monitoring data collected for hatchery evaluations. The database will contain and manage all data associated with aquaculture monitoring, juvenile monitoring, and adult monitoring.

All data entered into the database are evaluated for quality control and quality assurance by WDFW. Quality control checks using analyses such as modified Z-scores, boxplots, and the Generalized Extreme Studentized Deviate Procedure (Iglewicz and Hoaglin 1993) will be conducted for all data entry. In the event outliers are identified, discussion will occur on whether identified outliers are true data points or transcription errors. This process ensures that the data used to test statistical hypotheses are correct and accurate.

### ***5.2 Data Analysis***

The analyses proposed are consistent with the Monitoring and Evaluation Plan for PUD Hatchery Programs: 2013 Update (Hillman et al. 2013). Each of the objectives will be addressed using the appropriate statistical tests, as well as graphic analyses that convey relevant information.

### ***5.3 Reporting***

An annual M&E report will be generated following the completion of each calendar year and will be available for HCP-HC review by June 1 of the following year. Additionally, monthly progress reports will be made available to the HCP-HC.

## **6. Lake Wenatchee Sockeye Salmon**

The Chelan PUD will conduct monitoring and evaluation (M&E) activities to track key population attributes related to Lake Wenatchee sockeye salmon in 2018 (Table 6). In the absence of a sockeye hatchery program, M&E activities are no longer rooted in the context of evaluating the effects of sockeye salmon supplementation, but instead focus directly on the performance of the natural population, which is a unique departure from historic monitoring obligations. Broadly, the proposed M&E activities cover juvenile and adult life history stages and provide the data necessary to track or estimate viable salmonid population parameters (VSP): abundance, productivity, spatial structure and diversity (McElhaney et al. 2000). The data collected may also have utility in future hatchery compensation recalculation efforts.

Chelan PUD is conducting these M&E activities to support commitments made under the 2011 hatchery recalculation effort, which also included a steelhead production commitment for a sockeye species swap (SOA 2011). This section of the implementation plan describes the specific commitments by juvenile and adult life history stages.

### **6.1 Juvenile Monitoring**

Chelan PUD will conduct or fund activities to monitor and evaluate the temporal distribution and age/size of out-migrating smolts, and estimate smolt production (Table 6). Smolt production will be estimated from data collected at the lower Wenatchee smolt trap and via back calculations based on collected adult return data (i.e., age-at-return estimates, SARs, and adult escapement to the tributaries). Collectively, these activities include: (1) funding of the lower Wenatchee River smolt trap concurrent with efforts aimed at evaluating Chelan PUD funded supplemented populations in the Wenatchee River sub-basin; (2) tagging up to 5,000 PIT tags for natural-origin juveniles encountered during smolt trapping activities and collecting scale samples at this location; and (3) estimating adult escapement estimates to the tributaries, and collection of adult return data at Tumwater (see the *Adult Monitoring* section for details) to back-calculate smolt production.

The monitoring data obtained will provide a useful set of tools for evaluating the performance of natural origin sockeye salmon within the sub-basin and downstream and also support the evaluation of VSP parameters [e.g., outmigration timing and size (diversity); and PIT tagging juveniles for SAR estimates (productivity)].

### **6.2 Adult Monitoring**

Several M&E activities associated with adult returns of Lake Wenatchee sockeye salmon will be conducted and/or funded by Chelan PUD (Table 6). These efforts include (1) continuation of accurate adult counts at Rock Island, Rocky Reach, and Tumwater dams; (2) sampling of scales for age distribution, sex ratio determination, and returns of PIT-tagged adults at Tumwater Dam; (3) reach-specific conversion estimates between Rock Island Dam and spawning grounds in the White and Little Wenatchee rivers (i.e., Rock Island to Tumwater Dam to spawning tributaries); and (4) providing between 250 to 1,000 PIT tags to estimate adult spawning escapement in the Little Wenatchee and White rivers utilizing PIT tags and mark-recapture techniques (the software program Sample Size 2.0.7, developed by the University of Washington School of Aquatic and Fisheries Science (P. Westhagen, J. Lady, and J. Skalski) was used to determine the minimum number of tags required (i.e., 250) to estimate adult sockeye escapement at a +/- 7 percent confidence interval). Chelan PUD will adjust the number of PIT-tagged individuals in order to maintain precision in estimates at the lowest rate of interference to migrating populations, if it is warranted due to annual changes in escapement and detection probabilities. In an effort to PIT tag the run at large, adults will be PIT tagged at Tumwater consistent with the Tumwater Operations Protocol, daily throughout the run.

Collectively, these data will provide reliable metrics of adult returns and spawning escapement (abundance), recruits-per-spawner (productivity), distribution of spawners among tributaries (spatial structure), and run-timing and age structure for adult immigrants (diversity).

Table 6. Chelan PUD’s proposed Lake Wenatchee sockeye salmon monitoring and evaluation activities.

| Life History Stage | M&E Activity  | Entity Performing the Activity | Related analysis   | VSP parameter addressed                                   |
|--------------------|---|--------------------------------|--|---|
| Juvenile           | Concurrent operation of the lower Wenatchee smolt trap to collect juvenile outmigration data                    | WDFW                           | Generate distribution of outmigration timing, estimate smolt production and determine average smolt size.  | Diversity and productivity                                |
| Juvenile           | PIT tagging smolts at lower Wenatchee smolt trap (up to 5,000 fish annually) and collecting/aging scale samples | WDFW                           | Estimate smolt-to-adult returns.   | Productivity  |
| Juvenile           | Develop adult return based smolt production estimates   | WDFW                           | Use collected data (i.e., adult age-at-return data, SARs, adult escapement to the tributaries) to back-calculate smolt production.   | Productivity  |
| Adult              | Rock Island and Rocky Reach Dam adult counts  | CPUD                           | Initial spawner abundance (Okanogan stock separation)  | Abundance and spatial structure                           |
| Adult              | PIT tag subsample (250 adults) of returning adults at Tumwater Dam to support mark-recapture evaluation         | WDFW                           | Calculate spawner abundance and relative distribution among tributaries  | Abundance and spatial structure                           |
| Adult              | Collect and age scales <sup>1</sup> and determine sex via ultrasound from returning adults at Tumwater Dam      | WDFW                           | Estimate age-at-return, sex ratio, and relative productivity of contributing spawner cohorts   | Productivity and diversity                                |
| Adult              | Tumwater Dam adult counts   | WDFW                           | Estimate potential spawner abundance (pre Lake-Wenatchee harvest), potential productivity (recruits/spawner), and run timing distribution  | Abundance and diversity                                   |
| Adult              | Operate PIT detection arrays on Little Wenatchee and White River  | WDFW                           | Calculate spawner abundance (post-Lake Wenatchee harvest and other mortality), actual productivity (recruits/spawner), and entry-to-spawning-habitat timing distribution, and spatial spawner distribution among tributaries | Abundance, productivity, spatial structure, and diversity |
| All                | Data management, analysis, and reporting  | BioAnalysts<br>CPUD            | -----  | NA  |

<sup>1</sup> Scales would be collected concurrently from adults that are PIT tagged at Tumwater Dam.

---

# Chelan PUD Rocky Reach and Rock Island HCPs Final 2017 Fish Spill Report

## 2017 ROCKY REACH

### Summer Spill

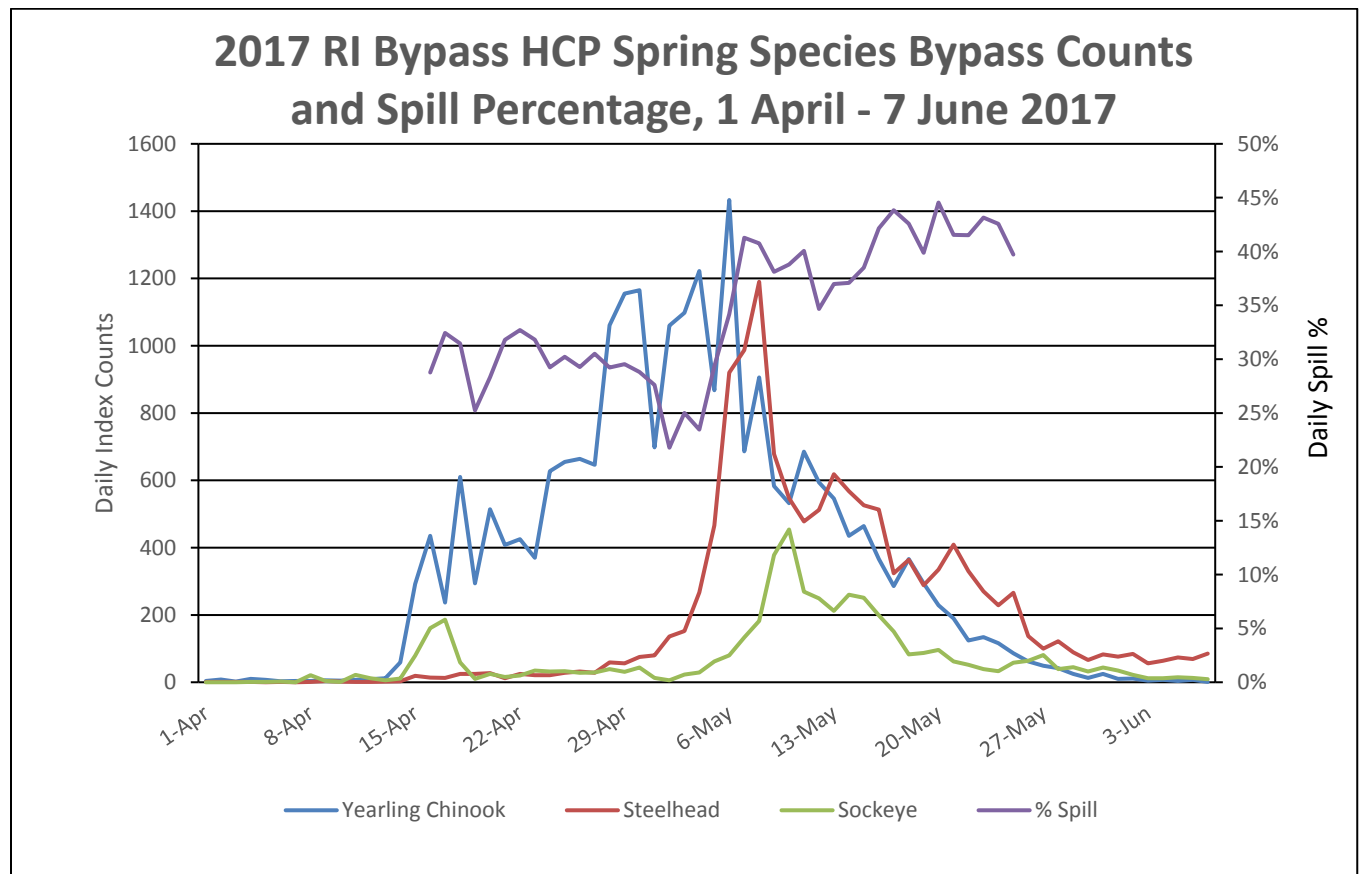

Target species: Subyearling Chinook  
 Spill target percentage: 9% of day average river flow  
 Spill start date: 26 May, 0001 hours  
 Spill stop date: 25 August, 2400 hours  
 95% Est. passage date: 14 August  
 Percent of run with spill: 98.5% on 25 August (estimated as of 31 August)  
 Cumulative index count: 27,404 subyearling Chinook (as of 31 August)  
 Summer spill percentage: 21.74% (9.06% fish spill, plus 12.68% forced spill)  
 Avg river flow at RR: 149,598 cfs (26 May - 25 August)  
 Avg spill rate at RR: 32,518 cfs (26 May - 25 August)  
 Total spill days: 92

**2017 ROCK ISLAND**

**Spring Spill**

Target species: Yearling Chinook, steelhead, sockeye  
 Spill target percentage: 10% of day average river flow  
 Spill start date: 16 April, 0001 hours  
 Spill stop date: 25 May, 2400 hours (immediate increase to 20% summer spill)  
 Percent of run with spill: Yearling Chinook – 98.4%; steelhead – 99.8%; sockeye – 97.0% (spring and summer fish spill combined)  
 Cumulative index count: 50,604 yearling Chinook; 32,135 steelhead; 11,117 sockeye (as of 31 August)  
 Spring spill percentage: 35.22% (9.69% fish spill, plus 25.53% forced spill)  
 Avg river flow at RI: 227,790 cfs (16 April – 25 May)  
 Avg spill flow at RI: 80,222 cfs (16 April – 25 May)  
 Total spill days: 40

## Summer Spill

Target species: Subyearling Chinook  
 Spill target percentage: 20% of day average river flow  
 Spill start date: 26 May, 0001 hours  
 Spill stop date: 18 August, 2400 hours  
 95% Est. passage date: 5 August  
 Percent of run with spill: 97.5% on 18 August (estimated as of 31 August)  
 Cumulative index count: 63,579 subyearling Chinook (as of 31 August)  
 Summer spill percentage: 29.47% (19.89% fish spill, plus 9.58% forced spill)  
 Avg river flow at RI: 162,085 cfs (26 May - 18 August)  
 Avg spill flow at RI: 47,774 cfs (26 May - 18 August)  
 Total spill days: 85

**Juvenile Index Counts 2007-2017 from the Rocky Reach Juvenile Fish Bypass Sampling Facility and Rock Island Bypass Trap Smolt Monitoring Program (SMP)**

| Subyearling Chinook | 15,686      | 15,940      | 8,189       | 23,205      | 27,397      | 27,298      | 17,170      | 34,527       | 15,349      | 13,270      | <b>63,579</b> |

\* In 2014, as directed by the HCP, Chelan PUD conducted bypass operations outside of the normal operating period of 1 April to 31 August to assess achievement of bypass operations for 95% of the subyearling Chinook outmigration. The Rocky Reach juvenile fish bypass operated from 1 April through 15 September, and the Rock Island bypass facility at powerhouse 2 operated from 1 April through 15 September.

## SECTION 1: INTRODUCTION

This document is an update of the monitoring and evaluation (M&E) plan of the salmon and steelhead hatchery programs funded by Douglas, Chelan, and Grant County Public Utility Districts (PUDs). Programmatic changes, evaluation of data collection methods, and M&E results from the past several years, along with shifting management paradigms affect M&E needs, all of which have occurred under advancing fish culture and monitoring techniques. As required by the programs, this document is a result of a five-year review intended to expand on and coalesce previous M&E documents (BAMP 1998; Cates et al. 2005; Murdoch and Peven 2005; Hays et al. 2006; Pearsons and Langshaw 2009a, 2009b; Hillman et al. 2013) with inclusion of new information.

Fishery management agencies developed the following general goal statements for hatchery programs, which were adopted by the HCPs Hatchery Committees and PRCC Hatchery Subcommittee (hereafter, Hatchery Committees):

1. Support the recovery of ESA-listed species by increasing the abundance of the natural adult population, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity.
2. Increase the abundance of the natural adult population of unlisted plan species, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity. In addition, provide harvest opportunities in years when spawning escapement is sufficient to support harvest.
3. Provide salmon for harvest and increase harvest opportunities, while segregating returning adults from natural tributary spawning populations.

Following the development of Hatchery and Genetic Management Plans (HGMPs), artificial supplementation programs are now characterized into three categories. The first type, integrated conservation programs, are intended to support or restore natural populations. These programs focus on increasing the natural production of targeted fish populations. A fundamental assumption of this strategy is that hatchery fish returning to the spawning grounds are reproductively similar to naturally produced fish. The second type, safety-net programs, are extensions of conservation programs, but are intended to function as reserve capacity for conservation programs in years of low returns. The safety-net provides a demographic and genetic reserve for the natural population. That is, in years of abundant returns they function like segregated programs, and in low return years they can be managed as conservation programs. Lastly harvest augmentation programs are intended to increase harvest opportunities while limiting interactions with wild-origin counterparts.

Monitoring is needed to determine if the hatchery programs are meeting the intended management objectives of conservation, safety-net, or harvest augmentation programs. Objectives for hatchery programs are generally grouped into three categories of performance indicators:

1. In-Hatchery: Is the program meeting the hatchery production objectives?
2. In-Nature: How do fish from the program perform after release?
  - a. Conservation Program:

- How does the program affect target population abundance and productivity?
  - How does the program affect target population long-term fitness?
  - b. Safety-Net Program:
    - How does the program affect target population long-term fitness?
  - c. Harvest Augmentation Program:
    - Does the program provide harvest opportunities?
3. Risk Assessment: Does the program pose risks to other populations?

Objectives in this plan have been organized in a hierarchy where productivity indicators are the primary metrics used to assess if conservation and safety-net program goals have been met; harvest rates and effects on non-targeted populations are used for harvest programs. In cases where productivity indicators are not available or results are equivocal, monitoring indicators may be used to help evaluate the performance of the program. Evaluations of monitoring indicators may not provide sufficiently powerful conclusions on which to base management actions, although they may provide insight as to why a productivity indicator did or did not meet the program goal. Therefore, the relationship between hatchery programs and indicators can be viewed in a chain-of-causation: management actions within the hatchery programs affect the status of monitoring indicators, which in turn influence productivity indicators (Figure 1).

**Figure 1. Relationship of indicators to the assessment of supplementation programs. Management actions affect monitoring indicators, which influence productivity indicators. Monitoring indicators may be used to hypothesize the magnitude of influence on productivity.**

The primary goal of a conservation program is to contribute to the rebuilding and recovery of naturally reproducing populations within their native habitat. In this plan, natural replacement rates (NRR), recruitment of naturally-produced fish (NOR), and juvenile productivity (juveniles per redd) are important indicators for assessing the success of supplementation. These indicators are difficult to measure precisely and are quite variable in space and time. Therefore, monitoring indicators can be evaluated to help assess if productivity was related to the hatchery programs or other factors (Table 1).

**Table 1. Program objectives, indicators, and goals for conservation hatchery programs including productivity and monitoring indicators (also applies to safety-net programs when used to support a conservation program).**

|   | Objective  | Indicator                            | Target                  | Program goals               |                            |                         |
|---|--|--------------------------------------|-------------------------|-----------------------------|----------------------------|-------------------------|
|   |  |                                      |                         | Rebuild natural populations | Maintain genetic diversity | Opportunity for harvest |

<sup>1</sup> Hatchery and natural-origin fish should spawn at the same time across the range of elevations within the spawning distribution of each stock.

<sup>2</sup> Hatchery and natural-origin fish should spawn in the same locations. Exceptions are the Carlton and Dryden Summer Chinook programs (see Appendix 4).

<sup>3</sup> HRR targets are identified in Appendix 2.

<sup>4</sup> Number and size targets are identified in Table 3 and Appendix 5.

A flow of information following sequential, logical steps will be employed to evaluate supplementation programs, consistent with the indicators described in Table 1. For example, a hatchery program, at a minimum, must be able to produce more adults per spawner than would occur in the natural environment. Should the program fail this test, hatchery operations should be evaluated to determine if improvements can correct the problem. If a program successfully replaces the required number of adults, it is then evaluated against a reference population or condition, if available, to determine if it has increased the overall number of naturally spawning fish (including both hatchery- and natural-origin adults), increased the number of natural-origin spawners, and to test if productivity of the natural population has changed. When these goals are met, the program is considered successful. When these goals are not met, monitoring indicators may infer why the program is not achieving its goals

If suitable reference populations are not available, other comparisons can be used to help evaluate treatment responses. Evaluation of programs may pursue the following approaches:

- Comparison to reference population(s) that do not contain pre-treatment data.
- Before treatment and after treatment comparisons.
- Comparison to standard(s).
- Comparison to other suitable reference conditions.

Methodologies for selecting reference streams, analyzing data from treatment and reference stream comparisons, and other comparisons are presented in Hillman et al. (2012) (see Appendix 6).

The primary goals of a safety-net program are to provide demographic and genetic reserves for a population that is supplemented by a conservation program (Table 2). Harvest and adult management may be used to control escapement of spawners when appropriate. Monitoring focuses on estimating the number of fish that escape to spawn naturally and stray rates and in-hatchery performance evaluation.

**Table 2. Program objectives, indicators, and goals for segregated harvest augmentation hatchery programs including monitoring indicators.**

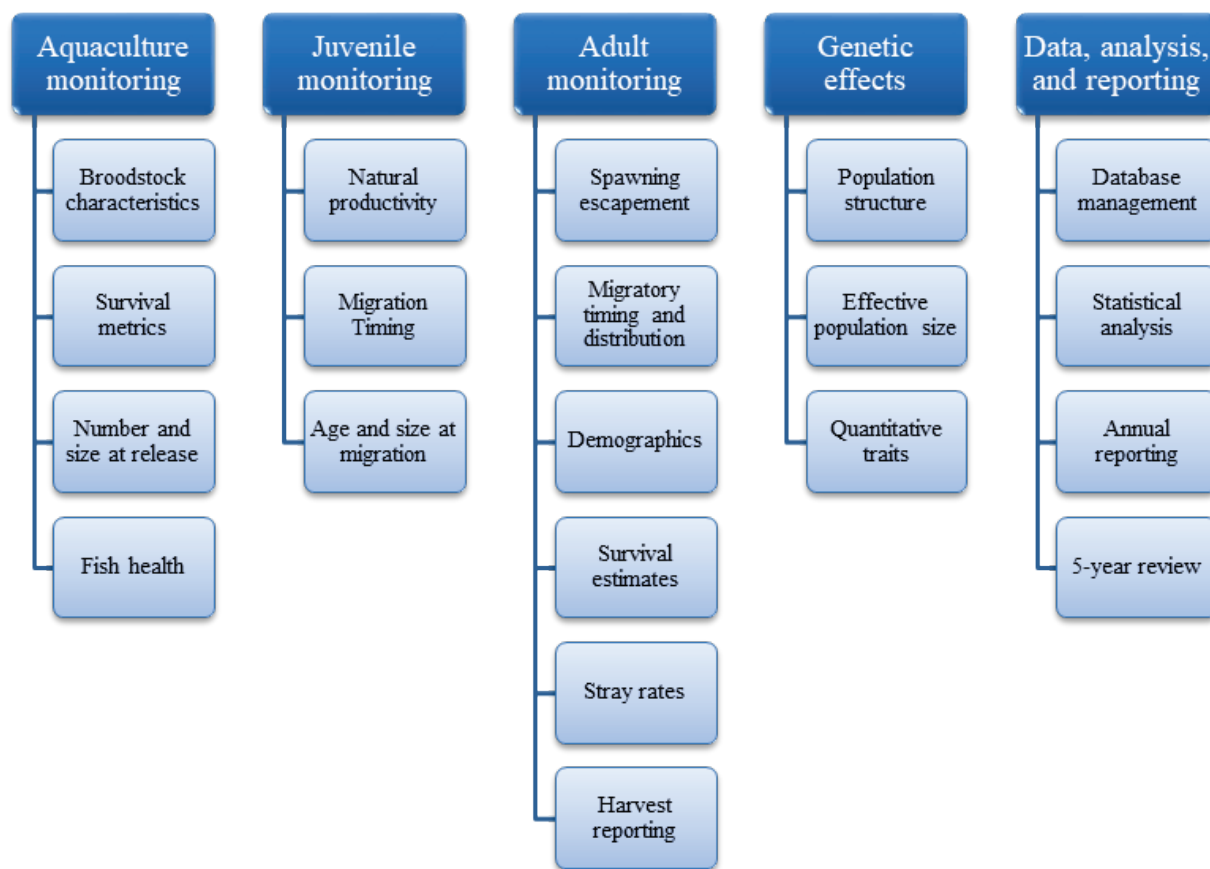

|                       | Objective   | Indicator       | Target                             | Program goals               |                            |                         |

<sup>1</sup> HRR targets are identified in Appendix 2.

<sup>2</sup> Number and size targets are identified in Table 3 and Appendix 5.

The primary goal of a harvest augmentation program is to increase harvest opportunities, while segregating adults from natural spawning populations. In this plan, harvest opportunity, survival rates, and stray rates are important indicators for assessing the success of harvest augmentation. These indicators are more readily quantified compared to productivity indicators (Table 2). A flow of information will be employed to evaluate harvest augmentation programs. Since harvest augmentation programs are typically segregated, monitoring indicators will be used to determine the success of a program.

Both monitoring and productivity indicators will be used to evaluate the success of hatchery programs. In the event that the statistical power of tests that involve productivity indicators is insufficient to inform sound management decisions, some of the monitoring indicators may be used to guide management. Figure 2 show the categories of indicators associated with each component of monitoring.

**Figure 2. Overview of Monitoring and Evaluation Plan Categories and Components (not including regional objectives).**

The overarching goals of conservation, safety-net, and harvest augmentation programs, as described above, are shown in detail in Figure 3. The flow chart (Figure 3) shows the relationship of overarching program goals, the strategies used to meet the goals, the monitoring and evaluation objectives used to evaluate the strategies and determine if goals are being met, and the adaptive

management cycle associated with the programs (see Tables 1 and 2 for the indicators under each objective). The logic depicted in this flow chart shall be used to assess M&E results and apply those results to management decisions. Table 3 presents the current hatchery programs releasing fish in the Upper Columbia Basin.

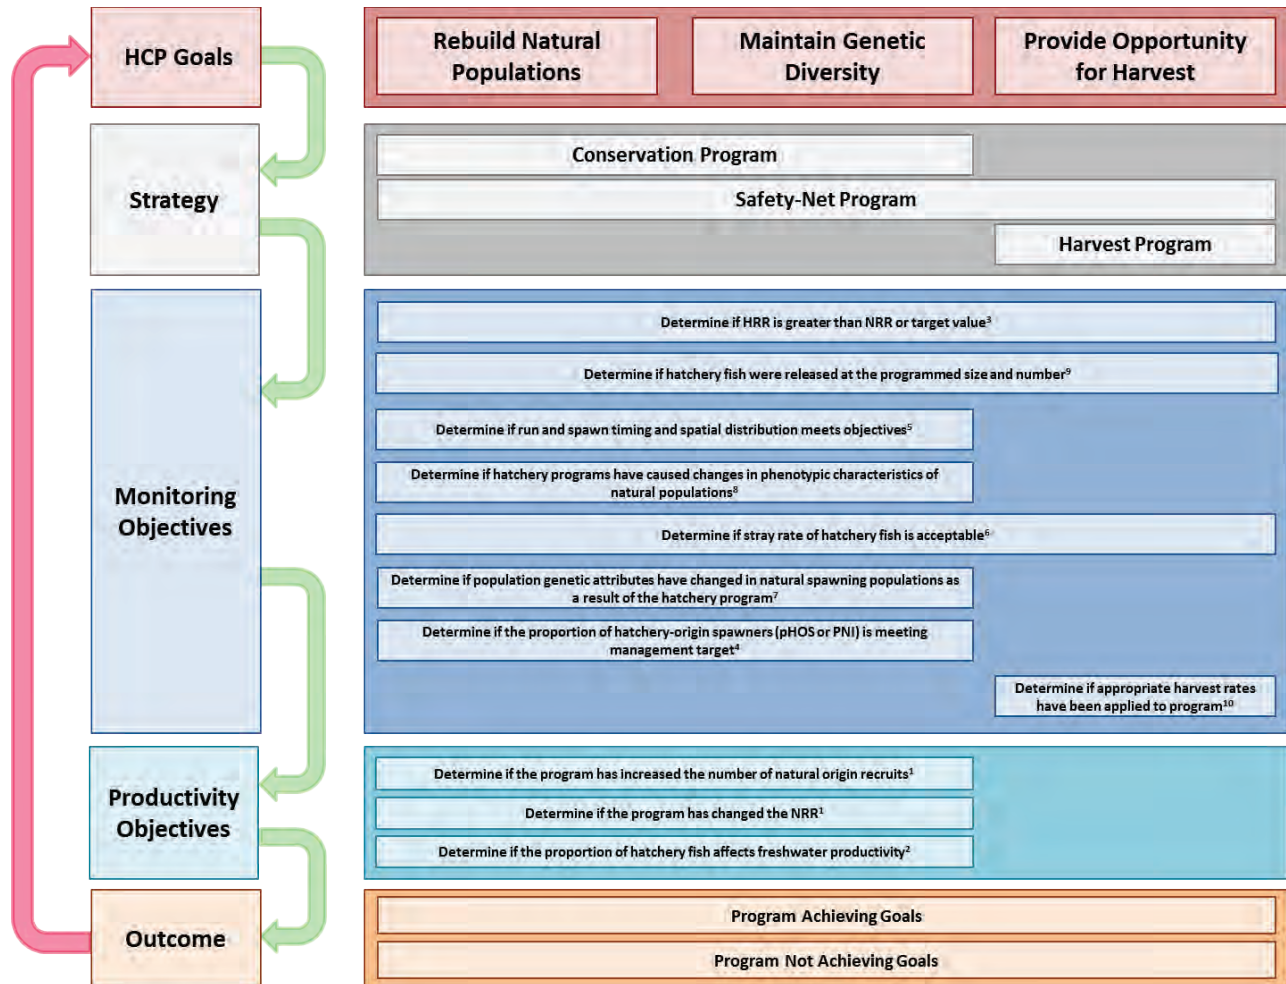

Figure 3. Adaptive management flow chart depicting HCP goals, associated strategies to meet the goals, the monitoring and evaluation objectives (indicated in superscript), and the adaptive management feedback cycle. The strategies, objectives, and outcomes are aligned vertically under the corresponding goals.

**Table 3. Hatchery programs in the mid-Columbia River Basin, 2012. Funding entities included Douglas PUD (D), Chelan PUD (C), Grant PUD (G), Bonneville Power Administration (B), Bureau of Reclamation (O), and Army Corps of Engineers (A) and are listed in order of contribution. Total artificial production targets in the mid-Columbia River exceeds 20 million juveniles annually.**

<sup>1</sup> Species listed under the Endangered Species Act.

<sup>2</sup> Segregated program.

<sup>3</sup> Sub-yearling production.

<sup>4</sup> Fry production.

<sup>5</sup> Program covered by this M&E Plan.

<sup>6</sup> Program also partially covered by CCT M&E Plan.

<sup>7</sup> Program affects PUD-funded programs covered by this plan.

<sup>8</sup> Planned to increase to 1,000,000.

<sup>9</sup> Part of the Mitchell Act suite of mitigation programs under the FCRPS BiOp.

## SECTION 2: ADULT PRODUCTIVITY

### 2.1 Natural Replacement Rates of Supplemented Populations<sup>1</sup>

**Objective 1:** Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.

At the core of a conservation program is the objective of increasing the number of spawning adults (i.e., the combined number of naturally produced and hatchery fish) in order to affect a subsequent increase in the number of returning naturally produced fish or natural-origin recruits (NOR). In order for the natural population to remain stable or to increase, the Natural Replacement Rate (NRR), or the ratio of NORs to the parent spawning population, must be at a level where parents are being replaced by their offspring as spawners in the next generation. It is possible to affect an increase in natural-origin spawners through supplementation with a stable or decreasing NRR. However, if the NRR is below replacement ( $NRR < 1.0$ ), termination of the supplementation program will result in a declining natural population should that state of NRR persist. The proportion of the hatchery-origin spawners (pHOS) that will increase natural production without creating adverse effects to the genetic diversity or reproductive success rate of the natural population is unknown, and may be dependent on how individual hatchery programs are operated, as well as available spawning and rearing habitat. Some programs restrict pHOS to reduce the risk to the natural population with the intent of optimizing productivity, concomitantly reducing the overall number of spawners. All other objectives of the M&E Plan either directly support this objective or seek to minimize negative effects of the conservation programs on non-target stocks of concern.

Differences in carrying capacities of supplemented and non-supplemented streams can confound the analysis of the effects of supplementation on total number of spawners returning to the streams. For example, if the supplemented population is at carrying capacity and the non-supplemented population is not, the total number of spawners returning to the non-supplemented population may show an increasing trend over time, while the supplemented population would show no increasing trend. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on total spawners, density corrections should be included in the analyses. Hypotheses that may require density corrections are noted under each monitoring question. Appendix 1 describes methods for estimating carrying capacities.

#### Monitoring Questions:

**Q1.1.1** Has the supplementation program changed the adult productivity (NRRs) of the supplemented populations?<sup>2</sup>

#### Target Species/Populations:

<sup>1</sup> Supplementation programs may include a safety-net component.

<sup>2</sup> Because adult productivity is affected by the abundance of the population (i.e., productivity decreases with increasing abundance), the goal of supplementation is to increase or maintain productivity, but not decrease it.

- Q1.1.1 applies to all conservation and safety-net stocks.

### **Statistical Hypotheses 1.1.1<sup>3</sup>:**

- Ho<sub>1.1.1.1</sub>: Slope in NRRs before supplementation  $\leq$  slope in NRRs after supplementation.
- Ho<sub>1.1.1.2</sub>: Differences in slopes in NRRs between supplemented and reference populations before supplementation  $\leq$  differences in slopes in NRRs between supplemented and reference populations after supplementation.
- Ho<sub>1.1.1.3</sub>: Mean NRRs before supplementation  $\leq$  mean NRRs after supplementation.
- Ho<sub>1.1.1.4</sub>: Mean ratio scores in NRRs before supplementation  $\leq$  Mean ratio scores in NRRs during supplementation.
- Ho<sub>1.1.1.5</sub>: Mean ratio scores in NRRs (adjusted for density dependence) before supplementation  $\leq$  Mean ratio scores in NRRs (adjusted for density dependence) during supplementation. [This hypothesis adjusts NRRs for density-dependent effects (see Hillman et al. 2012 for details; Appendix 6).]
- Ho<sub>1.1.1.6</sub>: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve;  $\rho = 0$ . [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

### **Measured Variables:**

- Number of hatchery and naturally produced fish on spawning grounds
- Number of naturally produced fish harvested

### **Derived Variables:**

- Number of naturally produced recruits by brood year for both naturally produced parents and hatchery parents ( $\geq$ age-3).
- NRRs (calculated as NORs/spawner).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NRRs (requires reference population[s]).
- Includes calculation of ratios NORs (requires reference population).
- Appendix 1: Spawning escapement and carrying capacity information (as applicable)

### **Spatial/Temporal Scale:**

- Calculated annually based on brood year.
- Time series.

### **Possible Statistical Analysis:**

---

<sup>3</sup> Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 6) for details.

- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 6). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NRRs.
- On a five-year period, correlate productivity with extraneous factors such as ocean productivity indices.

#### **Analytical Rules:**

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

## **2.2 Natural-Origin Recruits of Supplemented Populations**

#### **Monitoring Questions:**

**Q1.2.1:** Has the supplementation program changed the abundance of NORs within the supplemented population?

#### **Target Species/Populations:**

- Q1.2.1 applies to all supplemented or safety net stocks.

#### **Statistical Hypotheses 1.2.1<sup>4</sup>:**

- $H_{01.2.1.1}$ : Slope in NORs<sup>5</sup> before supplementation  $\geq$  slope in NORs after supplementation.
- $H_{01.2.1.2}$ : Differences in slopes in NORs between supplemented and reference populations before supplementation  $\geq$  differences in slopes in NORs between supplemented and reference populations after supplementation.
- $H_{01.2.1.3}$ : Mean NORs before supplementation  $\geq$  mean NORs after supplementation.
- $H_{01.2.1.4}$ : Mean ratio scores in NORs before supplementation  $\geq$  Mean ratio scores in NORs during supplementation.
- $H_{01.2.1.5}$ : Mean ratio scores in NORs/Maximum Recruitment before supplementation  $\geq$  Mean ratio scores in NORs/Maximum Recruitment during supplementation. [This hypothesis adjusts NORs for the capacity of the habitat; it tests the fraction of the habitat saturated with NORs (see Hillman et al. 2012 for details).]
- $H_{01.2.1.6}$ : There is no association between the proportion of hatchery-origin spawners (pHOS) and NORs;  $\rho = 0$ . [If there is a significant negative association between

<sup>4</sup> Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. 2012 (Appendix 7) for details.

<sup>5</sup> “Slope in NORs” refers to abundance of NORs across time (years).

pHOS and NORs, then hatchery fish may be reducing the reproductive success of the wild population.]

**Measured Variables:**

- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish taken for broodstock.
- Number of hatchery and naturally produced fish taken in harvest (if recruitment is to the Columbia).

**Derived Variables:**

- NORs (number of naturally produced recruits (total recruits) by brood year for both naturally produced parents and hatchery parents [ $\geq$ age-3]).
- Stock-recruit models, parameters, and residuals.
- Includes ratio scores of NORs (requires reference population[s]).
- Estimates of carrying capacity (see Appendix 1).

**Spatial/Temporal Scale:**

- Calculate annually based on brood year.
- Time series.

**Possible Statistical Analysis:**

- These analyses shall be performed every 5-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and NORs.
- On a five-year period, correlate NORs with extraneous factors such as ocean productivity indices.

**Analytical Rules:**

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

## SECTION 3: JUVENILE PRODUCTIVITY

### 3.1 Freshwater Juvenile Productivity

**Objective 2: Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.**

Out-of-basin effects (e.g., smolt passage through the hydro system, harvest, and ocean productivity, etc.) influence the survival of smolts after they migrate from the tributaries. These effects introduce substantial variability into the adult-to-adult survival rates (NRRs and HRRs) and may mask in-basin effects (e.g., habitat quality, density-dependent mortality, and differential reproductive success of hatchery and naturally produced fish). Therefore, an estimate of freshwater productivity may help inform the performance of hatchery and natural-origin spawners.

The objective of estimating freshwater productivity in the Upper Columbia ESU/DPS is to estimate the survival from egg to a critical juvenile life stage(s) of target stocks. Smolt or juvenile production models generated from the information obtained through these programs will provide a level of predictability with greater sensitivity to in-basin effects than spawner-recruitment models that consider all effects.

Differences in the current carrying capacities of supplemented and non-supplemented streams can confound the effects of supplementation on numbers of juveniles per redd. For example, if the supplemented population is at or above carrying capacity and the non-supplemented population is not, numbers of juveniles per redd in the non-supplemented population may be significantly greater than the number of juveniles per redd in the supplemented population. In addition, pHOS may be correlated with overall spawner abundance. In these cases, it is difficult or impossible to separate density-dependent effects from the influence of pHOS on freshwater productivity. To avoid concluding that the supplementation program has no effect or perhaps a negative effect on juveniles per redd, the capacity of the habitats must be included in the analyses. The Supplementary Hypotheses presented below are designed to address the confounding effects of different densities on the analyses.

**Monitoring Questions:**

- Q2.1.1:** Has the supplementation program changed the number of juveniles (smolts, parr, and/or emigrants) per redd within the supplemented population?
- Q2.2.1:** Does the number of juveniles per redd decrease as the proportion of hatchery spawners increases?<sup>6</sup>

**Target Species/Populations:**

- Both Q2.1.1 and Q2.2.1 apply to all conservation stocks.

**Statistical Hypotheses for 2.1.1<sup>7</sup>:**

<sup>6</sup> Information is needed to estimate the effects of density dependence on these questions. Consider spatial distribution of redds.

<sup>7</sup> Quality and quantity of data will determine which hypotheses are evaluated. See Hillman et al. (2012) for details.

- Ho<sub>2.1.1.1</sub>: Slope in juveniles/redd before supplementation  $\leq$  slope in juveniles/redd after supplementation.
- Ho<sub>2.1.1.2</sub>: Differences in slopes in juveniles/redd between supplemented and reference populations before supplementation  $\leq$  differences in slopes in juveniles/redd between supplemented and reference populations after supplementation.
- Ho<sub>2.1.1.3</sub>: Mean juveniles/redd before supplementation  $\leq$  mean juveniles/redd after supplementation.
- Ho<sub>2.1.1.4</sub>: Mean ratio scores in juveniles/redd before supplementation  $\leq$  Mean ratio scores in juveniles/redd during supplementation.
- Ho<sub>2.1.1.5</sub>: Mean ratio scores in juveniles/redd (adjusted for density dependence) before supplementation  $\leq$  Mean ratio scores in juveniles/redd (adjusted for density dependence) during supplementation. [This hypothesis adjusts juveniles/redd for density-dependent effects (see Hillman et al. 2012 for details; Appendix 6).]
- Ho<sub>2.1.1.6</sub>: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve;  $\rho = 0$ . [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]

#### Statistical Hypotheses for 2.2.1:

- Ho<sub>2.2.1.1</sub>: There is no association between the proportion of hatchery-origin spawners (pHOS) and the residuals from the smooth hockey stick stock-recruitment curve;  $\rho = 0$ . [If there is a significant negative association between pHOS and the residuals, then hatchery fish may be reducing the productivity of the wild population.]
- Ho<sub>2.2.1.2</sub>: The slope between proportion of hatchery spawners and juveniles/redd is  $\geq 0$ .

#### Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Numbers of redds.
- Number of juveniles (smolts, parr [where appropriate], and emigrants).

#### Derived Variables:

- Number of juveniles per spawner.
- Number of juveniles per redd.
- Carrying capacity (see Appendix 1).

#### Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

#### Possible Statistical Analysis:

- These analyses shall be performed every five-years. Use graphic analyses, trend analyses, t-tests, Aspin-Welch tests, and randomization tests to evaluate the statistical hypotheses (see Hillman et al. 2012; Appendix 6). The specific analysis used will depend on the availability of reference conditions.
- Correlation analysis will examine associations between hatchery adult composition and juveniles/redd.

**Analytical Rules:**

- This is a productivity indicator that will be used to assess the success of the supplementation program.
- Type I Error of 0.05.

## SECTION 4: NATURAL ENVIRONMENT MONITORING INDICATORS

### 4.1 Hatchery Replacement Rates (HRRs)

**Objective 3:** Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.

The survival advantage from the hatchery (i.e., egg-to-smolt) must be sufficient to produce a greater number of returning adults than if broodstock were left to spawn naturally. If a hatchery program cannot produce a greater number of adults than naturally spawning fish, then the program should be modified or discontinued. Production levels were initially developed using historical run sizes and smolt-to-adult survival rates (BAMP 1998). Using the stock specific NRR and agreed upon target values (see Appendix 2), comparisons to actual survival rates will be made to ensure the expected level of survival has been achieved.

#### Monitoring Questions:

**Q3.2.1:** Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the adult-to-adult survival rate (NRR) of naturally produced fish?

**Q3.2.2:** Is the adult-to-adult survival rate of hatchery fish (HRR) greater than or equal to the Target Value identified in Appendix 2<sup>8</sup>?

#### Target Species/Populations:

- Q3.2.1 applies to all conservation stocks.
- Q3.2.2 applies to all stocks.

#### Statistical Hypothesis 3.2.1:

- $H_{03.2.1.1}: HRR_{Year\ x} \geq NRR_{Year\ x}$

#### Statistical Hypothesis 3.2.2:

- $H_{03.2.2.1}: HRR \geq \text{Target Value identified in Appendix 2}$

#### Measured Variables:

- Number of hatchery and naturally produced fish on spawning grounds.
- Number of hatchery and naturally produced fish harvested.
- Number of hatchery and naturally produced fish collected for broodstock.
- Number of broodstock used by brood year (hatchery and naturally produced fish).

#### Derived Variables:

- Number of hatchery and naturally produced adults by brood year ( $\geq$ age-3).

---

<sup>8</sup> Target values may be adjusted by the hatchery committees.

- HRR (number of returning adults per brood year/broodstock)
- NRR (from Objective 1)
- Appendix 2: HRR targets identified in Appendix 2

**Spatial/Temporal Scale:**

- Calculate annually based on brood year.
- Time series.

**Possible Statistical Analysis:**

- For Q3.2.1 use graphic analysis and paired-sample quantile tests to compare HRR to NRR
- For Q3.2.2 use graphic analysis and one-sample quantile tests to compare HRR to the target value.
- On a five-year period, correlate HRRs with extraneous factors such as ocean productivity indices.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

## 4.2 Proportion of Hatchery-Origin Spawners (pHOS or PNI)

**Objective 4: Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.**

Certain hatchery programs have pHOS or PNI targets, while other do not. HGMPs and permits inform the selection of targets, which are identified in Appendix 3.

**Monitoring Questions:**

**Q4.1.1:** Is the estimated proportion of hatchery-origin spawners (pHOS) less than or equal to the management target, and/or, is the estimated Percent Natural Influence (PNI) greater than or equal to the management target identified in Appendix 3?

**Target Species/Populations:**

- Q4.1.1 applies to all conservation and safety-net stocks that have a defined pHOS or PNI target or sliding scale (see Appendix 3).

**Statistical Hypothesis 4.1.1:**

- $H_{04.1.1.1}$ :  $pHOS > \text{target value}$  or  $PNI_{\text{Supplemented population}} < \text{target value}$  identified in Appendix 3

**Measured Variables:**

- Number of hatchery and naturally produced fish on spawning grounds

**Derived Variables:**

- pHOS or PNI
- Appendix 3: PNI and pHOS targets and sliding scales identified in Appendix 3

**Spatial/Temporal Scale:**

- Calculate annually.
- Analyzed as time series.

**Possible Statistical Analysis:**

- Use graphic analysis and summary statistics to compare pHOS or PNI to the target value in Appendix 3.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.

### 4.3 Run Timing, Spawn Timing, and Spawning Distribution

**Objective 5:** Determine if the run timing, spawn timing, and spawning distribution of the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.

Strategies for conservation programs typically intend that hatchery and natural-origin fish spawn together and in similar locations. However, in some cases, strategies may differ from this paradigm (e.g., summer Chinook salmon in the Wenatchee and Methow rivers; see Appendix 4). Phenotypic plasticity or selection resulting from the hatchery environment (i.e., domestication) may affect run (migration) timing, spawn timing, and spawning distribution. If conservation programs do not adequately represent the genetic diversity of the natural population, and if phenotypic traits in supplementation fish related to fitness deviate from the naturally produced spawning population, the goals of supplementation may not be achieved. Hatchery adults that migrate and/or spawn at different times or are spatially segregated from natural-origin fish may be subject to reduced fitness. Hatchery adults that spawn at different times or locations than natural-origin fish would be reproductively isolated from the natural population. The extent of such isolation, ranging from no isolation to substantial isolation, may be exploited for management purposes in some cases.

#### Migration Timing

**Monitoring Questions:**

- Q5.1.1:** Is the migration timing of hatchery and natural-origin fish from the same age class similar?

**Target Species/Populations:**

- Q5.1.1 applies to all conservation stocks.

**Statistical Hypotheses 5.1.1:**

- $H_{05.1.1.1}$ : Migration timing<sub>Hatchery Age X</sub> = Migration timing<sub>Naturally produced Age X</sub>

- Ho<sub>5.1.1.2</sub>: The cumulative frequency of migration timing of hatchery-origin fish = the cumulative frequency of migration timing of natural-origin fish.
- Ho<sub>5.1.1.3</sub>: The 10<sup>th</sup> percentile, 50<sup>th</sup> percentile (mode), 90<sup>th</sup> percentile, and mean migration timing of hatchery-origin fish = the 10<sup>th</sup> percentile, 50<sup>th</sup> percentile (median), 90<sup>th</sup> percentile, and mean migration timing of natural-origin fish.

**Measured Variables:**

- Ages of hatchery and natural-origin fish sampled via PIT tags or stock assessment monitoring.
- Time (Julian date) of arrival at mainstem projects and within tributaries (e.g., traps, PIT arrays) with the intent to identify biologically significant differences.

**Derived Variables:**

- Mean Julian date for a given age class.

**Spatial/Temporal Scale:**

- Calculate annually based on return year and age class.
- Time series.

**Possible Statistical Analysis:**

- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

**Spawn Timing**

**Monitoring Questions:**

**Q5.2.1:** Is the timing of spawning similar for conservation hatchery and natural-origin fish?

**Target Species/Populations:**

- Q5.2.1: Applies to all semelparous species and populations supplemented by conservation programs. Steelhead can only be assessed for natural spawning in situations where hatchery and natural-origin fish can be appropriately marked and detected.

**Statistical Hypotheses 5.2.1:**

- Ho<sub>5.2.1.1</sub>: The cumulative frequency of spawn timing of hatchery-origin fish = the cumulative frequency of spawn timing of natural-origin fish.
- Ho<sub>5.2.1.2</sub>: The 10<sup>th</sup> percentile, 50<sup>th</sup> percentile (mode), 90<sup>th</sup> percentile, and mean spawn timing of hatchery-origin fish = the 10<sup>th</sup> percentile, 50<sup>th</sup> percentile (mode), 90<sup>th</sup> percentile, and mean spawn timing of natural-origin fish.

- $H_{05.2.1.3}$ : The relationship between elevation and spawn timing of hatchery-origin fish = the relationship between elevation and spawn timing of natural-origin fish.

#### Measured Variables:

- Time (Julian date) and elevation (m) of hatchery and natural-origin salmon carcasses or marked steelhead detected on spawning grounds within defined reaches.
- Time (Julian date) of ripeness of hatchery and natural-origin steelhead captured for broodstock.

#### Derived Variables:

- Mean Julian date.

#### Spatial/Temporal Scale:

- Calculate annually based on return year.
- Time series.

#### Possible Statistical Analysis:

- Use graphic analyses (cumulative frequency polygons), paired t-tests, Aspin-Welch tests, and randomization tests.
- Use graphic analyses, ANCOVA, and/or regression analysis to assess relationships between elevation and spawn timing.

#### Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

### Spatial Distribution of Redds

#### Monitoring Questions:

**Q5.3.1:** Is the distribution of redds similar for conservation hatchery and natural-origin fish?

**Q5.3.2:** Is the distribution of redds similar to defined management targets (see Appendix 4)?

#### Target Species/Populations:

- Q5.3.1 applies to all conservation program stocks.
- Q5.3.2 applies only to conservation program stocks with specific spawning distribution targets (Carlton and Dryden summer Chinook programs; Appendix 4).

#### Statistical Hypothesis 5.3.1:

- $H_{05.3.1.1}$ : The distribution of hatchery-origin redds (hatchery females) = the distribution of natural-origin redds (natural-origin females).

#### Statistical Hypothesis 5.3.2:

- Ho<sub>5.3.2.1</sub>: The distribution of hatchery-origin redds (hatchery females) = the target distribution identified in Appendix 4.

#### **Measured Variables:**

- Location (GPS coordinate) of female salmon carcasses observed on spawning grounds. The distribution of hatchery and naturally produced steelhead redds may be evaluated if marking or tagging efforts provide reasonable results.

#### **Derived Variables:**

- Location of female salmon carcass at the historic reach scale and at the 0.1 km scale.
- Calculate percent overlap in distribution across available spawning habitat or historical reaches.
- Appendix 4: Management targets for spatial distribution of spawners or redds (as applicable).

#### **Spatial/Temporal Scale:**

- Calculate annually based on return year.
- Time series.

#### **Possible Statistical Analysis:**

- Use graphic analysis and Yates' Chi-square analysis for both Q5.3.1 and Q5.3.2.

#### **Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

## **4.4 Stray Rates**

### **Objective 6: Determine if the recipient stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.**

Maintaining locally adapted traits among independent fish populations requires that returning hatchery fish have a high rate of site fidelity to the target population or stream. Hatchery practices (e.g., imprinting on water sources at key life history stages, release methodology, release location, age at return, broodstock used, spawner density, spawning habitat quality and access, and environmental conditions) are the main variables thought to affect stray rates. Regardless of the magnitude of homing of adult returns, if adult hatchery fish do not contribute to the natural population, the program will not meet the basic condition of a supplementation program.

Independent populations are populations that are genetically differentiated from other populations. In some cases, genetic differentiation may be assumed based on phenotypic traits or geographic isolation when molecular genetics analyses are not available. When populations are not independent, straying among them does not pose a risk of genetic homogenization. In addition, stray rates of hatchery-origin fish cannot be expected to be lower than for natural-origin fish. When estimates of stray rates for natural-origin fish are available and if they exceed the 5% among population stray rate or 10% within population stray rate thresholds identified in this plan, analysis

and interpretation of stray rates must take into account the concept that hatchery programs may be held to unattainable standards based on the natural stray rate. Current criteria established by the ICBTRT (2005) and the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) indicate that fish that do stray to other non-target populations should not comprise greater than 5% of the non-target spawning population. Likewise, fish that stray into non-target spawning areas within an independent population should not comprise greater than 10% of the non-target spawning aggregate (see Tables 6.1 and 6.2).

This plan identifies three stray rate metrics; brood-year stray rate, among population return-year stray rate, and within population return-year stray rate. The return-year stray rates have specific targets that are from the ICBTRT (2005) and Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007), and are linked to extinction risk. That is, hatchery strays from other populations cannot make up more than 5% of the spawning escapement within a non-target, recipient population. In addition, hatchery strays from other spawning aggregations within a population (e.g., Chiwawa spring Chinook) cannot make up more than 10% of the spawning escapement within a non-target, recipient spawning aggregate (e.g., White River). Brood-year stray rate, on the other hand, is not discussed in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007) or ICBTRT (2005) and therefore has no specific target. Nevertheless, it is important to track brood-year stray rates to determine if hatchery operations affect the homing and straying of specific brood years. These data support the return-year stray metrics and are used to inform possible changes in genetic variation among stocks.

### Brood-Year Stray Rates

#### Monitoring Questions:

**Q6.1.1:** What is the brood-year stray rate of hatchery fish?

#### Target Species/Populations:

- Q6.1.1 applies to all hatchery stocks.

#### Statistical Hypothesis 6.1.1:

- $H_{06.1.1.1}$ : None.

#### Measured Variables:

- Number of hatchery carcasses found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.
- Number of hatchery fish collected for broodstock.
- Number of hatchery fish taken in fishery.
- Locations of live and dead strays (used to tease out overshoot).

#### Derived Variables:

- Total number of hatchery carcasses and take in fishery estimated from expansion analysis.
- Percent of the total brood return that strays.

**Spatial/Temporal Scale:**

- Calculate annually based on brood year.
- Time series.

**Possible Statistical Analysis:**

- Use graphical analysis to track brood-year stray rates over time.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.

**Among-Population Return-Year Stray Rates****Monitoring Questions:**

**Q6.2.1:** Do hatchery strays make up less than 5% of the spawning escapement within their non-target independent populations?

**Target Species/Populations:**

- Q6.2.1 applies to all hatchery stocks.

**Statistical Hypothesis 6.2.1:**

- $H_{06.2.1.1}$ : Stray hatchery fish make up  $\geq 5\%$  of the spawning escapement (based on run year) within other independent populations<sup>9</sup>

**Measured Variables:**

- Number of hatchery carcasses (PIT-tagged steelhead) found in non-target and target spawning areas or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

**Derived Variables:**

- Total number of hatchery salmon carcasses (PIT-tagged steelhead, spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target population that is made up of hatchery strays.

**Spatial/Temporal Scale:**

- Calculate annually based on return year.
- Time series.

**Possible Statistical Analysis:**

---

<sup>9</sup> This stray rate is suggested based on a literature review and recommendations by the ICBTRT (2005) and is identified in the Upper Columbia Spring Chinook Salmon and Steelhead Recovery Plan (2007). It can be re-evaluated as more information on naturally-produced Upper Columbia salmonids becomes available. This will be evaluated on a species and program specific basis and decisions made by the HCP HC and PRCC HSC. It is important to understand the actual spawner composition of the population to determine the potential effect of straying.

- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (5%) stray rate.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

**Within-Population Return-Year Stray Rates**

**Monitoring Questions:**

- Q6.3.1:** Do hatchery strays make up less than 10% of the spawning aggregate within non-target spawning areas within the target population?

**Target Species/Populations:**

- Q6.3.1 applies to all hatchery stocks.

**Statistical Hypothesis 6.3.1:**

- $H_{06.3.1}$ : Stray hatchery fish make up  $\geq 10\%$  of spawning escapement (based on run year) within non-target spawning areas within the target population

**Measured Variables:**

- Number of hatchery carcasses (possibly PIT-tagged steelhead) found in non-target and target spawning aggregates or number of returning spawners counted via PIT-tag detection or at weirs in close temporal proximity to spawning areas.

**Derived Variables:**

- Total number of hatchery salmon carcasses (possibly PIT-tagged steelhead or spawners counted at weirs) estimated from expansion analysis.
- Percent of the non-target spawning aggregate that is made up of hatchery strays.

**Spatial/Temporal Scale:**

- Calculate annually based on return year.
- Time series.

**Possible Statistical Analysis:**

- Use graphical analysis and one-sample quantile tests to compare the estimated stray rate with the target (10%) stray rate.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

## 4.5 Population Genetics

**Objective 7:** Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.

The genetic component of the M&E Plan specifically addresses the potential for changes in genetic diversity in natural populations as a result of a hatchery program(s). The long-term fitness of populations is assumed to be related to maintaining the genetic diversity of natural populations. However, hatchery programs select a subset of individuals from the population to pass on genetic material to the next generation. This is often a relatively small number of individuals that produce a large number of offspring, and can result in changes in allele frequencies and reductions of effective population size. Therefore, it is important to monitor the genetic status of the natural populations to determine if there are signs of changes in genetic distance among populations, changes in allele frequencies, and to estimate effective population size. Assessing the genetic effects of the hatchery program does not require annual sampling, but does require regular sampling at generational scales. Meeting stray-rate targets (hypotheses tested under Objective 5) should reduce significant changes in population genetics. Stray rates may inform population genetic analyses. Testing statistical hypotheses associated with genetic components (Hypotheses 3.1, 3.2, and 3.3) should be conducted every ten years or two generations.

### Allele Frequency

#### Monitoring Questions:

**Q7.1.1:** Is the allele frequency of hatchery fish similar to the allele frequency of naturally produced and donor (broodstock) fish?

#### Target Species/Populations:

- Q7.1.1 applies to all conservation stocks.

#### Statistical Hypotheses 7.1.1:

- $H_{07.1.1.1}$ : Allele frequency<sub>Hatchery</sub> = Allele frequency<sub>Naturally produced</sub> = Allele frequency<sub>Donor pop.</sub>
- $H_{a7.1.1.1}$ : Allele frequency<sub>Hatchery</sub>  $\neq$  Allele frequency<sub>Naturally produced</sub> = Allele frequency<sub>Donor pop.</sub> **OR**
- $H_{a7.1.1.1}$ : Allele frequency<sub>Hatchery</sub> = Allele frequency<sub>Naturally produced</sub>  $\neq$  Allele frequency<sub>Donor pop.</sub> **OR**
- $H_{a7.1.1.1}$ : Allele frequency<sub>Hatchery</sub>  $\neq$  Allele frequency<sub>Naturally produced</sub>  $\neq$  Allele frequency<sub>Donor pop.</sub>

#### Measured Variables:

- SNP genotypes

#### Derived Variables:

- Allele frequency

#### Spatial/Temporal Scale:

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples within drainages.

**Possible Statistical Analysis:**

- Population differentiation tests, analysis of molecular variance (AMOVA), and relative genetic distances.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

**Genetic Distance Between Populations**

**Monitoring Questions:**

**Q7.2.1:** Does the genetic distance among subpopulations within a supplemented population remain the same over time?

**Target Species/Populations:**

- Q7.2.1 applies to all conservation and safety-net stocks.

**Statistical Hypothesis 7.2.1:**

- $H_{07.2.1.1}$ : Genetic distance between subpopulations  $_{Year\ x}$  = Genetic distance between subpopulations  $_{Year\ y}$

**Measured Variables:**

- SNP genotypes

**Derived Variables:**

- Allele frequencies

**Spatial/Temporal Scale:**

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.
- Compare samples among spawning aggregates.

**Possible Statistical Analysis:**

- Population differentiation tests, AMOVA, and relative genetic distances.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

**Effective Spawning Population**

**Monitoring Questions:**

**Q7.3.1:** Is the ratio of effective population size ( $N_e$ ) to spawning population size ( $N$ ) constant over time?

**Target Species/Populations:**

- Q7.3.1 applies to all supplemented stocks.

**Statistical Hypothesis 3.3:**

- $H_{07.3.1.1}$ :  $(N_e/N)_{t0} = (N_e/N)_{t1}$  for each population

**Measured Variables:**

- SNP genotypes

**Derived Variables:**

- Allele frequencies

**Spatial/Temporal Scale:**

- Analyze as a time series, initially comparing pre- and post-hatchery samples and thereafter every 10 years.

**Possible Statistical Analysis:**

- Population differentiation tests, relative genetic distances, statistics to calculate effective population size (e.g., harmonic means).

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

## 4.6 Phenotypic Traits

**Objective 8: Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.**

Fitness, or the ability of individuals to survive and pass on their genes to the next generation in a given environment, includes genetic, physiological, and behavioral components.<sup>10</sup> Maintaining the long-term fitness of supplemented populations requires a comprehensive evaluation of genetic and phenotypic characteristics. Evaluation of some phenotypic traits (i.e., run timing, spawn timing, spawning location, and stray rates) is addressed under Objective 5. Objective 8 assess the potential effects of domestication, including size at maturity, age at maturity, sex ratio, and fecundity. Age and size at maturity shall be assessed for both fish arriving in the Columbia system, and those recovered on the spawning grounds. Size (or age) selective mortality during migration through the Columbia system, such as through fisheries, could alter the age and size of fish on the spawning grounds.

---

<sup>10</sup> These metrics are difficult to measure, and phenotypic expression of these traits may be all we can measure and evaluate.

## Age at Maturity

### Monitoring Questions:

**Q8.1.1:** Is the age at maturity of hatchery and natural-origin fish similar at the time they enter the Columbia River and when they spawn?

### Target Species/Populations:

- Q8.1.1 applies to all conservation program stocks.

### Statistical Hypotheses 8.1.1:

- $H_{08.1.1.1}$ : Age at Maturity Hatchery produced spawners Gender X = Age at Maturity Naturally produced spawners Gender X
- $H_{08.1.1.2}$ : Age at Maturity All hatchery produced adults Gender X = Age at Maturity All naturally produced adults Gender X

### Measured Variables:

- Total and salt (ocean) age of hatchery and natural-origin salmon carcasses collected on spawning grounds.
- Total and salt age of broodstock.
- Total and salt age of fish at stock assessment locations (e.g., Dryden, Tumwater, Wells, Priest Rapids).
- Whenever possible, age at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).
- Assess age of fish, including harvested fish.

### Derived Variables:

- Total age and saltwater age
- Age of fish entering the Columbia River.

### Spatial/Temporal Scale:

- Calculate annually based on brood year.
- Time series.

### Possible Statistical Analysis:

- Use graphic analysis and Yates' Chi-square.

### Analytical Rules:

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

## Size at Maturity

### Monitoring Questions:

**Q8.2.1:** Is the size (length) at maturity of a given age and sex of hatchery fish similar to the size at maturity of a given age and sex of natural-origin fish?

**Target Species/Populations:**

- Q8.2.1 applies to all conservation and safety-net stocks.

**Statistical Hypothesis 8.2.1:**

- $H_{08.2.1.1}$ : Size (length) at Maturity Hatchery Age X and Gender Y = Size (length) at Maturity Naturally produced Age X and Gender Y
- $H_{08.2.1.2}$ : Size (length) at Maturity All hatchery adults Gender X = Size (length) at Maturity All naturally produced adults Gender X

**Measured Variables:**

- Size (length), age, and gender of hatchery and natural-origin salmon carcasses collected on spawning grounds.
- Size (length), age, and gender of broodstock.
- Size (length), age, and gender of fish at stock assessment locations (e.g., Priest Rapids, Dryden, Tumwater, Wells, Twisp Weir).
- Whenever possible, size at maturity will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling).

**Derived Variables:**

- Total age and saltwater age

**Spatial/Temporal Scale:**

- Calculate annually based on brood year.
- Time series.

**Possible Statistical Analysis:**

- Use graphic analysis and three-way ANOVA by origin, gender, and age

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

**Fecundity at Size<sup>11</sup>**

**Monitoring Questions:**

**Q8.3.1:** Is the fecundity vs. size relationship of hatchery and natural-origin fish similar?

---

<sup>11</sup> May not apply to all programs.

**Q8.3.2:** Is the gonadal mass vs. size relationship of hatchery and natural-origin fish similar?

**Target Species/Populations:**

- Both Q8.3.1 and Q8.3.2 apply to all conservation stocks using both natural- and hatchery-origin broodstock.

**Statistical Hypothesis 8.3.1:**

- $H_{08.3.1.1}$ : Slope of Fecundity vs. Size<sub>Hatchery</sub> = Slope of Fecundity vs. Size<sub>Naturally produced</sub>

**Statistical Hypothesis 8.3.2:**

- $H_{08.3.2.1}$ : Gonadal Mass vs. Size<sub>Hatchery</sub> = Gonadal Mass vs. Size<sub>Naturally produced</sub>

**Measured Variables:**

- Length, weight, and age (covariate) of hatchery and natural-origin broodstock after eggs have been removed.
- Number and weight of eggs

**Derived Variables:**

- Total age and saltwater age.
- Mean weight per egg.

**Spatial/Temporal Scale:**

- Calculate annually based on brood year.
- Time series.

**Possible Statistical Analysis:**

- Use graphic analysis, regression, t-test, and ANCOVA.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

**Sex Ratio**

**Monitoring Questions:**

**Q8.4.1:** Is the sex ratio of hatchery and natural-origin fish similar?

**Target Species/Populations:**

- Q8.4.1 applies to all conservation stocks.

**Statistical Hypothesis 8.4.1:**

- $H_{08.4.1.1}$ : Sex Ratio<sub>Hatchery</sub> = Sex Ratio<sub>Naturally produced</sub>

**Measured Variables:**

- Age and sex of hatchery and natural-origin salmon carcasses collected on spawning grounds or sampled at dams or weirs.
- Whenever possible sex ratio will be measured at weirs or dams near the spawning stream to avoid the size-related carcass recovery bias on spawning grounds (carcass sampling or ultrasound on live fish).

**Derived Variables:**

- Ratio of sexes based on brood year returns

**Spatial/Temporal Scale:**

- Calculate annually based on brood year.
- Time series.

**Possible Statistical Analysis:**

- Use graphic analysis and Yates'Chi-square.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

## SECTION 5: HATCHERY ENVIRONMENT MONITORING INDICATORS

### 5.1 Release Targets

**Objective 9: Determine if hatchery fish were released at the programmed size and number.**

The HCP outlines the number and size of fish that are to be released to meet NNI and inundation compensation levels. The size of the fish at release may be altered according to an adaptive management process in the Hatchery Committee(s), and the number of fish can be altered by survival study results and adjustment of hatchery production for population dynamics. Size of fish at release can affect survival, sex ratios, age at return, stray rate, and fecundity. In addition, the variation in size at release may affect performance of the fish.

The coefficient of variation (CV) will be evaluated to ascertain if program performance is related to variation in size at release. Note also that variation in a population is a natural condition and striving to control this variation could result in directional or stabilizing artificial selection that could have unforeseen long-term consequences. Attaining uniform or multi-modal growth in a hatchery environment may not be adaptive for fitness in the wild. Therefore, pursuit of a CV target should be seen as an informative exercise, but is not in itself indicative of success or failure of a hatchery program. Furthermore, growth regimes may prove to be important in affecting adult returns and age structure. Although many factors can influence both the size and number of fish released, past hatchery cultural experience with these stocks should assist in meeting program production levels. Appendix 5 presents the target size at release and CVs for the programs. These targets shall be assessed annually to ensure they are optimized to inform management decisions.

#### Size at Release of Hatchery Fish

**Monitoring Questions:**

**Q9.1.1:** Is the size (fish per pound; fpp) of hatchery fish released equal to the program goal identified in Appendix 5?

**Target Species/Populations:**

- Q9.1.1 applies to all hatchery stocks.

**Statistical Hypothesis 9.1.1:**

- $H_{09.1.1.1}$ : Hatchery fish  $fpp_{at\ release} = Programmed\ fpp_{at\ release}$  (see Appendix 5)

**Measured Variables:**

- Fork length and weights of random samples of hatchery juveniles at release.

**Derived Variables:**

- Mean length (FL), mean weight, and fish per pound
- Appendix 5: Rearing targets

**Spatial/Temporal Scale:**

- Calculate annually.
- Time series.

**Possible Statistical Analysis:**

- Use graphic analysis and descriptive statistics to compare the estimated fpp of hatchery fish at time of release with the program goal.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.

**Coefficient of Variation (CV) of Hatchery Fish Released****Monitoring Questions:**

- Q9.2.1:** Is the CV of hatchery fish released equal to the program target identified in Appendix 5?

**Target Species/Populations:**

- Q9.2.1 applies to all hatchery stocks.

**Statistical Hypothesis 9.2.1:**

- $H_{09.2.1.1}$ : Hatchery fish CV<sub>at release</sub> = Programmed CV in Appendix 5

**Measured Variables:**

- Length and weights of random samples of hatchery smolts.

**Derived Variables:**

- Coefficient of Variation:  $cv = (1 + 1/4n) \times (s/x)$  (where s = standard deviation, x = estimated mean, n = sample size)
- Appendix 5: Rearing targets

**Spatial/Temporal Scale:**

- Calculate annually.
- Time series.

**Possible Statistical Analysis:**

- Use graphic analysis and descriptive statistics to compare the estimated CV of size of hatchery fish released with the program goal.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.

**Condition Factor (K) of Hatchery Fish Released****Monitoring Questions:**

**Q9.3.1:** Is the K of hatchery fish released equal to the program target identified in Appendix 5?

**Target Species/Populations:**

- Q9.3.1 applies to all hatchery stocks.

**Statistical Hypothesis 9.3.1:**

- $H_{09.3.1.1}$ : Hatchery fish  $K_{\text{at release}} = \text{Programmed K identified in Appendix 5}$

**Measured Variables:**

- Monthly individual lengths and weights of random samples of hatchery juveniles.

**Derived Variables:**

- Condition Factor:  $K = W/L^3 \times 10^5$

**Spatial/Temporal Scale:**

- Calculate annually.
- Time series.

**Possible Statistical Analysis:**

- Use graphic analysis and descriptive statistics to compare the estimated K of released hatchery fish with the program goal.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

**Number of Hatchery Fish Released**

**Monitoring Questions:**

**Q9.4.1:** Is the number of hatchery fish released equal to the program goal identified in Appendix 5?

**Target Species/Populations:**

- Q9.4.1 applies to all hatchery stocks.

**Statistical Hypothesis 9.4.1:**

- $H_{09.4.1.1}$ : Hatchery Fish Number = Programmed Number identified in Appendix 5

**Measured Variables:**

- Numbers of smolts released from the hatchery.

**Derived Variables:**

- Appendix 5: Rearing targets

**Spatial/Temporal Scale:**

- Calculate annually.

- Time series.

**Possible Statistical Analysis:**

- Use graphic analysis and one-sample quantile tests to compare the estimated number of hatchery fish released with the program goal.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

## SECTION 6: HARVEST MONITORING INDICATORS

### 6.1 Harvest Rates

**Objective 10:** Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations.

Harvest will be applied to different types of programs in an effort to achieve the management objectives of those programs. Programs designed to augment harvest should routinely contribute to harvest at a rate that greatly reduces the incidence of straying to natural spawning grounds, but also allows the program to be sustained. Safety-net programs may be harvested as part of an adult management strategy to minimize excessive escapement of hatchery-origin fish to spawning grounds. Similarly, conservation programs may undergo harvest to manage returning adults, but the emphasis for these programs should be to achieve escapement goals. In all cases, harvest effort should not have the unintended consequence of removing excessive numbers of conservation or natural-origin fish. In years when the expected returns of hatchery adults are above the level required to meet program goals (i.e., supplementation of spawning populations and/or brood stock requirements), surplus fish may be available for harvest. The M&E Plan specifically addresses harvest and harvest opportunities upstream of Priest Rapids Dam. Harvest or removal of surplus hatchery fish from the spawning grounds may assist in reducing potential adverse ecological and genetic impacts to natural populations (e.g., loss of genetic variation within and between populations, loss of fitness, reduced effective population size, and density-dependent effects).

#### Monitoring Questions:

- Q10.1.1:** Conservation Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of conservation hatchery fish but low enough to sustain the hatchery program?
- Q10.1.2:** Safety-Net Programs: Is the harvest on conservation hatchery fish at an appropriate level to manage natural spawning of safety-net hatchery fish but low enough to sustain the hatchery program?
- Q10.1.3:** Is the harvest on hatchery fish produced from harvest-augmentation programs high enough to manage natural spawning but low enough to sustain the hatchery program?
- Q10.1.4:** Is the escapement of fish from conservation and safety-net programs in excess of broodstock and natural production<sup>12</sup> needs to provide opportunities for terminal harvest?

#### Target Species/Populations:

- Q10.1.1 applies to conservation programs.
- Q10.1.2 applies to safety-net programs.

<sup>12</sup> The current best estimates of carrying capacity (maximum recruits) will be used, as available.

- Q10.1.3 applies harvest augmentation programs.
- Q10.1.4 applies to conservation and safety-net programs.

**Statistical Hypothesis 10.1.1:**

- $H_{010.1.1.1}$ : Harvest rate  $\leq$  Maximum level to meet program goals

**Statistical Hypothesis 10.1.2:**

- $H_{010.1.2.1}$ : Harvest rate  $\leq$  Maximum level to meet program goals

**Statistical Hypothesis 10.1.3:**

- $H_{010.1.3.1}$ : Escapement  $\leq$  Maximum level to meet supplementation goals

**Statistical Hypothesis 10.1.4:**

- $H_{010.1.4.1}$ : Harvest rate  $\leq$  Maximum level to meet program goals

**Measured Variables:**

- Numbers of hatchery fish taken in harvest.
- Numbers of natural-origin fish taken in harvest.

**Derived Variables:**

- Total harvest by fishery estimated from expansion analysis.

**Spatial/Temporal Scale:**

- Calculated annually.
- Time series.

**Possible Statistical Analysis:**

- Use graphic analysis and one-sample quantile tests to compare the estimated harvest of hatchery fish with the program goal.

**Analytical Rules:**

- This is a monitoring indicator that will be used to support management decisions.
- Type I Error of 0.05.

## SECTION 7: REGIONAL OBJECTIVES

Hatchery programs have the potential to increase diseases that typically occur at low levels in the natural environment (Objective 9). In addition, hatchery fish can reduce the abundance, size, or distribution of non-target taxa through ecological interactions (Objective 10). In this section, we address incidence of disease and non-target taxa of concern.

### 7.1 Incidence of Disease

#### **Objective 11: Determine if the incidence of disease has increased in the natural and hatchery populations.**

The hatchery environment has the potential to amplify diseases that are typically found at low levels in the natural environment. Amplification could occur within the hatchery population (i.e., vertical and horizontal transmission) or indirectly from the hatchery effluent or commingling between infected and non-infected fish (i.e., horizontal transmission). Potential impacts to natural populations have not been extensively studied, but should be considered for programs in which the hatchery fish are expected to commingle with natural fish. This is particularly important for supplementation type programs. Specifically, the causative agent of bacterial kidney disease (BKD), *Renibacterium salmoninarum* (Rs), could be monitored at selected acclimation ponds, both in the water and fish, in which the risk and potential for transmission from the hatchery is highest. Although it is technologically possible to measure the amount of Rs in water or Rs DNA in smolts and adults non-lethally sampled, the biological meaning of these data are uncertain. Currently, the only metric available for M & E purposes is measuring the antigen level from kidney/spleen samples (i.e., ELISA, PCR). When available, non-lethal sampling may replace or be used in concert with lethal sampling.

Implementation of this objective will be conducted in a coordinated approach within the hatchery and natural environment. BKD management within the hatchery population (e.g., broodstock or juveniles) has the potential to reduce the prevalence of disease through various actions (e.g., culling or reduced rearing densities). BKD management must also take into account and support other relevant objectives of the M & E program (e.g., Hatchery Return Rate [HRR], number of smolts released). Hence, the goal of BKD management is to decrease the prevalence of disease and maintain hatchery production objectives (i.e., number and HRR).

As previously discussed, disease transmission from hatchery to naturally produced fish may occur at various life stages and locations. Of these, horizontal transmission from hatchery effluent, vertical transmission on the spawning grounds, and horizontal transmission in the migration corridor have been identified as disease interactions that could be examined under this objective, although others may also be relevant. Experimental designs addressing this objective may require technology not yet available, although in some instances samples may be collected, but not analyzed until a link can be established between bacteria levels in samples and disease prevalence.

Developing a complete set of questions and hypotheses statements for this objective may not be practical at this time, because there is currently no BKD Management Plan. However, while developing experimental designs for this objective, it may be feasible to incorporate both hatchery and natural environment monitoring under a single study design. Integration of the different

aspects of the objective would likely result in a more robust approach into understanding the effectiveness of disease management strategies.

**Proposed Tasks:**

- T1:** Assemble fish health data for fish used as brood (e.g., ELISA results).
- T2:** Conduct data exploration exercise to identify potential relationships between pathogen profiles and likely causative variables (e.g., rearing conditions and management actions).
- T3:** Develop hypotheses for potential testing to meet objective.

## 7.2 Non-Target Taxa of Concern (NTTOC)

**Objective 12: Determine if the release of hatchery fish affects non-target taxa of concern (NTTOC) within acceptable limits.**

Hatchery programs have the potential to affect non-target taxa through various types of interactions (e.g., competition and predation). These interactions can reduce the distribution, size, and abundance of non-target species. The non-target taxa of concern (NTTOC) ecological risk assessment was developed as a regional objective that would address ecological interactions on non-target taxa.

In 2008, the Wells HCP, Rocky Reach HCP, Rock Island HCP Hatchery Committees, and the Priest Rapids Hatchery Sub-Committee agreed to an approach to evaluate the potential effects of hatchery programs on NTTOC. The committees originally planned to convene a panel of experts to conduct a preliminary evaluation of the potential effects of Plan supplemented species on NTTOC. At the 15 October 2008 Hatchery Committees meeting, the members agreed to convene an expert panel to conduct a preliminary evaluation of potential effects of supplemented Plan Species on non-target taxa using an approach similar to that used in the Yakima Basin (Pearsons and Hopley 1999; Ham and Pearsons, 2001). The Committees agreed to convene the panel in spring or early summer 2009, and focus this initial effort on HCP Plan Species and the two non-Plan Species, westslope cutthroat trout and lamprey. The Committees identified species interactions, containment objectives for non-target species, and fisheries professionals who possessed the expertise to contribute as panel members. The Committees directed the Hatchery Evaluation Technical Team (HETT) to pursue assessment of the hatchery programs potential effects on NTTOC.

The HETT evaluated methods to conduct a risk assessment on NTTOC, and proposed using a combined modeling and a Delphi panel approach, whereby the modeling results would be compared and correlated with the Delphi panel results. The HETT identified the PCD Risk 1 model (Busack et al., 2005; Pearsons and Busack, 2012) to conduct the modeling evaluation. The PCD Risk 1 model is a data intensive, individual-based stochastic model. The HETT determined that the assembled data to be used as inputs for the PCD Risk 1 model would also serve to provide expert panelists the necessary data for them to conduct risk assessments. Hence, the HETT embarked on an extensive effort to gather, organize, and extract the required data from existing datasets, literature, and biologists familiar with the programs and/or particular NTTOC. Ultimately, the input data were assembled in a relational database that allowed the data to be output in user-friendly formats for modeling or Delphi panel use. The database also served to hold the modeling results, which could be extracted and summarized as needed. Following the modeling

work, the Committees decided not to assemble the expert panel, because the panel would not be able to evaluate adequately the very large number of possible interactions.

A report titled *Ecological Risk Assessment of Upper-Columbia Hatchery Programs on Non-Target Taxa of Concern* was drafted in 2013 and finalized in 2014, which included the modeling results to date. The results in the report represent a very extensive effort to model the risk of all the upper Columbia hatchery programs for the identified NTTOC for which data and model runs were available. Should new information become available, the Committees agreed to assess the suitability of the data as it relates to conducting future NTTOC evaluations as a regional objective.

## SECTION 8: ADAPTIVE MANAGEMENT

One of the challenges of evaluating PUD hatchery programs is that hatchery programs are modified resulting in hatchery treatments that are uneven throughout the duration of the hatchery program. Modifications occur as a result of recalculating hatchery release numbers every 10 years and also through adaptive management. To solve this evaluation challenge, we propose to conduct two scales of analysis. First, the entire duration of the program will be analyzed using the entire data set. This evaluation will analyze whether the overall adaptively managed program achieved objectives. Second, where appropriate, analyses will be compared across periods or programs to determine if major program changes have resulted in hypothesized changes to key response variables. We acknowledged that partitioning data into shorter periods will likely result in reduced statistical power so only the biggest changes will be evaluated. In the future, the hatchery committees will develop a table or figure that identifies major program changes in fish culture or M&E.

In the past, hatchery programs have been evaluated at the hatchery program scale (e.g., Nason Creek, Carlton summer Chinook). In some cases, it may be worthwhile to evaluate supplementation programs at different spatial scales. For example, the Nason Creek spring Chinook salmon program can be evaluated at the scale of Nason Creek, the combined effects of spring Chinook hatchery programs in the Wenatchee basin at the Wenatchee basin scale, and then all of the spring Chinook programs in the upper Columbia at the upper Columbia basin scale.

Comparisons of supplemented populations (treatments) to in-basin reference populations are the best way to evaluate whether treatments have caused changes to variables such as natural-origin recruits or productivity. Many suitable out-of-basin references are available (see Appendix 6), but these references do not control for unique factors that may be happening in the upper Columbia or areas outside the upper Columbia. For example, large fires that occur in the Upper Columbia may not occur at similar times in areas outside of this area. Candidate in-basin reference populations are not ideal for spring Chinook salmon because they are small and are above a lake (e.g., Little Wenatchee River) or they have had a long history of hatchery stocking (e.g., Entiat River). Every population of upper Columbia summer and fall Chinook is supplemented so in-basin references are not currently available. Without a suitable number of in-basin reference populations that are similar in size and distribution to treated populations, it will be difficult to unambiguously assess hatchery effects on certain variables. Although not ideal, the only way to increase in-basin reference comparisons is to strategically reduce the number of places where hatchery fish are released such as was done for the Entiat River.

Previous stocking history will lessen the value of reference populations; however, they can still be of value. For instance, the Committees can still test whether NORs are increased under supplementation compared to periods when other populations are not supplemented (i.e., a reverse BACI analysis).

## SECTION 10: GLOSSARY

|                                     |  |
|-------------------------------------|--|
| Adult-to-Adult survival (Ratio)     | The number of parent broodstock relative to the number of returning adults.  |
| Age at maturity                     | The age of fish at the time of spawning (hatchery or naturally).   |
| Augmentation                        | A hatchery strategy where fish are released for the sole purpose of providing harvest opportunities.   |
| Broodstock                          | Adult salmon and steelhead collected for hatchery fish egg harvest and fertilization.  |
| Donor population                    | The source population for supplementation programs before hatchery fish spawned naturally.   |
| Effective population size ( $N_e$ ) | The number of reproducing individuals in an ideal population (i.e., $N_e = N$ ) that would lose genetic variation due to genetic drift or inbreeding at the same rate as the number of reproducing adults in the real population under consideration (Hallerman 2003). |
| ESA                                 | Endangered Species Act passed in 1973. The ESA-listed species refers to fish species added to the ESA list of endangered or threatened species and are covered by the ESA.   |
| Expected value                      | The number of smolts or adults derived from survival rates agreed to in the Biological Assessment and Management Plan (BAMP 1998).   |
| Extraction rate                     | The proportion of the spawning population collected for broodstock.  |
| Genetic diversity                   | All the genetic variation within a species of interest, including both within and between population components.   |
| Genetic stock structure             | A type of assortative mating, in which the gene pool of a species is composed of a group of subpopulations, or stocks, that mate panmictically within themselves.  |
| Genetic variation                   | All the variation due to different alleles and genes in an individual, population, or species.   |
| HCP                                 | Habitat Conservation Plan is a plan that enables an individual or organization to obtain a Section 10 Permit which outlines what will be done to “minimize and mitigate” the impact of the permitted take on a listed species.   |

|                                    |   |
|------------------------------------|---|
| HCP-HC                             | Habitat Conservation Plan Hatchery Committee is the committee that directs actions under the hatchery program section of the HCP's for Chelan and Douglas PUDs.   |
| HRR                                | Hatchery Replacement Rate is the ratio of the number of returning hatchery adults relative to the number of adults taken as broodstock, both hatchery and naturally produced fish (i.e., adult-to-adult replacement rate).                        |
| Long-term fitness                  | Long-term fitness is the ability of a population to self-perpetuate over successive generation.   |
| Naturally produced                 | Progeny of fish that spawned in the natural environment, regardless of the origin of the parents.   |
| Mean Ratio                         | The ratio between a treatment and control population, with the mean taken across a time period, such as years. Used in analysis in Before-After-Control-Impact studies.   |
| Ne                                 | Effective population size.  |
| Non-target taxa of concern (NTTOC) | Species, stocks, or components of a stock with high value (e.g., stewardship or utilization) that may suffer negative effects because of a hatchery program.  |
| NRR                                | Natural replacement rate is the ratio of the number of returning naturally produced adults relative to the number of adults that naturally spawned, both hatchery and naturally produced.   |
| NTTOC                              | Non-target taxa of concern.   |
| pHOS                               | Proportion of Hatchery Origin Spawners.   |
| PNI                                | Proportionate Natural Influence.  |
| pNOB                               | Proportion of Natural Origin Broodstock.  |
| PRCC HSC                           | Priest Rapids Coordinating Committee Hatchery Subcommittee.   |
| Productivity                       | The capacity in which juvenile fish or adults can be produced.  |
| Reference population               | A population in which no directed artificial propagation is currently directed, although may have occurred in the past. Reference populations are used to monitor the natural variability in survival rates and out of basin impacts on survival. |
| Smolt-to-adult survival rate (SAR) | Smolt-to-adult survival rate is a measure of the number of adults that return from a given smolt population.  |
| Segregated                         | A type of hatchery program in which returning adults are spatially or temporally isolated from other populations.   |

|                                       |  |
|---------------------------------------|--|
| Size at maturity                      | The length or weight of a fish at a point in time during the year in which spawning will occur.  |
| Smolts per redd                       | The total number of smolts produced from a stream divided by the total number of redds from which they were produced.  |
| SNP or single-nucleotide polymorphism | A single-nucleotide polymorphism is a variation in a single nucleotide that occurs at a specific position in the genome, where each variation is present to some appreciable degree within a population. |
| Spawning Escapement                   | The number of adult fish that survive to spawn.  |
| Stray rate                            | The rate at which fish spawn outside of natal rivers or the stream in which they were released.  |
| Supplementation                       | A hatchery strategy where the main purpose is to increase the relative abundance of natural spawning fish without reducing the long-term fitness of the population.                                      |
| Target population                     | A specific population in which management actions are directed (e.g., artificial propagation, harvest, or conservation).   |

## APPENDIX 1: ESTIMATION OF CARRYING CAPACITY

In the ecological literature, carrying capacity is often defined as the maximum population size that can be supported indefinitely by the environment (Cain et al. 2014). Said another way, carrying capacity is the maximum number or biomass of a species that a given habitat can support. This maximal environment load is often referred to as “habitat capacity” and is identified with the letter “C.” In contrast, the carrying capacity parameter “K” in population models (e.g., logistic equation, Beverton-Holt model, hockey stick model, and the Ricker model) defines a maximum equilibrium population size. Maximum equilibrium population size is generated from density dependent mechanisms that reduce population growth rates as population size increases (negative density dependence). This is referred to as compensation. Population size fluctuates about the maximum equilibrium size because of variability in vital rates that are unrelated to density (density independent factors) and measurement error. Maximum equilibrium population size is often referred to as “population capacity.” The two capacities (habitat capacity and population capacity) are related but not identical and therefore should not be confused. Habitat capacity will usually be greater than population capacity.

Estimation of carrying capacity is important because hatchery managers use it to inform supplementation programs, harvest managers use it to set appropriate harvest and escapement levels, modelers use it in life-cycle models to predict the effects of different recovery scenarios, and restoration practitioners use it to guide restoration actions. The purpose of this paper is to describe methods that can be used to estimate carrying capacity for stocks within the Upper Columbia River basin. We apply these methods to Wenatchee and Chiwawa River spring Chinook salmon.<sup>13</sup> Data used in this exercise are shown in Tables 1 and 2 and come from Hillman et al. (2017). We begin by identifying simple methods used to detect density dependence. We then describe the use of population models to estimate population capacity. We also discuss the use of habitat models and quantile regression to estimate habitat capacity. We end by comparing results of different methods and offering recommendations for estimating carrying capacity.

**Table 1.** Numbers of redds, adult spawners (estimated from redd surveys), eggs (estimated as the number of redds times average brood-year fecundity), summer parr (estimated using snorkel surveys), and yearling smolts (estimates using a rotary screw trap) by brood year for spring Chinook salmon in the Chiwawa River watershed. Smolts represent the number of yearling Chinook produced entirely within the Chiwawa River watershed. Data are from Hillman et al. (2017). NS = not sampled.

| Brood year | Numbers of Chiwawa spring Chinook |          |           |        |        |
|------------|-----------------------------------|----------|-----------|--------|--------|
|            | Redds                             | Spawners | Eggs      | Parr   | Smolts |
| 1991       | 104                               | 242      | 478,400   | 45,483 | 42525  |
| 1992       | 302                               | 676      | 1,570,098 | 79,113 | 39723  |
| 1993       | 106                               | 233      | 556,394   | 55,056 | 8662   |
| 1994       | 82                                | 184      | 485,686   | 55,241 | 16472  |
| 1995       | 13                                | 33       | 66,248    | 5,815  | 3830   |

<sup>13</sup> Technically, Wenatchee River spring Chinook are one population. Chiwawa River spring Chinook are a subgroup of the Wenatchee spring Chinook population.

| Brood year | Numbers of Chiwawa spring Chinook |          |           |         |        |
|------------|-----------------------------------|----------|-----------|---------|--------|
|            | Redds                             | Spawners | Eggs      | Parr    | Smolts |
| 1996       | 23                                | 58       | 106,835   | 16,066  | 15475  |

\* From 2000-2010 the smolt trap operated near the Town of Monitor; from 2013 to present the trap operated near the Town of Cashmere.

## Evidence of Density Dependence

To calculate population capacity, the size of the population or stock must be influenced to a large degree by density-dependent factors. That is, population growth is affected by mechanisms whose effectiveness increases as population size increases. As population density increases, factors such as competition, predation, and disease (and parasites) cause birth rates to decrease, death rates to increase, and dispersal to increase. When densities decrease, the opposite occurs; birth rates increase and death and emigration rates decrease. In general, when the density of the population becomes high enough, density-dependent factors decrease population size because food or space are in short supply (Chapman 1966). In the ecological literature, this is referred to as “population regulation.”

A simple way to determine if density-dependent factors regulate population size is to plot population growth rate (or appropriate surrogate) against population size. If population regulation is occurring, the relationship between population size and population growth rate decreases exponentially (decreases linearly if data are log-transformed). Surrogates for population growth rate include survival rates, natality (birth rates), productivity, recruits, individual growth rates, and movement. Figure 1 shows the relationship between productivity (parr/spawner and smolts/spawner) and spawning escapement for Wenatchee River and Chiwawa River spring Chinook. One could use redd counts as a surrogate for spawning abundance. Because most female spring Chinook construct only one redd (Murdoch et al. 2009), redd counts reflect the number of female spawners in the population. In this report, we use number of spawners (spawning escapement) because most management decisions are based on spawning escapement.

**Figure 1.** Relationship between spawner abundance and smolts/spawner for Wenatchee spring Chinook (top figures), spawner abundance and parr/spawner for Chiwawa spring Chinook (middle figures), and spawner abundance and smolts/spawner for Chiwawa spring Chinook (bottom figures). Figures on the right show natural log transformed productivity data.

The negative relationship between spawner abundance and juvenile productivity indicates the presence of density dependence in Chiwawa spring Chinook. Although there is a hint of density dependence in the Wenatchee River productivity data, the relationship was not significant statistically. This in part may be related to changes in sampling over the 13-year period. The negative relationship was significant for both summer parr and yearling smolts in the Chiwawa River watershed. We caution, however, that there may be a bias in the simple regression analysis presented in the figures. That is, the dependent (productivity) and independent (abundance) variables are not independent and this can produce a negative bias in regression estimates of slope. Nevertheless, the decline in juvenile productivity with increasing spawner abundance indicates the

presence of density dependence. Given the presence of density dependence, we should be able to estimate population capacity.

## Estimating Carrying Capacity

Several different methods can be used to estimate population capacity. For example, time series analyses, including the logistic or Gompertz functions, or stock-recruitment models can be used to estimate population capacity. Common stock-recruitment models include Ricker, Beverton-Holt, and smooth hockey stick models. These models incorporate environmental variability and can be used to estimate the size of the spawning population needed to produce the maximum number of recruits. Habitat capacity, on the other hand, can be estimated using fish-habitat models. In general, these models estimate habitat capacity as the product of habitat area and fish/habitat relationships. These range from simple models such as percent habitat saturation models to more complex models including habitat suitability, quantile regression forest models, dynamic food-web models, and bioenergetic or net rate of energy intake models. In this report, we explore the use of stock-recruitment models to estimate population capacity. We apply quantile regression to stock-recruitment models to estimate habitat capacity and compare those results to a habitat model, the quantile regression forest model.

### Population Capacity

To estimate population capacity, we evaluated the fit of three different stock-recruitment models to Chiwawa and Wenatchee River spring Chinook data: Ricker, Beverton-Holt, and smooth hockey stick models. In using these models, we assume:

- Density-dependent mortality—For some time period before recruitment, the brood instantaneous mortality rate is proportional to the number of parent spawners (Ricker 1954).
- Lognormal variation—At any particular spawning stock size, the variation in recruitment is log-normally distributed about its average, and acts multiplicatively (Quinn and Deriso 1999).
- Measurement error—Error in spawning stock size estimates (measurement error) is small relative to the range of spawning stock sizes observed (Hilborn and Walters 1992). Variation in realized recruitment at any particular spawning stock size (process error) dominates recruitment measurement error.
- Stationarity—The average stock-recruitment relationship is constant over time (Hilborn and Walters 1992). That is, environmental conditions randomly affect survival independent of stock size or time.

In general, the methods we used to fit the models to the data followed those outlined in Hilborn and Walters (1992) and Froese (2008). The Ricker model, which assumes that the number of recruits increases to a maximum and then declines as the number of spawners increases, takes the form:

$$E(R) = \alpha S e^{-\beta S}$$

where  $E(R)$  is the expected recruitment,  $S$  is spawner abundance,  $\alpha$  is the number of recruits per spawner at low spawning levels, and  $\beta$  describes how quickly the recruits per spawner drop as the number of spawners increases. We estimated population capacity ( $K$ ) as:

$$K = \left(\frac{\alpha}{\beta}\right) e^{-1}$$

and the number of spawners (SP) needed to produce the maximum number of recruits as:

$$SP = \frac{1}{\beta}$$

The Beverton-Holt model assumes that the number of recruits increases constantly toward an asymptote as the number of spawners increases. After the asymptote is reached, the number of recruits neither increases nor decreases. The asymptote represents the maximum number of recruits the system can support (i.e., population capacity for the system;  $K$ ). The Beverton-Holt curve takes the form:

$$E(R) = \frac{(\alpha S)}{(\beta + S)}$$

where  $E(R)$  and  $S$  are as above,  $\alpha$  is the maximum number of recruits produced (i.e.,  $\alpha = K$ ), and  $\beta$  is the number of spawners needed to produce (on average) recruits equal to one-half the maximum number of recruits. The number of spawners needed to produce the maximum number of recruits is  $\infty$  in the Beverton-Holt model.

Like the Beverton-Holt model, the smooth hockey stick model assumes that the number of recruits increases toward an asymptote (population capacity;  $K$ ) as the number of spawners increases. After the carrying capacity is reached, the number of recruits neither increases nor decreases. The carrying capacity represents the maximum equilibrium number of recruits the system can support. This curve takes the form (Froese 2008):

$$E(R) = R_{\infty} \left(1 - e^{-\left(\frac{\alpha}{R_{\infty}}\right)S}\right)$$

where  $E(R)$  and  $S$  are as above,  $\alpha$  is the slope at the origin of the spawner-recruitment curve, and  $R_{\infty}$  is the carrying capacity of recruits (i.e.,  $R_{\infty} = K$ ). There is no direct estimate of SP in the smooth hockey stick model. Therefore, we estimated SP as the number of spawners needed to produce  $0.95(K)$ .

We used non-linear regression to fit the three models to spawner-recruitment data. Before fitting the models, we transformed recruitment data using natural logs. We estimated bias and uncertainty measures (95% CI) for the model parameters using bootstrap procedures, which assumed that the  $\{R, S\}$  sample represented or approximated the population. The number of bootstrap samples was 3,000. We computed and stored the non-linear regression results for each bootstrap sample. We then calculated the bootstrap 95% CI by arranging the 3,000 bootstrap parameter values in sorted order and selected the 2.5 and 97.5 percentiles from the list.

We used Akaike's Information Criterion for small sample size ( $AIC_c$ ) to determine which model(s) best explained the relationship between spawners and recruitment in the supplemented and reference populations.  $AIC_c$  was estimated as:

$$AIC_c = -2\log(\mathcal{E}(\theta|data)) + 2K + \left(\frac{2K(K+1)}{n-K-1}\right)$$

where  $\log(\mathcal{L}(\theta|data))$  is the maximum likelihood estimate,  $K$  is the number of estimable parameters (structural parameters plus the residual variance parameter), and  $n$  is the sample size (Burnham and Anderson 2002). We used least-squares methods to estimate  $\log(\mathcal{L}(\theta|data))$ , which was calculated as  $\log(\sigma^2)$ , where  $\sigma^2$  = residual sum of squares divided by the sample size ( $\sigma^2 = RSS/n$ ).  $AIC_c$  assessed model fit in relation to model complexity (number of parameters). The model with the smallest  $AIC_c$  value represented the “best approximating” model within the model set. Remaining models were ranked relative to the best model using  $AIC_c$  difference scores ( $\Delta AIC_c$ ), Akaike weights ( $w_i$ ), and evidence ratios. Models with  $\Delta AIC_c$  values less than 2 indicated that there is substantial support for these models as being the best-fitting models within the set (Burnham and Anderson 2002). Models with values greater than 2 had less support. Akaike weights are probabilities estimating the strength of the evidence supporting a particular model as being the best model within the model set. Models with small  $w_i$  values are less plausible as competing models (Burnham and Anderson 2002). If no single model could be specified as the best model, a “best subset” of competing models was identified using (1)  $AIC_c$  differences to indicate the level of empirical support each model had as being the best model, (2) evidence ratios based on Akaike weights to indicate the relative probability that any model is the best model, and (3) coefficients of determination ( $R^2$ ) assessing the explanatory power of each model.

### Chiwawa River Spring Chinook Parr

We successfully fit the three stock-recruitment curves to the Chiwawa spring Chinook parr data (Figure 2).

**Figure 2.** Relationship between numbers of spring Chinook parr and numbers of spawners in the Chiwawa River watershed, 1992-2016 (no sampling occurred in 2000). Figure shows the fit of the Beverton-Holt, Ricker, and smooth hockey stick models to the data.

For summer parr, the use of AIC<sub>c</sub> indicated that the Beverton-Holt model best approximated the information in the productivity data. The estimated structural parameters for this model were:

$$Parr = \frac{(150,902 \times Spawners)}{(438 + Spawners)}$$

where the bootstrap estimated standard errors for the two parameters were 21,142 and 145, respectively. The adjusted R<sup>2</sup> = 0.812.

The second-best model was the smooth hockey stick model, which was 0.245 AIC<sub>c</sub> units from the best model. The estimated parameters for this model were:

$$LN(Parr) = 11.6 + LN\left(1 - e^{-\left(\frac{312.9}{113,801}\right)Spawners}\right)$$

where the bootstrap estimated standard errors of the two parameters were 0.097 and 57.578, respectively, and the R<sup>2</sup> = 0.810.

The AIC<sub>c</sub> difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for both the Beverton-Holt and smooth hockey stick models. There was less support for the Ricker model, which was > 2 AIC<sub>c</sub> units from the best models. This was further supported by the fact that, relative to the best models, the Ricker model had an evidence ratio greater than 3.

Depending on the stock-recruitment model used, population capacity ranged from 113,801 to 150,902 parr (Table 3). The Beverton-Holt model estimated the highest capacity, while the smooth hockey stick model estimated the lowest. The number of spawners needed to produce the population capacity of parr ranged from 1,089 to 1,163 (Table 3).

**Table 3.** Estimates of Beverton-Holt, smooth hockey stick, and Ricker model parameters, parr capacity (K), parr productivity (parr per spawner), and the number of spawners needed to produce the maximum number of parr for Chiwawa River spring Chinook.

| Model               | Parameter   |         | Population capacity (K) | Intrinsic productivity | Spawners |
|---------------------|-------------|---------|-------------------------|------------------------|----------|
|                     | A           | B       |                         |                        |          |
| Beverton-Holt       | 150,902.145 | 437.655 | 150,902                 | 345                    | ∞        |
| Smooth Hockey Stick | 11.642      | 312.913 | 113,801                 | 313                    | 1,089    |
| Ricker              | 272.696     | 0.0009  | 116,650                 | 273                    | 1,163    |

It is important to note that the population capacity estimates are based on the number of parr counted in the Chiwawa River watershed during August. There are spring Chinook fry and parr that move out of the Chiwawa River watershed during spring and early summer (Hillman et al. 2017). It is unknown if these fish leave because of density-dependent pressures, they are flushed out during high flows, it is a life-history characteristic, or a combination of these. Regardless of the mechanism or reason, some of these fish may survive and rear in the Wenatchee or Columbia rivers. These emigrants are not included in the capacity estimates shown in Table 3.

The capacity estimates for spring Chinook parr apply only to the Chiwawa River watershed, a watershed within the Wenatchee River basin. Estimating parr capacity for the entire Wenatchee River basin using stock-recruitment models is difficult because there is no long-term time series of parr data for the entire basin. However, we can extrapolate parr capacity estimates from the

Chiwawa River watershed to the entire Wenatchee River basin using intrinsic potential (IP). Multiplying the parr capacity per intrinsic potential within the Chiwawa River watershed by the total intrinsic potential within the Wenatchee River basin yields an estimate of parr capacity for the Wenatchee River basin (Table 4). The Interior Columbia Basin Technical Recovery Team estimated IP based on wetted width, valley width (confinement), and gradient (see Cooney and Holzer 2006). They used sedimentation and temperature to refine IP for each 200-m long reach. We used the total stream area (km<sup>2</sup>) weighted by intrinsic potential and temperature limited to extrapolate parr capacity to the entire Wenatchee River basin.

**Table 4.** Estimates of Wenatchee River basin parr capacity based on intrinsic potential (IP). The amount of IP within the Chiwawa River watershed is 0.481 km<sup>2</sup>; the total amount of IP within the Wenatchee River basin is 1.798 km<sup>2</sup>.

| Model               | Chiwawa parr capacity | Chiwawa parr/IP | Wenatchee parr capacity |
|---------------------|-----------------------|-----------------|-------------------------|
| Beverton-Holt       | 150,902               | 313,726         | 564,079                 |
| Smooth Hockey Stick | 113,801               | 236,593         | 425,395                 |
| Ricker              | 116,650               | 242,516         | 436,043                 |

Using this simple method, we estimate the Wenatchee River basin supports about 425,395-564,079 parr depending on which model is used. An important assumption of this simple method is that each unit of IP supports the same number of parr. This is clearly not true given that the quality of habitat within each unit of IP can vary greatly. That is, one unit of IP may contain more habitat structure (e.g., wood and cover) than another unit of IP. Importantly, the ratio of parr to IP comes from the Chiwawa River watershed, which contains some of the highest quality habitat within the Wenatchee River basin. Therefore, the estimated total parr capacity for the entire Wenatchee River basin is likely biased high. If habitat conditions throughout the Wenatchee River basin are enhanced to conditions similar to those in the Chiwawa River watershed, we may expect parr abundance to approach those estimated with this simple method.

#### **Chiwawa River Spring Chinook Smolts**

We successfully fit the three stock-recruitment curves to the Chiwawa spring Chinook smolt data (Figure 3). This information allows us to better understand the quality and quantity of overwintering habitat in the Chiwawa River basin.

## Chiwawa Spring Chinook

**Figure 3.** Relationship between numbers of spring Chinook smolts and numbers of spawners in the Chiwawa River watershed, 1992-2015. Figure shows the fit of the Beverton-Holt, Ricker, and smooth hockey stick models to the data.

For yearling smolts produced entirely within the Chiwawa River watershed, the use of  $AIC_c$  indicated that the smooth hockey stick model best approximated the information in the productivity data. The estimated structural parameters for this model were:

$$LN(Smolts) = 10.7 + LN\left(1 - e^{-\left(\frac{174.1}{45,161}\right)Spawners}\right)$$

where the bootstrap estimated standard errors for the two parameters were 0.13 and 41.29, respectively. The adjusted  $R^2 = 0.569$ .

The second-best model was the Ricker model, which was 0.234  $AIC_c$  units from the best model. The estimated parameters for this model were:

$$Smolts = 149.45 \times Spawners(e^{-0.00111 \times Spawners})$$

where the bootstrap estimated standard errors of the two parameters were 26.23 and 0.00018, respectively, and the  $R^2 = 0.573$ .

The third-best model was the Beverton-Holt model, which was 0.725  $AIC_c$  units from the best model. The estimated parameters for this model were:

$$Smolts = \frac{(55,702 \times Spawners)}{(273 + Spawners)}$$

where the bootstrap estimated standard errors of the two parameters were 10,421.9 and 123.0, respectively, and the  $R^2 = 0.560$ .

The  $AIC_c$  difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for all three models. Relative to the best model, the other two models had evidence ratios less than 1.5.

Depending on the stock-recruitment model used, population capacity ranged from 45,161 to 55,702 smolts (Table 5). The Beverton-Holt model estimated the highest capacity, while the smooth hockey stick model estimated the lowest. The number of spawners needed to produce the population capacity of smolts ranged from 777 to 901 (Table 5).

**Table 5.** Estimates of Beverton-Holt, smooth hockey stick, and Ricker model parameters, smolt capacity (K), smolt productivity (smolts per spawner), and the number of spawners needed to produce the maximum number of smolts for Chiwawa River spring Chinook.

| Model               | Parameter  |         | Population capacity (K) | Intrinsic productivity | Spawners |
|---------------------|------------|---------|-------------------------|------------------------|----------|
|                     | A          | B       |                         |                        |          |
| Smooth hockey stick | 10.718     | 174.077 | 45,161                  | 174                    | 777      |
| Ricker              | 149.452    | 0.00111 | 49,532                  | 149                    | 901      |
| Beverton-Holt       | 55,702.281 | 273.910 | 55,702                  | 203                    | $\infty$ |

It is important to note that the population capacity estimates are based on the number of smolts produced entirely within the Chiwawa River watershed. As noted earlier, there are spring Chinook fry and parr that move out of the Chiwawa River watershed during spring, early summer, and fall (Hillman et al. 2017). Fall emigration is common and occurs even when densities of juveniles are very low, indicating that fall emigration is a life-history characteristic. Regardless of why the fish emigrate as fry and parr, some of these fish survive and rear in the Wenatchee or Columbia rivers. Some survive to smolt (unpublished WDFW data), but are not included in the smolt capacity estimates shown in Table 5.

As with parr, the capacity estimates for spring Chinook smolts apply only to the Chiwawa River watershed. As before, we can extrapolate smolt capacity estimates from the Chiwawa River watershed to the entire Wenatchee River basin using intrinsic potential (IP). In this case, we multiply the smolt capacity per intrinsic potential within the Chiwawa River watershed by the total intrinsic potential within the Wenatchee River basin. This yields an estimate of smolt capacity for the Wenatchee River basin (Table 6).

**Table 6.** Estimates of Wenatchee River basin smolt capacity based on intrinsic potential (IP). The amount of IP within the Chiwawa River watershed is 0.481 km<sup>2</sup>; the total amount of IP within the Wenatchee River basin is 1.798 km<sup>2</sup>.

| Model               | Chiwawa smolt capacity | Chiwawa smolts/IP | Wenatchee smolt capacity |
|---------------------|------------------------|-------------------|--------------------------|
| Beverton-Holt       | 55,702                 | 115,805           | 208,218                  |
| Smooth Hockey Stick | 45,161                 | 93,891            | 168,816                  |
| Ricker              | 49,532                 | 102,976           | 185,152                  |

Using this simple method, we estimate the population capacity for the Wenatchee River basin at 168,816-208,218 smolts depending on which model is used. Based on smolt trapping in the lower Wenatchee River over a 13-year period, total smolt abundance has ranged from 36,752 to 302,116 smolts (average = 107,300 smolts) (Table 2).<sup>14</sup> Thus, recent (2000-2014) smolt production appears to be below capacity estimates for most years but higher in some years.

An important assumption of this simple method is that each unit of IP supports the same number of smolts. As we noted earlier, this is not the case given that the quality of habitat within each unit of IP can vary greatly. Nevertheless, the ratio of smolts to IP comes from the Chiwawa River watershed, which contains some of the highest quality habitat within the Wenatchee River basin. Therefore, the estimated total smolt capacity for the entire Wenatchee River basin is likely biased high. If habitat conditions throughout the Wenatchee River basin are enhanced to conditions similar to those in the Chiwawa River watershed, we may expect smolt abundance to approach those estimated with this simple method.

### **Wenatchee River Spring Chinook Smolts**

Rather than extrapolate results from the Chiwawa River watershed to the entire Wenatchee River basin, we can fit stock-recruitment models to the smolt data collected in the lower Wenatchee River and estimate population capacity directly from the population models. We successfully fit the three stock-recruitment curves to the Chiwawa spring Chinook smolt data; although, the models explained little of the variation in the stock-recruitment data ( $R^2 < 0.05$ ) (Figure 3).

---

<sup>14</sup> It is important to point out that the trapping location has changed over time. During the period 2000-2008 and 2011-2012, the trap was located near the Town of Monitor. During the period 2013-present, the trap was located near the Town of Cashmere.

## Wenatchee Spring Chinook

**Figure 4.** Relationship between numbers of spring Chinook smolts and numbers of spawners in the Wenatchee River basin, 2000-2014 (no data were collected in 2009 or 2010). Figure shows the fit of the Beverton-Holt, Ricker, and smooth hockey stick models to the data.

For yearling smolts produced within the Wenatchee River basin, the use of  $AIC_c$  indicated that the Beverton-Holt model best approximated the information in the productivity data. The estimated structural parameters for this model were:

$$Smolts = \frac{(108,696 \times Spawners)}{(359 + Spawners)}$$

where the bootstrap estimated standard errors for the two parameters were 49,948 and 836, respectively. The adjusted  $R^2 = 0.026$ .

The second-best model was the smooth hockey stick model, which was 0.112  $AIC_c$  units from the best model. The estimated parameters for this model were:

$$LN(Smolts) = 11.4 + LN\left(1 - e^{-\left(\frac{20.72}{93,560}\right)Spawners}\right)$$

where the bootstrap estimated standard errors of the two parameters were 30.74 and 225.43, respectively, and the  $R^2 = 0.017$ .

The third-best model was the Ricker model, which was 0.0.808  $AIC_c$  units from the best model. The estimated parameters for this model were:

$$Smolts = 114.10 \times Spawners (e^{-0.00042 \times Spawners})$$

where the bootstrap estimated standard errors of the two parameters were 56.16 and 0.00021, respectively, and the  $R^2 = 0.001$ .

The  $AIC_c$  difference scores, Akaike weights, and evidence ratios indicated that there was substantial support for all three models. Relative to the best model, the other two models had evidence ratios less than 2.0.

Depending on the stock-recruitment model used, population capacity for the Wenatchee River basin ranged from 93,560 to 108,696 smolts (Table 7). The Beverton-Holt model estimated the highest capacity, while the smooth hockey stick model estimated the lowest. The number of spawners needed to produce the population capacity of smolts ranged from 1,389-2,381 (Table 7).

**Table 7.** Estimates of Beverton-Holt, smooth hockey stick, and Ricker model parameters, smolt capacity (K), smolt productivity (smolts per spawner), and the number of spawners needed to produce the maximum number of smolts for Wenatchee River spring Chinook.

| Model               | Parameter   |         | Population capacity (K) | Intrinsic productivity | Spawners |
|---------------------|-------------|---------|-------------------------|------------------------|----------|
|                     | A           | B       |                         |                        |          |
| Smooth hockey stick | 11.446      | 201.724 | 93,560                  | 202                    | 1,389    |
| Ricker              | 114.104     | 0.00042 | 99,944                  | 114                    | 2,381    |
| Beverton-Holt       | 108,696.009 | 358.616 | 108,696                 | 303                    | $\infty$ |

The population capacity estimates reported here are based on the number of smolts produced within the Wenatchee River basin. It is likely that some juvenile spring Chinook rear in the Columbia River and survive to smolt. Those fish are not included in these estimates of capacity.

### Habitat Capacity

Habitat capacity can be estimated using fish-habitat models and creative modeling of stock-recruitment data. As we noted earlier, there are several different fish-habitat models that can be used to estimate habitat capacity. In this paper, we explore the use of two different methods, quantile regression applied to stock-recruitment functions and the Quantile Regression Random Forest model. The former relies on simple stock and recruitment data, while the latter requires estimates of habitat quality and quantity, and functional relationships between maximum fish density and habitat conditions.

#### Quantile Regression Analysis of Stock-Recruitment Data

To estimate population capacity, we used non-linear regression techniques to fit stock-recruitment functions to the data. These techniques approximate the conditional mean of the recruitment data given the range of stock sizes. As such, the functions (curves) estimated from the analyses lie near the center of the distribution of data resulting in data points above and below the curve. Although this technique is useful for estimating population capacity, it is not appropriate for estimating habitat capacity. The fact that there are actual recruitment data above the estimated population capacity indicates that habitat capacity must be greater than the population capacity, or that measurement error is high. The former explanation is more likely than the latter.

One way to possibly estimate habitat capacity with stock-recruitment data is to fit stock-recruitment functions to the juvenile spring Chinook data using quantile regression techniques. Quantile regression estimates quantiles of the recruitment data given the range of stock sizes. Thus,

we can use quantile regression to fit a stock-recruitment function to, say, the upper 90% or 95% of the recruitment distribution. In other words, we fit a stock-recruitment function to the upper limits of the recruitment data given the range of stock sizes. In this case, the resulting stock-recruitment curve is above most of the recruitment data and therefore few data points lie above the curve. Calculation of capacity from these functions should more closely represent habitat capacity, provided there is an adequate range of stock sizes. Quantile regression gives results similar to those obtained from calculating reference intervals (RI).

In this exercise, we calculated the upper 90% RI for the Beverton-Holt and Ricker functions. We assume the 90% RI will closely represent the habitat capacity for juvenile spring Chinook. We calculated the 90% RI only for the Beverton-Holt and Ricker models, because these functions can be transformed into linear function (see Hilborn and Walters 1992). RIs are easier to calculate on linear functions than non-linear functions. We were unable to transform the smooth hockey stick model into a linear function and therefore we did not calculate RIs for this function.

*Chiwawa River Spring Chinook Parr*—We calculated 90% RIs for Chiwawa Chinook parr data for both the Ricker and Beverton-Holt models (Figure 5). The estimated parameters for the 90% RI for the Ricker model were:

$$\log\left(\frac{Parr}{Spawners}\right) = 6.152 - \frac{6.152}{5,984.436}(Spawners)$$

This resulted in an estimated habitat capacity of 168,071 parr, which is about 1.4 times greater than the population capacity estimated with the Ricker model.

The estimated parameters for the 90% RI for the Beverton-Holt model were:

$$\frac{Spawners}{Parr} = \frac{196.91}{181,818} + \frac{1}{181,818}(Spawners)$$

This function resulted in an estimated habitat capacity of 181,818 parr, which was about 1.2 times greater than the population capacity estimated with the Beverton-Holt model.

**Figure 5.** Relationship between numbers of spring Chinook parr and numbers of spawners in the Chiwawa River watershed, 1992-2016. Upper figure shows the fit of the Ricker model and its 90% reference interval to the data; lower figure shows the fit of the Beverton-Holt model and its 90% reference interval.

If we extrapolate the habitat capacity estimates for Chiwawa spring Chinook parr to the entire Wenatchee River basin (using the IP method described earlier), we estimate the habitat capacity for the Wenatchee River basin to be 628,256 parr from the Ricker model and 679,645 parr from the Beverton-Holt model.

Chiwawa River Spring Chinook Smolts—As with parr, we calculated 90% RIs for Chiwawa Chinook smolt data for both the Ricker and Beverton-Holt models (Figure 6). The estimated parameters for the 90% RI for the Ricker model were:

$$\log\left(\frac{\text{Smolts}}{\text{Spawners}}\right) = 5.687 - \frac{5.687}{4,687.964}(\text{Spawners})$$

This resulted in an estimated habitat capacity of 89,425 smolts, which is about 1.8 times greater than the population capacity estimated with the Ricker model.

The estimated parameters for the 90% RI for the Beverton-Holt model were:

$$\frac{\text{Spawners}}{\text{Smolts}} = \frac{102.129}{64,516} + \frac{1}{64,516}(\text{Spawners})$$

This function resulted in an estimated habitat capacity of 64,516 smolts, which was about 1.2 times greater than the population capacity estimated with the Beverton-Holt model.

**Figure 6.** Relationship between numbers of spring Chinook smolts and numbers of spawners in the Chiwawa River watershed, 1992-2015. Upper figure shows the fit of the Ricker model and its 90% reference interval to the data; lower figure shows the fit of the Beverton-Holt model and its 90% reference interval.

If we extrapolate the habitat capacity estimates for Chiwawa spring Chinook smolts to the entire Wenatchee River basin (using the IP method described earlier), we estimate the habitat capacity

for the Wenatchee River basin to be 334,276 smolts based on the Ricker model and 241,164 smolts from the Beverton-Holt model.

*Wenatchee River Spring Chinook Smolts*—We calculated 90% RIs for Wenatchee River Chinook smolt data for both the Ricker and Beverton-Holt models (Figure 7). The estimated parameters for the 90% RI for the Ricker model were:

$$\log\left(\frac{\text{Smolts}}{\text{Spawners}}\right) = 5.320 - \frac{5.320}{16,642.420}(\text{Spawners})$$

This resulted in an estimated habitat capacity of 235,131 smolts, which is about 2.4 times greater than the population capacity estimated with the Ricker model.

The estimated parameters for the 90% RI for the Beverton-Holt model were:

$$\frac{\text{Spawners}}{\text{Smolts}} = \frac{357.593}{186,567} + \frac{1}{186,567}(\text{Spawners})$$

This function resulted in an estimated habitat capacity of 186,567 smolts, which was about 1.7 times greater than the population capacity estimated with the Beverton-Holt model.

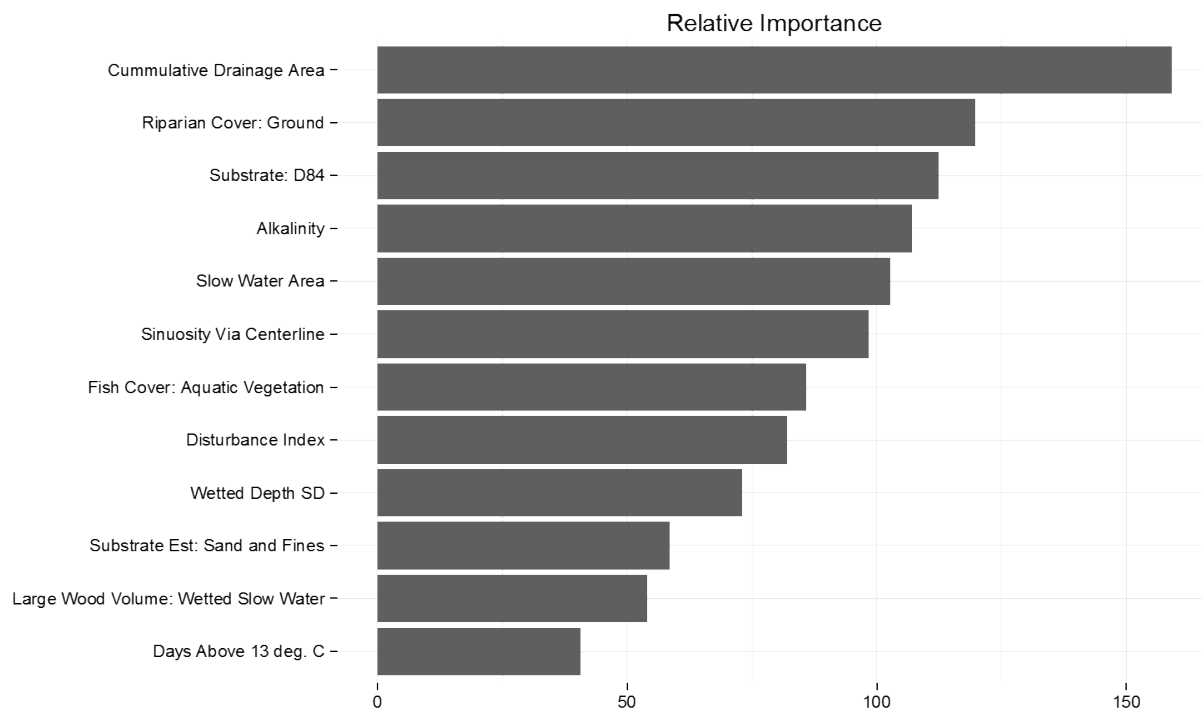

**Figure 7.** Relationship between numbers of spring Chinook smolts and numbers of spawners in the Wenatchee River basin, 2000-2015 (no data were collected in 2009 or 2010). Upper figure shows the fit of the Ricker model and its 90% reference interval to the data; lower figure shows the fit of the Beverton-Holt model and its 90% reference interval.

### **Quantile Regression Random Forest Model**

Researchers with the Integrated Status and Effectiveness Monitoring Program (ISEMP) developed a model that estimates Chinook parr habitat capacity based on fish-habitat relationships (ISEMP/CHaMP 2015). Based on extensive sampling throughout the Columbia River basin, these researchers developed relationships between maximum densities of Chinook parr (summer estimates) and various habitat variables. Quantile regression forest (QRF) models use these relationships to estimate carrying capacities for juvenile Chinook. Very simply, QRF analysis develops non-linear relationships between fish density and different habitat variables. In this case, however, QRF analysis predicts the 90% quantile of fish density rather than the mean or median density. The researchers assume that the 90% quantile represents habitat capacity. This is important because the numbers of fish counted in some field sampling sites may not have been at maximum capacity. That is, it is likely that not all sites sampled were fully “seeded” with Chinook salmon. Thus, using the mean or median (50% quantile) would not represent habitat capacity, but some level below habitat capacity.

Researchers fit the QRF model to parr density data and 12 habitat variables that were collected from 227 sites within the distribution of Chinook throughout the Columbia River basin (within CHaMP/ISEMP watersheds). These variables were selected to represent a variety of types of habitat variables (e.g., substrate, riparian, complexity, temperature, etc.), contain the most “fish information,” and be as uncorrelated as possible (ISEMP/CHaMP 2015). The 12 habitat variables and their relative importance are shown in Figure 8.

**Figure 8.** Relative importance of habitat variables included in juvenile Chinook salmon quantile regression forest models (Figure is from ISEMP/CHaMP 2015).

As a way of testing the model, ISEMP researchers used their QRF model to estimate Chinook parr capacities in different watersheds, including the Chiwawa River watershed, and compared their

estimates to those generated from fish population data using stock-recruitment modeling. Figure 9 shows the relationship between the QRF model results and population model results for the Chiwawa River watershed. The red curve was generated using the QRF model and the blue curve was generated using the Beverton-Holt model. At the time of this analysis, the Beverton-Holt model was fit to 21 years of parr data, not the 24 years of data used in the analyses above.

**Figure 9.** Comparison of productivity curves for Chiwawa spring Chinook parr generated from the QRF model (red line) and Beverton-Holt model (blue line). Dashed horizontal lines represent carrying capacity estimates. Shading about the capacity estimates represent the 95% confidence bounds. Figure is from ISEMP/CHaMP (2015).

The comparison shows that although the curves are very similar, the carrying capacity estimates (dashed horizontal lines) differed, with the habitat capacity generated from the QRF model being larger than the population capacity generated from the population data. That is, the QRF model estimated a habitat capacity of about 164,000 spring Chinook parr, while the population model estimated a population capacity of about 145,000 parr. Including more recent parr data in the Beverton-Holt model indicates that the population capacity estimate is about 151,000 parr for the Chiwawa River watershed. The 90% RI for the Beverton-Holt model estimated a habitat capacity of about 182,000, which is 1.1 times greater than the estimate from the QRF model. Note that the 90% RI for the Ricker model estimated a habitat capacity of about 168,000, which is close to the QRF model estimate.

## Comparing Results

We estimated capacities for both spring Chinook parr and smolts for the Chiwawa River watershed and the entire Wenatchee River basin using different analytical tools. In this section, we compare the results from the different approaches.

### Parr Capacity

Depending on the population model used, population capacity estimates for the Chiwawa River watershed ranged from 113,801 to 150,902 parr (Table 8). Not surprisingly, the Beverton-Holt model generally predicts the highest capacity estimates, while the smooth hockey stick model predicts the lowest. As expected, the population capacity estimates for Chiwawa parr were less than the habitat capacity estimates for parr. Habitat capacity estimates were about 1.2 to 1.5 times greater than the population capacity estimates (Table 8). Importantly, the fish-habitat model (QRF model) calculated a habitat capacity estimate that was close to that estimated from calculating 90% RI for the population models. Extrapolating Chiwawa capacity estimates to the entire Wenatchee River basin resulted in population capacities of 425,395 to 564,079 parr and habitat capacity estimates of 613,040 to 679,645 parr (Table 8).

**Table 8.** Comparison of spring Chinook parr capacity estimates for the Chiwawa River watershed and the Wenatchee River basin. Population capacities were estimated directly from the stock-recruitment functions; habitat capacities were estimated by calculating 90% reference intervals (using quantile regression; QR) for the stock-recruitment models and using a fish-habitat model (Quantile Regression Forest Model; QRF). Capacities for the Wenatchee River basin were estimated by extrapolating Chiwawa capacities using intrinsic potential.

| Capacity type       | Model               | Chiwawa parr capacity | Wenatchee parr capacity |
|---------------------|---------------------|-----------------------|-------------------------|
| Population capacity | Beverton-Holt       | 150,902               | 564,079                 |
|                     | Smooth Hockey Stick | 113,801               | 425,395                 |
|                     | Ricker              | 116,650               | 436,043                 |
| Habitat capacity    | QR Beverton-Holt    | 181,818               | 679,645                 |
|                     | QR Ricker           | 168,071               | 628,256                 |
|                     | QRF Model           | 164,000               | 613,040                 |

The number of spawners needed to achieve parr capacity also varied depending on the population model used (Table 9). For the Chiwawa River watershed, maximum spawners needed to achieve population capacity for parr ranged from 1,089 to 1,163 adults. Extrapolating Chiwawa results to the entire Wenatchee River basin resulted in maximum spawner estimates of 4,070 to 4,347 adults. We were able to estimate habitat capacity only with the Ricker model (Table 9). Using quantile regression to calculate the 90% RI for the Ricker model resulted in a maximum spawner abundance of 973 adults, which is less than the number needed to achieve population capacity. This is because the 90% RI for the Ricker function estimates a higher intrinsic productivity, which shifts the “hump” of the curve to the left resulting in a higher capacity estimate but a lower maximum spawner estimate (see Figure 5).

**Table 9.** Comparison of the number of spawners needed to achieve parr capacities in the Chiwawa River watershed and the Wenatchee River basin. For the Chiwawa River watershed, maximum spawners were estimated directly from the stock-recruitment functions. Maximum spawners for the entire Wenatchee River basin were estimated as the product of the extrapolated parr numbers times the ratio of maximum spawners to parr capacity for Chiwawa spring Chinook. Because of the nature of the Beverton-Holt model, no maximum spawners can be calculated from that model.

| Capacity type       | Model               | Spawners need to achieve parr capacity |           |
|---------------------|---------------------|--|-----------|
|                     |                     | Chiwawa                                | Wenatchee |
| Population capacity | Smooth Hockey Stick | 1,089                                  | 4,070     |
|                     | Ricker              | 1,163                                  | 4,347     |
| Habitat capacity    | QR Ricker           | 973                                    | 3,636     |

### Smolt Capacity

As with parr estimates, population capacity estimates for smolts varied depending on the population model used. For Chiwawa spring Chinook smolts, population capacities ranged from 45,161 to 55,702 smolts, with the smooth hockey stick providing the lowest estimate and the Beverton-Holt model providing the highest (Table 10). The population capacity estimates were about 55 to 86% of the habitat capacity estimates. Extrapolating Chiwawa capacity estimates to the entire Wenatchee River basin resulted in population capacities of 168,816 to 208,218 smolts and habitat capacity estimates of 241,164 to 334,276 smolts (Table 10). These were greater than those estimated using smolt and spawner data for the entire Wenatchee River basin. Fitting population models to smolt and spawner data for the entire basin resulted in population capacities of 93,560 to 108,696 smolts and habitat capacities of 186,567 to 235,131 smolts (Table 10).

**Table 10.** Comparison of spring Chinook smolt capacity estimates for the Chiwawa River watershed and the Wenatchee River basin. Population capacities were estimated directly from the stock-recruitment functions; habitat capacities were estimated by calculating 90% reference intervals (using quantile regression; QR) for the stock-recruitment models. Capacities for the Wenatchee River basin were estimated by extrapolating Chiwawa capacities using intrinsic potential and by fitting population models to the smolt and spawner data for the entire basin.

| Capacity type       | Model               | Chiwawa smolt capacity | Wenatchee smolt capacity |                |
|---------------------|---------------------|------------------------|--------------------------|----------------|
|                     |                     |                        | Chiwawa extrapolation    | Wenatchee data |
| Population capacity | Beverton-Holt       | 55,702                 | 208,218                  | 108,696        |
|                     | Smooth Hockey Stick | 45,161                 | 168,816                  | 93,560         |
|                     | Ricker              | 49,532                 | 185,152                  | 99,944         |
| Habitat capacity    | QR Beverton-Holt    | 64,516                 | 241,164                  | 186,567        |
|                     | QR Ricker           | 89,425                 | 334,276                  | 235,131        |

The number of spawners needed to achieve smolt capacity varied depending on the population model used (Table 11). For the Chiwawa River watershed, maximum spawners needed to achieve

population capacity for smolts ranged from 777 to 901 adults. Note that the maximum number of adults needed to achieve population capacity for smolts is less than those needed to achieve population capacity for parr. Extrapolating Chiwawa results to the entire Wenatchee River basin resulted in maximum spawner estimates of 2,904 to 3,368 adults. These estimates are considerably higher than those estimated from fitting population models to Wenatchee River basin data. The latter estimated maximum spawners ranging from 1,389 to 2,381 adults. We were able to estimate habitat capacity only with the Ricker model (Table 11). Using quantile regression to calculate the 90% RI for the Ricker model resulted in a maximum spawner abundance of 824 adults for the Chiwawa River watershed and 3,129 adults for the entire Wenatchee River basin. Extrapolating Chiwawa results to the entire Wenatchee River basin resulted in a maximum spawner estimate of 3,080, which is close to the estimate generated by fitting the model to Wenatchee River basin data.

**Table 11.** Comparison of the number of spawners needed to achieve smolt capacities in the Chiwawa River watershed and the Wenatchee River basin. Maximum spawners were estimated directly from the stock-recruitment functions. Maximum spawners for the entire Wenatchee River basin were also estimated as the product of the extrapolated smolt numbers times the ratio of maximum spawners to smolt capacity for Chiwawa spring Chinook. Because of the nature of the Beverton-Holt model, no maximum spawners can be calculated from that model.

| Capacity type       | Model               | Spawners need to achieve smolt capacity |                       |                |
|---------------------|---------------------|---|-----------------------|----------------|
|                     |                     | Chiwawa                                 | Wenatchee             |                |
|                     |                     |   | Chiwawa extrapolation | Wenatchee data |
| Population capacity | Smooth Hockey Stick | 777                                     | 2,904                 | 1,389          |
|                     | Ricker              | 901                                     | 3,368                 | 2,381          |
| Habitat capacity    | QR Ricker           | 824                                     | 3,080                 | 3,129          |

As an additional exercise, we calculated smolt capacities and maximum spawners generated from fitting population models to smolt and spawner data in the Chiwawa River, Nason Creek, and White River watersheds, and compared the sum of those estimates to the Wenatchee River basin estimates. Only the Ricker model could be fit to the White River and Nason Creek data (see Hillman et al. 2017). Estimated population capacities from the Ricker model were 49,532 smolts in the Chiwawa, 4,412 smolts in Nason Creek, and 4,659 smolts in the White River, resulting in a cumulative population capacity of 58,603 smolts (1,550 spawners are needed to achieve this cumulative smolt capacity). The cumulative population capacity estimate is nearly 60% of the total population capacity calculated from fitting the Ricker model to the entire Wenatchee River basin data. If these estimates are correct, this means that about 40% of the current Wenatchee River basin smolt capacity is outside the Chiwawa River, Nason Creek, and White River watersheds. Hillman et al. (2017) report that over the period 1989 to 2016, on average, 76% of spring Chinook spawning occurs in the three watersheds. Thus, a large percentage of smolt capacity is generated outside the major spawning areas. We believe this highlights the importance of the mainstem Wenatchee River as a rearing area for juvenile spring Chinook.

## Recommendations

Based on the simple analyses conducted in this report, we offer the following recommendations:

1. Where sufficient stock and recruitment data are available, and the data have sufficient contrast, then use population (stock-recruitment) modeling as the primary method to calculate population capacity and the number of spawners needed to produce the maximum number of recruits under current or average habitat conditions. Select the best fitting stock-recruitment model based upon  $AIC_c$ , unless other factors suggest otherwise, such as evidence for a biological mechanism. A biological mechanism supporting a Ricker function, for example, would be that there is a stock-dependent effect on the mortality of eggs and juveniles (i.e., mortality is proportional to the initial cohort size). When  $AIC_c$  values are not appreciably different, then select the model that is most useful (e.g., Ricker and smooth hockey stick models are easier to work with than the Beverton-Holt model).
2. Adult-to-adult data are the most relevant because they account for all life stages and delayed effects in freshwater (e.g., small size at migration), but they are also the most variable (i.e., low  $R^2$ ). Therefore, adult-to-juvenile data (e.g., parr, yearling smolts, total migrants) are likely the most useful for determining freshwater population capacity. Where data are available, pre-spawn adult to spawning adult survival can also be assessed using population models to evaluate density dependence and pre-spawn adult capacity.
3. The population models used to estimate population capacity should also be used in reference streams so one can make comparisons of carrying capacities and density-corrected productivities. Unless there are good reasons for selecting a different juvenile life-stage, the default should be to use yearling smolts because they represent the capacity of the tributaries to produce yearlings and it is also a clear identification and quantification of a migrant life-stage.
4. In the absence of fish-habitat models, quantile regression can be used to estimate habitat capacity by calculating reference intervals for the population models. The percentage of the reference interval should be set using the error in the estimation of the recruits and the level of desire to exclude anomalous data. For example, if the 95% confidence interval is approximately 10% of the recruitment estimate, then the reference interval should be set at 90% (e.g.,  $RI = 100\% - C.I.\%$ ).
5. Where sufficiency conditions in (1) are not met, use habitat-based expansion of density at capacity for the most ecologically similar population. For example, use Twisp capacity estimates for habitat-based expansions in the Methow. The habitat expansion metric should be “total stream area weighted by intrinsic potential and temperature limited,” unless there are good reasons for a different expansion. The primary idea is to exclude areas that are known to not produce fish because of passage, temperature, or other limitations.
6. Capacity estimates should be described within the context of the information that was used to derive estimates. For example, spawner distribution of hatchery-origin fish could influence estimates of capacity if they are within poor habitat. However, the capacity estimates do reflect the historic and current hatchery practices. It is unknown how the capacity estimates would change if a different hatchery program that produced different spawning distributions was to be implemented. However, if those data do become available, then capacity estimates can be revised. Similarly, significant enhancements (e.g.,

improved passage) or degradations (e.g., fire) in habitat can also change capacity and can be incorporated into future estimates of capacity.

7. Regardless of the method used to estimate capacity, always describe the limitations of the data and assumptions of the models. Note where assumptions are violated and how these violations could affect the results of the analysis.

## APPENDIX 2: HATCHERY REPLACEMENT RATES

Based on ideas developed by the HETT, in February 2016, the HCP Hatchery Committees and PRCC Hatchery Subcommittee agreed to the following rules and HRR targets:

1. Use the estimated 40% HRR Target during 5-year statistical evaluation periods.
2. Use varying degrees of action depending on the numbers of years that annual HRR deviates from Target.
  - a. Green Light (below Target for  $\leq 2$  years).
  - b. Red Light (below Target for  $> 2$  years).
3. Each program will have its own HRR target with the following exceptions.
  - a. Nason Creek spring Chinook will use the Chiwawa Target (there are currently no data to calculate a target for Nason Creek spring Chinook).
  - b. Methow and Chewuch spring Chinook will use the greater of their two Targets (they are MetComp stock and evaluated similarly).

**Table 1.** Release numbers and 5-year hatchery replacement rates (HRR) targets for Upper Columbia River Hatchery Programs.

<sup>3</sup> Harvest not included.

## APPENDIX 3: PNI and pHOS Targets and Sliding Scales

Select CPUD, DPUD, and GPUD funded hatchery mitigation programs have PNI management targets, while others do not. Table 1 summarizes management strategies by species and population. Detailed information can be found in the sections that follow. Descriptions provided in the following sections are taken directly from HGMPs and/or issued and draft permits.

**Table 1.** Summary of management strategies by species and population.

| Species        | Population           | Management Strategy                         | Comments                             |
|----------------|----------------------|---|--------------------------------------|
| Spring Chinook | Wenatchee            | Sliding Scale of PNI management             | Details can be found in Section 2.0  |
|                | Methow               | Two—population sliding scale PNI management | Details can be found in Section 3.0  |
|                | Okanogan             | None Currently                              | Details can be found in Section 4.0  |
| Steelhead      | Wenatchee            | Two-zone management.                        | Details can be found in 5.0          |
|                | Methow               | In-development                              | Details forthcoming; Section 6.0     |
|                | Okanogan             | None Currently                              | Details can be found in Section 7.0  |
| Summer Chinook | Wenatchee            | None Currently                              | Details can be found in Section 9.0  |
|                | Methow               | None Currently                              | Details can be found in Section 10.0 |
|                | Okanogan             | 0.67; pHOS 0.30                             | Details can be found in Section 11.0 |
|                | Upper Columbia River | None Currently                              | Details can be found in Section 12.0 |
| Fall Chinook   | Hanford Reach        | 0.67  | Details can be found in Section 13.0 |

### 2.0 Wenatchee Spring Chinook

Wenatchee spring Chinook will be managed according to the sliding scale identified in the Wenatchee Spring Chinook Management Plan (2010) and Permit Numbers 18118 and 18121. The sliding scale is based upon the estimated number of natural origin spring Chinook over Tumwater Dam. As more information becomes available the sliding scale may be adjusted as a result of gaining a better understanding of the pre-spawn mortality rate and carrying capacity.

**Table 2.** Sliding scale of PNI goals based on natural origin spring Chinook run size expected to the Wenatchee River basin. Percentiles are based on adult returns observed between 1999 and 2008.

| Percentile | NOR Run Size |             |       |                             | PNI    |
|------------|--------------|-------------|-------|-----------------------------|--------|
|            | Chiwawa      | Nason Creek | White | Wenatchee River (above TWD) |        |
| >75th      | >372         | >350        | >87   | >910                        | ≥ 0.80 |
| 50% - 75%  | 278-372      | 259-349     | 68-86 | 631-909                     | ≥ 0.67 |
| 25% - 50%  | 209-277      | 176-258     | 41-67 | 525-630                     | ≥ 0.50 |
| 10%-25%    | 176-208      | 80-175      | 20-40 | 400-524                     | ≥ 0.40 |

|       |      |     |     |      |         |
|-------|------|-----|-----|------|---------|
| <10th | <175 | <80 | <20 | <400 | Any PNI |
|-------|------|-----|-----|------|---------|

### 3.0 Methow/ Chewuch Spring Chinook

The following sliding scale (Table 3) is presented in the April 14, 2016 draft Methow Hatchery Spring Chinook Section 10-Draft. It is anticipated that no further changes will be made to the sliding scale prior to issuance of the final permits.

**Table 3.** PUD PNI sliding scale calculations for a range of natural run sizes.

| Natural Origin Returns | PUD pHOS                             | WNFH pHOS | PUD pNOB | 2-Pop PNI | PUD PNI (equation) |
|------------------------|--------------------------------------|-----------|----------|-----------|--------------------|
| <300                   | Ensure minimum of 500 total spawners |           |          |           |                    |
| 300                    | 0.40                                 | 0.2       | 0.75     | 0.67      | 0.67               |
| 500                    | 0.40                                 | 0.2       | 0.80     | 0.68      | 0.76               |
| 900                    | 0.30                                 | 0.15      | 1.00     | 0.78      | 0.80               |
| 1500                   | 0.25                                 | 0.1       | 1.00     | 0.8       | 0.80               |
| 2000                   | 0.25                                 | 0.1       | 1.00     | 0.8       | 0.80               |
| 2500                   | 0.25                                 | 0.1       | 1.00     | 0.8       | 0.80               |

### 4.0 Okanogan Spring Chinook

The Okanogan spring Chinook program is a re-introduction effort implemented as a non-essential experimental population under ESA Section 10j to re-introduce spring Chinook into the Okanogan River. As a non-essential experimental population targeting re-introduction and establishment of a local population of spring Chinook, the Okanogan spring Chinook program will not conduct adult management actions to reduce the proportion of 10j hatchery fish on the spawning grounds or conduct broodstocking efforts in the Okanogan for a 10-year period (2014 – 2023), as such, no PNI or pHOS objectives have been identified for this program in this 10-year period.

CJH Program segregated production released into the mainstem Columbia River are non-listed Leavenworth stock released reared/acclimated/released at CJH. Although no PNI or pHOS targets are identified for the Okanogan 10j population, minimizing strays from the CJH segregated spring Chinook program is a program objective, as such, returning segregated program fish will be subject to directed harvest and aggressive adult surplus at CJH to minimize straying to the Okanogan River Basin as well as other extant upper Columbia River spring Chinook populations. Stray targets for the segregated program are 5% or less stray rate (i.e. spawning contribution to other upper Columbia River spring Chinook populations).

### 5.0 Wenatchee Steelhead

Interim escapement goal for Wenatchee River steelhead will be 1,500 spawners with an additional goal of attaining an average PNI of 0.67 for the Wenatchee River basin population as a whole. To achieve the stated goal, the Wenatchee steelhead program will use a two-zone management approach wherein the upper basin (above TWD) will be managed for recovery using an integrated recovery program, a separate spawning escapement goal, and a PNI standard to achieve the overall basin goal of an average PNI over time of 0.67 (Table 4). Areas below TWD will be managed to minimize hatchery supplementation with a pHOS goal of < 0.10.

Steelhead returning upstream of TWD will be managed as an integrated recovery program with a pNOB goal of 1.0. The above TWD escapement goal will be 1,094 spawners. Working within this framework, pNOB will be maximized above TWD while pHOS will be minimized.

**Table 4.** Wenatchee steelhead two-zone management and PNI targets.

| Location    | Run Escapement Goal | pNOB Conservation Program | pNOB Safety Net Program | pHOS    | PNI            |
|-------------|---------------------|---------------------------|-------------------------|---------|----------------|
| Above TWD   | 1,094               | 1.0                       | 0.0                     | Varies  | Varies         |
| Below TWD   | 406                 | N/A                       | N/A                     | < 0.10  | < 0.67         |
| Basin Total | 1,500               | N/A                       | N/A                     | Minimal | Average = 0.67 |

## 6.0 Methow Steelhead

Methow steelhead PNI targets are currently in development.

## 7.0 Okanogan Steelhead

Current program has no PNI goal. CTCR submitted an Okanogan steelhead HGMP to NOAA Fisheries on February 4, 2014. Within the HGMP provisions were included to allow a greater collection of natural-origin broodstock and multiple adult management strategies to address over-escapement of hatchery-origin steelhead to the spawning grounds. The HGMP also identified a near-term (1-4 years) and a long-term PNI objectives of 0.50 and > 0.67, respectively. Once NOAA has completed the consultation and issued a new permit, providing the opportunity to increase the proportion of natural-origin fish in the broodstock and additional adult management strategies, the program will adopt the PNI objectives and this Appendix can be amended accordingly.

## 8.0 Wells Columbia Mainstem Safety-net Steelhead

The Safety-Net Mainstem Columbia component released below Wells Dam will be managed primarily at the Wells Hatchery volunteer channel. The objective of the adult management of the Safety-Net Mainstem Columbia component is to prevent runs of this component from moving into natural spawning areas. This will be accomplished through in-river harvest and removal of volunteers at the Wells Hatchery outfall. There are no PNI goals for this component.

## 9.0 Wenatchee Summer Chinook

No PNI goals are established.

## 10.0 Methow Summer Chinook

No PNI goals are established.

## 11.0 Okanogan Summer Chinook

Okanogan summer/fall Chinook will be managed to achieve a 5-year rolling average PNI of 0.67 and pHOS of 0.30. Strategies to achieve that PNI target include up to 100% pNOB, aggressive removal of hatchery-origin Chinook in selective fisheries, at the Okanogan weir, and during surplus at CJH ladder. Reduction in the number of juveniles released in the Okanogan River Basin (integrated program) is also a management option, should adult management actions be unable to control the proportion of hatchery fish on the spawning grounds to achieve that PNI target.

CJH segregated summer/fall Chinook program rears/acclimates/releases smolts into the mainstem Columbia River at CJH. Broodstock are 100% hatchery-origin, as such no PNI target for this production component. Stray rate (i.e. contribution to upper Columbia summer/fall Chinook populations) is 5% or less. Adult management on returning adults from the segregated program include fisheries, removal at the Okanogan weir, and removal at the CJH ladder.

### **12.0 Upper Columbia Summer Chinook (Chelan Falls and Wells)**

No PNI goals are established. Chelan Falls and Wells FH summer Chinook programs are segregated harvest programs designed to provide opportunity for harvest. Adult returns are not intended to spawn naturally; therefore, there is no escapement goal for natural spawning areas. Adult returns will be managed to meet program objectives. Chelan Falls and Wells Hatchery summer Chinook are available for harvest in the ocean and Columbia River commercial, tribal, and recreational fisheries.

### **13.0 Priest Rapids Fall Chinook**

The Hanford Reach fall Chinook population is intentionally supplemented by Grant PUD at the Priest Rapids Hatchery and the ACOE at the Priest Rapids and Ringold Springs hatcheries. Managers desire to achieve a population level PNI that includes all hatchery programs of  $\geq 0.67$ . Grant PUD and the HSC do not have control over operation or expansion of the ACOE program and therefore will strive to operate the Priest Rapids Hatchery fall Chinook program in a way that does its fair share of achieving a population level PNI of 0.67.

## APPENDIX 4: SPATIAL DISTRIBUTION OF SPAWNERS OR REDDS

Strategies for conservation programs typically intend that hatchery and naturally produced fish spawn together and in similar locations. However, in some cases, strategies may differ from this paradigm. In Table 1, conservation programs that have a spatial distribution management plan that deviates from similar to the natural spawning spatial distributions are presented. Otherwise, conservation programs are intended to have a spawning distribution similar to the natural origin spawning spatial distributions, as described by M&E Objective 5.3.

**Table 1.** Management targets for the spatial distribution of hatchery-origin redds for conservation programs that deviate from Objective 5.3.

| Program                | Target  | Rational   | Source   |
|------------------------|---|--|--|
| Carlton Summer Chinook | The observed spawning distribution of hatchery origin Methow summer Chinook from 2005-2010 represents the base-line spawner distribution for evaluating the performance of the hatchery program (i.e., M&E plan check-ins). It is acknowledged that this distribution is lower in the River than the spawning distribution of natural origin summer Chinook salmon. | Based upon an assessment of summer Chinook and ESA-listed spring Chinook abundance and spawner distribution, it was determined that an increase in summer Chinook spawning abundance in the upper most range of natural origin summer Chinook distribution or potentially above the current range may pose an unknown and potentially adverse impact to ESA listed spring Chinook. Due to the concern for spring Chinook, the HSC has endorsed an acclimation site in the Methow Basin that is lower in the basin than may be required to attain exact replication of natural and hatchery origin summer Chinook spawner distribution. | SOA 2011-02 Priest Rapids Coordinating Committee Hatchery Subcommittee<br>Statement of Agreement on Monitoring & Evaluation (M&E) Objective for Spawning Distribution of Hatchery-Origin Summer Chinook              |
| Dryden Summer Chinook  | The observed spawning distribution of hatchery origin Wenatchee summer Chinook from 2008-2013 (previous 5 years to the current M&E check-in cycle) represents the base-line spawner distribution for evaluating the performance of the  | The primary site endorsed by the HSC for Grant PUD overwinter acclimation of summer Chinook is the Dryden Pond, and is the current acclimation and release site for the existing summer Chinook supplementation program  | Adapted from SOA 2011-02 Priest Rapids Coordinating Committee Hatchery Subcommittee<br>Statement of Agreement on Monitoring & Evaluation (M&E) Objective for Spawning Distribution of Hatchery-Origin Summer Chinook |

|  |  |  |  |
|--|--|--|--|
|  | hatchery program (i.e., M&E plan check-ins). | funded and owned by Chelan PUD. Because current data indicates that spawning distribution of hatchery summer Chinook from the existing program is lower in the Wenatchee River than natural origin spawners, expectations are that acclimation of Grant PUD's summer Chinook at Dryden Pond would continue to return hatchery origin summer Chinook that result in different spawning distributions for hatchery and natural summer Chinook. |  |
|--|--|--|--|

## APPENDIX 5: WITHIN HATCHERY REARING TARGETS

Rearing Targets for Upper Columbia River Hatchery Programs. K-factor or fork length targets will be determined based on data from the pending “Five-Year Report.”

**Table 1.** Numbers, fish per pound (fpp), coefficient of variation (CV), and condition factor (K) targets at release of Upper Columbia River Hatchery Programs.

| Hatchery     | Species        | Life Stage  | Basin     | Release number        | FPP             | CV  | K-factor |
|--------------|----------------|-------------|-----------|-----------------------|-----------------|-----|----------|
| Methow       | Spring Chinook | Yearling    | Methow    | 193,765 <sup>1</sup>  | 15              | <10 | TBD      |

| Dryden       | Summer Chinook | Yearling    | Wenatchee | 500,001               | 18              | 9.0 | TBD      |
| Priest       | Fall Chinook   | Subyearling | Columbia  | 7.3 M <sup>8</sup>    | 50              | <10 | TBD      |
| Ringold      | Fall Chinook   | Subyearling | Columbia  | 3.5 M                 | 50              | <10 | TBD      |

<sup>1</sup> The total release includes the release of 108,249 into the Methow River at the Methow Fish Hatchery, 25,000 into the Methow River at the Goat Wall site, and 60,516 into the Chewuch River at the Chewuch Acclimation Facility.

<sup>2</sup> These fish come from Winthrop National Fish Hatchery (MetComp) eyed eggs.

<sup>3</sup> The total release includes 125,000 conservation fish and 98,670 safety net fish.

<sup>4</sup> The combined Okanogan and Omak steelhead release number is 100,000.

<sup>5</sup> The total release includes 66,771 fish into Nason Creek, 53,170 into the Chiwawa River, 102,359 into the Wenatchee River, and 25,000 into Blackbird Pond.

<sup>6</sup> The Wells subyearling Chinook are not reared to achieve a specific size target. The fish are released on a date to optimize survival and are grown to the largest size possible before release.

<sup>7</sup> The total release is divided equally among the Omak, Riverside, and Similkameen Acclimation Ponds.

<sup>8</sup> The total release consists of 5.6 m fall Chinook for the Grant PUD program and 1.7 M fall Chinook for the Army Corps of Engineers program.

## APPENDIX 6: IDENTIFYING AND ANALYZING REFERENCE POPULATIONS

An important goal of supplementation is to increase spawning abundance and natural-origin recruitment of the supplemented population, and not reduce the productivity of the supplemented population. Indeed, a successful supplementation program must increase spawning abundance and natural-origin recruitment to levels above those that would have occurred without supplementation. There are several methods that can be used to test the effects of supplementation programs on these population metrics. One important method is to compare the performance of population metrics (e.g., spawning abundance, natural-origin recruitment, and productivity) in the supplemented population to those in un-supplemented (reference) populations. By comparing supplemented populations to reference populations, one can determine if the supplementation programs benefit, harm, or have no effect on the supplemented populations. These comparisons, however, are only valid if the performance of the reference populations is similar to the performance of the supplemented population prior to the period of supplementation. If the performance of the two populations differs significantly before any supplementation occurs, then any results from comparing the two populations after supplementation will be suspect. It is therefore important to select reference populations that are as similar as possible to the supplemented populations.

One of the goals of the Conceptual Approach to Monitoring and Evaluating the Chelan County PUD Hatchery Programs (Murdoch and Peven 2005) is to use reference populations to analyze the potential effects of hatchery supplementation programs on natural-origin salmon and steelhead spawner abundance and productivity<sup>15</sup>. Murdoch and Peven (2005) identified specific objectives to evaluate the performance of the program. For example, Objective 1 determines if the supplementation programs have increased the number of naturally spawning and naturally produced adults of the target population (supplemented population) relative to a reference population. Objective 7 determines if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity (e.g., number of juveniles per redd) of supplemented streams when compared to reference streams. The relevant questions tested under each objective are as follows:

### Objective 1:

- Is the annual change in the number of natural-origin recruits produced from the supplemented populations greater than or equal to the annual change in natural-origin recruits in an un-supplemented population?
- Is the change in natural replacement rates within the supplemented population greater than or equal to the change in natural replacement rates in an un-supplemented population?

### Objective 7:

---

<sup>15</sup> Productivity is defined as adult recruits per spawner, where recruits are the number of adults produced from a given brood year (i.e., spawners plus adults harvested).

- Is the change in numbers of juveniles (smolts, parr, or emigrants) per redd in the supplemented population greater than or equal to that in an un-supplemented population?<sup>16</sup>

In this paper, we describe methods used to identify suitable reference streams and statistical techniques that can be used to compare reference populations with supplemented populations. Although we apply the methods described in this paper to Chiwawa spring Chinook salmon (hereafter referred to as Chinook), the methods should also apply to steelhead and other supplemented salmon stocks in the Upper Columbia Basin.

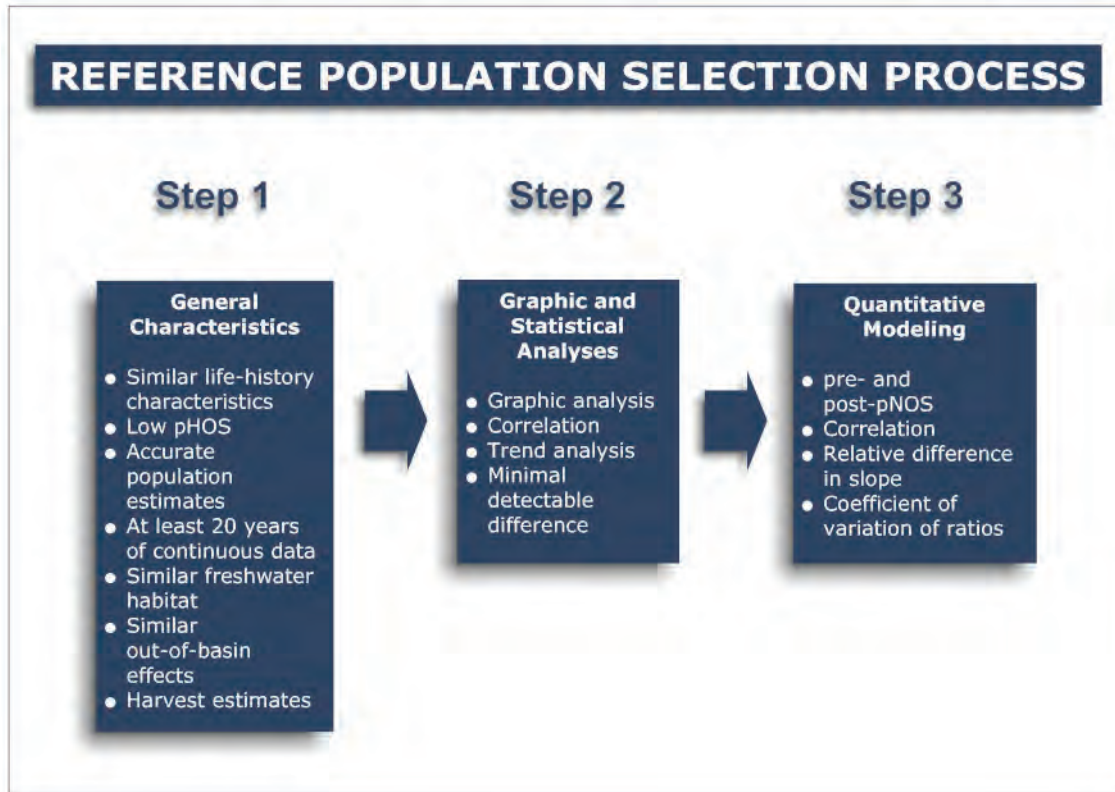

## Identification of Reference Populations

Reference populations are an important component of an effectiveness monitoring design because they provide the standard by which treatment conditions are compared (ISRP and ISAB 2005; Murdoch and Peven 2005; Galbreath et al. 2008). Selecting appropriate reference areas and maintaining them over long periods of time is needed to establish the effectiveness of supplementation programs.

We developed a three-step process for identifying suitable reference populations (Figure 1). Each step serves as a filter. That is, potential reference populations are evaluated based on specific criteria under each step. Populations that pass through each step are considered suitable reference populations for a specific supplemented population.

---

<sup>16</sup> In this paper, we only address adult recruits, not juvenile recruits. This is because we were unable to find suitable reference populations for analysis of juveniles. However, the methods described in this paper would also apply to juveniles.

**Figure 1.** Criteria evaluated during each step in the process of identifying suitable reference populations.

### Step 1: General Characteristics

Under step 1, potential reference populations are evaluated based on several general criteria. When compared to the supplemented population, potential reference populations should have:

- Similar life-history characteristics (e.g., run timing, migration characteristics, etc.).
- No or few hatchery fish in the reference area (pHOS < 10%).
- Accurate abundance estimates.
- Long time series of natural-origin abundance and productivity estimates (at least 20 years of continuous data).
- Similar trends in freshwater habitat.
- Similar out-of-basin effects (i.e., similar migration and ocean survivals).
- Harvest estimates for adjusting escapement estimates.

We used these criteria to begin the process of selecting suitable reference populations for the Chiwawa spring Chinook program. We began by identifying stream-type Chinook populations within the Columbia Basin. Galbreath et al. (2008; their Table 1) identified stream-type Chinook populations within the Columbia River Basin that may serve as suitable reference populations for hatchery programs. Supplementing their work with data from the NOAA Fisheries Salmon Population Summary Database, we identified 18 candidate stream-type Chinook populations that may serve as reference populations for the Chiwawa supplementation program (Table 1).

**Table 1.** Populations of stream-type Chinook salmon and their comparison to Chiwawa spring Chinook.

| Population             | Similar life-history | No or few hatchery fish | Accurate abundance estimates | Long time series (at least 20 years) | Similar freshwater habitat impairments | Similar out-of-basin effects | Comments                |
|------------------------|----------------------|-------------------------|------------------------------|--------------------------------------|--|------------------------------|-------------------------|
| Deschutes River        | Yes                  | Yes                     | Yes                          | Yes                                  | No                                     | No                           |                         |

| Naches River           | Yes                  | Yes                     | Yes                          | Yes                                  | Yes                                    | No                           |                         |
| Little Wenatchee River | Yes                  | No                      | Yes                          | Yes                                  | Yes                                    | Yes                          | Hatchery strays (>10%)  |
| Entiat River           | Yes                  | No                      | Yes                          | Yes                                  | No                                     | No                           | Hatchery release ending |

We then assessed the accuracy and length of the series of abundance estimates. We assumed that abundance estimates generated from expanded redd counts or adjusted weir counts would compare well with estimates in the Chiwawa Basin, which were based on expanded redd counts. In addition, we looked for populations that had an abundance data series that extended from at least 1981 to present. Based on this analysis, we identified 18 populations with abundance estimates that could be compared to those from the Chiwawa Basin (Table 1).

Next, we determined if the potential reference populations came from watersheds with habitat conditions similar to those in the Chiwawa Basin. For this exercise, we searched recovery plans and draft recovery plans to identify tributary factors that limit Chinook abundance, productivity, and survival within the reference populations. We compared these factors with those limiting

Chinook salmon in the Chiwawa Basin. Based on this analysis, we identified eight populations with habitat impairments similar to those in the Chiwawa Basin (Table 1).

Finally, we examined the potential reference populations to see if they experienced out-of-basin effects similar to spring Chinook from the Chiwawa Basin. In this case, we compared the number of mainstem dams that each potential reference population passes during migration. Six of the potential reference populations pass less than six mainstem dams; the other populations pass eight mainstem dams (Table 1). Only the Little Wenatchee population passes seven dams, similar to the Chiwawa population.

In sum, there were no reference populations that matched the Chiwawa spring Chinook population on all the criteria identified above. Differential out-of-basin effects and freshwater habitat conditions prevented most reference populations from matching with Chiwawa spring Chinook. However, some of the potential reference populations were similar to the Chiwawa population on several criteria and warranted further investigation. We selected the following populations for further investigation: Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River.

We included the Little Wenatchee because it is within the Wenatchee River basin and experiences similar out-of-basin effects and has the same climatic and environmental conditions as the Chiwawa. A confounding effect with the Little Wenatchee is that Chiwawa hatchery fish have strayed into the Little Wenatchee. However, straying of Chiwawa hatchery fish should decrease with the change in source water to the Chiwawa acclimation ponds in 2006. We also included the Entiat River because it is an adjacent basin to the Chiwawa and experiences similar climatic and environmental conditions. The spring Chinook hatchery program that has operated in the Entiat since 1975 has been discontinued. Therefore, this population offers a unique opportunity to compare the Chiwawa population to a population in which the hatchery program has been discontinued.

## **Step 2: Graphic and Statistical Analysis**

### Graphic Analysis

Although we were unable to find potential reference populations that matched with the Chiwawa population on all criteria considered under Step 1, spawner abundance, natural-origin recruits (NORs), and productivity of some of the potential reference populations may nevertheless track closely with the Chiwawa population. If the time series of abundance, NORs, and productivity of a potential reference population tracks closely with the abundance, NORs, and productivity of the Chiwawa population, the reference population may provide a reasonable reference condition for testing the effects of supplementation on the Chiwawa population.

Under Step 2, we used graphing techniques to examine the relationship of abundance, NORs, and productivity between the Chiwawa population and the five reference populations (Sesech River, Marsh Creek, Naches River, Little Wenatchee, and Entiat River). We compiled spawner abundance, NORs, and productivity data from local biologists and the NOAA Fisheries Salmon Population Summary Database. We then compared time series plots of spawner abundance, NORs, and productivity data of potential reference populations with the Chiwawa population (Figures 2, 3, and 4; plots on the left side of figures). The time series only included the period 1981 to 1992, which represented the period before supplementation of the Chiwawa population (pre-treatment period). We also plotted the relationship between the abundance, NORs, and productivity of each

potential reference population to the Chiwawa population (Figures 2, 3, and 4; plots on right side of figures). These plots show whether the reference populations closely tracked the Chiwawa population. As a point of reference, data points that fall along the dashed line would represent a perfect relationship between the two populations (i.e., both populations have identical abundance, NORs, and productivity estimates). While a perfect relationship between two independent populations is unrealistic, a strong linear relationship between the two populations indicates populations with similar trends.

Based on analysis of spawner abundance, the Naches River time series tracked more closely with the abundance of Chiwawa spring Chinook than did the other potential reference populations. The poor relationship with the other potential reference streams was largely because of the relatively high abundance of Chiwawa spring Chinook during the mid-1980s. As with spawner abundance, analyses of NORs indicated a close relationship between the Naches and Chiwawa populations. The other potential reference populations tracked poorly with the Chiwawa. The analyses of productivity indicated close relationships between potential reference populations and the Chiwawa population. The Naches, Sesech, and Little Wenatchee populations tracked the closest with the Chiwawa population.

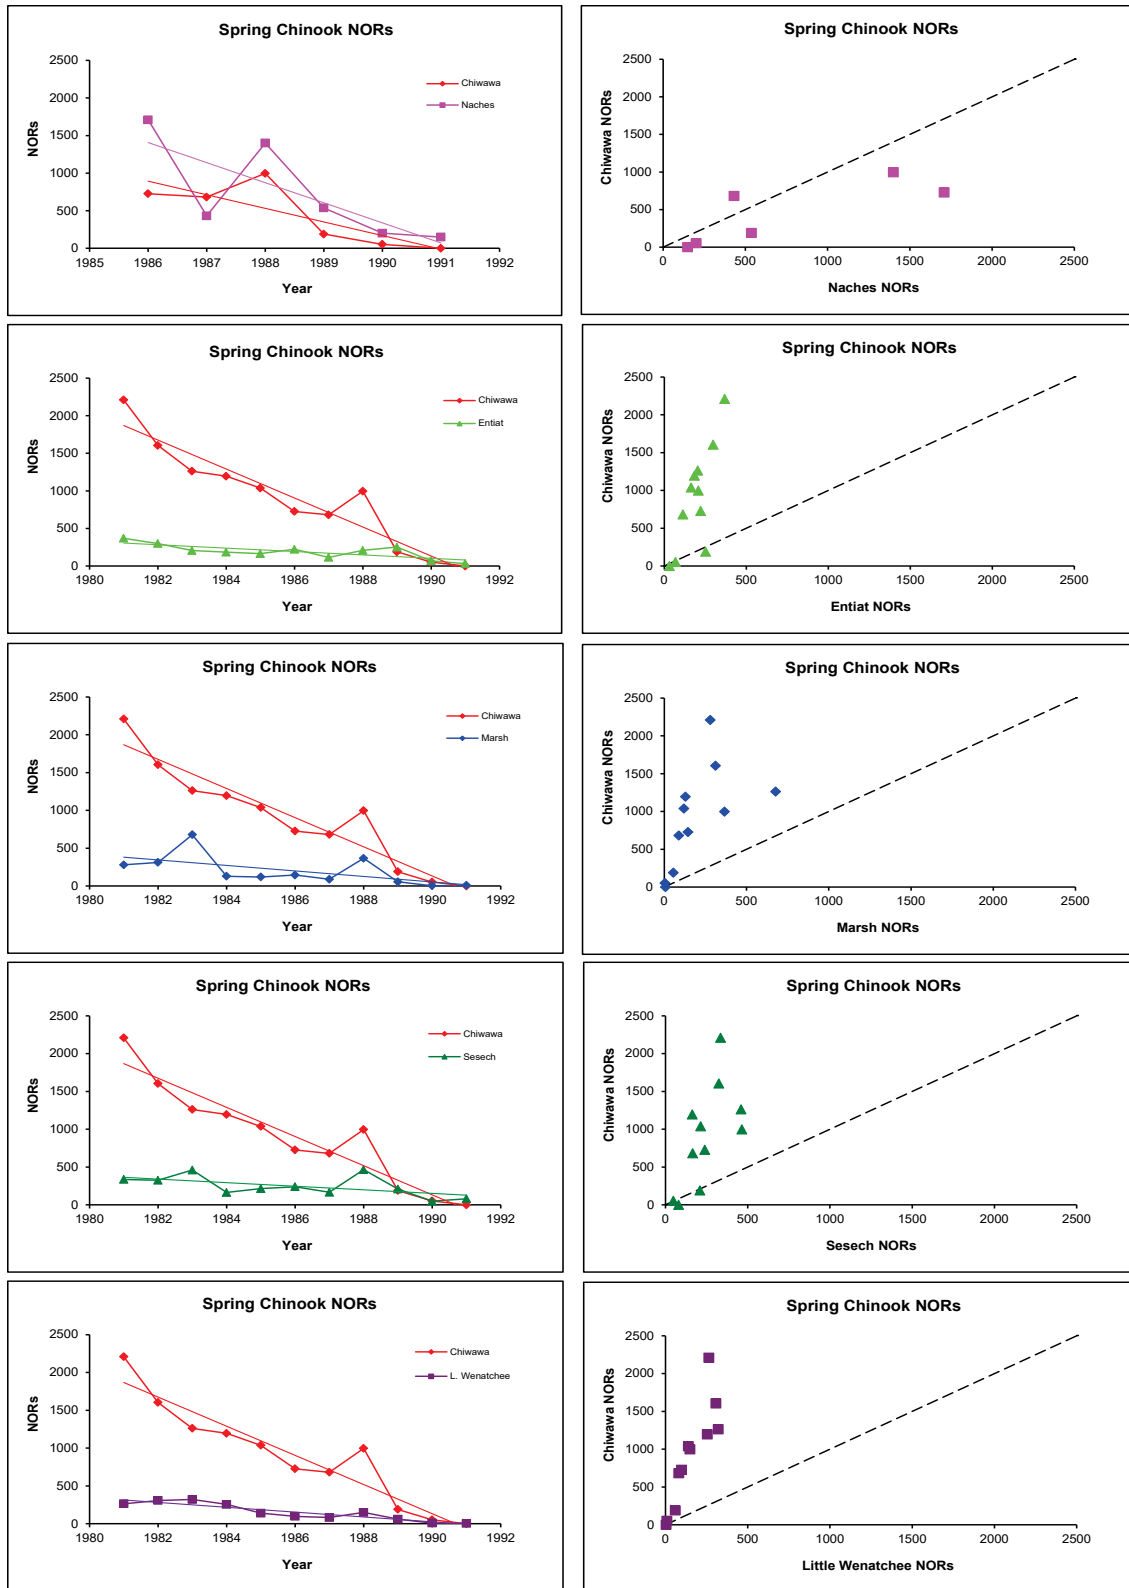

When analyzing the potential effects of a supplementation program on fish performance, it is common to transform the data to meet various assumptions of statistical analysis. The most common transformation used to adjust abundance, NORs, and productivity data is the natural logarithm (LN or  $\log_e$ ). We therefore transformed the spawner abundance, NORs, and productivity data using LN and re-plotted the relationships between the potential reference populations and the Chiwawa population (Figures 5, 6, and 7). We added 1 to each observation before taking its logarithm to avoid taking the logarithm of 0, which is undefined (note that the LN of 1 is 0).

By transforming spawner abundance, NORs, and productivity data, most of the potential reference populations tracked more closely with the Chiwawa population. The Naches, Entiat, and Little Wenatchee abundance data tracked the closest with the Chiwawa abundance data (Figure 5). For NORs, Marsh Creek and the Little Wenatchee populations tracked the closest with the Chiwawa (Figure 6). For productivity, the Naches, Sesech, and Little Wenatchee tracked the closest with the Chiwawa (Figure 7).

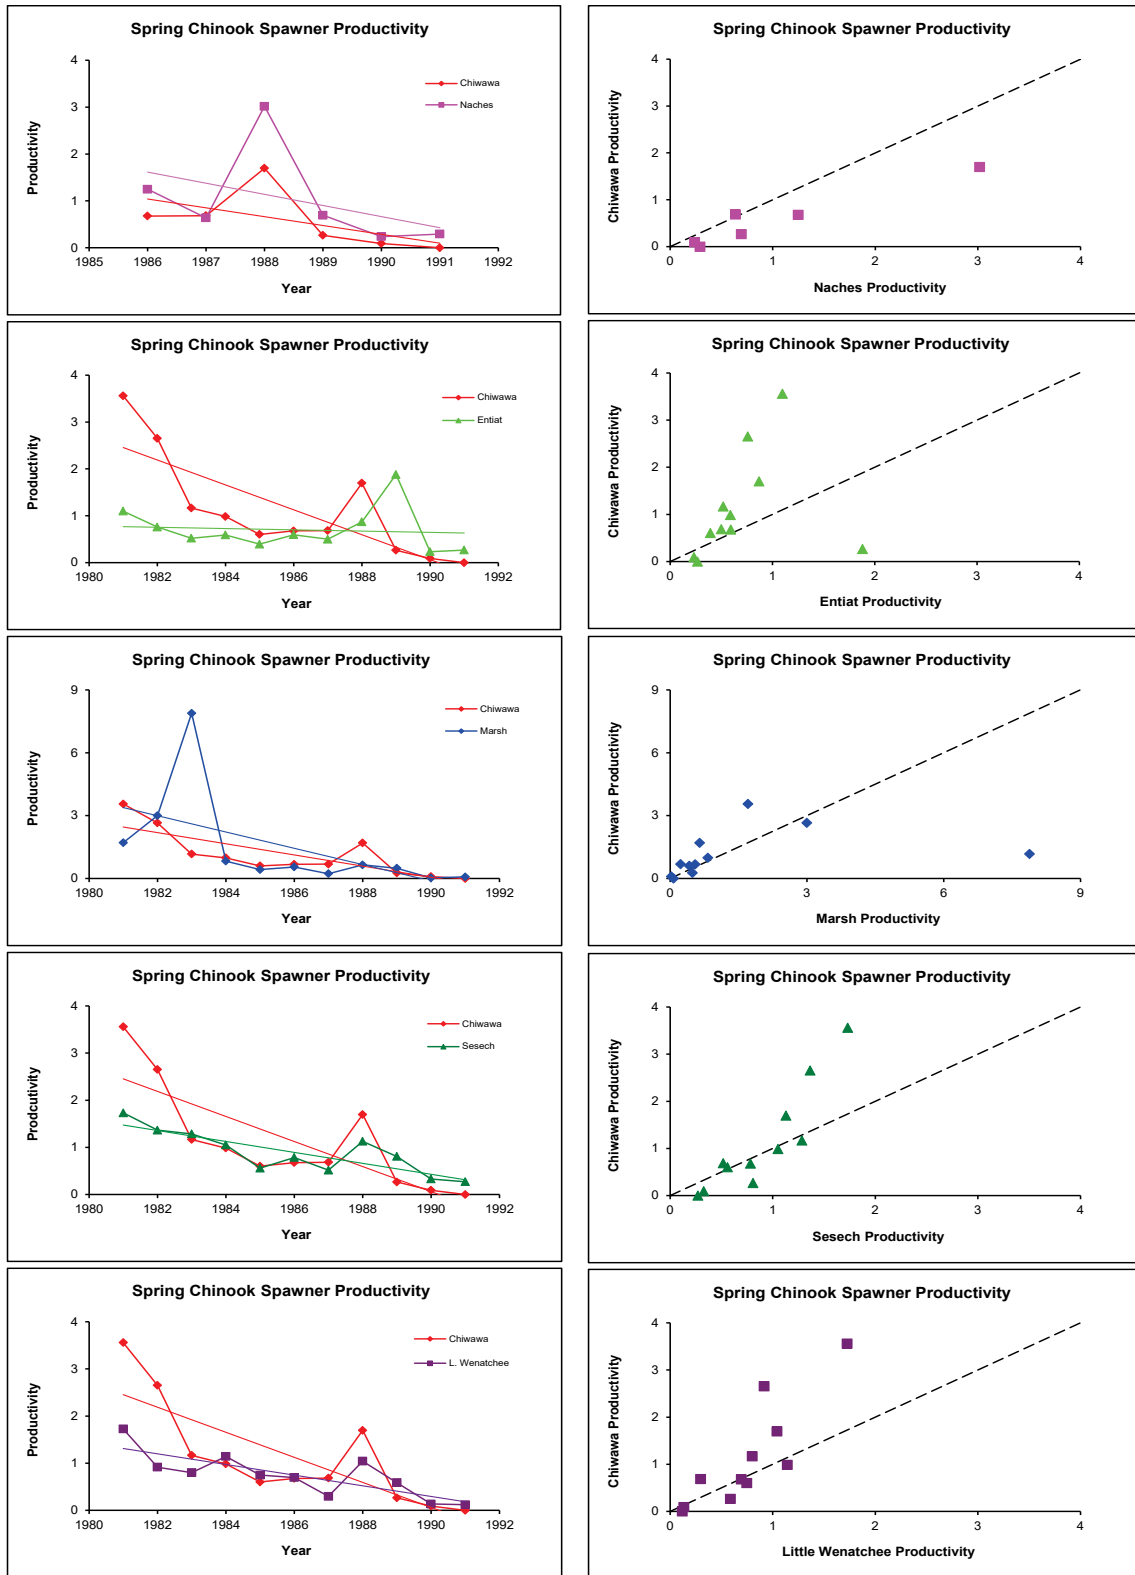

**Figure 2.** Time series of spawner abundance of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

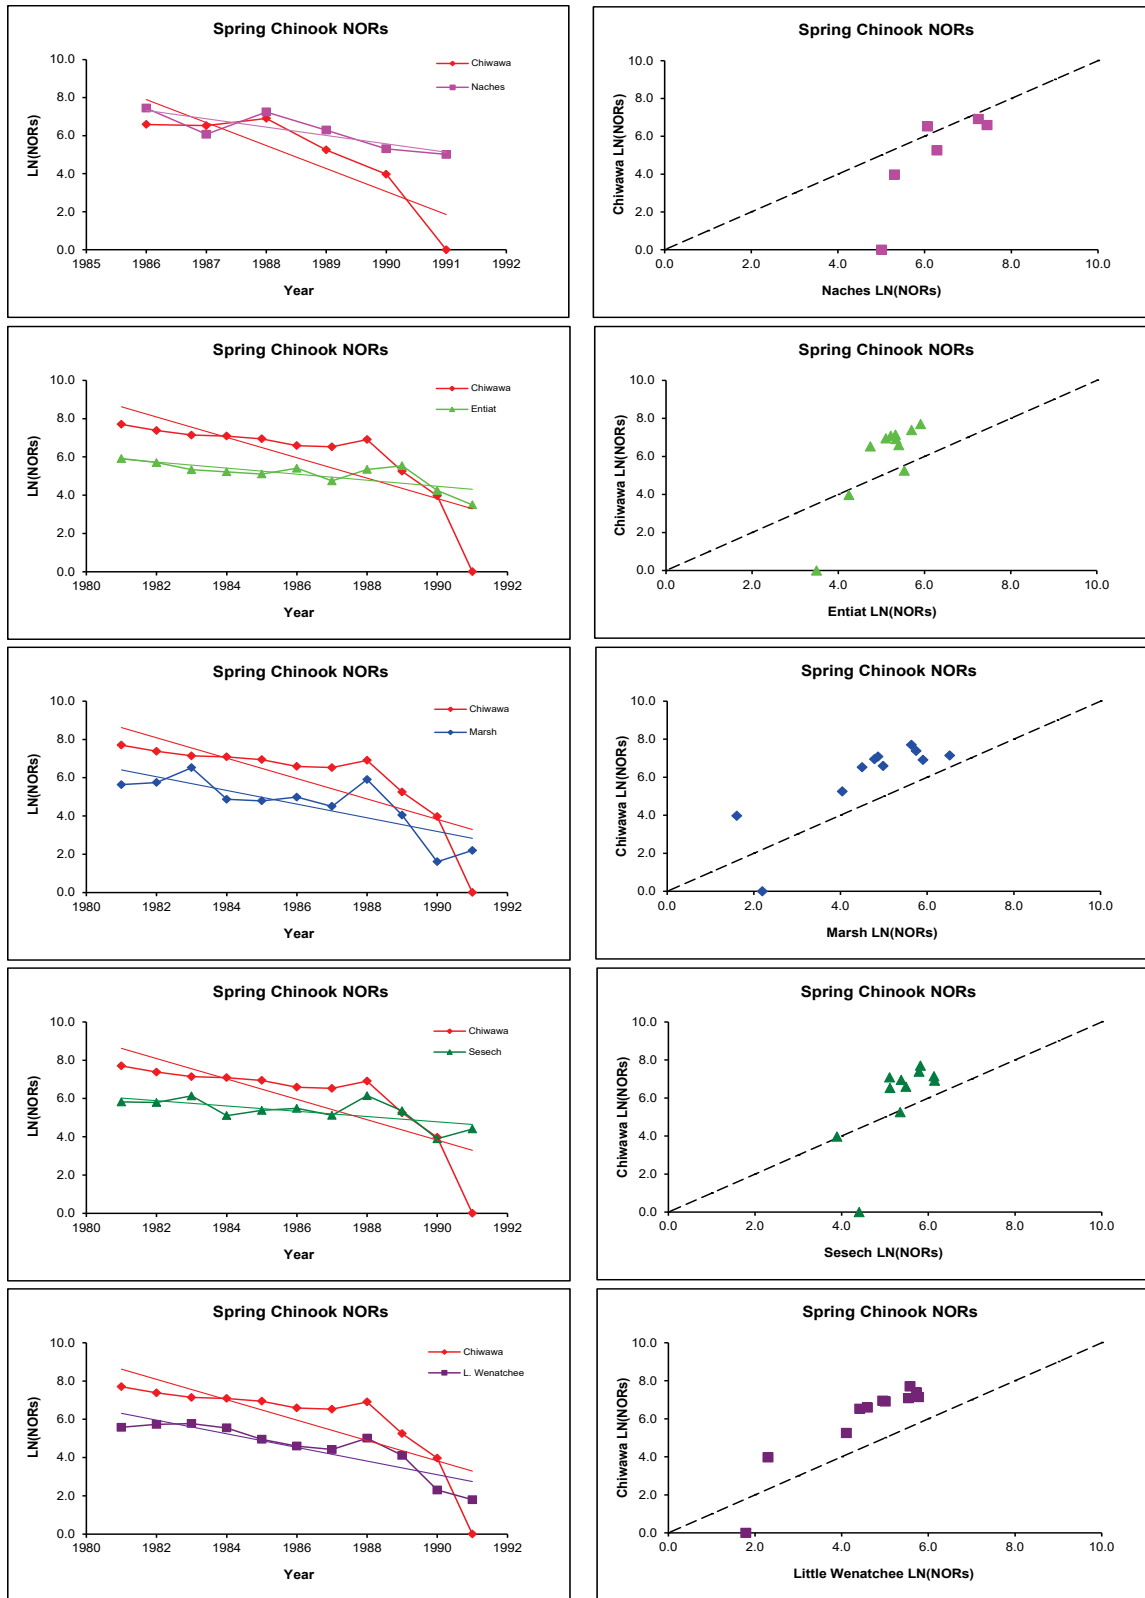

**Figure 3.** Time series of natural-origin recruits (NORs) of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

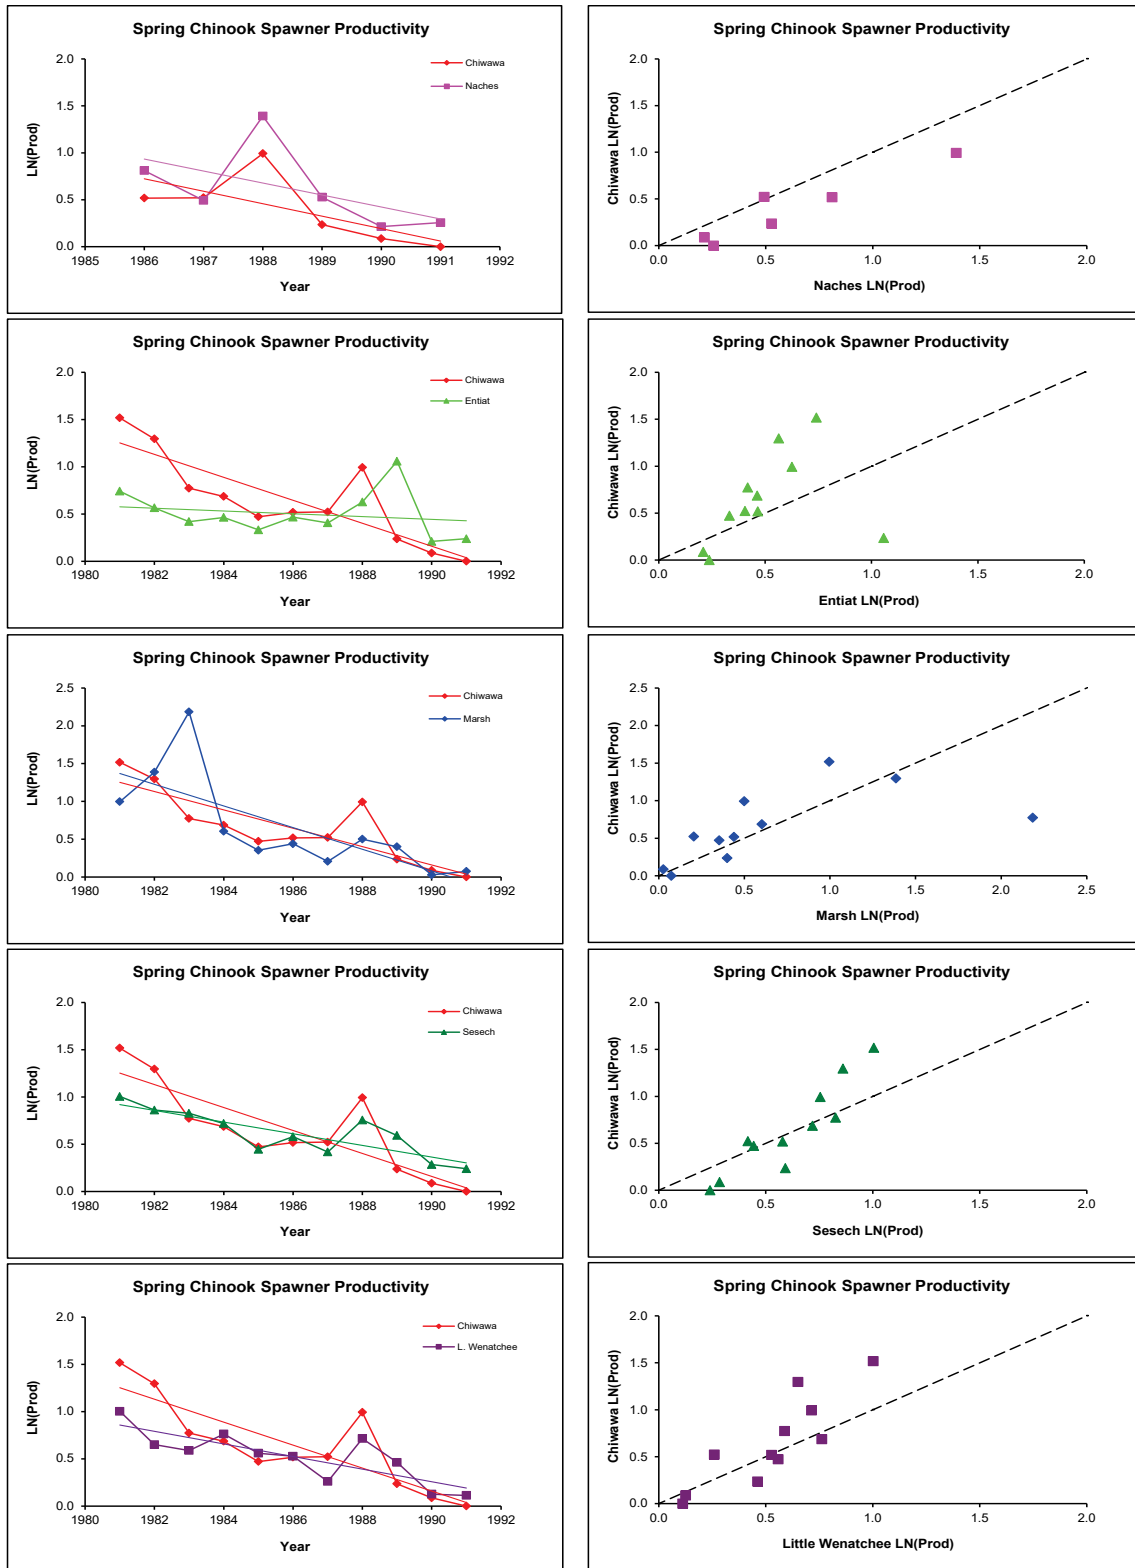

**Figure 4.** Time series of adult productivity of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

**Figure 5.** Time series of natural log spawner abundance of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

**Figure 6.** Time series of natural log natural-origin recruits (NORs) of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

**Figure 7.** Time series of natural log adult productivity of potential reference populations and the Chiwawa spring Chinook population before the Chiwawa population was supplemented with hatchery fish.

### Correlations and Trends

Other methods for evaluating the suitability of potential reference populations under Step 2 include correlation and trend analyses. For correlation analysis, we simply calculated the Pearson correlation coefficient, which is an index of the strength of the association between the potential reference populations and the Chiwawa population. The coefficient ranges from -1 to 1, where a value near 1 or -1 represents that strongest association between the populations. A value of 0 means no association. We used only spawner abundance, NORs, and productivity data during the pre-treatment period (1981-1992). We assumed that populations with coefficients greater than 0.6 represented reasonable reference conditions.

For trend analyses, we used least squares techniques to compute a straight-line trend through the spawner abundance and productivity data for the potential reference populations and the Chiwawa population. Trends were fit to the pre-treatment time series data (1981-1992). We then used t-tests to determine if the slopes of the trends between potential reference populations and the Chiwawa population differed significantly.

It is important to note that time-series trend analyses are susceptible to temporal correlations in the data. Autoregressive integrated moving average (ARIMA) models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). However, these models require a long time series ( $N > 40$ ) and therefore we could not use them to model the spring Chinook data. As such, we were unable to correct for any temporal correlation that may exist within the time series.

Tests of correlation with spawner abundance data indicated that the Naches River closely correlated with the Chiwawa population (Table 2). There was no difference in abundance trends between the potential reference populations and the Chiwawa population (Table 2; Figure 2). For NORs, all potential reference populations correlated with the Chiwawa population (Table 2). However, trends in NORs of all reference populations, except Naches, differed significantly from the Chiwawa population (Table 2; Figure 3). For productivity, the Naches, Sesech, and Little Wenatchee correlated with the Chiwawa population (Table 2). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 2; Figure 4).

**Table 2.** Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (\*) indicates significance at  $P < 0.05$ .

| Reference populations          | Pearson correlation coefficient | t-test on slopes |      |         |
|--------------------------------|---------------------------------|------------------|------|---------|
|                                |                                 | t-value          | d.f. | P-value |

We also ran correlation and trend analyses on natural-log transformed spawner abundance, NORs, and productivity data. These analyses indicated that the Naches, Entiat, and Little Wenatchee abundance data correlated with the Chiwawa population data (Table 3). None of the abundance trends of the potential reference populations differed significantly from the Chiwawa population trend (Table 3; Figure 5). For NORs, all potential reference populations correlated with the Chiwawa population (Table 3). Only trends in NORs of the Entiat and Sesech differed significantly from the Chiwawa population (Table 2; Figure 6). For productivity, the Naches, Marsh, Sesech, and Little Wenatchee correlated with the Chiwawa population data (Table 3). Only the Entiat productivity trend differed significantly from the Chiwawa population trend (Table 3; Figure 7).

**Table 3.** Pearson correlation coefficients and t-test results comparing slopes of trends between potential reference populations and the Chiwawa spring Chinook population; d.f. = degrees of freedom and for correlation coefficients, an asterisk (\*) indicates significance at  $P < 0.05$ . Analyses were conducted on natural-log transformed abundance and productivity data.

In summary, based on correlation, trend, and graphic analyses, the Naches, Entiat, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. For NORs, the Naches, Marsh, and Little Wenatchee appear to be reasonable reference populations. For productivity, the Naches, Marsh, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for the Chiwawa population.

#### Minimal Detectable Differences (MDD)

Given a suite of potential reference populations, it is important to conduct power analyses to determine the minimum differences that can be detected when comparing the reference populations to the supplemented population. As a final exercise under Step 2, we examined potential reference populations for the smallest minimal detectable differences. Before conducting power analyses, several decisions needed to be made, including what statistical procedures will be used to analyze the data, the desired level of statistical power (probability of rejecting a false null hypothesis), the size of the type-I error (the probability of rejecting a true null hypothesis of no difference), and the number of samples (i.e., years) included in the analysis. In this case, the number of samples represents the number of treatment (supplementation) years. The number of pre-treatment years (1981-1992) was based on the number of years of quality data available for Chiwawa spring Chinook and potential reference populations.

We designed the study as a modified BACI (Before-After, Control-Impact) design, which includes replication before and after supplementation in both the treated (T) population and the reference (R) populations. A common approach used to analyze data from BACI designs includes analysis of difference scores (Stewart-Oaten et al. 1992; Smith et al. 1993). Differences are calculated between paired treatment and reference population scores (i.e., T-R). Another approach is to calculate ratios (treatment/reference; T/R) for paired treatment and reference population scores (Skalski and Robson 1992). Finally, differences in annual changes in paired treatment and reference population scores can be calculated (i.e.,  $\Delta T - \Delta R$ ) (Murdoch and Peven 2005; Hays et al. 2006).<sup>17</sup> These derived difference and ratio scores are then analyzed for a before-after treatment effect with a two-sample t-test, Aspin-Welch modification of the t-test, or a randomization test. For power analyses, we calculated minimal detectable differences assuming the use of an independent two-sample t-test with a type-I error rate of 0.05, power of 0.80 (beta or type-II error rate of 0.20), and sample sizes (treatment years) of 5, 10, 15, 20, 25, and 50 years.

<sup>17</sup> The difference of annual difference scores was estimated by first subtracting the population parameter (e.g., spawner abundance) in year 2 from year 1. This continues for all years in the data series for both treatment ( $T_{t+1} - T_t$ ) and reference populations ( $R_{t+1} - R_t$ ). We then calculated differences between paired treatment and reference annual difference scores [ $(T_{t+1} - T_t) - (R_{t+1} - R_t) = \Delta T - \Delta R$ ].

The power analysis calculated the minimal detectable difference between mean difference or ratio scores before and during supplementation. We used existing data to calculate variances for the pre-supplementation and supplementation periods. Thus, variances were known and unequal. For both spawner abundance and NORs, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was less than the mean difference during supplementation (one-tail test; Difference < 0). For productivity, the null hypothesis tested was that the mean difference or ratio before supplementation equaled the mean difference or ratio during supplementation. The alternative hypothesis was that the mean difference or ratio before supplementation was greater than the mean difference during supplementation (one-tail test; Difference > 0).

Based on spawner abundance data, power analysis indicated that the Sesech-Chiwawa pairing consistently produced the smallest detectable differences (Table 4). However, when the abundance data were transformed using natural logs, the Entiat-Chiwawa pairing produced the smallest detectable difference (Table 5). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 334 to 394 adult spawners; transformed data ranged from 0.479 to 1.010. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing spawner abundance data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

**Table 4.** Minimal detectable differences between mean difference and ratio scores before and during supplementation. Analyses were conducted on spawner abundance data.

| Response variable   | Treatment years | Minimal detectable differences by reference population |        |        |        |                  |
|---------------------|-----------------|--|--------|--------|--------|------------------|

Based on NORs, power analysis indicated that the Entiat-Chiwawa, Marsh-Chiwawa, and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 6). When NORs were transformed using natural logs, the Little Wenatchee-Chiwawa pairing produced the smallest detectable difference (Table 7). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 483 to 640 NORs; transformed data ranged from 0.958 to 2.262. These analyses indicate that the Entiat, Marsh, and Little Wenatchee populations appear to be reasonable reference populations for comparing NORs with Chiwawa data.

**Table 6.** Minimal detectable differences between mean difference and ratio scores before and during supplementation. Analyses were conducted on natural-origin recruits.

| Response variable   | Treatment years | Minimal detectable differences by reference population |        |       |        |                  |

Using untransformed productivity data, power analysis indicated that the Little Wenatchee-Chiwawa pairing consistently produced the smallest detectable differences (Table 8). The Marsh-Chiwawa pairings produced the largest detectable differences. When we analyzed natural-log transformed productivity data, the Naches-Chiwawa and Little Wenatchee-Chiwawa pairings produced the smallest detectable differences (Table 9). Minimal detectable differences, based on mean difference scores on untransformed data and a treatment period of 20 years, ranged from 0.754 to 1.839; transformed data ranged from 0.277 to 0.477. These analyses indicate that the Naches, Entiat, Sesech, and Little Wenatchee populations appear to be reasonable reference populations for comparing productivity data with Chiwawa data. The Marsh Creek population produced some of the largest detectable differences and based on these analyses may not be a reasonable reference population.

**Table 8.** Minimal detectable differences between mean difference and ratio scores before and during supplementation. Analyses were conducted on productivity data.

### Step 3: Quantitative Method for Ranking Selection Criteria

Not surprisingly, different selection criteria produced different results (Table 10). Determining whether a given population is or is not a suitable reference population based on selection criteria such as graphic analysis can be subjective. In addition, treating each selection criterion as equally important may not be appropriate. For example, using the information in Table 10, is it appropriate to select a reference population that has two or three “Yes” entries, or should only populations with four “Yes” entries be selected as suitable reference populations? This approach does not allow certain selection criteria to carry more weight in the overall selection process. That is, correlation may be more important than graphic analysis in the overall selection process. In order to reduce

subjectivity, we developed a method of scoring and weighting each selection criterion. This method allows a more quantitative process for selecting suitable reference populations.

**Table 10.** Summary of results from graphic analysis, correlations, trend analysis, and power analysis (minimal detectable differences). “Yes” indicates that the population is a suitable reference population for the Chiwawa population; “No” indicates that it may not be a suitable reference population.

| Potential reference populations | Graphic analysis | Correlation | Trends | Minimal detectable differences |
|---------------------------------|------------------|-------------|--------|--------------------------------|
| <i>Spawner Abundance</i>        |                  |             |        |                                |
| Naches                          | Yes              | Yes         | Yes    | Yes                            |
| Entiat                          | Yes              | Yes         | Yes    | Yes                            |
| Marsh                           | No               | No          | Yes    | No                             |
| Sesech                          | No               | No          | Yes    | Yes                            |
| Little Wenatchee                | Yes              | Yes         | Yes    | Yes                            |
| <i>Natural-Origin Recruits</i>  |                  |             |        |                                |
| Naches                          | Yes              | Yes         | Yes    | No                             |
| Entiat                          | No               | Yes         | No     | Yes                            |
| Marsh                           | Yes              | Yes         | Yes    | Yes                            |
| Sesech                          | No               | Yes         | No     | No                             |
| Little Wenatchee                | Yes              | Yes         | Yes    | Yes                            |
| <i>Productivity</i>             |                  |             |        |                                |
| Naches                          | Yes              | Yes         | Yes    | Yes                            |
| Entiat                          | No               | No          | No     | Yes                            |
| Marsh                           | No               | Yes         | Yes    | No                             |
| Sesech                          | Yes              | Yes         | Yes    | Yes                            |
| Little Wenatchee                | Yes              | Yes         | Yes    | Yes                            |

We developed scoring methods for each of the following five selection criteria:

- (1) The proportion of natural-origin spawners (pNOS) in the reference population for the period before supplementation (pre-pNOS);
- (2) pNOS in the reference population for the period following supplementation (post-pNOS);
- (3) The correlation between the reference and supplemented populations before supplementation;
- (4) The relative difference in slopes between the reference and supplemented populations before supplementation; and
- (5) The coefficient of variation (CV) of the ratio of supplemented to reference populations before the period of supplementation.

Each selection criteria was scored from 0 to 1, with 0 being the worst possible score and 1 being the best.

The pre- and post-pNOS values were calculated as the average pNOS values before and after supplementation, respectively. Because pNOS values range from 0-1, we did not need to rescale

these values. When using reference populations to evaluate the effects of supplementation programs, it is important that the reference populations maintain high values of pNOS throughout the life of the monitoring program. Therefore, we heavily weighted the mean pNOS scores. We assigned weights of 30 and 40 to the mean pre- and post-pNOS scores, respectively. The relatively larger weight for the post-supplementation period is to reduce the likelihood of retaining a reference population that becomes influenced by hatchery fish during the supplementation period.

We assessed the association between the reference and supplemented populations during the pre-supplementation period by calculating the Pearson correlation coefficient, which ranges from -1 to 1. To scale the coefficient between 0 and 1, we took the absolute value of the coefficient. Thus, a coefficient of -0.92 would be reported as 0.92. For our analyses, we were not concerned with the direction of the relationship, only the strength of the relationship. The correlation coefficient was given a weight of 12.5.

As noted earlier, we used least squares to fit a linear trend to each of the reference populations and the supplemented population during the pre-supplementation period. Using the slope estimates for each trend line, we calculated the relative difference in slopes as the slope of the supplemented population minus the slope of the reference population, divided by the slope of the reference population. To scale this value between 0 and 1, we used absolute values, and depending on the direction of the slopes, we subtracted the relative difference from 1. The latter was needed to make sure a larger relative difference value indicated a small difference in slopes between the supplemented and reference populations. The relative difference score was given a weight of 7.5.

Finally, as a means to score effect size, we calculated the CV of the ratio of supplemented to reference population parameters (i.e., T/R). The CV was calculated as the standard deviation of the ratios divided by the absolute value of the mean ratios. The CV was subtracted from 1. This scaled the value from 0 to 1 with larger values representing the best condition. The CV was given a weight of 10, which is greater than the weight for trend, but less than the weight for correlation.

The total score for a reference population was calculated by multiplying the estimated value, which ranged from 0 to 1, by its weight. The sum of the five weighted values provided a total score, which ranged from 0 to 100. Based on several simulations, we set the cut-off score at 81. That is, if the total score for a given reference population equaled or exceeded 81, the population was included as a suitable reference population. If the total score fell below 81, the population was not considered a suitable reference. Based on the distribution of all scores possible, a score of 81 or greater represented only 3% of the total distribution. Thus, a cut-off of 81 is quite conservative.

Under Step 3, we used this method to select the final suite of suitable reference populations. Table 11 shows results from scoring each of the reference populations using the quantitative method. Using the cut-off criterion of 81, only the Naches, Marsh, and Sesech populations would be considered suitable reference populations for the Chiwawa supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values).

**Table 11.** Results from scoring potential reference populations using the selection criteria (pNOS, correlation, trend, and effect size). Populations with scores less than 81 were considered unsuitable as reference populations. Populations with scores equal to or greater than 81 were considered suitable references. These results were based on natural-log transformed data.

| Potential reference populations | Population metric |      |              |
|---------------------------------|-------------------|------|--------------|
|                                 | Abundance         | NORs | Productivity |
| Naches                          | 85                | 88   | 91           |
| Entiat                          | 23                | 21   | 16           |
| Marsh                           | 79                | 91   | 87           |
| Sesech                          | 84                | 85   | 88           |
| Little Wenatchee                | 51                | 53   | 49           |

An important benefit from scoring the different selection criteria is that the total scores can be used to weight the outcome of differing statistical results. For example, analyses may show that when three suitable reference populations are compared to the supplemented population, two of the reference populations may indicate a significant treatment effect, while the third indicates no effect. Under this scenario it is not clear if the supplementation program has or has not affected the abundance or productivity of the supplemented population. If, however, the two reference populations that produced a significant result had higher total scores than the reference population that did not indicate a significant result, one can place more weight on the results from populations with higher total scores.

### Conclusions

The purpose of this exercise was to develop a method for selecting suitable reference populations that could be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity. The selection process included a three-step process (Figure 8). Step 1 identified populations with similar life-history characteristics, few or no hatchery spawners, a long time series of accurate abundance and productivity estimates, and similar freshwater habitat impairments and out-of-basin effects. Populations that met these criteria were then examined for their graphical and statistical relationship with the supplemented population (Step 2). The statistical analysis under Step 2 were converted to a quantitative model (Step 3) that was used to generate a weighted score for pNOS, correlation, trends, and effect sizes for each potential reference population. Reference populations with total scores of 81 or greater were selected as suitable reference populations.

**Figure 8.** Three-step process for selecting suitable reference populations for supplemented populations.

We used this approach to select suitable reference populations for analyzing the effects of the Chiwawa spring Chinook supplementation program on fish abundance and productivity. The method indicated that the Naches, Marsh, and Sesech populations would serve as suitable reference populations for the Chiwawa spring Chinook supplementation program. Both the Entiat and Little Wenatchee populations failed to meet the minimum score, largely because of the influence of hatchery fish within those populations (i.e., relatively low pNOS values). However, because the presence of hatchery spring Chinook within those populations should decrease, they may serve as unique reference populations in which the comparisons change from all populations receiving

hatchery fish to only the Chiwawa population receiving hatchery fish. Therefore, we will continue to include both the Little Wenatchee and Entiat populations in future analyses.

An important assumption in the use of reference populations is that the supplemented and reference populations that tracked each other before supplementation would continue to track each other in the absence of supplementation. Given that the reference populations did not match the Chiwawa population on all criteria examined (Table 1) and some reference populations tracked the Chiwawa population more poorly than others (Figures 2-7; Tables 2-4), there may be some uncertainty as to whether differences observed between the Chiwawa and reference populations during the supplementation period are associated with the hatchery program, “nuisance” factors<sup>18</sup>, or a combination of both. In addition, we have no ability to regulate or control activities in reference areas. Any large-scale change (man-made or natural) in reference areas could affect our ability to assess the effectiveness of the supplementation program.

Because we have no ability to maintain reference areas for long periods of time and may not be able to control all activities even within the supplemented populations, we propose the use of a “causal-comparative” approach to strengthen the certainty of our inferences (Pearsons and Temple 2010). The causal-comparative approach relies on correlative data to try and make a case for causal inference.<sup>19</sup> Correlation is used to rule out alternative hypotheses (note that we make our case as much if not more by disproving plausible alternatives as we do by showing that the data are consistent with a hypothesis). For example, large scale land-use activities or natural events can affect stream flows, fine sediment recruitment, and water temperatures. Changes in these factors can affect the freshwater survival and productivity of fish independently of supplementation programs. If changes in habitat, migratory, and ocean conditions do not affect reference and treatment populations similarly, inferences associated with supplementation programs may be confounded. By measuring and tracking these extraneous factors within reference and treatment areas, we can assess the effects of these state variables on population conditions independent of the supplementation programs. This allows us to more effectively assess the influence of supplementation programs on populations.

To that end, we recommend that the following state variables be measured and tracked within the Chiwawa Basin and each of the reference areas: mean annual precipitation, total and riparian forest cover, road density, impervious surface, and alluvium. These variables can be used to describe differences in water temperatures at different life stages (pre-spawning, egg incubation, and summer rearing) and substrate characteristics, including fine sediments and embeddedness (Jorgensen et al. 2009). They can be used to assess possible changes in spawner abundance, NORs, and productivity that are independent of supplementation.

---

<sup>18</sup> A “nuisance” factor is any factor that is outside the control of the experimenter and can affect the response variable (spawner abundance or productivity). In this case, nuisance factors may include differences in freshwater habitat trends and conditions, out-of-basin effects (e.g., migration and ocean survival), and hatchery strays that affect the Chiwawa and reference populations differently.

<sup>19</sup> It is important to point out that correlation does not demonstrate cause-and-effect. It only suggests a relationship between variables. Thus, inferences based on correlation lack the certainty that is associated with a design-based approach.

## Analyses with Reference Populations

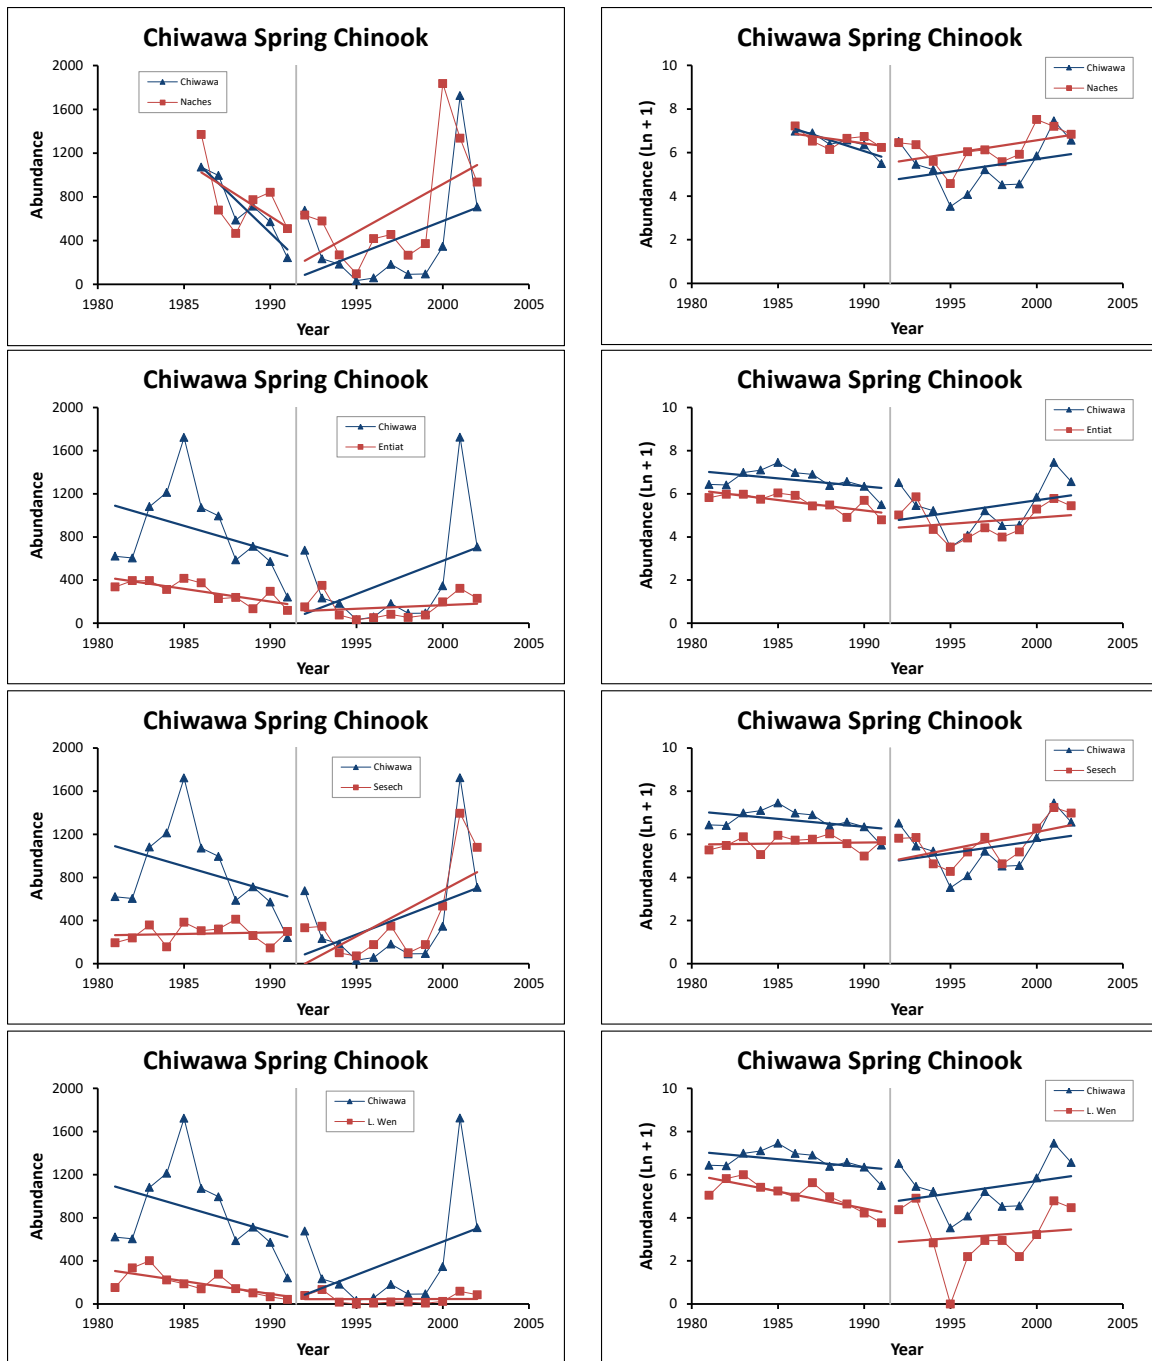

Once suitable reference populations are selected, methods for analyzing the supplemented and reference populations need to be identified. What follows is a description of different analyses that can be used to assess the effects of supplementation programs on spawner abundance, NORs, and productivity using reference populations. Later in this report we describe methods for assessing supplementation effects when reference populations are not available.

We used some of the reference populations selected for the Chiwawa program to illustrate the different methods for evaluating the effects of the supplementation program on spawner abundance, NORs, and productivity. For abundance, we selected the Naches, Entiat, Little Wenatchee, and Sesech populations as suitable references for the Chiwawa population. For NORs, we selected the Naches, Entiat, Marsh, and Little Wenatchee populations as suitable references. For productivity, we selected the Naches, Sesech, Little Wenatchee, and Marsh Creek as suitable references for the Chiwawa. As noted earlier, we included the Little Wenatchee and Entiat populations, even though they did not meet all the criteria for suitable reference populations.

### Analysis of Trends

As a first step, we used trend analyses to assess the effects of the Chiwawa supplementation program on spring Chinook spawner abundance, NORs, and productivity. Here, we compared the slopes of the trends between each treatment/reference pair before and during supplementation using t-tests. If the hatchery program is successfully supplementing the natural spring Chinook population, trends in spawner abundance and NORs should deviate significantly (i.e., the slope of the supplemented population should be greater than the slopes of the reference populations during the supplementation period). For productivity, the slope of the supplemented population, relative to the reference population, should increase or remain the same.

Trend analysis indicated that the relationship of slopes of spawner abundance between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 9; Table 12). This was true for both transformed and untransformed abundance data. Before supplementation, spawner abundances trended down in both the Chiwawa and reference populations (Figure 9). During the period of supplementation, abundances in both the Chiwawa and reference populations trended upward. Interestingly, in nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the supplementation period than in the pre-supplementation period (Table 12). This was most evident in the transformed abundance data (Figure 9).

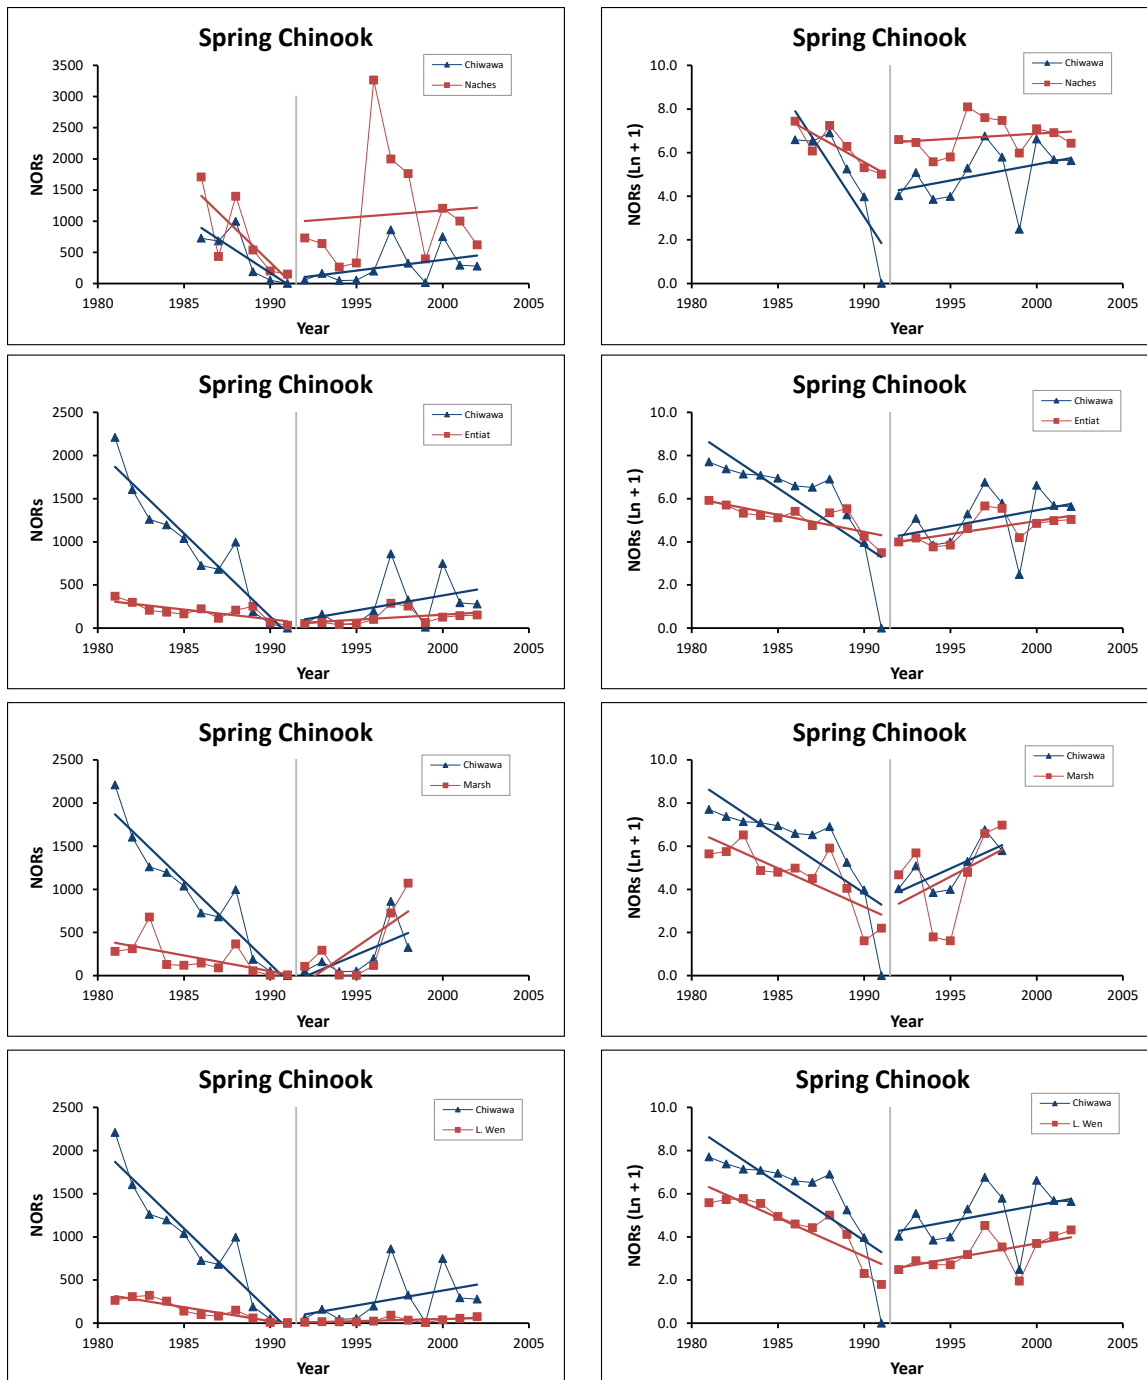

**Figure 9.** Trends in spring Chinook spawner abundance in the Chiwawa and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed spawner abundance data; those on the right include natural-log transformed data.

**Table 12.** Pearson correlation coefficients and t-test results comparing slopes of spawner abundance trends between reference populations and the Chiwawa spring Chinook population before and during the supplementation periods; for correlation coefficients, an asterisk (\*) indicates significance at  $P < 0.05$ . Analyses include both untransformed and natural-log transformed spawner abundance data.

| Reference population        | Pearson correlation coefficient |        | Test on slopes |        |         |        |
|-----------------------------|---------------------------------|--------|----------------|--------|---------|--------|
|                             |                                 |        | t-value        |        | P-value |        |
|                             | Before                          | During | Before         | During | Before  | During |
| <i>Spawner Abundance</i>    |                                 |        |                |        |         |        |
| Naches                      | 0.684*                          | 0.595  | -0.659         | -0.414 | 0.528   | 0.684  |
| Entiat                      | 0.598*                          | 0.672* | -0.596         | 1.162  | 0.559   | 0.260  |
| Sesech                      | 0.274                           | 0.904* | -1.265         | -0.418 | 0.222   | 0.681  |
| Little Wenatchee            | 0.399                           | 0.685* | -0.591         | 1.330  | 0.562   | 0.200  |
| <i>LN Spawner Abundance</i> |                                 |        |                |        |         |        |
| Naches                      | 0.642*                          | 0.813* | -1.323         | -0.047 | 0.222   | 0.963  |
| Entiat                      | 0.652*                          | 0.860* | 0.412          | 0.422  | 0.685   | 0.678  |
| Sesech                      | 0.149                           | 0.878* | -1.431         | -0.333 | 0.170   | 0.743  |
| Little Wenatchee            | 0.670*                          | 0.861* | 1.325          | 0.316  | 0.202   | 0.756  |

Trend analysis indicated that the relationship of slopes of NORs between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 10; Table 13). Before supplementation, Chiwawa NORs trended downward more strongly than the reference populations (Figure 10). However, during the supplementation period, both the Chiwawa and reference population NORs trended upward in parallel. In nearly all treatment/reference comparisons, the Pearson correlation coefficient was greater in the pre-supplementation period than in the supplementation period (Table 13).

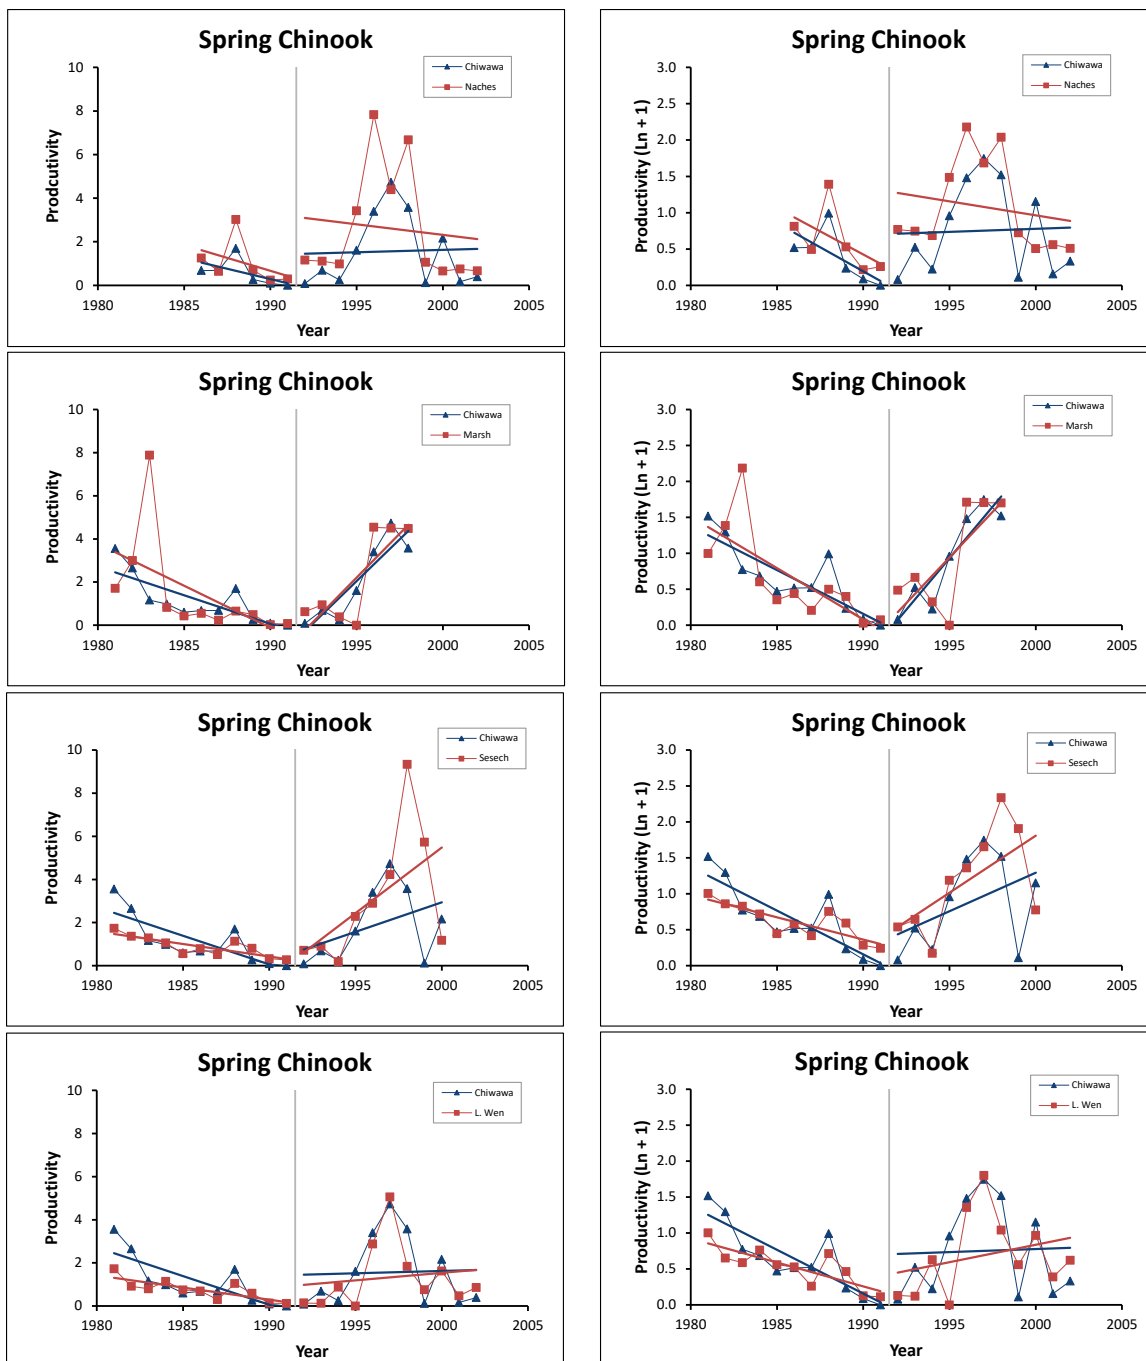

**Figure 10.** Trends in spring Chinook natural-origin recruits (NORs) in the Chiwawa and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed NORs; those on the right include natural-log transformed data.

**Table 13.** Pearson correlation coefficients and t-test results comparing slopes of natural-origin recruits trends between reference populations and the Chiwawa spring Chinook population before and during the supplementation periods; for correlation coefficients, an asterisk (\*) indicates significance at  $P < 0.05$ . Analyses include both untransformed and natural-log transformed natural-origin recruits.

| Reference population              | Pearson correlation coefficient |        | Test on slopes |        |         |        |
|-----------------------------------|---------------------------------|--------|----------------|--------|---------|--------|
|                                   |                                 |        | t-value        |        | P-value |        |
|                                   | Before                          | During | Before         | During | Before  | During |
| <i>Natural-Origin Recruits</i>    |                                 |        |                |        |         |        |

As with NORs and spawner abundance data, trend analysis indicated that the relationship of slopes of productivity (recruits/spawner) between the Chiwawa and reference populations did not change significantly after the initiation of supplementation (Figure 11; Table 14). This was true for both transformed and untransformed productivity data. Before supplementation, productivities trended down in both the Chiwawa and reference populations (Figure 11). During the period of supplementation, productivities fluctuated widely in both the Chiwawa and reference populations. Nevertheless, during the supplementation period, productivities generally increased in both the reference and Chiwawa populations. Unlike with spawner abundance, the Pearson correlation coefficients resulting from analysis of productivity data were generally higher in the pre-supplementation period than during the supplementation period (Table 14).

**Figure 11.** Trends in spring Chinook productivity (recruits/spawner) in the Chiwawa (supplemented) and reference populations. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left include untransformed productivity data; those on the right include natural-log transformed data.

**Table 14.** Pearson correlation coefficients and t-test results comparing slopes of productivity (recruits/spawner) trends between reference populations and the Chiwawa spring Chinook population before and during the supplementation periods; for correlation coefficients, an asterisk (\*) indicates significance at  $P < 0.05$ . Analyses include both untransformed and natural-log transformed productivity data.

| Reference population   | Pearson correlation coefficient |        | Test on slopes |        |         |        |

Using trend analysis, we found no evidence that the supplementation program has significantly increased the spawner abundance and NORs of spring Chinook in the Chiwawa Basin. Even though we documented an increasing trend in spawner abundance and NORs during the supplementation period, a similar increase in spawner abundance and NORs was observed in the reference populations. In addition, we found no evidence that the supplementation program has increased the productivity of spring Chinook in the Chiwawa Basin. Importantly, the productivity of spring Chinook in the Chiwawa Basin did not trend downward during the supplementation period. Thus, based on trend analysis, it appears that the supplementation program has not increased or decreased the abundance and productivity of spring Chinook in the Chiwawa Basin.

We note that this exercise only tests the slopes of the trend lines. It does not test for differences in elevations of the trend lines. A supplementation program could increase spawner abundance, NORs, and productivity of the target population without changing the slopes of the trend lines. That is, supplementation could cause the elevation of the trend line to be greater during the supplementation period than during the pre-supplementation period. In the next section we evaluate elevation differences by testing mean differences before and after supplementation.

### Analysis of Mean Differences, Ratios, and Rates

For assessing mean differences between supplemented and reference populations, we derived three different response variables using transformed and untransformed spawner abundance, NORs, and productivity data. The first included difference scores, which were calculated as the difference between paired treatment and reference data (T-R). The second included ratios, which were calculated as the ratio of paired treatment and reference data (T/R). Finally, we calculated the differences in annual changes in paired treatment and reference population data ( $\Delta T - \Delta R$ ; see footnote #2).

If the hatchery program is successfully supplementing the natural spring Chinook population, the mean difference or ratio score of paired spawner abundance data and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean difference or ratio score during the supplementation period should be equal to or higher than the pre-supplementation period. We tested the following statistical hypotheses.

Spawner Abundance and NORs:

Ho: Mean Difference (or Ratio) before supplementation  $\geq$  Mean Difference (or Ratio) during supplementation.

Ha: Mean Difference (or Ratio) before supplementation  $<$  Mean Difference (or Ratio) during supplementation (i.e.,  $\mu_{\text{pre}} - \mu_{\text{post}} < 0$ ).

Productivity (Recruits/Spawner):

Ho: Mean Difference (or Ratio) before supplementation  $\leq$  Mean Difference (or Ratio) during supplementation.

Ha: Mean Difference (or Ratio) before supplementation  $>$  Mean Difference (or Ratio) during supplementation (i.e.,  $\mu_{\text{pre}} - \mu_{\text{post}} > 0$ ).<sup>20</sup>

For each set of response variables, we tested before/after supplementation effects using a one-tailed Aspin-Welch unequal-variance test. We used the Aspin-Welch unequal-variance test instead of Student's t-test, because in nearly every case, the variances of response variables in the pre-treatment and supplementation periods were unequal.<sup>21</sup> This was true even for natural-log transformed variables. We used the modified Levene equal-variance test to assess the equality of variance. In some cases, the distributions of response variables were not normal (based on the Omnibus Normality test and examination of histograms, normal probability plots, and box plots). Therefore, we also used a randomization test, based on 10,000 Monte Carlo simulations, to assess differences in response variables before and during supplementation. The randomization procedure only allowed the testing of two-tailed hypotheses. Therefore, we generated 95% confidence intervals on the mean difference ( $\mu_{\text{pre}} - \mu_{\text{post}}$ ) using bootstrapping methods to determine the direction of the difference. We generated 5,000 bootstrap samples to calculate confidence intervals.

All these statistical methods assume that the samples of derived difference or ratio scores from the pre-supplementation and supplementation periods were independent. However, BACI designs, like time-series trend analysis, are repeated-measures designs and therefore are susceptible to temporal correlations in the data. This means that the two samples of difference or ratio scores may not be independent. Under this scenario, ARIMA models can be used to describe the correlation structure in temporal data (Gotelli and Ellison 2004). ARIMA models can be fit individually to the reference and supplemented time series data, or to a derived data series created by taking the ratio or difference of the supplemented/reference data at each time step. ARIMA models, however, require a long time series ( $N > 40$ ) and therefore we could not use them to model

<sup>20</sup> Because of the logic of null hypothesis testing, the rejection of the null hypothesis of no difference in productivity would mean that the supplementation program has reduced the productivity of the target population (here rejection of the null indicates "harm"). Notice that the rejection of the null hypothesis of no difference in spawner abundance means that the supplementation program has improved the spawner abundance in the target population (here rejection of the null indicates "benefit").

<sup>21</sup> In cases in which the variances were equal, both the Aspin-Welch test and Student's t-test gave the same result.

the spring Chinook data. Thus, we acknowledge that our analyses may be confounded if the samples are not independent.

*Difference Scores (T-R)*

Analysis of supplementation effects on spawner abundance using difference scores indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 15; Figure 12). Only the Little Wenatchee-Chiwawa pairing using transformed abundance data indicated a significant increase in spawning abundance following supplementation. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction (i.e., CIs > 0). That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 12).

**Table 15.** Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed spawner abundance data. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

| Reference population        | Aspin-Welch unequal-variance test |         |             | Randomization test<br>P-value | Bootstrap 95%<br>CI |

Analysis of supplementation effects on productivity (adult recruits/spawner) using difference scores indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 17; Figure 12). All tests, regardless of treatment-reference pairs, indicated that productivity did not change significantly during the supplementation period. These tests indicate that supplementation has not negatively affected the productivity of spring Chinook salmon in the Chiwawa Basin.

**Table 17.** Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data. Tests determined if the mean difference scores during the supplementation period were less than mean difference scores during the pre-supplementation period.

Ratio Scores (T/R)

As with difference scores, analysis of supplementation effects on spawner abundance using ratios indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 18; Figure 13). Only the Little Wenatchee-Chiwawa pairing indicated a significant increase in spawning abundance following supplementation. Analysis with both transformed and untransformed Little Wenatchee-Chiwawa data indicated a significant effect. In contrast, only difference scores derived from transformed data indicated a significant effect. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction. That is, compared to the reference populations, spawner abundance decreased in the Chiwawa Basin during the supplementation period (Figure 13).

**Table 18.** Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed spawner abundance data. Tests determined if the mean ratios during the supplementation period were greater than mean ratios during the pre-supplementation period.

| Reference population        | Aspin-Welch unequal-variance test |         |             | Randomization test<br>P-value | Bootstrap 95%<br>CI |

**Figure 13.** Mean ratios (Treatment/Reference) scores of untransformed (figures on the left) and transformed (figures on the right) spawner abundance, natural-origin recruits (NORs), and productivity data before (pre) and after (post) spring Chinook supplementation in the Chiwawa Basin. Positive effects of supplementation on spawner abundance and NORs are indicated when the post-supplementation (red) bars are greater than their corresponding pre-supplementation (blue) bars. Negative effects of supplementation on productivity are indicated when the pre-supplementation (blue) bars are greater than their corresponding post-supplementation (red) bars.

Analysis of supplementation effects on NORs using ratios indicated that supplementation did not significantly increase NORs in the Chiwawa Basin (Table 19; Figure 13). Only the Little Wenatchee-Chiwawa pairing indicated a significant increase in transformed NORs following supplementation. The randomization test indicated significant differences in several of the treatment-reference pairs; however, the bootstrap CIs indicated that those differences were in the wrong direction. That is, compared to the reference populations, NORs decreased in the Chiwawa Basin during the supplementation period (Figure 13).

**Table 19.** Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed natural-origin recruits. Tests determined if the mean ratios during the supplementation period were greater than mean ratios during the pre-supplementation period.

| Marsh                             | 0.603                             | 0.721   | 0.161       | 0.579                      | -0.272 – 0.681   |
| Little Wenatchee                  | -1.914                            | 0.038   | 0.277       | 0.027                      | -0.504 – 0.031   |

Analysis of supplementation effects on productivity (adult recruits/spawner) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 20; Figure 13). Although the Aspin-Welch test indicated a significant effect when comparing the Chiwawa to the Marsh Creek population, both the randomization test and the bootstrap CI did not indicate a significant effect. These tests indicate that supplementation has probably not negatively affected the productivity of spring Chinook salmon in the Chiwawa Basin.

**Table 20.** Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data. Tests determined if the mean ratios during the supplementation period were less than mean ratios during the pre-supplementation period.

*Difference of Annual Difference Scores ( $\Delta T - \Delta R$ )*

Analysis of supplementation effects on spawner abundance using difference scores of annual changes indicated that supplementation did not significantly increase spawning abundance in the Chiwawa Basin (Table 21; Figure 14). None of the statistical analyses detected a significant increase in annual change in the Chiwawa Basin relative to the reference populations.

**Table 21.** Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed spawner abundance data. Tests determined if mean difference scores of annual change during the supplementation period were greater than mean difference scores of annual change during the pre-supplementation period.

**Figure 14.** Mean difference scores of annual changes ( $\Delta\text{Treatment} - \Delta\text{Reference}$ ) of untransformed (figures on the left) and transformed (figures on the right) spawner abundance and productivity data before (pre) and after (post) spring Chinook supplementation in the Chiwawa Basin.

Analysis of supplementation effects on NORs using difference scores of annual changes indicated that supplementation did not significantly increase NORs in the Chiwawa Basin (Table 22; Figure 14). None of the statistical analyses detected a significant increase in annual change in the Chiwawa Basin relative to the reference populations.

**Table 22.** Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed natural-origin recruits. Tests determined if mean difference scores of annual change during the supplementation period were greater than mean difference scores of annual change during the pre-supplementation period.

Analysis of supplementation effects on productivity (adult recruits/spawner) using difference scores of annual changes indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 23; Figure 14). All tests, regardless of treatment-reference pairs, indicated that productivity did not change significantly during the supplementation period.

**Table 23.** Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data. Tests determined if the mean difference scores of annual change during the supplementation period were less than mean difference scores of annual change during the pre-supplementation period.

We believe results from analysis of mean differences of annual change ( $\Delta T - \Delta R$ ) in spawning abundance, NORs, and productivity are difficult to interpret and may be insensitive to treatment effects. A simpler analysis, which is also easier to interpret, is the use of trend analysis. Therefore, we recommend that analyses using differences of annual change be replaced with trend analysis.

### Corrections for Density Dependence and Carrying Capacity

The analyses described above assume that the density of spawners or recruits does not affect the survival and productivity of fish. However, it is well known that the density of fish can affect the number of recruits as well as the productivity of the population. This occurs through the relationship between density and mortality. Mortality of fish can be generally classified as density independent and density dependent. In general, when densities are low, the mortality is density independent, but as densities increase, the amount of density-dependent mortality increases. Monitoring programs can make use of this information to derive density-corrected estimates of productivity. In this section, we describe two different methods for deriving density-corrected estimates of productivity.

The first method controlled the effects of density on productivity (adult recruits/spawner;  $R/S$ ) by partitioning observed productivities into density-independent and density-dependent productivity. When abundance is below the minimum number of spawners ( $S$ ) needed to produce the maximum number of recruits ( $K_{sp}$ ), the observed productivity is used in statistical tests. However, when the abundance is equal to or above  $K_{sp}$ , the modeled value of productivity ( $R/K_{sp}$ ) is used in statistical tests.

$$Adj\ R/S = \begin{cases} R/S, & \text{if } S < K_{sp} \\ R/K_{sp}, & \text{if } S \geq K_{sp} \end{cases}$$

The density-independent and density-dependent productivities were then combined in a single test.

The second method was based on one of the goals of supplementation, which is to fill the capacity of the environment with fish. This method corrects for differences in carrying capacities between the supplemented and reference populations. We did this by calculating the percent saturation of NORs. That is, we calculated the fraction of the habitat ( $\tau$ ) that was filled with NORs by dividing the observed NOR by the modeled maximum number of NORs ( $K_R$ ) that the habitat could support.

$$\tau = \frac{NOR_{obs}}{K_R}$$

Note that  $1 - \tau$  represents the unused portion of the carrying capacity and is the term that is multiplied by the exponential growth equation to derive the logistic growth equation. We included  $\tau$  in the statistical analyses.

These two methods require the estimation of carrying capacity ( $K_R$ ) and the spawning abundance that produces the maximum number of recruits ( $K_{sp}$ ). We estimated these parameters for both reference populations and the supplemented population using Ricker, Beverton-Holt, and smooth hockey stick stock-recruitment models. We used only spawner abundance as a predictor of subsequent brood recruitment. We made the following assumptions in proceeding with the analysis:

- Density-dependent mortality—For some time period before recruitment, the brood instantaneous mortality rate is proportional to the number of parent spawners (Ricker 1954).
- Lognormal variation—At any particular spawning stock size, the variation in recruitment is log-normally distributed about its average, and acts multiplicatively (Quinn and Deriso 1999).
- Measurement error—Error in spawning stock size estimates (measurement error) is small relative to the range of spawning stock sizes observed (Hilborn and Walters 1992). Variation in realized recruitment at any particular spawning stock size (process error) dominates recruitment measurement error.
- Stationarity—The average stock-recruitment relationship is constant over time (Hilborn and Walters 1992). That is, environmental conditions randomly affect survival independent of stock size or time.

In general, the methods we used to fit the models to the data followed those outlined in Hilborn and Walters (1992) and Froese (2008). The Ricker model, which assumes that the number of recruits increases to a maximum and then declines as the number of spawners increases, takes the form:

$$E(R) = \alpha S e^{-\beta S}$$

where  $E(R)$  is the expected recruitment,  $S$  is spawner abundance,  $\alpha$  is the number of recruits per spawner at low spawning levels, and  $\beta$  describes how quickly the recruits per spawner drop as the number of spawners increases. We estimated  $K_R$  as:

$$K_R = \left(\frac{\alpha}{\beta}\right) e^{-1}$$

and  $K_{sp}$  as:

$$K_{sp} = \frac{1}{\beta}$$

The Beverton-Holt model assumes that the number of recruits increases constantly toward an asymptote as the number of spawners increases. After the asymptote is reached, the number of recruits neither increases nor decreases. The asymptote represents the maximum number of recruits the system can support (i.e., carrying capacity for the system;  $K_R$ ). The Beverton-Holt curve takes the form:

$$E(R) = \frac{(\alpha S)}{(\beta + S)}$$

where  $E(R)$  and  $S$  are as above,  $\alpha$  is the maximum number of recruits produced ( $K_R$ ), and  $\beta$  is the number of spawners needed to produce (on average) recruits equal to one-half the maximum number of recruits. Because  $K_{sp} = \infty$  in the Beverton-Holt model, we estimated  $K_{sp}$  as the number of spawners needed to produce  $0.99(K_R)$ .

Like the Beverton-Holt model, the smooth hockey stick model assumes that the number of recruits increases toward an asymptote (carrying capacity;  $K_R$ ) as the number of spawners increases. After the carrying capacity is reached, the number of recruits neither increases nor decreases. The carrying capacity represents the maximum number of recruits the system can support. This curve

takes the form (Froese 2008):

$$E(R) = R_{\infty} \left( 1 - e^{-\left(\frac{\alpha}{R_{\infty}}\right)S} \right)$$

where  $E(R)$  and  $S$  are as above,  $\alpha$  is the slope at the origin of the spawner-recruitment curve, and  $R_{\infty}$  is the carrying capacity of recruits (note that  $R_{\infty} = K_R$ ). As with the Beverton-Holt model, we estimated  $K_{sp}$  as the number of spawners needed to produce  $0.99(K_R)$ .

We used non-linear regression to fit the three models to spawner-recruitment data. Before fitting the models, we transformed recruitment data using natural logs. We estimated bias and uncertainty measures (95% CI) for the model parameters using bootstrap procedures, which assumed that the  $\{R, S\}$  sample represented or approximated the population. The number of bootstrap samples was 3,000. We computed and stored the non-linear regression results for each bootstrap sample. We then calculated the bootstrap 95% CI by arranging the 3,000 bootstrap parameter values in sorted order and selected the 2.5 and 97.5 percentiles from the list.

We used Akaike's Information Criterion for small sample size ( $AIC_c$ ) to determine which model(s) best explained the relationship between spawners and recruitment in the supplemented and reference populations.  $AIC_c$  was estimated as:

$$AIC_c = -2\log(\mathcal{L}(\theta|data)) + 2K + \left( \frac{2K(K+1)}{n-K-1} \right)$$

where  $\log(\mathcal{L}(\theta|data))$  is the maximum likelihood estimate,  $K$  is the number of estimable parameters (structural parameters plus the residual variance parameter), and  $n$  is the sample size (Burnham and Anderson 2002). We used least-squares methods to estimate  $\log(\mathcal{L}(\theta|data))$ , which was calculated as  $\log(\sigma^2)$ , where  $\sigma^2$  = residual sum of squares divided by the sample size ( $\sigma^2 = RSS/n$ ).  $AIC_c$  assessed model fit in relation to model complexity (number of parameters). The model with the smallest  $AIC_c$  value represented the "best approximating" model within the model set. Remaining models were ranked relative to the best model using  $AIC_c$  difference scores ( $\Delta AIC_c$ ), Akaike weights ( $w_i$ ), and evidence ratios. Models with  $\Delta AIC_c$  values less than 2 indicated that there is substantial support for these models as being the best-fitting models within the set (Burnham and Anderson 2002). Models with values greater than 2 had less support. Akaike weights are probabilities estimating the strength of the evidence supporting a particular model as being the best model within the model set. Models with small  $w_i$  values are less plausible as competing models (Burnham and Anderson 2002). If no single model could be specified as the best model, a "best subset" of competing models was identified using (1)  $AIC_c$  differences to indicate the level of empirical support each model had as being the best model, (2) evidence ratios based on Akaike weights to indicate the relative probability that any model is the best model, and (3) coefficients of determination ( $R^2$ ) assessing the explanatory power of each model.

### Stock-Recruitment Analysis

We successfully fit stock-recruitment models to the Chiwawa and reference population data. The span of spawner data for the Chiwawa and reference populations was greater than 14 times the minimum observed spawners, which should provide sufficient contrast for estimation of model parameters. In addition, the span of recruitment data was greater than 12 times the minimum observed recruitment, again providing sufficient contrast for estimation of parameters. The relationship between natural log R/S and spawners indicated that some of the highest productivities occurred at the lower spawner levels and the lowest productivities generally occurred at the highest spawner levels (Figure 15). This is consistent with the assumption of density-dependent mortality.

Although model fits were generally poor, explaining less than 40% of the residual variation in natural-log recruitment data, we were able to estimate average maximum recruitment levels ( $K_R$ ) and the spawning levels needed to produce maximum recruitment ( $K_{sp}$ ) (Table 24; Figure 15). For all populations examined, Akaike information criterion was unable to identify a best approximating model (i.e.,  $\Delta AIC_c$  values were less than 2, indicating support for all three models). However, evaluation of 95% CIs and the asymptotic correlation coefficients indicated that the smooth hockey stick model may be the best approximating model for each population. Therefore, we used estimates of  $K_R$  and  $K_{sp}$  derived from the smooth hockey stick model to correct for density dependence and different carrying capacities in treatment-reference comparisons.

As part of the regression diagnostics, we examined the dependence of the model residuals on time and found a significant ( $P < 0.05$ ), positive, one-year-lag autocorrelation for the Entiat (0.562), Marsh (0.551), Sesech (0.564), and Little Wenatchee (0.629) populations. For the purposes of our work here, we did not attempt to correct for this one-year-lag correlation in the residuals. Future analyses will explore the use of autoregressive models (e.g., AR1; Noakes et al. 1987) to correct for autocorrelation.

**Figure 15.** Relationships between natural log recruits/spawner (LN R/S) and spawners (Stock) in the Chiwawa and reference populations (figures on the left) and relationships between numbers of untransformed recruits and spawners in the Chiwawa and reference populations (figures on the right). Figures on the right also show the fit of the Ricker, Beverton-Holt, and the smooth hockey stick models to the data (black straight line represents R=S).

**Table 24.** Results from fitting Ricker, Beverton-Holt, and smooth hockey stick models to stock-recruitment data from the Chiwawa and reference populations. 95% CI on parameter estimates are based on 3,000 bootstrap trials; Corr coef = asymptotic correlation of the parameter estimates;  $K_R$  = maximum natural origin recruits (recruits at carrying capacity);  $K_{sp}$  = number of spawners needed to produce  $K_R$ ; AICc = Akaike's Information Criterion for small sample size; Adj  $R^2$  = coefficient of determination that is adjusted for the number of parameters in the model.

| Model                         | Parameter | Parameter value | Bootstrap 95% CI      | Corr coef | $K_R$ | $K_{sp}$ | AICc    | Adj $R^2$ |

*Method 1: Productivity Data Adjusted for Density Dependence*

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects based on the smooth hockey stick model) using difference scores indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 25; Figure 16). All tests, regardless of treatment-reference pairs, indicated that productivity did not change significantly during the supplementation period, even though productivity did decrease during the supplementation period (Figure 16). These results are consistent with those based on unadjusted productivity data (Table 17). This is because most abundance estimates were below the level of assumed density dependence.

**Table 25.** Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

**Figure 16.** Mean differences (Treatment – Reference; figures on the top) and mean ratios (Treatment/Reference; figures on the bottom) of transformed and untransformed productivity data (adjusted for density dependence) before (pre) and after (post) spring Chinook supplementation in the Chiwawa Basin. Negative effects of supplementation on productivity are indicated when the pre-supplementation (blue) bars are greater than their corresponding post-supplementation (red) bars.

Analysis of supplementation effects on productivity (adult recruits/spawner adjusted for density-dependent effects) using ratios indicated that supplementation did not significantly decrease productivity in the Chiwawa Basin (Table 26; Figure 16). The Aspin-Welch test and the 95% CIs did indicate a significant effect when comparing the Chiwawa to the Marsh Creek population. These results are consistent with those using unadjusted productivity data (Table 20). Again, this is because most abundance estimates were below the level of assumed density dependence.

**Table 26.** Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on transformed and untransformed productivity data corrected for density dependence. Tests determined if the mean ratios during the supplementation period were less than mean ratios during the pre-supplementation period.

Our analyses assume that there is a spawner abundance ( $K_{sp}$ ) at which density-independent effects end and density-dependent effects begin. In reality, density-dependent effects occur at low spawning abundance and intensify as spawning abundance increases (evident in the changing slope of the three stock-recruitment curves used in our analyses). We did not account for these increasing density-dependent effects at spawner abundances less than  $K_{sp}$ . If we accounted for the increasing effects of density dependence at spawning abundances less than  $K_{sp}$ , the analysis with and without productivity adjustments may give different results.

*Method 2: Fraction of Carrying Capacity Filled with NORs*

We analyzed the effects of supplementation on filling the capacity of the habitat with natural-origin recruits. The smooth hockey stick model derived the carrying capacity ( $K_R$ ) estimates for the Chiwawa and reference populations. The fraction of the carrying capacity filled with Chinook recruits before and during supplementation for the Chiwawa and reference populations is provided in Table 27. These data indicate that for the Chiwawa population, the mean fraction of the  $K_R$  filled with fish decreased significantly from the pre-supplementation period through the supplementation period (Table 27). Likewise, the Entiat and Little Wenatchee populations showed a significant decline in the mean fraction of  $K_R$  filled with adult recruits. In contrast, the mean fraction of  $K_R$  in the Naches and Marsh Creek populations increased during the same period (Table 27).<sup>22</sup> Interestingly, the fraction of  $K_R$  filled with adult recruits for all populations trended downward during the pre-supplementation period (Figure 17). During the supplementation period, however, the fraction of  $K_R$  filled with adult recruits trended upward for all populations. These results suggest that agents of mortality outside the Chiwawa and reference populations were reducing recruitment to the populations.

<sup>22</sup> Although we do not show the results here, statistical analysis of the mean fraction of carrying capacity filled by adult recruits using natural-log transformed data produced the same result as using untransformed data. This was true for all populations.

**Table 27.** Fraction of the carrying capacity that was filled with Chinook salmon adult recruits in the Chiwawa and reference populations before (pre) and during (post) supplementation in Chiwawa Basin. The smooth hockey stick model estimated carrying capacity for each population. Statistical results from comparing the pre and post mean scores using the Aspin-Welch unequal-variance test are provided at the bottom of the table.

| Supplementation period                             | Chiwawa                 | Reference populations    |                         |                          |                         |

**Figure 17.** Trends in the fraction of the carrying capacity that was filled with Chinook salmon adult recruits in the Chiwawa and reference populations before (pre) and during (post) supplementation in Chiwawa Basin. The vertical lines in the figures separate the pre- and post-supplementation periods. The smooth hockey stick model estimated carrying capacity for each population.

We then compared the mean difference scores and ratios between the Chiwawa and reference populations before and during supplementation using data representing the fraction of  $K_R$  filled with adult recruits. In most of the Chiwawa-reference population comparisons, the absolute value of the mean difference between the fraction of  $K_R$  filled with recruits was greater in the supplementation period than during the pre-supplementation period; two of the four pairings were significant (Table 28; Figure 18). Analysis of difference scores using natural-log transformed data indicated that three of the four pairings were significant (Table 28).

Results from analyses using ratios were similar to results using difference scores. Mean ratio scores were generally smaller during the supplementation period than during the pre-supplementation period (Figure 18). This indicated that the mean fraction of  $K_R$  filled by adult recruits in most reference populations was greater during the supplementation period than during the pre-supplementation period (i.e., the denominator in the ratio increased between the pre- and post-supplementation periods). In contrast, the fraction of  $K_R$  filled by adult recruits in the Chiwawa decreased from the pre- to post-supplementation period (i.e., the numerator in the ratio decreased between the pre- and post-supplementation periods). Thus, unlike the Chiwawa population, the capacity of most reference populations was becoming more saturated during the period when the Chiwawa was being supplemented. Statistical analysis with mean ratios indicated that two of the four pairings were significant (Table 29).

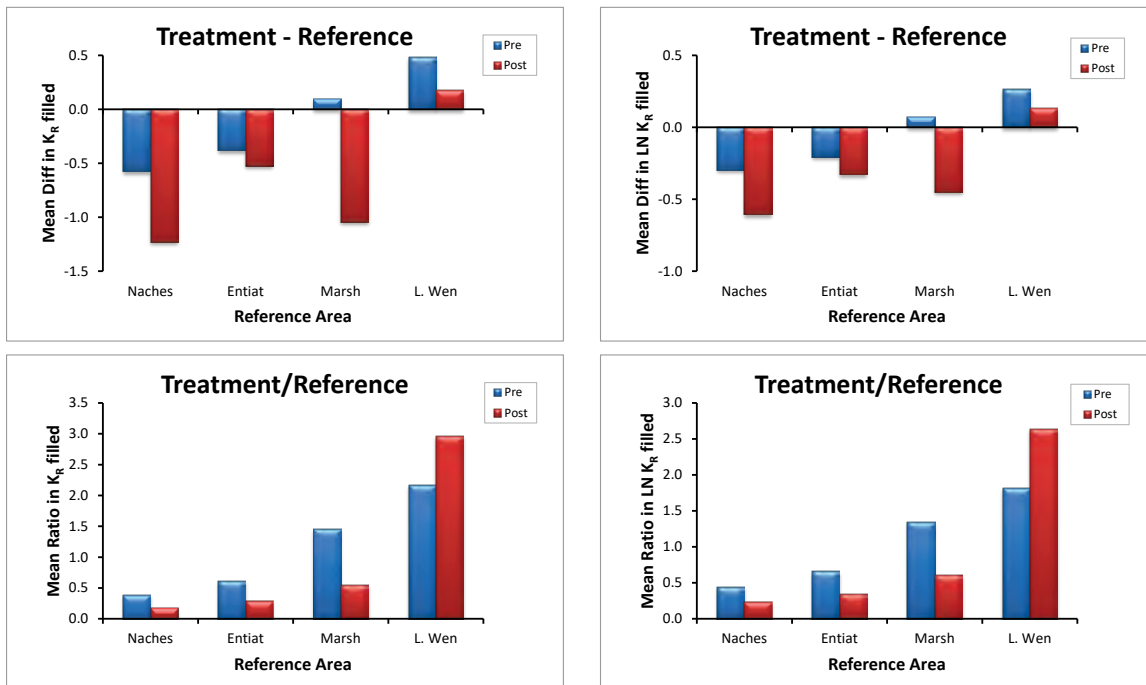

Analyses comparing the Little Wenatchee with the Chiwawa indicate that adult recruits to the Little Wenatchee have been well below its carrying capacity. During the pre-supplementation period, the capacity of the Little Wenatchee was on average 37% saturated with adult recruits. During the supplementation period, the capacity of the Little Wenatchee declined to 8% saturation

with adult recruits (a 22% decline). The Chiwawa, during the pre-supplementation period, was on average 86% saturated. During the supplementation period, percent saturation in the Chiwawa decreased to 26% (a 30% decrease). During the same time periods, the capacity of the Entiat population, which until recently has been supplemented, declined from 124% to 78% saturation (a 63% decline).

**Table 28.** Results of the Aspin-Welch unequal-variance test, randomization test (based on 10,000 Monte Carlo samples), and 95% CI (based on 5,000 bootstrap samples) on the fraction of the habitat capacity ( $K_R$ ) that is filled with natural origin recruits. Analyses include both transformed and untransformed data. Tests determined if the mean difference scores during the supplementation period were greater than mean difference scores during the pre-supplementation period.

### Comparing Stock-Recruitment Curves

As a final set of treatment and reference population comparisons, we compared the stock-recruitment curves of the Chiwawa population (using {R, S} data only from the supplementation period) to the reference populations (using all available {R, S} data). Specifically, we tested whether the regression parameters were equal between the Chiwawa population and the reference populations, and whether the fitted curves coincided between populations. Earlier in this report we described the data, methods, and results of fitting the Ricker, Beverton-Holt, and smooth hockey stick curves to the data. Because  $AIC_c$  was unable to identify a best approximating model, here we included all three models in our analyses. We tested the following hypotheses.

Parameter equivalence:

Ho: Stock-recruitment parameters ( $\alpha$  and  $\beta$ ) of the Chiwawa population = Stock-recruitment parameters of the reference populations.

Ha: Stock-recruitment parameters ( $\alpha$  and  $\beta$ ) of the Chiwawa population  $\neq$  Stock-recruitment parameters of the reference populations.

Curve equivalence:

Ho: Modeled stock-recruitment curves of the Chiwawa population = Modeled stock-recruitment curves of the reference populations.

Ha: Modeled stock-recruitment curves of the Chiwawa population  $\neq$  Modeled stock-recruitment curves of the reference populations.

We used two-sided randomization tests to test the null hypotheses of equal model parameters and that fitted curves coincided. Because the total number of permutations was in the millions, we used a Monte Carlo approach to randomly select 10,000 permutations. The test statistic for comparing the model parameters was formed by summing the difference between the population parameter estimates for each pair of populations. The test statistic for comparing the whole curve was formed by summing the difference between the estimated predicted values for each pair of populations at 500 equally spaced points along the curve.

#### Ricker Relationships

Ricker curves differed significantly between the Chiwawa and reference populations (Figure 19; Table 30). Interestingly, however, the parameters in the Ricker model did not differ significantly among most populations (Table 30). Only the  $\beta$  parameter differed significantly between the Chiwawa and Entiat populations.

In the Ricker model, the  $\alpha$  parameter represents intrinsic productivity (i.e., recruits per spawner at low spawner densities). In this analysis, there was not enough evidence in the stock-recruitment data to reject the hypothesis of inequality in intrinsic productivity. Thus, this test was unable to demonstrate that supplementation, based on the Ricker curve, affected productivity in the Chiwawa population.

**Figure 19.** Scatter plot of the number of spawners and natural log adult recruits and fitted Ricker curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

**Table 30.** Randomization test results comparing the equality of Ricker curves and equality of parameter values ( $\alpha$  and  $\beta$ ). Randomization tests were based on 10,000 Monte Carlo samples. Equality of curves was based on 500 points along the x-axis (spawner abundance axis).

Beverton-Holt Relationships

Beverton-Holt curves differed significantly only between the Chiwawa and Naches populations (Figure 20; Table 31). There was no significant difference in curves between the Chiwawa and the other reference populations. The parameters in the Beverton-Holt model did not differ significantly among any of the populations (Table 31). This was true even for the Chiwawa and Naches populations.

**Figure 20.** Scatter plot of the number of spawners and natural log adult recruits and fitted Beverton-Holt curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

**Table 31.** Randomization test results comparing the equality of Beverton-Holt curves and equality of parameter values ( $\alpha$  and  $\beta$ ). Randomization tests were based on 10,000 Monte Carlo samples. Equality of curves was based on 500 points along the x-axis (spawner abundance axis).

Smooth Hockey Stick Relationships

Smooth hockey stick curves differed significantly between the Chiwawa and Naches populations and the Chiwawa and Sesech populations (Figure 21; Table 32). There was no significant difference in curves between the Chiwawa and the other reference populations. Most of the parameters in the smooth hockey stick model did not differ significantly among the populations (Table 32). However, the productivity parameter  $\beta$  did differ significantly between the Chiwawa and the Naches and the Chiwawa and Little Wenatchee populations. The  $\beta$  parameter for the Naches was significantly greater than the Chiwawa, while the  $\beta$  parameter for the Little Wenatchee was significantly less than the Chiwawa.

**Figure 21.** Scatter plot of the number of spawners and natural log adult recruits and fitted smooth hockey stick curves to the Chiwawa (supplemented population) and reference (un-supplemented) populations.

**Table 32.** Randomization test results comparing the equality of smooth hockey stick curves and equality of parameter values ( $\alpha$  and  $\beta$ ). Randomization tests were based on 10,000 Monte Carlo samples. Equality of curves was based on 500 points along the x-axis (spawner abundance axis).

Comparing different stock-recruitment curves and their parameters did not provide strong evidence that the supplementation program has negatively affected the productivity of the Chiwawa population.

## Analysis without Reference Populations

In some cases, suitable reference populations may not exist to compare with supplemented populations. It is therefore important to have alternative analyses to assess supplementation effects. In this section, we describe methods that can be used to assess supplementation effects when suitable reference populations are not available. We discuss before-after comparisons, correlation analysis, and comparisons to standards as alternatives when reference populations are unavailable.

### Before-After Comparisons

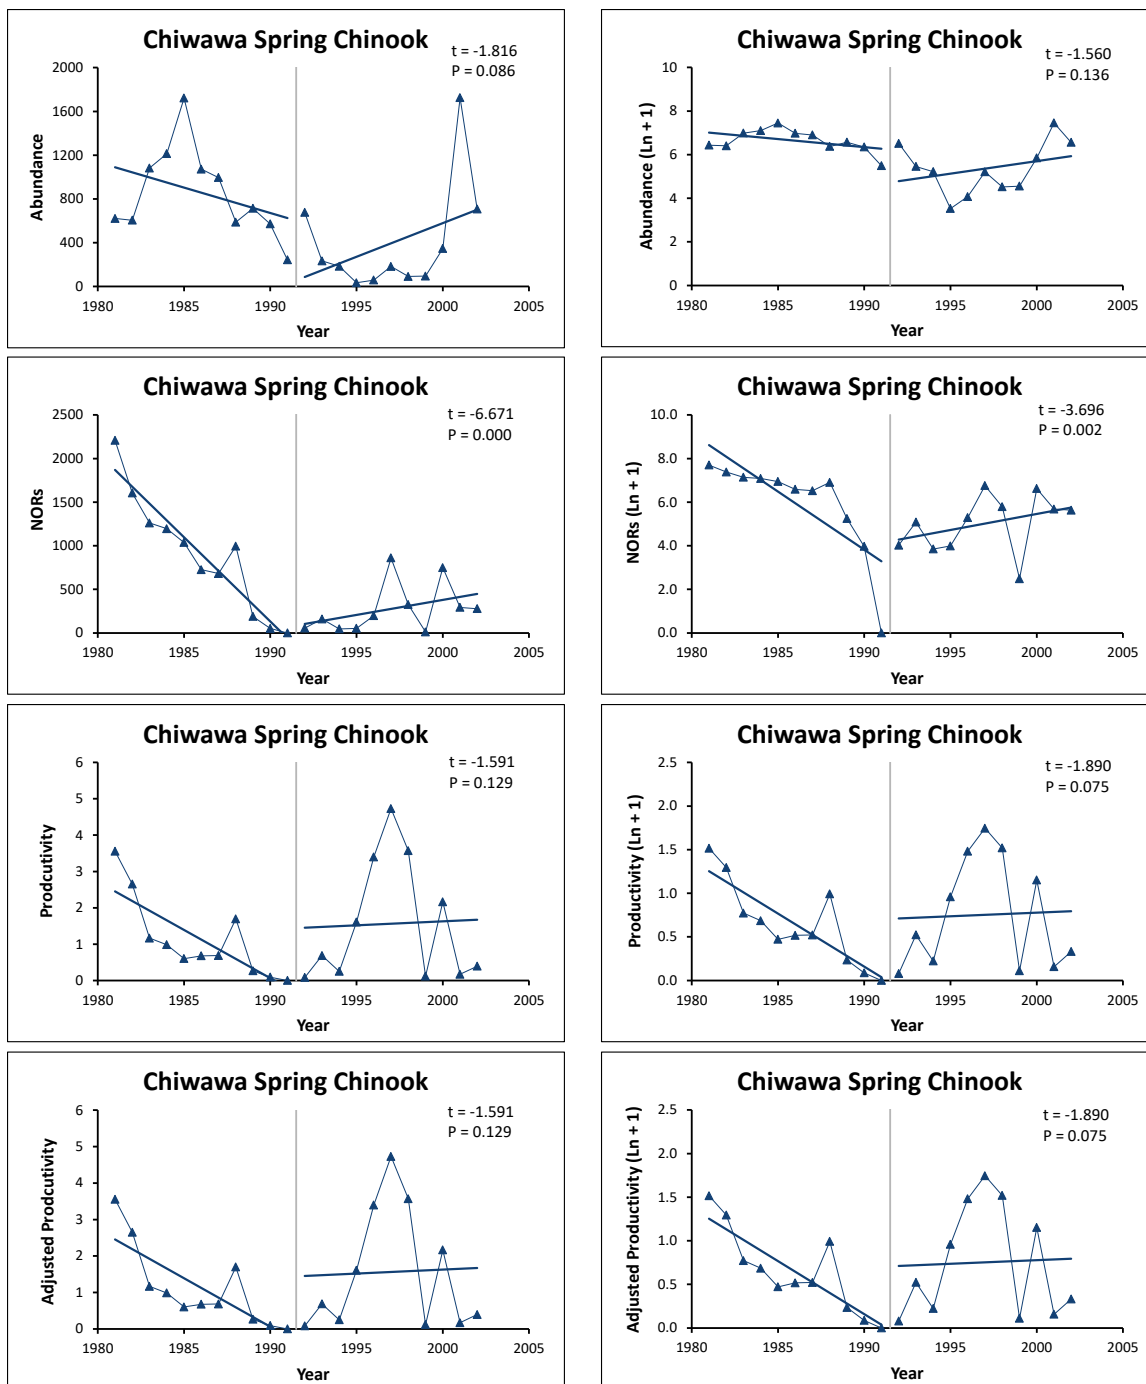

Before-after analyses compare population metrics (spawner abundance, NORs, and productivity) before supplementation to those during supplementation. In this case, data collected before supplementation represent the reference condition. The assumption is that population trajectories measured during the pre-supplementation period would continue in the absence of supplementation. We compared trends in abundance and productivity, mean abundance and productivity, and stock-recruitment relationships before and after supplementation.

#### *Trend Analysis*

Comparing trends before and after supplementation can be used to assess the effects of supplementation. Here, we compared the slopes of trends of spawner abundance, NORs, and productivity before and during supplementation using t-tests. If the hatchery program is successfully supplementing the natural spring Chinook population, the trend for spawner abundance and NORs during supplementation should be greater than the slope during the pre-supplementation period. For productivity, the slope during the supplementation period should increase or remain the same as that during the pre-supplementation period.

Visual examination of trends of Chiwawa data indicates that spawner abundance, NORs, and productivity decreased during the pre-supplementation period, but increased during the supplementation period (Figure 22). Only the changes in NOR trends were significant (Figure 22). This was true for both transformed and untransformed data.

**Figure 22.** Trends in Chiwawa spring Chinook spawner abundance, natural-origin recruits (NORs), productivity (adults recruits per spawner), and adjusted productivity (adjusted for density dependence) before and during supplementation. The vertical lines in the figures separate the pre- and post-supplementation periods. Figures on the left show untransformed data; figures on the right include natural-log transformed data. Figures include results of t-tests comparing slope of trends before and during supplementation.

Analysis of Mean Scores

We also compared mean spawner abundance, NORs, and productivity data before and after supplementation. If the hatchery program is successfully supplementing the natural spring Chinook population, mean spawner abundance and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean productivity during the supplementation period should be equal to or higher than the pre-supplementation period. We tested the following statistical hypotheses.

Spawner Abundance and NORs:

Ho: Mean spawner abundance and NORs before supplementation  $\geq$  Mean spawner abundance and NORs during supplementation.

Ha: Mean spawner abundance and NORs before supplementation  $<$  Mean spawner abundance and NORs during supplementation.

Productivity (Recruits/Spawner):

Ho: Mean productivity before supplementation  $\leq$  Mean productivity during supplementation.

Ha: Mean productivity before supplementation  $>$  Mean productivity during supplementation.

We tested before-after supplementation effects using a one-tailed Aspin-Welch unequal-variance test. We also used a randomization test, based on 10,000 Monte Carlo simulations, to assess differences in spawner abundance and productivity before and during supplementation. The randomization procedure only allowed the testing of two-tailed hypotheses. Therefore, we generated 95% confidence intervals on the mean difference ( $\mu_{pre} - \mu_{post}$ ) using bootstrapping methods to determine if the significant result from the randomization test was in the right direction. We generated 5,000 bootstrap samples to calculate confidence intervals.

Mean spawner abundance during the supplementation period was significantly less than the pre-supplementation spawner abundance (Table 33). Mean spawner abundance decreased 46% between the pre- and post-supplementation periods. Likewise, mean NORs decreased significantly between the two periods (Table 33). On the other hand, productivity increased slightly, but not significantly, between the pre- and post-supplementation periods (Table 33). This was true for both adjusted and transformed productivity data.

**Table 33.** Statistical results comparing mean scores of spawner abundance, natural-origin recruits (NORs), and productivity (using both untransformed and natural-log transformed) before and during supplementation of Chiwawa spring Chinook. Randomization tests were based on 10,000 Monte Carlo samples and 95% CI were based on 5,000 bootstrap samples.

| Population metric   | Mean scores |        | Test on means    |         |                     |                  |
|---------------------|-------------|--------|------------------|---------|---------------------|------------------|
|                     |             |        | Aspin-Welch test |         | Random test P-value | Bootstrap 95% CI |

#### Analysis of Stock-Recruitment Curves

The third method compared stock-recruitment curves of the Chiwawa population during supplementation with those generated before supplementation. Specifically, we tested whether the regression parameters were equal between the pre- and post-supplementation periods, and whether the fitted curves coincided between the two time periods. We used the methods described earlier to fit the Ricker, Beverton-Holt, and smooth hockey stick curves to the two data sets. We tested the following hypotheses.

Parameter equivalence:

Ho: Stock-recruitment parameters ( $\alpha$  and  $\beta$ ) of the pre-supplementation period = Stock-recruitment parameters of the supplementation period.

Ha: Stock-recruitment parameters ( $\alpha$  and  $\beta$ ) of the pre-supplementation period  $\neq$  Stock-recruitment parameters of the supplementation period.

Curve equivalence:

Ho: Modeled stock-recruitment curves from the pre-supplementation period = Modeled stock-recruitment curves from the pre-supplementation period.

Ha: Modeled stock-recruitment curves from the pre-supplementation period  $\neq$  Modeled stock-recruitment curves from the pre-supplementation period.

We were only able to fit stock-recruitment curves to the post-supplementation data. Non-linear regression was unable to converge on a solution using only pre-supplementation data. Therefore, we were unable to use this method to test supplementation effects on the Chiwawa spring Chinook population. If we could have fit curves to both the pre- and post-supplementation periods, we would have used two-sided randomization tests to evaluate the null hypotheses of equal model parameters and that fitted curves coincided.

Before describing correlation approaches, it is important to note that comparing before-after data can sometimes be misleading. For example, the spawner abundance, NORs, and productivity data presented in Figure 22 suggest that supplementation is increasing the abundance and productivity of spring Chinook in the Chiwawa Basin. However, when we compared these trends to those from reference populations during the same time periods (Figures 9-11), it becomes clear that supplementation was not responsible for increasing the trends in spawner abundance, NORs, and productivity of the Chiwawa population. Thus, whenever possible, it is wise to compare before-after data with a reference population.

### **Correlation Analyses**

A simple way to see if the supplementation program is increasing or decreasing productivity is to assess the association between the proportion of adult spawners that are made up of hatchery adults (pHOS) and productivity (recruits/spawner). If the supplementation program is working as planned, the increase in hatchery fish spawning naturally should increase the productivity of the population. It should not decrease the productivity of the population.

We tested the association between pHOS and adult productivity<sup>23</sup> using Pearson correlation. During the pre-supplementation period, productivity averaged 1.13 recruits/spawner; during the supplementation period, productivity averaged 1.39 recruits/spawner. This increase in productivity did not appear to be strongly correlated to pHOS (Figure 23). Correlation analysis showed that there was no significant association between pHOS and productivity, even though productivity increased with increasing pHOS.

---

<sup>23</sup> Note that the analysis could also include juvenile productivity (e.g., smolts/spawner).

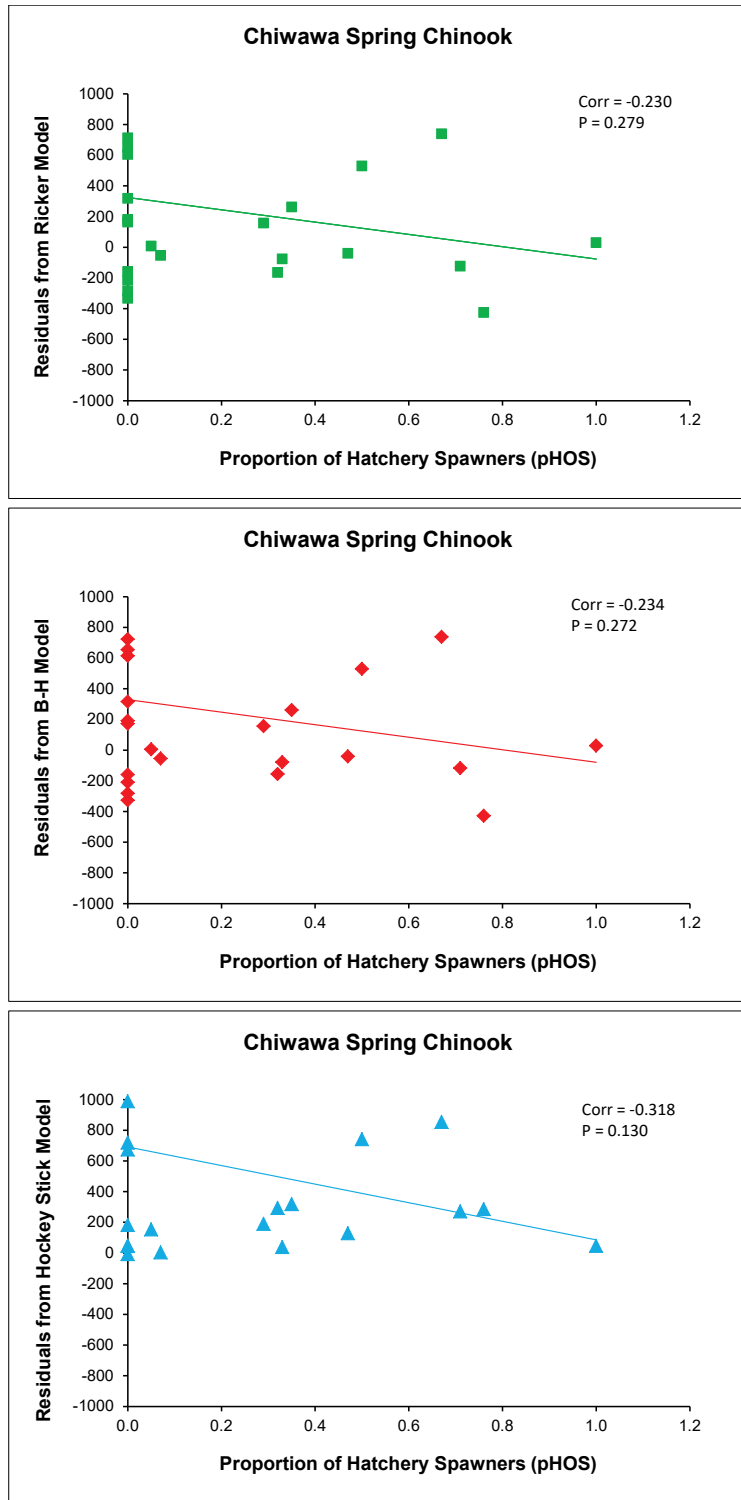

**Figure 23.** Association between the proportion of spawners that are made up of hatchery adults (pHOS) and the number of natural-origin recruits. The Pearson correlation coefficient (Corr) and its P-value (P) are shown in the figure.

The association between pHOS and productivity can also be assessed by testing the correlation between pHOS and the residuals from stock-recruitment curves fitted to the Chiwawa spawner and natural-origin recruitment data. This approach removes the effects of density dependence on the relationship between pHOS and productivity. A significant negative association provides evidence that hatchery-origin spawners may not be as productive as natural-origin spawners.

The Ricker, Beverton-Holt, and smooth hockey stick models were fit to the Chiwawa stock and recruitment data (including {S, R} data from both the pre- and post-supplementation period, 1981-2004) using methods described earlier. Residuals were calculated by subtracting the predicted recruitment values from the observed (modeled) values. Pearson correlation then tested the association between pHOS and the residuals from each model.

Although there was a negative trend in residuals with increasing pHOS, suggesting that hatchery-origin spawners may not be as productive as natural-origin spawners, the association was not significant (Figure 24). Thus, based on these analyses, there is no strong evidence that the supplementation program has significantly benefited or harmed the natural spring Chinook population.

**Figure 24.** Association between the proportion of spawners that are made up of hatchery adults (pHOS) and the residuals from Ricker, Beverton-Holt (B-H), and smooth hockey stick stock-recruitment models. The Pearson correlation coefficient (Corr) and its P-value (P) are shown in the figures.

### Comparison to Standards

In those cases in which suitable reference populations are not available and there are no pre-supplementation data, the investigator is left with comparing population parameters to relevant standards. Standards can include performance of natural-origin fish in similar environments (a type of reference condition), mitigation requirements, quantitative objectives of the program, Biological Assessment and Management Plan (BAMP) values, or other appropriate standards. An example of a statistical hypothesis would be:

Ho: Productivity (Recruits/Spawner) of the supplemented population  $\geq$  standard productivity.

Ha: Productivity (Recruits/Spawner) of the supplemented population  $<$  standard productivity.

For these analyses to be useful, the standards must be based on biological reality.

### Conclusions and Recommendations

Hatcheries are an important component of fish production within the Upper Columbia Basin. The goal of some of these programs is to supplement natural production in declining populations. The supplementation programs generally use both hatchery and natural (spawned and reared in nature from either wild or hatchery parents) adults for hatchery broodstock. These programs are designed to supplement natural populations by increasing natural reproduction while preventing the establishment of a domesticated hatchery stock. Thus, the programs should increase total spawning escapement and NORs, and not reduce the productivity of the natural population. Measuring the success of these programs is challenging and expensive.

In this paper, we described methods that can be used to determine if supplementation programs are achieving some of their goals. This paper focused on the use of reference populations to determine if the supplementation programs increase total spawning escapement, NORs, and maintain or increase productivities. In some cases, suitable reference populations may not be available (e.g., we found no suitable reference populations for Upper Columbia steelhead and sockeye). In these cases, alternative methods are needed to assess supplementation effects. We also described these alternative methods in this paper.

#### Identification of Reference Populations

Finding suitable reference populations that match well with supplemented populations is a difficult and time-consuming process. Our three-step selection process included identification of populations with similar life-history characteristics, few or no hatchery spawners, a long time series of accurate abundance and productivity estimates, and similar freshwater habitat impairments and out-of-basin effects. Those populations that met these criteria were then examined for their relationship with the supplemented population (in this case, the Chiwawa spring Chinook population). Several criteria were scored, including pNOS, correlation, trend, and effect size. Reference populations with total weighed scores of 81 or greater were selected as suitable reference populations.

This selection process provided a valuable framework for selecting suitable reference populations for supplemented populations. Interestingly, we found that a given reference population may match well with one parameter of the supplemented population (e.g., spawning escapement), but not for all parameters (e.g., not NORs or productivity). The reason for this may be related to errors

in the estimation of population parameters and/or differential factors limiting population parameters of supplemented and reference populations. Therefore, depending on the parameter analyzed, a different suite of reference populations may be needed.

An important assumption in the use of reference populations is that the supplemented and reference populations that tracked each other before supplementation would continue to track each other in the absence of supplementation. Given that the reference populations did not match the Chiyawa population on all criteria examined, and some reference populations tracked the Chiyawa population more poorly than others, there may be some uncertainty as to whether differences observed between the supplemented and reference populations during the supplementation period are associated with the hatchery program, or other unaccounted factors. For example, any large-scale change (man-made or natural) within the reference or supplemented population could affect our ability to assess the effectiveness of the supplementation program.

To account for some of these uncontrollable factors, we recommend the use of a “causal-comparative” approach to strengthen the certainty of our inferences. This approach relies on correlative data to try and make a case for causal inference. We recommend that the following state variables be measured and tracked within the supplemented and reference populations: mean annual precipitation, total and riparian forest cover, road density, impervious surface, and alluvium. These variables can be used to describe differences in water temperatures at different life stages (pre-spawning, egg incubation, and summer rearing) and substrate characteristics, including fine sediments and embeddedness. These state variables can be used to help explain possible changes in spawner abundance, NORs, and productivity that are independent of supplementation. In addition, the use of multiple reference streams reduces the possibility that man-made changes to a single reference stream will influence the interpretation of the results.

### **Analyses with Reference Populations**

Using reference populations, we evaluated the effects of supplementation on natural-log transformed and untransformed total spawning escapement, NORs, and productivity by comparing trends, analyzing mean differences, ratios, and rates, and comparing stock-recruitment curves and their parameters. For trend analysis, we compared the slopes of the trends between each supplemented/reference pair before and during supplementation. If the hatchery program is successfully supplementing the natural population, trends in spawner abundance and NORs should deviate significantly during the supplementation period (i.e., the slope of the supplemented population should be greater than the slopes of the reference populations during the supplementation period), but not during the pre-supplementation period. For productivity, the slope of the supplemented population, relative to the reference population, should increase or remain the same.

Because trend analysis only tests the slopes of the trend lines, it does not test for differences in elevations of the trend lines, additional analyses were needed to determine if supplementation increased spawner abundance, NORs, and productivity of the target population without changing the slopes of the trend lines. To do this, we derived three different response variables using natural-log transformed and untransformed spawner abundance, NORs, and productivity data. The first derived variable included difference scores, which were calculated as the difference between paired treatment and reference data (T-R). The second included ratios, which were calculated as the ratio of paired treatment and reference data (T/R). Finally, we calculated the differences in annual changes in paired treatment and reference population data ( $\Delta T - \Delta R$ ). If the hatchery

program is successfully supplementing the natural population, the mean difference or ratio score of paired spawner abundance data and NORs during the supplementation period should be greater than the pre-supplementation period. For productivity, the mean difference or ratio score during the supplementation period should be equal to or higher than the pre-supplementation period.

As a final set of analyses, we compared the stock-recruitment curves of the supplemented population (using stock and recruitment data only from the supplementation period) to the reference populations (using all available stock and recruitment data). Specifically, we tested whether the regression parameters were equal between the supplemented population and the reference populations, and whether the fitted curves coincided between populations. Here, we were most interested in comparing the productivity parameters in the models.

Surprisingly, these different analyses yielded similar results when they were applied to the Chiwawa spring Chinook and reference population data. Trend analysis was unable to detect a significant difference in trends between the supplemented and reference populations during the supplementation period. Even though we measured an increasing trend in spawner abundance, NORs, and productivity in the supplemented population during the supplementation period, these same parameters trended upward in the reference populations. Likewise, we were unable to detect a significant supplementation effect using difference scores, ratios, and differences in annual changes. However, we found the results from analysis of mean differences of annual change difficult to interpret and they may be insensitive to treatment effects. A simpler analysis, which is also easier to interpret, is to use trend analysis. Finally, comparing stock-recruitment curves and their parameters did not provide strong evidence that supplementation has affected the productivity of the natural population.

Based on these results, we do not recommend using difference scores of annual change ( $\Delta T - \Delta R$ ), nor do we recommend comparing stock-recruitment curves and their parameters. As noted above, difference scores of annual change are difficult to interpret and may be redundant with trend analysis. Testing stock-recruitment curves and their parameters appears redundant with testing differences in productivity using difference scores or ratios. In addition, the analyses are computer intensive and do not appear to be very sensitive to changes.

There was little difference in results using difference scores and ratios. It appears that ratios may be more sensitive to change than difference scores (e.g., we found significant differences in some comparisons using ratios but not with difference scores), but ratios can be more difficult to interpret than difference scores. Nevertheless, we recommend the use of ratios in future analyses.

### **Correcting for Density Dependence and Carrying Capacity**

The analyses described so far assumed that the density of spawners or recruits did not affect the survival and productivity of fish. However, without controlling for density effects, productivity of the population would continue to decline with increasing abundance. This scenario could occur in supplementation programs that increase the number of spawners, and could result in lower productivities relative to reference populations. In addition, lower productivities may be caused by differential environmental carrying capacities rather than the capacity of the supplemented fish to produce offspring. Therefore, we described two different methods for deriving density-corrected estimates of productivity. The first controlled the effects of density on productivity by partitioning observed productivities into density-independent and density-dependent productivity. These productivities were then combined in a single test. The second method corrected for differences in carrying capacities between the supplemented and reference populations. This was accomplished

by calculating the percent saturation of NORs, which was estimated as the ratio of observed NORs to the maximum number of NORs that the habitat could support.

We fit Ricker, Beverton-Holt, and smooth hockey stick models to stock and recruitment data to estimate the maximum number of NORs (NORs at carrying capacity) and the maximum number of spawners needed to produce maximum NORs. We fit models to the supplemented and reference populations. Using information-theoretic criterion and evaluating the precision of estimated parameters, we found that the smooth hockey stick model provided the best estimates of maximum NORs and spawners. We used these modeled values to estimate density-independent and density-dependent productivities, and saturation of NORs.

Statistical analyses, using difference scores and ratios of adjusted Chiwawa spring Chinook productivity data, found no significant effects of supplementation on the productivity of the supplemented population. Indeed, the results from correcting for density dependence were similar to those without correcting for density dependence. This is in part because the abundance of the supplemented and reference populations has been below their respective carrying capacities in most years. This was clearly demonstrated in the analyses of NORs corrected for carrying capacity. In the supplemented population, the mean fraction of the carrying capacity filled with NORs decreased significantly during the supplementation period. In other words, the carrying capacity was filled with more NORs during the pre-supplementation period than during the supplementation period, which is contrary to the goal of supplementation. By comparison, two of the reference populations showed a similar decrease in saturation, while the other two reference populations actually increased in saturation. Analyzing the saturation scores using BACI-design analyses indicated that two of the four pairings differed significantly. That is, the percent saturation of the supplemented population decreased significantly relative to two reference populations.

Because productivity can be affected by the abundance of spawners and recruits, we recommend that future analyses comparing supplemented and reference populations adjust for density-dependent effects and differential carrying capacities. Although we detected only slight differences between adjusted and unadjusted results, as supplemented stocks recover, it will become more important to adjust productivities to account for density dependence. Importantly, the analyses using percent saturation placed NORs in the context of the carrying capacity of the environment. This will help managers determine if supplementation programs are filling or over-filling the capacity of the habitat with NORs.

As we noted earlier, analyses using productivities adjusted for density dependence assume that there is a spawner abundance at which density-independent effects end and density-dependent effects begin. In reality, density-dependent effects occur at low spawning abundance and intensify as spawning abundance increases. We did not account for these increasing density-dependent effects at lower spawner abundances. This is an area that needs additional attention.

### **Analyses without Reference Populations**

Because of the rigorous criteria we used to select reference populations, it is likely that reference populations may not exist for making comparisons with supplemented populations. For example, we used the criteria described in this paper to identify reference populations for supplemented steelhead and sockeye populations in the Upper Columbia Basin. We were unsuccessful in identifying any suitable reference populations. Therefore, in the absence of suitable reference populations, it is important to have alternative methods for assessing supplementation effects. We described three different types of analyses one can use to assess supplementation effects in the

absence of reference populations. They include before-after comparisons, correlation analysis, and comparisons to standards.

Before-after analyses compare population metrics before supplementation with those during supplementation. In this case, data collected before supplementation represent the reference condition. The assumption is that population trajectories measured during the pre-supplementation period would continue in the absence of supplementation. We compared trends in spawner abundance, NORs, and productivity before and after supplementation. In addition, we compared mean scores in these three parameters before and after supplementation. Finally, we attempted to compare stock-recruitment parameters before and after supplementation. The hypotheses examined were that the spawner abundance and NORs would be greater during the supplementation period, and that productivities would not decline during the supplementation period.

Trend analysis indicated that the all three Chiwawa spring Chinook population parameters trended downward during the pre-supplementation period, but trended upward during supplementation. On the other hand, mean spawner abundance and NORs were lower during the supplementation period than during the pre-supplementation period. Mean productivities increased, but not significantly, during the supplementation period. We were unable to compare pre- and post-supplementation stock-recruitment curves because we were unable to fit stock-recruitment models to the pre-supplementation data.

We used correlation analyses to determine if the proportion of hatchery-origin fish that spawn naturally on the spawning grounds (pHOS) increased productivity. In addition, we used correlation to assess the association between pHOS and the residuals from stock-recruitment relationships. A significant negative association provides evidence that hatchery-origin spawners may not be as productive as natural-origin spawners. The analysis indicated that the productivity of Chiwawa spring Chinook increased with increasing pHOS, but the association was not significant. In contrast, there was a negative association between pHOS and the stock-recruitment residuals, but again the association was not significant. The latter analysis accounts for density-dependent effects.

In concert, the before-after comparisons and correlation analyses do not provide conclusive evidence that the supplementation program has increased spawner abundance and NORs, or that it has significantly reduced the productivity of the supplemented population. Although increasing the number of hatchery fish on the spawning grounds appears to reduce NORs and productivity, mean productivity actually increased during the supplementation period compared to the pre-supplementation period.

It is important to note that relying on only one set of analysis could result in drawing a wrong conclusion. For example, if we had only conducted trend analysis, we may have concluded wrongly that the Chiwawa spring Chinook supplementation program significantly increased spawner abundance, NORs, and productivity in the supplemented population. The analysis of mean scores and correlations indicates that the supplementation program has not increased spawner abundance or NORs in the supplemented population. Therefore, in the absence of suitable reference populations, we recommend that analyses include the evaluation of trends, means scores, and correlations. By conducting more than one set of analyses, one can use weight-of-evidence to assess the effects of supplementation programs.

Under the scenario that there are no reference populations or pre-supplementation data, one is left with comparing population parameters to relevant standards. These standards could come from mitigation requirements, quantitative objectives, or published or unpublished standards. One could also use correlation to evaluate the association between productivity and pHOS, but this requires a wide range in pHOS values to be most effective. A more extreme approach, which probably would not gain much traction with managers, is to shutoff the supplementation program for some time and then evaluate the effects of the program in a before-after design. The Entiat spring Chinook hatchery program provides a unique opportunity to evaluate this type of management decision.

### **Some Concerns and Limitations**

No matter how hard we try to explain different sources of variation in population data, we are limited by the quality of the data. Teasing out the effects of supplementation requires long time series of population data. Because funding levels and methods change over time, the quality (i.e., accuracy and precision) of the data also changes over time. Importantly, the population parameters examined in this paper (spawner abundance, NORs, and productivity) are rarely measured directly in the field. That is, other population metrics, such as numbers of redds, number of fish counted at weirs or dams, scales, tags, etc., are sampled in the field. These metrics are then used to calculate spawner abundance<sup>24</sup>, NORs, and productivity, often based on assumptions about fish/redd, pre-spawning loss, marking rates, and sampling rates. This has a tendency to increase the variability in the data independent of supplementation programs. In our studies, we can only control sampling within the supplemented populations, and even that is limited by available funding. We have no control over the sampling within reference populations. Thus, we have to assume that sampling within the reference populations will continue and that sampling effort will remain comparable to that in the supplemented populations.

In our analyses, we included both the Entiat and Little Wenatchee populations as references for the Chiwawa population. In the analyses, we treated them as equivalent to the other reference populations. That is, the statistical procedures used to compare the supplemented population to each reference population were identical. This is appropriate. However, the interpretation of the results must be different when comparing the Entiat and Little Wenatchee to the supplemented population, because they are populations that were influenced by hatchery fish. As noted earlier, the Entiat spring Chinook hatchery program has been discontinued. Therefore, it provides a unique type of reference where the comparison changes from both populations being supplemented to only one population being supplemented. For the Little Wenatchee, nearly all the strays came from the Chiwawa program. Straying should stop or be greatly reduced with the change in water supply to the Chiwawa Rearing Ponds. In sum, one must be careful in how they interpret these test-reference results.

Finally, it is important to point out that for this paper, we conducted 463 statistical tests. Because we set our Type I error rate at 0.05, by random chance alone, we may have incorrectly rejected about 23 null hypotheses. Inasmuch as this work was designed to evaluate different ways to analyze test-reference data, the number of future analyses will be greatly reduced based on the results from this work. However, if the Type I error rate is a concern to managers, researchers can

---

<sup>24</sup> The smooth hockey stick model, which we used to estimate density-dependent correction factors for productivity and NORs, is sensitive to errors in spawner escapement estimates. Therefore, it is important to use accurate and precise estimates of spawner escapement.

use a lower error rate, such as  $\alpha = 0.01$ . Another option is to analyze test-reference data graphically. Although this is subjective, there are no statistical analyses and therefore no concerns with violating assumptions of statistical tests, including temporal correlation. We believe researchers should use the statistical procedures recommended in this report to support graphic analysis.

## LIST OF APPENDICES

---

- Appendix A:** Abundance and Total Numbers of Chinook Salmon and Trout in the Chiwawa River Basin, Washington, 2016.
- Appendix B:** Fish Trapping at the Chiwawa and Wenatchee Smolt Traps during 2016.
- Appendix C:** Summary of CSS PIT-Tagging Activities in the Wenatchee River Basin, 2016.
- Appendix D:** Wenatchee Steelhead Spawning Escapement Estimates, 2016.
- Appendix E:** Examining the Genetic Structure of Wenatchee River Basin Steelhead and Evaluating the Effects of the Supplementation Program.
- Appendix F:** NPDES Hatchery Effluent Monitoring, 2016.
- Appendix G:** Steelhead Stock Assessment at Priest Rapids Dam, 2016.
- Appendix H:** Wenatchee Sockeye Salmon Spawning Escapement, 2016.
- Appendix I:** Genetic Diversity of Wenatchee Sockeye Salmon.
- Appendix J:** Wenatchee Spring Chinook Redd Estimates, 2016.
- Appendix K:** Genetic Diversity of Natural Chiwawa River Spring Chinook Salmon.
- Appendix L:** Fish Trapping at the Nason Creek Smolt Trap during 2016.
- Appendix M:** Fish Trapping at the White River Smolt Trap during 2016.
- Appendix N:** Genetic Diversity of Upper Columbia Summer Chinook Salmon.
- Appendix O:** Summer Chinook Spawning Ground Surveys in the Methow and Chelan Rivers, 2016.

## PREFACE

---

This annual report is the result of coordinated field efforts conducted by Washington Department of Fish and Wildlife (WDFW), the Confederated Tribes and Bands of the Yakama Nation (Yakama Nation), Chelan County Public Utility District (Chelan PUD), the Confederated Tribes of the Colville Reservation (Colville Tribes), the U.S. Fish and Wildlife Service (USFWS), and BioAnalysts, Inc. An extensive amount of work was conducted in 2006 through 2016 to collect the data needed to monitor the effects of the Chelan and Grant County PUD Hatchery Programs. This work was directed and coordinated by the Habitat Conservation Plans (HCP) Hatchery Committees, consisting of the following members: Bill Gale and Matt Cooper, USFWS; Justin Yeager and Craig Busach, National Marine Fisheries Service (NMFS); Catherine Willard and Alene Underwood, Chelan PUD; Tom Scribner and Keely Murdoch, the Yakama Nation; Mike Tonseth, WDFW; Kirk Truscott, Colville Tribes; and Tracy Hillman, BioAnalysts (Chair). This report also includes monitoring efforts funded by Grant County Public Utility District (Grant PUD). Grant PUD helps fund the spring and summer Chinook monitoring programs. Work funded by Grant PUD was directed and coordinated by the Priest Rapids Coordinating Committee (PRCC) Hatchery Sub-Committee, which consists of the same agency and tribal representatives listed for the HCP Hatchery Committee and replaces Chelan PUD representatives with Grant PUD representatives, Todd Pearsons, Peter Graf, and Deanne Pavlik-Kunkel.

The approach to monitoring the hatchery programs was guided by the updated monitoring and evaluation plan for PUD hatchery programs (Hillman et al. 2013). Technical aspects of the updated monitoring and evaluation program were developed by the Hatchery Evaluation Technical Team (HETT), which consisted of the following scientists: Matt Cooper, USFWS; Tracy Hillman, BioAnalysts; Tom Kahler, Douglas PUD; Greg Mackey, Douglas PUD; Andrew Murdoch, WDFW; Keely Murdoch, Yakama Nation; Todd Pearsons, Grant PUD; Mike Tonseth, WDFW; and Catherine Willard, Chelan PUD. The updated plan also directs the analyses of hypotheses developed by the HETT. Most of the analyses outlined in the updated plan will be conducted in the comprehensive reports.

Most of the work reported in this document was funded by Chelan and Grant PUDs. Bonneville Power Administration purchased some of the Passive Integrated Transponder (PIT) tags that were used to mark juvenile Chinook and steelhead captured in tributaries and also helped fund a portion of the screw trap efforts in Nason Creek. We thank Charlie Paulsen for analyzing PIT-tag data for each program. This is the 11<sup>th</sup> annual report written under the direction of the HCP.

*“I often say that when you can measure something and express it in numbers, you know something about it. When you cannot measure it, when you cannot express it in numbers, your knowledge is of a meager and unsatisfactory kind. It may be the beginning of knowledge, but you have scarcely in your thoughts advanced to the stage of science, whatever it may be.”*

*Lord Kelvin*

## SECTION 1: INTRODUCTION

Chelan and Grant PUDs implement hatchery programs as part of their respective agreements related to the operation of Rocky Reach, Rock Island, Wanapum, and Priest Rapids Hydroelectric Projects. The fish resource management agencies developed the following general goal statements for the hatchery programs, which were adopted by the HCP Hatchery Committees and PRCC Hatchery Sub-Committee (hereafter, Hatchery Committees):

1. *Support the recovery of ESA-listed species by increasing the abundance of the natural adult population, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity.*

Includes the Wenatchee spring Chinook, Wenatchee summer steelhead, and Methow spring Chinook programs.

2. *Increase the abundance of the natural adult population of unlisted plan species, while ensuring appropriate spatial distribution, genetic stock integrity, and adult spawner productivity. In addition, provide harvest opportunities in years when spawning escapement is sufficient to support harvest.*

Includes the Wenatchee sockeye, Wenatchee summer/fall Chinook, Methow summer/fall Chinook, Okanogan summer/fall Chinook, and Okanogan sockeye programs.

3. *Provide salmon for harvest and increase harvest opportunities, while segregating returning adults from natural tributary spawning populations.*

Includes the Chelan Falls summer Chinook program.

Following the development of the Hatchery and Genetic Management Plans (HGMPs), artificial propagation programs are now characterized into three categories. The first type, integrated conservation programs, are intended to support or restore natural populations. These programs focus on increasing the natural production of targeted fish populations. A fundamental assumption of this strategy is that adults spawned in the hatchery will produce more adult offspring than if they were left to spawn in the river and ultimately provide a demographic boost to the natural population. The second type, safety-net programs, are extensions of conservation programs, but are intended to function as reserve capacity for conservation programs in years of low returns. The safety-net provides a demographic and genetic reserve for the natural population. That is, in years of abundant returns, they function like segregated programs, and in years of low returns, they can be managed as conservation programs. Lastly, harvest augmentation programs are intended to increase harvest opportunities while limiting interactions with wild-origin counterparts.

Monitoring is needed to determine if the hatchery programs are meeting the intended management objectives of conservation, safety-net, or harvest augmentation programs. Objectives for hatchery programs are generally grouped into three categories of performance indicators:

1. In-Hatchery Indicators: Are the programs meeting the hatchery production objectives?
2. In-Nature Indicators: How do hatchery fish from the programs perform after release?

- a. Conservation Programs:
    - How do the programs affect target population abundance and productivity?
    - How do the programs affect target population long-term fitness?
  - b. Safety-Net Programs:
    - How do the programs affect target population long-term fitness?
  - c. Harvest Augmentation Programs:
    - Do the programs provide harvest opportunities?
3. Risk Assessment Indicators: Do the programs pose risks to other populations?

The specific objectives identified in the updated monitoring and evaluation plan are as follows:

1. *Determine if conservation programs have increased the number of naturally spawning and naturally produced adults of the target population and if the program has reduced the natural replacement rate (NRR) of the supplemented population.*
2. *Determine if the proportion of hatchery fish on the spawning grounds affects the freshwater productivity of supplemented stocks.*
3. *Determine if the hatchery adult-to-adult survival (i.e., hatchery replacement rate, HRR) is greater than the natural adult-to-adult survival (i.e., natural replacement rate, NRR) and the target hatchery survival rate.*
4. *Determine if the proportion of hatchery-origin spawners (pHOS or PNI) is meeting management target.*
5. *Determine if the run timing, spawn timing, and spawning distribution of both the hatchery component is similar to the natural component of the target population or is meeting program-specific objectives.*
6. *Determine if stray rate of hatchery fish is below the acceptable levels to maintain genetic variation among stocks.*
7. *Determine if genetic diversity, population structure, and effective population size have changed in natural spawning populations as a result of the hatchery program.*
8. *Determine if hatchery programs have caused changes in phenotypic characteristics of natural populations.*
9. *Determine if hatchery fish were released at the programmed size and number.*
10. *Determine if appropriate harvest rates have been applied to conservation, safety-net, and segregated harvest programs to meet the HCP/SSSA goal of providing harvest opportunities while also contributing to population management and minimizing risk to natural populations*

Two additional regional objectives that were not explicit in the goals specified above but were included in the updated monitoring and evaluation plan because they relate to goals and concerns of all artificial production programs include:

11. Determine if the incidence of disease has increased in the natural and hatchery populations.
12. Determine if the release of hatchery fish affects non-target taxa of concern (NTTOC) within acceptable limits.

Objective 12 was completed using an extensive risk assessment that concluded risks from the PUD hatchery programs were within containment objectives approved by the Hatchery Committees (Mackey et al. 2014; Pearsons et al. 2012).

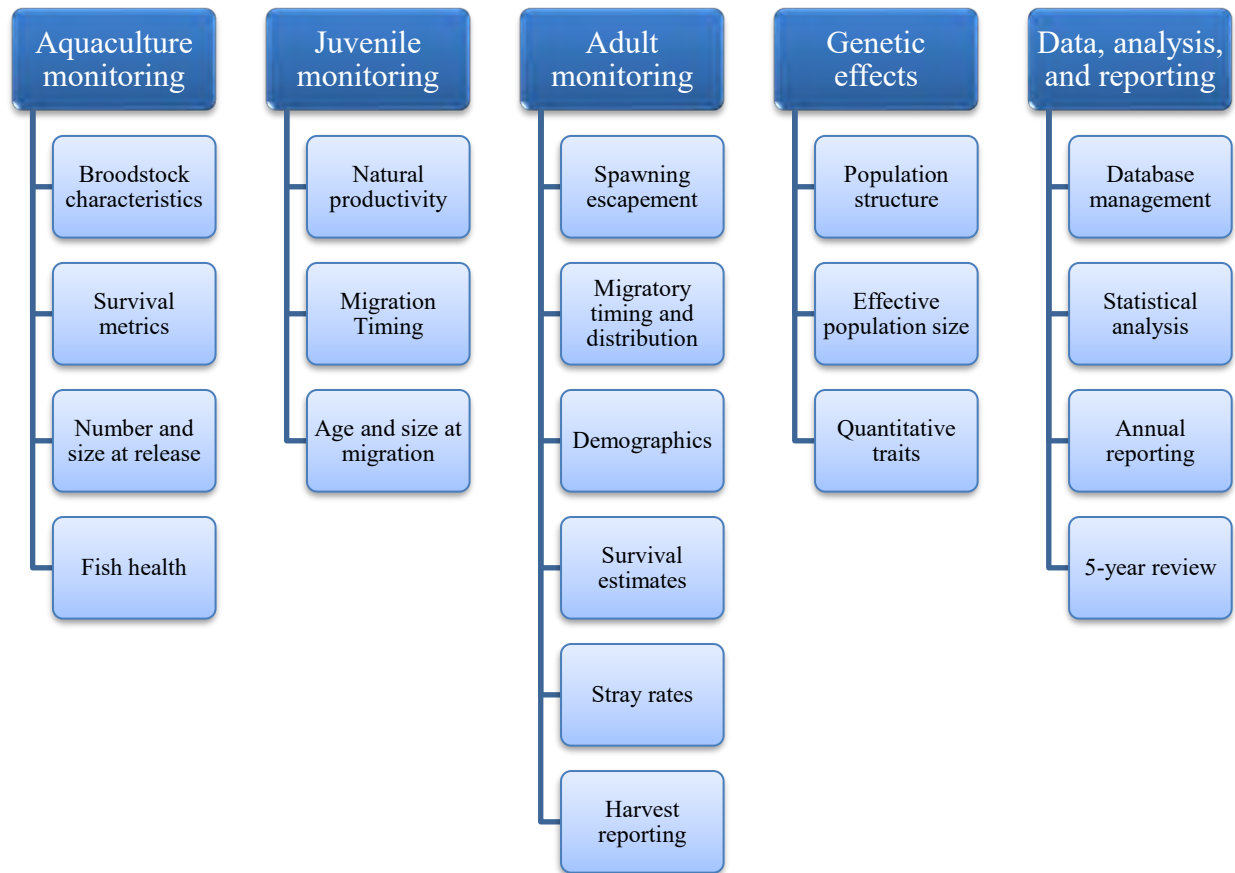

Objectives in the updated plan have been organized in a hierarchy where productivity indicators are the primary metrics used to assess if conservation and safety-net program goals have been met; harvest rates and effects on non-targeted populations are used for harvest programs. In cases where productivity indicators are not available, or results are equivocal, monitoring indicators may be used to help evaluate the performance of the program. Evaluations of monitoring indicators may not provide sufficiently powerful conclusions on which to base management actions; although they may provide insight as to why a productivity indicator did or did not meet the program goal. Therefore, the relationship between hatchery programs and indicators can be viewed in a chain-of-causation: management actions within the hatchery programs affect the status of monitoring indicators, which in turn influence productivity indicators (Figure 1.1).

**Figure 1.1.** Relationship of indicators to the assessment of propagation programs. Management actions affect monitoring indicators, which influence productivity indicators. Monitoring indicators may be used to hypothesize the magnitude of influence on productivity.

Attending each objective is one or more testable hypotheses (see Hillman et al. 2013). Each hypothesis will be tested statistically following the routines identified in the updated monitoring and evaluation plan. Most of these analytical routines will be conducted at the end of five-year monitoring blocks, as outlined in the updated plan.

Both monitoring and productivity indicators will be used to evaluate the success of the hatchery programs. If the statistical power of tests that involve productivity indicators is insufficient to inform sound management decisions, some of the monitoring indicators may be used to guide management. Figure 1.2 shows the categories of indicators associated with each component of monitoring.

**Figure 1.2.** Overview of monitoring and evaluation plan categories and components (not including regional objectives).

Throughout each five-year monitoring period, annual reports will be generated that describe the monitoring and evaluation data collected during a specific year. This is the 11<sup>th</sup> annual report developed under the direction of the Hatchery Committees. The purpose of this report is to describe monitoring activities conducted in 2016. Activities included broodstock collection, collection of life-history information, within hatchery spawning and rearing activities, juvenile monitoring within streams, and redd and carcass surveys. Data from reference areas are not included in this annual report (reference data are in the five-year reports). To the extent currently possible, we have included information collected before 2016.

This report is divided into several sections, each representing a different species, stock, or spawning aggregate (i.e., steelhead, sockeye salmon, spring Chinook salmon, and summer Chinook salmon). For all species, we provide annual broodstock information; hatchery rearing history, release data, and survival estimates; disease information; juvenile migration and productivity estimates; redd counts, distribution, and spawn timing; spawning escapements; and life-history characteristics. For salmon species, we also provide information on carcasses. Brood year 2011 was the final sockeye salmon hatchery release, and beginning in 2013, only natural adult and juvenile sockeye productivity monitoring results are reported. Beginning in 2013, we added a separate section on Nason Creek spring Chinook salmon and in 2014 we added a separate section on White River spring Chinook salmon. The Colville Tribes began conducting monitoring of

Okanogan summer Chinook in 2013; however, we retained the Okanogan summer Chinook section in this report because the PUDs have summer Chinook mitigation obligations in the Okanogan River basin. The Okanogan summer Chinook section includes monitoring information up to the return of brood year 2013 Chinook. Monitoring results for brood years 2013 to present can be found in annual reports prepared by the Colville Tribes to Bonneville Power Administration (BPA). Monitoring results of Grant PUD's fall Chinook salmon mitigation produced at Priest Rapids Hatchery can be found in annual reports written by WDFW and Grant PUD.

Finally, we end each section by addressing compliance issues with ESA/HCP mandates. For each Hatchery Program, WDFW and the PUDs are authorized annual take of ESA-listed spring Chinook and steelhead through Section 10 of the Endangered Species Act (ESA), including:

1. ESA Section 10(a)(1)(A) Permit No. 1395, which authorizes the annual take of adult and juvenile endangered upper Columbia River (UCR) spring Chinook and endangered UCR steelhead associated with implementing artificial propagation programs for the enhancement of UCR steelhead. The authorization includes takes associated with adult broodstock collection, hatchery operations, juvenile fish releases, monitoring and evaluation activities, and management of adult returns related to UCR steelhead artificial propagation programs in the UCR region (NMFS 2003a).
2. ESA Section 10(a)(1)(A) Amended Permit No. 18121, which authorizes the annual take of adult and juvenile endangered UCR spring Chinook and endangered UCR steelhead associated with implementing artificial propagation programs in the Chiwawa River for the enhancement of UCR spring Chinook. The authorization includes takes associated with adult broodstock collection, hatchery operations, juvenile fish releases, and monitoring and evaluation activities supporting UCR spring Chinook artificial propagation programs in the UCR region (NMFS 2003, amended in 2015).
3. ESA Section 10(a)(1)(A) Permit No. 18118, which authorizes the annual take of adult and juvenile endangered UCR spring Chinook and endangered UCR steelhead associated with implementing artificial propagation programs in Nason Creek for the enhancement of UCR spring Chinook. The authorization includes takes associated with adult broodstock collection, hatchery operations, juvenile fish releases, and monitoring and evaluation activities supporting UCR spring Chinook artificial propagation programs in the UCR region (NMFS 2003, amended in 2015).
4. ESA Section 10(a)(1)(A) Permit No. 18119, which authorizes the annual take of adult and juvenile endangered UCR spring Chinook and endangered UCR steelhead associated with implementing artificial propagation programs in the White River for the enhancement of UCR spring Chinook. The authorization includes takes associated with adult broodstock collection, hatchery operations, juvenile fish releases, and monitoring and evaluation activities supporting UCR spring Chinook artificial propagation programs in the UCR region (NMFS 2003, amended in 2015).
5. ESA Section 10(a)(1)(A) Permit No. 1347, which authorizes the annual incidental take of adult and juvenile endangered UCR spring Chinook and endangered UCR steelhead through actions associated with implementing artificial propagation programs for the enhancement of non-listed anadromous fish populations in the UCR. The authorization includes incidental takes associated with adult broodstock collection, hatchery operations, juvenile fish releases, and monitoring and evaluation activities associated with non-listed

summer Chinook, fall Chinook, and sockeye salmon artificial propagation programs in the UCR region (NMFS 2003b).

## SECTION 2: SUMMARY OF METHODS

Sampling in 2016 followed the methods and protocols described in Hillman et al. (2013). In this section, we only briefly review the methods and protocols. More detailed information can be found in the updated monitoring and evaluation plan (Hillman et al. 2013).

### 2.1 Broodstock Collection and Sampling

Methods for collecting broodstock are described in the Annual Broodstock Collection Protocols (WDFW 2016). Generally, broodstock were collected over the migration period (to the extent allowed in ESA-permit provisions) in proportion to their temporal occurrence at collection sites, with in-season adjustments dictated by 2016 run timing and trapping success relative to achieving weekly and annual collection objectives. Pre-season weekly collection objectives are shown in Table 2.1 and assumptions associated with broodstock trapping are provided in Table 2.2.

**Table 2.1.** Weekly collection objectives for steelhead and Chinook in 2016.

| Collection week beginning day | Chiwawa/Nason Spring Chinook <sup>a</sup> |            | Hatchery Chelan Falls Summer Chinook | Wild Wenatchee Summer Chinook | Wild Methow Summer Chinook | Wenatchee Steelhead |           |
|-------------------------------|---|------------|--------------------------------------|-------------------------------|----------------------------|---------------------|-----------|
|                               | Hatchery                                  | Wild       |                                      |                               |                            | Hatchery            | Wild      |
| 30 May                        | 6   | 4          |                                      |                               |                            |                     |           |

<sup>a</sup> Chiwawa NOR spring Chinook (n = up to 80) were collected from the Chiwawa Weir with no specific weekly objectives generated, which is consistent with the Broodstock Collection Protocols. Previously PIT-tagged Chiwawa NOR spring Chinook were also targeted at Tumwater Dam. All Nason Creek spring Chinook were collected at Tumwater Dam from the week of 30 May

through the week of 11 July proportionate to run timing. For 2016, HOR Chiwawa spring Chinook were collected for the Nason spring Chinook safety net program.

Several biological parameters were measured during broodstock collection at adult collection sites. Those parameters included the date and start and stop time of trapping; number of each species

<sup>1</sup> Throughout this document, “HxH” refers to hatchery-origin by hatchery-origin crosses and “WxW” refers to natural-origin by natural-origin crosses.

collected for broodstock; origin, size, and sex of trapped fish; age from scale analysis; and pre-spawn mortality. For each species, trap efficiency, extraction rate, and trap operation effectiveness were estimated following procedures in Hillman et al. (2013). In addition, a representative sample of most species trapped but not taken for broodstock were sampled for origin, sex, age, and size (stock assessment).

## 2.2 Within Hatchery Monitoring

Methods for monitoring hatchery activities are described in Hillman et al. (2013). Biological information collected from all spawned adult fish included age at maturity, length at maturity, spawn time, and fecundity of females. In addition, all fish were checked for tags and females were sampled for pathogens.

Throughout the rearing period in the hatchery, fish were sampled for growth, health, and survival. Each month, lengths and weights were collected from a sample of fish and rearing density indices were calculated. In addition, fish were examined monthly for health problems following standard fish health monitoring practices for hatcheries. Various life-stage survivals were estimated for each hatchery stock. These estimates were then compared to the “standard” survival rates identified in Table 2.3 to provide insight as to how well the hatchery operations were performing. Failure to achieve a survival standard could indicate a problem with some part of the hatchery program. However, failure to meet a standard may not be indicative of the overall success of the program to meet the goals identified in Section 1.

**Table 2.3.** Standard life-stage survival rates for fish reared within the Chelan PUD hatchery programs (from Hillman et al. 2013).

| Life stage                       | Standard survival rate (%) |
|----------------------------------|----------------------------|
| Collection-to-spawning (females) | 90                         |
| Collection-to-spawning (males)   | 85                         |
| Unfertilized egg-to-eyed         | 92                         |
| Unfertilized egg-to-ponding      | 98                         |
| 30 d after ponding               | 97                         |
| 100 d after ponding              | 93                         |
| Ponding-to-release               | 90                         |
| Transport-to-release             | 95                         |
| Unfertilized egg-to-release      | 81                         |

Nearly all hatchery fish from each stock were marked (adipose fin clip) or tagged (coded-wire tag) in 2016. Different combinations of marks and tags were used depending on the stock. In addition, Chelan PUD personnel PIT tagged 10,207 juvenile WxW Chiwawa spring Chinook and 10,104 juvenile Nason Creek spring Chinook (5,052 WxW and 5,050 HxH); 5,050 Wenatchee WxW steelhead (Circular Ponds), 12,626 Wenatchee WxW and HxH steelhead (Raceway), and 2,525 Wenatchee steelhead (Blackbird Pond); and 10,103 Chelan River summer Chinook, 5,064 Methow (Carlton) summer Chinook, and 20,994 Wenatchee summer Chinook (10,565 Raceway and 10,429 Circular Ponds). PIT tags will be used to estimate migration timing and survival rates (e.g., smolt-to-adult) outside the hatchery.

Lastly, the size and number of fish released were assessed and compared to programmed production levels. The goal of the program is that numbers released and their sizes should fall within 10% of the programmed targets identified in Table 2.4. However, because of constraints due to run size and proportions of wild and hatchery adults, production levels may not be met every year.

**Table 2.4.** Targets for fish released from the PUD hatchery programs; CV = coefficient of variation.

| Hatchery stock                          | Release targets | Size targets     |            |                 |
|---|-----------------|------------------|------------|-----------------|
|   |                 | Fork length (CV) | Weight (g) | Fish/pound      |
| Wenatchee Summer Chinook                | 500,001         | 163 (9.0)        | 45.4       | 18 <sup>a</sup> |
| Methow Summer Chinook                   | 200,000         | 163 (9.0)        | 45.4       | 13-17           |
| Chelan Falls Summer Chinook (yearlings) | 576,000         | 161 (9.0)        | 45.4       | 13 <sup>b</sup> |
| Chiwawa Spring Chinook                  | 144,026         | 155 (9.0)        | 37.8       | 18              |
| Nason Spring Chinook                    | 223,670         | 155 (9.0)        | 37.8       | 18              |
| Wenatchee Steelhead                     | 247,300         | 191 (9.0)        | 75.6       | 6               |

<sup>a</sup>An experimental release size of 30-45 grams (10-15 FPP) was in place for brood years 2012-2014.

<sup>b</sup>An experimental release size of 20-45 grams (10-22 FPP) was in place for brood years 2012-2014.

## 2.3 Juvenile Sampling

Juvenile sampling within streams included operation of rotary screw traps, snorkel observations, and PIT tagging. Methods for sampling juvenile fish are described in Hillman et al. (2013).

A smolt trap was located on the Wenatchee River near the town of Cashmere at RM 8.3 (Lower Wenatchee Trap), in Nason Creek about 0.6 miles upstream from the mouth, in the White River about 5.8 miles upstream from the mouth, and in the Chiwawa River about 0.4 miles upstream from the mouth (Chiwawa Trap). All traps operated throughout the smolt migration period. The Chiwawa Trap operated between 2 March and 21 November 2016. The Nason Creek Trap operated from 1 March to 30 November in 2016. The White River trap operated from 1 March through 30 November 2016. The Lower Wenatchee Trap operated between 29 January and 26 June 2016. Throughout the trapping period, the traps were briefly inoperable during periods when flows were too high or low, during high water temperatures, during large hatchery releases, and because of heavy debris loads, ice, and mechanical malfunctions.

The following data were collected at each trap site: water temperature, discharge, number and identification of all species captured, degree of smoltification for anadromous fish, presence of marks and tags, size (fork lengths and weights), and scales from smolts. Trap efficiencies at each trap site were estimated by using mark-recapture trials conducted over a wide range of discharges. Linear regression models relating discharge and trap efficiencies were developed to estimate daily trap efficiencies during periods when no mark-recapture trials were conducted. The total number of fish migrating past the trap each day was estimated as the quotient of the daily number of fish captured and the estimated daily trap efficiency. Summing the daily totals resulted in the total emigration estimate.

Snorkel observations were used to estimate the number of juvenile spring Chinook salmon, juvenile rainbow/steelhead, and bull trout within the Chiwawa River basin. The focus of the study was on juvenile spring Chinook salmon. Sampling followed a stratified random design with

proportional allocation of sites among strata. Strata were identified based on unique combinations of geology, land type, valley bottom type, stream state condition, and habitat types. A total of 187 randomly selected sites were surveyed during August (Table 2.5). Counts of fish within each sampling site were adjusted based on detection efficiencies, which were related to water temperature. That is, non-linear models that described relationships between water temperatures and detection efficiencies (Hillman et al. 1992) were used to estimate total numbers of fish within sampling sites. These numbers were then converted to densities by dividing total fish numbers by the wetted surface area and water volume of sample sites. Total numbers within a stratum were estimated as the product of fish densities times the total wetted surface or water volume for the stratum. The sum of fish numbers across strata resulted in the total number of fish within the basin. The calculation of total numbers, densities, and degrees of certainty are explained fully in Hillman and Miller (2004).

**Table 2.5.** Location of strata and numbers of randomly sampled snorkel sites within each stratum that were sampled in the Chiwawa River Basin in 2016.

| Reach/stratum                                 | River miles (RM) | Number of randomly selected sites |
|---|------------------|-----------------------------------|
| <b>Chiwawa River</b>                          |                  |                                   |

Working in collaboration with the Comparative Survival Study (CSS) funded by BPA, crews PIT tagged juvenile wild Chinook, wild steelhead, wild sockeye, and in some instances wild coho salmon collected at the smolt traps and collected within the Chiwawa River and Nason Creek using electrofishing techniques. The proposed number of wild spring Chinook and steelhead to be tagged at each location is provided in Table 2.6. The goal of this tagging program is to estimate freshwater juvenile productivity, better understand life-history characteristics, overwinter movement, and survival of salmonids, and to calculate SARs for spring Chinook salmon in the Wenatchee River basin. The PIT tagging effort funded by the PUDs in the Chiwawa River and Nason Creek is specifically directed at addressing uncertainties of estimating abundance using screw traps (e.g., fish passage during times when trapping is not possible).

**Table 2.6.** Number of wild spring Chinook, steelhead ( $\geq 65$  mm), and sockeye proposed for PIT tagging at different locations within the Wenatchee River basin, 2016. NT = no sample size target.

| Sampling location       | Target sample size  |                |              |
|-------------------------|---------------------|----------------|--------------|
|                         | Wild spring Chinook | Wild steelhead | Wild Sockeye |
| Chiwawa Trap            | 2,500-8,000         | 500-2,000      | NT           |
| Nason Creek Trap        | 2,500-8,000         | 500-2,000      | NT           |
| White River Trap        | 200-500             | NT             | NT           |
| Lower Wenatchee Trap    | 1,000-2,500         | 50-250         | 3,000-5,000  |
| Chiwawa Remote Sampling | 3,000               | NT             | NT           |
| Nason Remote Sampling   | 3,000               | NT             | NT           |

Survival rates for various juvenile life-stages were calculated based on estimates of seeding levels (total egg deposition), parr abundance, numbers of emigrants, and smolt abundance. Total egg deposition was estimated as the product of the number of redds counted in the basin times the mean fecundity of female spawners. Fecundity was estimated from females collected for broodstock using an electronic egg counter. Numbers of emigrants and smolts were estimated at trapping sites and numbers of parr were estimated using snorkel observations only in the Chiwawa River basin. Survival estimates could not be calculated for some stocks (e.g., summer Chinook) because specific life-stage abundance estimates were lacking.

## 2.4 Spawning/Carcass Surveys

Methods for conducting carcass and spawning ground surveys are detailed in Hillman et al. (2013). Information collected during spawning surveys included spawn time, redd distribution, and redd abundance. Data collected during carcass surveys included sex, size (fork length and postorbital-to-hypural length), scales for aging<sup>2</sup>, degree of egg voidance, DNA samples, and identification of marks or tags. The sampling goal for carcasses was 20% of the spawning population.

<sup>2</sup> In this report, we use two methods of describing age. One is termed the “European Method.” This method has two digits, separated by a period. The first digit represents the number of winters the fish spent in freshwater before migrating to the sea. The second digit indicates the number of winters the fish spent in the ocean. For example, a fish designated as 1.2 spent one winter in freshwater and two in the ocean. A fish designated as 0.3 migrated to the ocean

Steelhead surveys were conducted throughout the mainstem Wenatchee River and downstream from PIT-tag interrogation systems on the Chiwawa River, Nason Creek, and Peshastin Creek. These surveys were conducted during March through June in reaches and index areas described in Table 2.7. Total redd counts in these reaches were estimated by expanding counts within non-index areas by expansion factors developed within index areas.

**Table 2.7.** Description of reaches and index areas surveyed for steelhead redds in the Wenatchee River basin.

| Stream          | Code            | Reach*                             | Index/reference area                     |

\* Reaches 2, 6, 8, 9, and 10 (major spawning areas) are surveyed weekly, while Reaches 1, 3, 5, and 7 (minor survey areas) are surveyed during peak spawning.

Beginning in 2014, adult steelhead escapement estimates in the majority of tributaries in the Wenatchee River basin were generated using mark-recapture techniques based on steelhead PIT tagged at Priest Rapids Dam. Mark-recapture estimates in the tributaries were then added to the estimates based on redd surveys to generate a total spawning escapement to the Wenatchee River basin.

Spring Chinook redd and carcass surveys were conducted during August through September in the Chiwawa River (including Rock and Chikamin creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), upper Wenatchee River, Little Wenatchee River, and the White River (including the Napeequa River and Panther Creek). Survey reaches for spring Chinook are described in Table 2.8.

**Table 2.8.** Description of reaches surveyed for spring Chinook redds and carcasses in the Wenatchee River basin.

| Stream        | Code | Reach                        | River mile (RM) |
|---------------|------|------------------------------|-----------------|

The sockeye salmon hatchery program ended after the 2011 brood year. As a result, monitoring activities that focused on evaluating the effects of the supplementation program on the natural population switched to monitoring the abundance and productivity of the natural population (McElhane et al. 2000). Thus, estimation of spawn time and carcass surveys were discontinued in 2014. Nevertheless, this report retains the results of carcass sampling during the period 1993-2013. Survey reaches in which carcasses and live fish (for area-under-the-curve estimates) were conducted are identified in Table 2.9.

From 2009-2013, mark-recapture methods were used to estimate sockeye spawning escapement within the White River, while area-under-the-curve (AUC) methods were used to estimate

spawning escapement within the Little Wenatchee River. Beginning in 2014, mark-recapture methods were used to estimate the spawning escapement of sockeye in both the White River and Little Wenatchee watersheds.

**Table 2.9.** Description of reaches surveyed for sockeye salmon carcasses and live fish in the Wenatchee River basin during survey years 1993-2013.

| Stream                 | Code | Reach                                 | River mile (RM) |

Wenatchee summer Chinook redd and carcass surveys were conducted from September through November throughout the entire mainstem Wenatchee River, which was divided into ten reaches (Table 2.10). Surveys were conducted weekly in all reaches. All redds were enumerated during weekly census counts.

**Table 2.10.** Description of reaches surveyed for summer Chinook redds in the Wenatchee River basin.

| Code | Reach                              | River mile |
|------|------------------------------------|------------|
| W1   | Mouth to Sleepy Hollow Br          | 0.0-3.3    |

Summer Chinook redd and carcass surveys were also conducted in the Methow and Chelan rivers from September through November. Total (map) redd counts were conducted in these rivers. Table 2.11 describes the survey reaches on the Methow River. The Colville Tribes conducted summer Chinook redd and carcass surveys in the Okanogan River basin. Those results are reported in a separate report (annual report to BPA).

**Table 2.11.** Description of reaches surveyed for summer Chinook redds and carcasses on the Methow, Okanogan, and Similkameen rivers.

For summer and spring Chinook, total spawning escapements for each population were estimated as the product of total number of redds times the ratio of fish per redd for a specific stock.<sup>3</sup> Fish per redd ratios were estimated as the ratio of males to females sampled at broodstock collection sites and monitoring sites (e.g., Leavenworth National Fish Hatchery, Dryden Dam, Tumwater Dam, Chiwawa Weir, etc.). For steelhead, spawning escapement was estimated with a combination of PIT-tag-based tributary and redd-based mainstem Wenatchee River estimates. Total spawning escapement for sockeye salmon in the Little Wenatchee and White River watersheds was estimated using mark-recapture methods. Adult sockeye were PIT tagged at Tumwater Dam and Bonneville Dam<sup>4</sup> and detected in the Little Wenatchee and White rivers with stationary PIT-tag interrogation systems.

Derived metrics calculated from carcass surveys, broodstock sampling, stock assessments, and harvest records included proportion of hatchery spawners, stray rates, age-at-maturity, length-at-age, smolt-to-adult survival (SAR), hatchery replacement rates (HRR), harvest rates, and natural replacement rates (NRR). The target HRRs (from Hillman et al. 2013) for different stocks raised in the PUD hatchery programs are provided in Table 2.12. Methods for calculating derived variables are described in Hillman et al. (2013) and in “White Papers” developed by the Hatchery Evaluation Technical Team (HETT) (see Appendices in Hillman et al. 2012). The abundance of hatchery and natural-origin Chinook salmon spawners was based upon the proportion of carcasses by origin that were collected on the spawning grounds.

<sup>3</sup> Expansion factor =  $(1 + (\text{number of males}/\text{number of females}))$ .

<sup>4</sup> Adult sockeye that were tagged at Bonneville Dam and detected at Tumwater Dam were included in the mark-recapture analyses.

**Table 2.12.** Hatchery replacement rate (HRR) targets for stocks raised in the PUD Hatchery Programs.

| Program                    | Number of broodstock | Smolts released | HRR targets |
|----------------------------|----------------------|-----------------|-------------|
| Chiwawa Spring Chinook     | 74                   | 144,026         | 6.7         |
| Nason Creek Spring Chinook | 66                   | 125,000         | 6.7         |
| Wenatchee Summer Chinook   | 278                  | 500,001         | 5.7         |
| Methow Summer Chinook      | 100                  | 200,000         | 3.0         |
| Wenatchee Steelhead        | 130                  | 247,300         | 6.9         |

Derived data that rely on CWTs (e.g., HRR, SAR, stray rates, etc.) are five or more years behind release information because of the lag time for returning adult fish to enter the fishery and spawning grounds, and the processing of tags. Consequently, complete information on rates and ratios based on CWTs is generally only available for brood years before 2010.

## SECTION 3: WENATCHEE STEELHEAD

The goal of summer steelhead supplementation in the Wenatchee Basin is to use artificial production to replace adult production lost because of mortality at Rock Island and Rocky Reach dams, as well as inundation compensation for Rocky Reach Dam, while not reducing the natural production or long-term fitness of steelhead in the basin. The Rock Island Fish Hatchery Complex began operation in 1989 under funding from Chelan PUD. The Complex operated originally through the Rock Island Settlement Agreement, but since 2004 has operated under the Rock Island and Rocky Reach Anadromous Fish Agreement and Habitat Conservation Plans.

Prior to 1998, steelhead eggs were received from Wells Hatchery (adult broodstock were collected at Wells Dam); fish were reared at Eastbank Fish Hatchery and then released into the Wenatchee River. Beginning in 1998, the program changed to collecting broodstock within the Wenatchee Basin. Currently, adult hatchery steelhead are collected from the run-at-large at the right and left-bank traps at Dryden Dam, and at Tumwater Dam if the weekly quotas cannot be achieved at Dryden Dam. Natural-origin (WxW) adult steelhead are collected from the run-at-large at Tumwater and Dryden dams if the weekly quotas cannot be achieved at Dryden Dam.

Before 2012, the goal was to collect up to 208 adult steelhead (50% natural-origin fish and 50% hatchery-origin fish) for the Wenatchee steelhead program. In 2011, the Hatchery Committees reevaluated the amount of hatchery compensation needed to achieve NNI. Based on that evaluation, the goal of the program was revised. The current goal (which began in 2012) is to collect 130 adult steelhead (64 natural-origin and 66 hatchery-origin fish) for a 247,300 smolt program, but the number of broodstock collected cannot exceed 33% of the natural Wenatchee steelhead population. Broodstock collection occurs from about 1 July through 15 November at Dryden and Tumwater dams, with trapping occurring up to 24 hours per day, five days a week. The intent of the current program is to target adults necessary to meet a 50% natural-origin, conservation-oriented program and a 50% hatchery-origin safety-net program.

Before the 2012 brood year, adult steelhead were held and spawned at Wells Fish Hatchery because of unsuitable adult holding temperatures at Eastbank Fish Hatchery. Beginning with the 2012 brood year, adult steelhead holding and spawning have occurred at Eastbank Fish Hatchery with the installation of a water chiller system. Before 2012, juvenile steelhead were reared at a combination of facilities including Eastbank, Chelan, Turtle Rock, Rocky Reach Annex, and Chiwawa facilities. Juvenile steelhead reared in these facilities were trucked to release locations on the Wenatchee River, Chiwawa River, and Nason Creek. A percentage of the fish have also been released voluntarily from Blackbird Pond and Rolfing Pond. Beginning in the fall of 2012, the entire Wenatchee steelhead program overwinters at the Chiwawa Acclimation Facility. Some of these fish are transferred to short-term remote acclimation sites (e.g., Blackbird Pond and Rolfing Pond), while others are planted from trucks throughout the Wenatchee, Nason, and Chiwawa basins.

Before 2012, the production goal for the Wenatchee steelhead supplementation program was to release 400,000 yearling smolts into the Wenatchee Basin at six fish per pound. Since 2012, the revised production goal is to release 247,300 smolts (123,650 for conservation and 123,650 for safety net). Targets for fork length and weight are 191 mm (CV = 9.0) and 75.6 g, respectively; the target size at release is six fish per pound. Over 96% of these fish receive CWTs. In addition,

since 2006, juvenile steelhead from different parental-cross groups (e.g., WxW, HxW, and HxH) have been PIT tagged annually. No HxW crosses have occurred since brood year 2009.

Beginning in 2010 and consistent with ESA Section 10(a)(1)(A) permit 1395, adult management activities have been conducted to remove excess hatchery-origin steelhead before they spawn in the natural environment. This is accomplished through removal at Tumwater Dam and/or through conservation fisheries. The objective of these activities is to achieve proportion of hatchery-origin spawners (pHOS) and Proportionate Natural Influence (PNI) goals for the Wenatchee steelhead program. Results of adult management activities are submitted to NOAA Fisheries in a separate annual report by 31 August of the year the adult management was concluded.

### 3.1 Broodstock Sampling

This section focuses on results from sampling 2015 and 2016 brood years of Wenatchee steelhead, which were collected at Dryden and Tumwater dams. The 2015 brood begins the tracking of the life cycle of steelhead released in 2016. The 2016 brood is included because juveniles from this brood are still maintained within the hatchery.

#### Origin of Broodstock

A total of 136 Wenatchee steelhead from the 2014 return (2015 brood) were collected at Dryden and Tumwater dams (Table 3.1). About 56% of these were natural-origin (adipose fin present and no CWT) fish and the remaining 44% were hatchery-origin (CWT and adipose fin present) adults. Origin was determined by analyzing scales and/or otoliths. The total number of steelhead spawned from the 2015 brood was 110 adults (52.7% natural-origin and 47.3% hatchery-origin).

A total of 132 steelhead were collected from the 2015 return (2016 brood) at Dryden and Tumwater dams; 67 (50.8%) natural-origin (adipose fin present and no CWT) and 66 (45.5%) hatchery-origin (CWT and adipose fin present) adults. A total of 132 steelhead were spawned; 50% were natural-origin fish and 50% were hatchery fish (Table 3.1). Origin was confirmed by sampling scales and/or otoliths.

**Table 3.1.** Numbers of wild and hatchery steelhead collected for broodstock, numbers that died before spawning, and numbers of steelhead spawned, 1998-2016. Unknown origin fish (i.e., undetermined by scale analysis, no elastomer, no CWT, no fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes fish killed at spawning and surplus broodstock.

| Brood year | Wild steelhead   |                            |           |                |                 | Hatchery steelhead |                            |           |                |                 | Total number spawned |
|------------|------------------|----------------------------|-----------|----------------|-----------------|--------------------|----------------------------|-----------|----------------|-----------------|----------------------|
|            | Number collected | Prespawn loss <sup>a</sup> | Mortality | Number spawned | Number released | Number collected   | Prespawn loss <sup>a</sup> | Mortality | Number spawned | Number released |                      |
| 1998       | 35               | 0                          | 0         | 35             | 0               | 43                 | 4                          | 2         | 37             | 0               | 72                   |
| 1999       | 58               | 5                          | 1         | 52             | 0               | 67                 | 1                          | 2         | 64             | 0               | 116                  |

<sup>a</sup> Pre-spawn loss represents the number of fish that died during the holding period before spawning. Mortality is the number of fish that were surplus following spawning.

<sup>b</sup> This average and median represent the program before recalculation in 2011.

<sup>c</sup> This average and median represent the current program, which began in 2012.

### Age/Length Data

Broodstock ages were determined from examination of scales and/or otoliths. For the 2015 brood year, natural-origin steelhead consisted primarily of 2-salt adults, while hatchery steelhead consisted almost equally of 1 and 2-salt adults (Table 3.2). For the 2016 brood year, natural and hatchery-origin steelhead consisted primarily of 2-salt adults (Table 3.2).

**Table 3.2.** Percent of hatchery and wild steelhead of different ages (saltwater ages) collected from broodstock, 1998-2016.

| Brood year | Origin   | Saltwater age |      |     |
|------------|----------|---------------|------|-----|
|            |          | 1             | 2    | 3   |
| 1998       | Wild     | 39.4          | 60.6 | 0.0 |
|            | Hatchery | 20.9          | 79.1 | 0.0 |
| 1999       | Wild     | 50.0          | 48.3 | 1.7 |
|            | Hatchery | 81.8          | 18.2 | 0.0 |
| 2000       | Wild     | 56.4          | 43.6 | 0.0 |
|            | Hatchery | 67.9          | 32.1 | 0.0 |
| 2001       | Wild     | 51.7          | 48.3 | 0.0 |
|            | Hatchery | 14.9          | 85.1 | 0.0 |
| 2002       | Wild     | 55.6          | 44.4 | 0.0 |
|            | Hatchery | 94.6          | 5.4  | 0.0 |
| 2003       | Wild     | 13.1          | 85.3 | 1.6 |
|            | Hatchery | 29.4          | 70.6 | 0.0 |
| 2004       | Wild     | 94.8          | 5.2  | 0.0 |
|            | Hatchery | 95.2          | 4.8  | 0.0 |
| 2005       | Wild     | 22.1          | 77.9 | 0.0 |

| Brood year     | Origin          | Saltwater age |             |            |
|----------------|-----------------|---------------|-------------|------------|
|                |                 | 1             | 2           | 3          |

There was little difference between mean lengths of hatchery and natural-origin steelhead in the 2015 and 2016 brood years (Table 3.3). Natural-origin fish were on average 1 to 3 cm larger than hatchery-origin fish of the same age.

**Table 3.3.** Mean fork length (cm) at age (saltwater ages) of hatchery and wild steelhead collected from broodstock, 1998-2016; N = sample size and SD = 1 standard deviation.

| Brood year | Origin   | Steelhead fork length (cm) |    |    |        |    |    |        |   |    |
|------------|----------|----------------------------|----|----|--------|----|----|--------|---|----|

## Sex Ratios

Male steelhead in the 2015 brood year made up about 50% of the adults collected, resulting in an overall male to female ratio of 1.00:1.00 (Table 3.4). For the 2016 brood year, males made up about 50.4% of the adults collected, resulting in an overall male to female ratio of 1.02:1.00. On average (1998-2016), the sex ratio is slightly less than the 1:1 ratio assumed in the broodstock protocol (Table 3.4).

**Table 3.4.** Numbers of male and female wild and hatchery steelhead collected for broodstock, 1998-2016. Ratios of males to females are also provided.

| Brood year   | Number of wild steelhead |             |                  | Number of hatchery steelhead |             |                  | Total M/F ratio  |
|--------------|--------------------------|-------------|------------------|------------------------------|-------------|------------------|------------------|

## Fecundity

Fecundities for Wenatchee steelhead in brood years 2015 and 2016 averaged 5,895 and 5,174 eggs per female, respectively (Table 3.5). Mean fecundity for the 2015 brood year was greater while the 2016 brood year was less than the 5,678 eggs per female assumed in the broodstock protocol.

**Table 3.5.** Mean fecundity of wild, hatchery, and all female steelhead collected for broodstock, 1998-2016.

| Brood year     | Mean fecundity |              |              |
|----------------|----------------|--------------|--------------|
|                | Wild           | Hatchery     | Total        |

## 3.2 Hatchery Rearing

### Rearing History

#### *Number of eggs taken*

From 1998-2011, a total of 493,827 eggs were required to meet the program release goal of 400,000 smolts. This was based on the unfertilized egg-to-release survival standard of 81%. In 2012, the egg take target was reduced to 305,309, which is needed to meet the revised release target of 247,300 smolts. Between 1998 and 2011, the egg take goal was reached 57% of the time (Table 3.6). Since 2011, the target has been reached or exceeded 100% of the time (Table 3.6).

**Table 3.6.** Numbers of eggs taken from steelhead broodstock, 1998-2016.

| Brood year | Number of eggs taken |
|------------|----------------------|
| 1998       | 224,315              |
| 1999       | 303,083              |
| 2000       | 280,872              |
| 2001       | 549,464              |

| Brood year                    | Number of eggs taken |
|-------------------------------|----------------------|
| 2002                          | 503,030              |

| 2016                          | 341,511              |
| <i>Average (2012-present)</i> | <i>354,455</i>       |
| <i>Median (2012-present)</i>  | <i>341,511</i>       |

### Number of acclimation days

Juvenile WxW steelhead from the Chelan Fish Hatchery and HxH steelhead from the Eastbank Fish Hatchery were transferred to Chiwawa Acclimation Facility in November 2015. In March 2016, about 25,000 HxH steelhead were transferred from the Chiwawa Acclimation Facility to Blackbird Pond near Leavenworth for final acclimation on Wenatchee River water. Fish were acclimated for 23 d at Blackbird Pond before a volitional release was initiated on 20 April. The remainder stayed at the Chiwawa Acclimation Facility until they were volitionally and forced released from the facility during late April to early-May.

Juvenile Wenatchee steelhead at the Chiwawa Acclimation Facility were acclimated and reared on Wenatchee and Chiwawa River water. Before 2012, Wenatchee steelhead were reared on Columbia River water from January through May before being trucked and released into the Wenatchee River basin (Table 3.7).

**Table 3.7.** Water source and mean acclimation period for Wenatchee steelhead, brood years 1998-2016.

| Brood year | Release year | Parental origin | Water source      | Number of Days |

<sup>a</sup> Steelhead overwintered in Pond 3 at the Chiwawa Acclimation Facility on Chiwawa River water before they were transferred to Blackbird Pond.

## Release Information

### Numbers released

In 2011, the HCP Hatchery Committee agreed to reduce the Wenatchee summer steelhead program from 400,000 smolts to 247,300 smolts. Based on this new goal and the number of WxW steelhead present, all HxH steelhead were transferred to the Ringold Fish Hatchery to be included in their production program for the 2012 release.

The release of 2015 brood Wenatchee steelhead achieved 79% of the 247,300 target with about 195,344 smolts released into the Wenatchee and Chiwawa rivers and Nason Creek (Table 3.8). Distribution of juvenile steelhead released in each of the three streams was determined by the mean proportion of steelhead redds in each basin. About 28.2% and 19.3% of the steelhead were released in Nason Creek and the Chiwawa River, respectively. The balance of the program was split between the Wenatchee River downstream from Tumwater Dam (10.9%) and the Wenatchee River upstream from the dam (41.5%).

**Table 3.8.** Numbers of steelhead smolts released from the hatchery, brood years 1998-2015. Before brood year 2011, the release target for steelhead was 400,000 smolts. Beginning with brood year 2011, the release target is 247,300 smolts.

### *Numbers marked*

Wenatchee hatchery steelhead from the 2015 brood were marked with coded wire tags (CWT) in the snout. About 44.9% of the juveniles released were also adipose fin clipped (Table 9).

**Table 3.9.** Release location and marking scheme for the 1998-2015 brood Wenatchee steelhead.

### Numbers PIT tagged

Table 3.10 summarizes the number of hatchery steelhead of different parental origins that have been PIT-tagged and released into the Wenatchee River basin.

**Table 3.10.** Summary of PIT-tagging activities for Wenatchee hatchery steelhead, brood years 2006-2015.

| Brood year | Release location         | Parental origin | Number of fish tagged | Number of tagged fish that died | Number of tags shed | Number of tagged fish released |
|------------|--------------------------|-----------------|-----------------------|---------------------------------|---------------------|--------------------------------|
| 2006       | Wenatchee River          | H x W (early)   | 10,036                | 479                             | 24                  | 9,533                          |

**2016 Brood Wenatchee WxW Summer Steelhead (Circular Ponds)**—A total of 5,050 Wenatchee WxW summer steelhead were PIT tagged at the Chiwawa Acclimation Facility on 23-24 February 2017. These fish were tagged in circular ponds #1 and #3. Fish were not fed during tagging or for two days before and after tagging. Fish averaged 141-149 mm in length and 29-38 g at time of tagging.

**2016 Brood Wenatchee HxH and WxW Summer Steelhead (Raceway)**—A total of 12,626 Wenatchee HxH and WxW summer steelhead were PIT tagged at the Chiwawa Acclimation Facility on 27 February to 3 March 2017. These fish were tagged in raceway #2. Fish were not fed during tagging or for two days before and after tagging. Fish averaged 129-130 mm in length and 22-26 g at time of tagging.

**2016 Brood Wenatchee Summer Steelhead (Blackbird Pond)**—A total of 2,525 Wenatchee summer steelhead destined for Blackbird Pond were PIT tagged at the Chiwawa Acclimation Facility on 21-22 February 2017. These fish were tagged in raceway #3. Fish were not fed during tagging or for two days before and after tagging. Fish averaged 133 mm in length and 25 g at time of tagging.

#### *Fish size and condition at release*

Except for the Blackbird Pond release, all 2015 brood steelhead were trucked and released as yearling smolts in April and May 2016. The Blackbird Pond group was released volitionally beginning on 20 April. Both WxW and HxH fish did not meet the targets for length, weight, or coefficient of variation (CV) for fork length (Table 3.11). The HxH group was combined with the WxW group in Pond 2 once they were transferred to Chiwawa Acclimation Facility. The HxH fish were larger than the WxW fish at the time of transfer but smaller at the time of release.

**Table 3.11.** Mean lengths (FL, mm), weight (g and fish/pound), and coefficient of variation (CV) of steelhead smolts released from the hatchery, brood years 1998-2015. Size targets are provided in the last row of the table.

| Brood year | Release year | Parental origin | Fork length (mm) |      | Mean weight |            |
|------------|--------------|-----------------|------------------|------|-------------|------------|
|            |              |                 | Mean             | CV   | Grams (g)   | Fish/pound |
| 1998       | 1999         | H x H           | 201              | 11.1 | 92.3        | 5          |
|            |              | H x W           | 190              | 12.8 | 76.9        | 6          |

### Survival Estimates

Overall survival of Wenatchee steelhead (WxW and HxH) from green (unfertilized) egg to release was below the standard set for the program. This is largely because of lower unfertilized egg to eyed egg survival (Table 3.12).

The Wenatchee steelhead program, from its inception, has experienced highly variable fertilization rates. It is unknown at this time what mechanisms may be influencing stock performance at these stages.

**Table 3.12.** Hatchery life-stage survival rates (%) for steelhead, brood years 1998-2015. Survival standards or targets are provided in the last row of the table.

| Brood year        | Collection to spawning |       | Unfertilized egg-eyed | Eyed egg-ponding | 30 d after ponding | 100 d after ponding | Ponding to release | Transport to release | Unfertilized egg-release |
|-------------------|------------------------|-------|-----------------------|------------------|--------------------|---------------------|--------------------|----------------------|--------------------------|
|                   | Female                 | Male  |                       |                  |                    |                     |                    |                      |                          |

<sup>a</sup> Survival estimates are only for WxW steelhead.

### 3.3 Disease Monitoring

Rearing of the 2015 brood Wenatchee summer steelhead was similar to previous years with fish being held on Chelan spring water, Eastbank well water, and Chelan well water before being transferred for overwinter acclimation at the Chiwawa Acclimation Facility. Volitional and force-released fish were released into Nason Creek, Chiwawa River, and the Wenatchee River. The 2015 WxW Wenatchee steelhead had no significant health issues during the rearing period.

### 3.4 Natural Juvenile Productivity

During 2016, juvenile steelhead were sampled at the Lower Wenatchee, Chiwawa, and Nason Creek traps and counted during snorkel surveys within the Chiwawa River basin. Because the snorkel surveys targeted juvenile Chinook salmon, the entire distribution of juvenile steelhead in the Chiwawa River basin was not surveyed. Therefore, the parr numbers presented below represent a minimum estimate.

#### Parr Estimates

A total of 16,244 ( $\pm 14\%$ ) age-0 (<100 mm) and 4,031 ( $\pm 15\%$ ) age-1+ (100–200 mm)<sup>5</sup> steelhead/rainbow were estimated in the Chiwawa River basin in August 2016 (Table 3.13 and 3.14). During the survey period 1992–2016, numbers of age-0 and 1+ steelhead/rainbow have ranged from 1,410 to 45,727 and 754 to 22,130, respectively, in the Chiwawa River basin (Table 3.13 and 3.14; Figure 3.1). Numbers of all fish counted in the Chiwawa River basin are reported in Appendix A.

Juvenile steelhead/rainbow were distributed primarily throughout the lower seven reaches of the Chiwawa River (downstream from Rock Creek). Their densities were highest in the lower portions of the river and in tributaries. Age-0 steelhead/rainbow most often used riffle and multiple channel habitats in the Chiwawa River, although they also associated with woody debris in pool and glide habitat. In tributaries, they were generally most abundant in small pools. Those that were observed in riffles selected stations in quiet water behind small and large boulders, or occupied stations in quiet water along the stream margin. In pool and multiple-channel habitats, age-0 steelhead/rainbow used the same kinds of habitat as age-0 Chinook salmon.

Age-1+ steelhead/rainbow most often used pool, riffle, and multiple-channel habitats. Those that used pools were usually in deeper water than subyearling steelhead/rainbow and Chinook salmon. Like age-0 steelhead/rainbow, age-1+ steelhead/rainbow generally selected stations in quiet water behind boulders in riffles, but the two age groups rarely occurred together. Age-1+ steelhead/rainbow used deeper and faster water than did subyearling steelhead/rainbow.

<sup>5</sup> A steelhead/rainbow trout larger than 200 mm (8 in) was considered a resident trout.

**Table 3.13.** Total numbers of age-0 steelhead/rainbow trout estimated in different streams in the Chiwawa River basin during snorkel surveys in August 1992-2016; NS = not sampled.

### Emigrant and Smolt Estimates

Numbers of steelhead smolts and emigrants were estimated at the Chiwawa, Nason, and Lower Wenatchee traps in 2016.

#### Chiwawa Trap

The Chiwawa Trap operated between 2 March and 21 November 2016. During the trapping period, the trap was inoperable for 72 days due to high or low river discharge, debris, major hatchery releases, and mechanical issues. The trap operated in a single position throughout the sampling season. Monthly captures of all fish collected at the Chiwawa Trap are reported in Appendix B.

A total of 195 wild steelhead/rainbow smolts, 1,518 hatchery smolts, and 1,522 wild parr and fry were captured at the Chiwawa Trap. Most (99%) of the hatchery steelhead were collected in May, while most (75%) of the wild steelhead smolts were captured in April through June (Figure 3.2). Although steelhead/rainbow parr and fry emigrated throughout the sampling period, peaks in emigration were observed in April through June and in October (Figure 3.2). Of the total number of wild steelhead captured, 87% were classified as parr and fry. Three mark-recapture efficiency trials were conducted with a pooled trap efficiency of 8.1%.

**Figure 3.2.** Monthly captures of wild smolts, wild parr, and hatchery smolt steelhead/rainbow at the Chiwawa Trap, 2016.

#### Nason Creek Trap

The Nason Creek Trap operated between 1 March and 30 November 2016. During the nine-month sampling period the trap was inoperable for 62 days because of low discharge and flooding. The trap captured a total of 9 wild steelhead smolts, 98 hatchery steelhead smolts, 663 wild steelhead parr, and 335 wild steelhead fry. The estimated wild steelhead emigration for brood year 2013 was

13,417 ( $\pm$  9,133). Egg-to-emigrant survival rate for brood year 2012 steelhead was 1.7% and the egg-to-emigrant survival rate for brood year 2012 was 3.0%. Productivity, measured as emigrants-per-redd, was 99.

**Lower Wenatchee Trap**

The Lower Wenatchee Trap operated between 29 January and 26 June 2016. During that time, the trap was inoperable for 23 days because of too high and low river discharge, debris, elevated river temperatures, large hatchery releases, and mechanical issues. During the sampling period, a total of 329 wild steelhead parr and fry, 88 wild steelhead smolts, and 259 hatchery steelhead were captured at the trap. Because of the low numbers of steelhead encountered at the trap, it was not possible to carry out mark-recapture trials using steelhead. In addition, because there was a poor relationship between trap efficiency and river flow, a pooled estimate was used to derive the number of steelhead emigrants. Using this pooled method, it was estimated that 10,135 ( $\pm$ 102,145) steelhead >50 mm FL emigrated out of the Wenatchee during the trapping season. Figure 3.3 shows the monthly captures of all steelhead collected at the Lower Wenatchee Trap. All fish captured in the trap are reported in Appendix B.

**Figure 3.3.** Monthly captures of wild smolts, wild parr, and hatchery smolt steelhead/rainbow at the Lower Wenatchee Trap, 2016.

**PIT Tagging Activities**

As part of the Comparative Survival Study (CSS) and PUD studies, a total of 1,980 juvenile steelhead/rainbow trout (1,979 wild and one hatchery) were PIT tagged and released in 2016 in the Wenatchee River basin (Table 3.15a). Most of these were tagged at the Chiwawa Trap. See Appendix C for a complete list of all fish captured, tagged, lost, and released.

**Table 3.15a.** Numbers of wild and hatchery steelhead/rainbow trout that were captured, tagged, and released at different locations within the Wenatchee River basin, 2016. Numbers of fish that died or shed tags are also given.

| Sampling Location    | Species and Life Stage    | Number captured | Number of recaptures | Number tagged | Number died | Shed tags | Total tags released | Percent mortality |

<sup>1</sup> 2013 was the last year that the Upper Wenatchee Trap operated.

### 3.5 Spawning Surveys

Surveys for steelhead redds were conducted during March through early June 2016, in the mainstem Wenatchee River and portions of select tributaries (Chiwawa River, Nason Creek, and Peshastin Creek). Beginning in 2014, adult steelhead escapement estimates in the majority of tributaries in the Wenatchee River basin were generated using mark-recapture techniques based on steelhead PIT tagged at Priest Rapids Dam (BPA funded; see Appendix D and Truscott et al. 2016 for details).

#### Redd Counts

A total estimate of 126 steelhead redds were counted in the Wenatchee River and the lower portions of select tributaries in 2016 (Table 3.16). Because steelhead escapement estimates in tributaries are based on mark-recapture techniques, there are no or limited redd counts in tributaries beginning in 2014. Additionally, mainstem redd counts since 2014 were expanded based on

estimates of observer efficiency (see Appendix D). Thus, evaluation of trends in redd counts is appropriate only before 2014.

**Table 3.16.** Numbers of steelhead redds estimated within different streams/watersheds within the Wenatchee River basin, 2001-2016; NS = not surveyed. Redd counts from 2004-2013 have been conducted within the same areas and with the same methods. Beginning in 2014, complete redd counts were conducted only within the mainstem Wenatchee River. Therefore, trends in redd counts are only appropriate for the mainstem Wenatchee River from 2004 through 2013.

| Survey year | Number of steelhead redds |       |                  |       |                              |        |           |       |

<sup>a</sup> Includes redds in Beaver and Chiwaukum creeks.

<sup>b</sup> Steelhead redd counts in the mainstem Wenatchee River were expanded based on estimated observer efficiency (see Appendix D).

### Redd Distribution

Steelhead redds were not evenly distributed among survey reaches on the Wenatchee River in 2016 (Table 3.17). About 91.3% of the spawning in the Wenatchee River occurred upstream from Tumwater Dam (Table 3.17).

**Table 3.17.** Numbers and percentages of steelhead redds counted within different reaches on the Wenatchee River during March through early June, 2016; CV = coefficient of variation, NA = not available, NS = not surveyed.

| Reach            | Reach type | Number of redds counted | Expanded redd counts |    | Percent of redds within stream/watershed |
|------------------|------------|-------------------------|----------------------|----|--|
|                  |            |                         | Estimated            | CV |  |

### Spawn Timing

Steelhead began spawning during the second week of March in the Wenatchee River. Spawning activity appeared to begin once the mean daily stream temperature reached about 5.5°C and was observed in water temperatures ranging from 3.7-8.8°C. Steelhead spawning peaked during the third week of April in the Wenatchee River (Figure 3.4).

**Figure 3.4.** Numbers of steelhead redds counted during different weeks on the Wenatchee River, March through early June 2016.

## Spawning Escapement

Before 2014, steelhead spawning escapement upstream from Tumwater Dam was calculated as the number of redds (in the Wenatchee River and tributaries upstream from the dam) times the fish per redd ratio (based on sex ratios estimated at Tumwater Dam using video surveillance).<sup>6</sup> Beginning in 2014, escapement in tributaries was estimated using PIT-tag mark-recapture techniques (Truscott et al. 2016; Table 3.18), while observer efficiency expanded redd counts were used to estimate escapement in the mainstem Wenatchee River (Appendix D). Total redd counts were also used to estimate escapement in the lower portions of the main tributaries (downstream from the PIT interrogation sites).

**Table 3.18.** Spawning escapement estimates for natural-origin and hatchery-origin steelhead within tributaries of the Wenatchee River, brood year 2016. Escapement estimates were based on PIT-tag mark-recapture techniques (Truscott et al. 2016). CV = coefficient of variation and NA = not available.

| Tributary       | Natural-origin steelhead |      | Hatchery-origin steelhead |      |
|-----------------|--------------------------|------|---------------------------|------|
|                 | Estimate                 | CV   | Estimate                  | CV   |
| Mission Creek   | 33                       | 0.38 | 13                        | 0.69 |
| Peshastin Creek | 151                      | 0.19 | 0                         | NA   |
| Chumstick Creek | 74                       | 0.27 | 39                        | 0.37 |
| Icicle Creek    | 72                       | 0.25 | 18                        | 0.53 |
| Chiwaukum Creek | 64                       | 0.36 | 11                        | 1.00 |
| Chiwawa River   | 45                       | 0.44 | 134                       | 0.35 |
| Nason Creek     | 57                       | 0.39 | 94                        | 0.32 |

The estimated fish per redd ratio for steelhead in 2016 was 1.65 (Table 3.19). Multiplying this ratio by the total number of redds estimated in the Wenatchee River upstream from Tumwater Dam resulted in a spawning escapement of 167 steelhead (Table 3.19). Adding this estimate to the mark-recapture estimates of tributary escapement (239 hatchery + 166 wild = 405) indicates that 572 (CV = 0.167) escaped to spawning areas upstream from Tumwater Dam in 2016 (see Appendix D).

**Table 3.19.** Numbers of steelhead counted at Tumwater Dam, fish/redd estimates (based on male-to-female ratios estimated at Tumwater Dam), numbers of steelhead redds counted upstream from Tumwater Dam, total spawning escapement upstream from Tumwater Dam (estimated as the total number of redds times the fish/redd ratio), and the proportion of the Tumwater Dam count that made up the spawning escapement. Beginning in 2014, escapements include estimates from redd counts in the Wenatchee River and mark-recapture techniques in tributaries.

| Survey year | Total count at Tumwater Dam | Fish/redd | Number of redds |                |             | Spawning escapement <sup>a</sup> | Proportion of Tumwater count that spawned |
|-------------|-----------------------------|-----------|-----------------|----------------|-------------|----------------------------------|---|
|             |                             |           | Index area      | Non-index area | Total redds |                                  |   |

<sup>a</sup> Escapement estimates before 2014 were based on expanded redd counts in the Wenatchee River and tributaries; escapement estimates beginning in 2014 were based on expanded redd counts within the Wenatchee River and mark-recapture techniques in tributaries.

<sup>b</sup> The average and median are based on estimates from 2004 to 2013.

<sup>c</sup> The average and median are based on estimates from 2014 to present.

### 3.6 Life History Monitoring

Life history characteristics of steelhead were assessed by examining fish collected at broodstock collection sites, examining videotape at Tumwater Dam, and by reviewing tagging data and fisheries statistics. Before brood year 2011, some statistics could not be calculated because few steelhead were tagged with CWTs. Since brood year 2011, all steelhead released from the hatchery program have been tagged with CWTs. In addition, about 23,101 of the 2015 brood were PIT tagged. With the placement of remote PIT tag detectors in spawning streams in 2007 and 2008, statistics such as origin on spawning grounds, stray rates, and SARs can be estimated more accurately.

#### Migration Timing

Sampling at Tumwater Dam indicates that steelhead migrate throughout the year; however, the migration distribution is bimodal, indicating that steelhead migrate past Tumwater Dam in two pulses: one pulse during summer-autumn the year before spawning and another during winter-spring the year of spawning (Figure 3.5). Most steelhead passed Tumwater Dam during July through October and April. The highest proportion of both wild and hatchery fish migrated during October.

**Figure 3.5.** Proportion of wild and hatchery steelhead sampled at Tumwater Dam for the combined brood years of 1999-2016.

Because the migration of steelhead is bimodal, we estimated migration statistics separately for each migration pulse (i.e., summer-autumn migration and winter-spring migration). That is, we compared migration statistics for wild and hatchery steelhead passing Tumwater Dam during the summer-autumn period independent of those for the winter-spring migration period. We estimated the week and month that 10%, 50% (median), and 90% of the wild and hatchery steelhead passed Tumwater Dam during the two migration periods. We also estimated the mean weekly and monthly migration timing for wild and hatchery steelhead.

Migration timing of wild and hatchery fish at Tumwater Dam varied depending on the migration season (Table 3.20a and b; Figure 3.5). For the summer-autumn migration period, wild steelhead arrived at the dam about one week earlier than hatchery steelhead. In contrast, there was little difference in migration timing of wild and hatchery steelhead during the winter-spring migration period.

**Table 3.20a.** The week that 10%, 50% (median), and 90% of the wild and hatchery steelhead passed Tumwater Dam during their summer-autumn migration (June through December) and during their winter-spring migration (January through May), 1999-2016. The average week is also provided for both migration periods. Migration timing is based on video sampling at Tumwater. The presence of eroded fins and/or missing adipose fins was used to distinguish hatchery fish from wild fish during video monitoring at Tumwater Dam. Estimates also include steelhead collected for broodstock.

| Spawn year | Origin   | Steelhead Migration Time (week)   |     |     |      |             |                                   |     |     |      |             |

**Table 3.20b.** The month that 10%, 50% (median), and 90% of the wild and hatchery steelhead passed Tumwater Dam during their summer-autumn migration (June through December) and during their winter-spring migration (January through May), 1999-2016. The average month is also provided for both migration periods. Migration timing is based on video sampling at Tumwater. The presence of eroded fins and/or missing adipose fins was used to distinguish hatchery fish from wild fish during video monitoring at Tumwater Dam. Estimates also include steelhead collected for broodstock.

| Spawn year | Origin   | Steelhead Migration Time (month)  |     |     |      |             |                                   |     |     |      |             |

### Age at Maturity

Nearly all steelhead broodstock collected at Tumwater and Dryden dams lived in saltwater 1 to 2 years (saltwater age) (Table 3.21). Very few saltwater age-3 fish returned and those that did were wild fish. On average, there was a difference between the saltwater age at return of wild and hatchery fish. A greater proportion of hatchery fish returned as saltwater age-1 fish than did wild fish. In contrast, a greater number of wild fish returned as saltwater-2 fish than did hatchery fish (Figure 3.6).

**Table 3.21.** Proportions of wild and hatchery steelhead broodstock of different ages collected at Tumwater and Dryden dams, brood years 1998-2016. Age represents the number of years the fish lived in salt water.

| Brood year | Origin   | Saltwater age |      |      | Sample size |
|------------|----------|---------------|------|------|-------------|
|            |          | 1             | 2    | 3    |             |
| 1998       | Wild     | 0.39          | 0.61 | 0.00 | 35          |
|            | Hatchery | 0.21          | 0.79 | 0.00 | 43          |

**Figure 3.6.** Proportions of wild and hatchery steelhead of different saltwater ages sampled at Tumwater Dam for the combined years 1998-2016.

### Size at Maturity

On average, hatchery steelhead collected at Tumwater and Dryden dams were about 2 to 3 cm smaller than wild steelhead (Table 3.22).

**Table 3.22.** Mean fork length (cm) at age (saltwater ages) of hatchery and wild steelhead collected from broodstock, brood years 1998-2016; N = sample size and SD = 1 standard deviation.

| Brood year | Origin   | Steelhead fork length (cm) |    |    |        |    |    |        |   |    |

### Contribution to Fisheries

Nearly all harvest on Wenatchee steelhead occurs within the Columbia basin. Harvest rates on steelhead in the Lower Columbia River fisheries (both tribal and non-tribal) are generally less than 5-10% (NMFS 2004). A sport fishery may be opened on Upper Columbia River steelhead when the natural-origin steelhead run is predicted to exceed 1,300 fish at Priest Rapids Dam and the total Upper Columbia River steelhead run is predicted to exceed 9,550 steelhead. To minimize effects on natural-origin steelhead in the tributary fisheries, a three-tiered system as outlined in Permit 1395 is used to determine maximum allowable natural-origin steelhead take during the fishery (Table 3.23a).

**Table 3.23a.** Three-tiered system for determining natural-origin effects during the recreational fishery on steelhead in tributaries upstream from Rock Island Dam.

| Tier       | Wenatchee        |                     | Methow           |                     | Okanogan         |                     |

<sup>1</sup> Estimated natural-origin escapement to tributaries.

<sup>2</sup> Maximum allowable take on natural-origin fish.

WDFW implemented a selective recreational steelhead fishery in the upper Columbia River during fall 2015 through winter 2016 (Table 3.23b). The fishery was conducted as a conservation measure to reduce the proportion of hatchery-origin steelhead on the spawning grounds. There were 56 hatchery steelhead harvested and an additional eight wild steelhead hook-and-release mortalities estimated for the Wenatchee River basin. Over the eight years that the Wenatchee River had a recreational fishery, average harvest has been about 183 hatchery steelhead and 16 wild steelhead hook-and-release mortalities. In the mixed population fishery within the mainstem Columbia from Priest Rapids Dam to Chief Joseph Dam, the average harvest of hatchery steelhead has been 861 steelhead with 17 wild hook-and-release mortalities.

**Table 3.23b.** Harvest and mortality estimates for Upper Columbia steelhead in the Wenatchee and mainstem Columbia River (Priest Rapids Dam to Chief Joseph Dam). Estimated steelhead sport harvest on Wenatchee hatchery steelhead and hook-and-release mortality on wild steelhead (WDFW 2016). The wild steelhead mortality estimate is based on a hook-and-release mortality rate of 5%. Mainstem harvest from Priest Rapids Dam to Chief Joseph Dam is a mixed-population steelhead fishery that may contain fish from the Wenatchee, Entiat, Methow, and Okanogan rivers.

### Origin on Spawning Grounds

With the implementation of PIT-tag mark-recapture techniques in 2014, we can estimate the contribution of natural-origin and hatchery-origin fish on the spawning grounds (Table 3.24). Based on mark-recapture estimates, naturally produced steelhead made up about 60.6% of the escapement in 2016. Importantly, the abundance of hatchery fish in the upper Wenatchee Basin was regulated through surplus (removal) at Tumwater Dam. A total of 290 hatchery steelhead were surplus at the dam resulting in the passage of 1,025 steelhead over the dam in 2016. Natural-origin steelhead comprised 59.4% (N = 609) of the steelhead that passed the dam.

**Table 3.24.** Spawning escapement estimates for natural-origin and hatchery-origin steelhead within the Wenatchee River, brood years 2014-2016. Escapement estimates were based on PIT-tag mark-recapture techniques (see Appendix D).

### Straying

Stray rates of Wenatchee steelhead can be estimated by examining the locations where PIT-tagged hatchery steelhead were last detected. PIT tagging of steelhead began with brood year 2005, which allows estimation of stray rates by brood return. These data only provide estimates for brood years 2005 through 2012, because later brood years are still rearing in the ocean. The most recent completed brood year is 2012.

Based on PIT-tag analyses, about 5.1% of brood year 2012 was last detected in streams outside of the Wenatchee River basin. Beginning with brood year 2011, steelhead have been overwinter-acclimated at the Chiwawa Acclimation Facility. This may be the reason for the observed reduction in stray rates since 2011. On average, for brood years 2011 through 2012, about 4% of the hatchery steelhead returns were last detected in streams outside the Wenatchee River basin (Table 3.25).

Steelhead have been detected in the Entiat and Methow rivers as well as in the Deschutes and Tucannon rivers. Several were last detected at Wells Dam. The numbers in Table 3.25 should be considered rough estimates because they are not based on confirmed spawning (only last detections).

**Table 3.25.** Number and percent of hatchery-origin Wenatchee steelhead that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and hatchery programs for brood years 2005-2012. Estimates were based on last detections of PIT-tagged hatchery steelhead. Percent strays should be less than 5%.

\* Homing to the target hatchery includes Wenatchee hatchery steelhead that are captured and included as broodstock in the Wenatchee Hatchery program. These hatchery fish are typically collected at Dryden and Tumwater dams.

## Genetics

Genetic studies were conducted in 2012 to determine the potential effects of the Wenatchee Supplementation Program on natural-origin summer steelhead in the Wenatchee River basin (Seamons et al. 2012; the entire report is appended as Appendix E). Temporal collections were obtained from hatchery and natural-origin adult summer steelhead captured at Dryden and Tumwater dams during summer and fall of 1997 through 2009 (excepting 2004 and 2005). Natural-origin steelhead consisted of a mixed collection representing all the spawning subpopulations located upstream. Therefore, to determine population substructure within the basin, samples were also taken from juvenile steelhead collected at smolt traps located within the Chiwawa River, Nason Creek, and Peshastin Creek, and from the Entiat River. Samples were also taken from juvenile steelhead collected at the smolt trap in the lower Wenatchee River. These, like natural-origin adult collections, consisted of a mixed collection representing all subpopulations located upstream. A total of 1,468 hatchery-origin and natural-origin adults were processed and 1,542 juvenile steelhead from the Wenatchee and Entiat Rivers were processed for genetic variation with 132 genetic (single nucleotide polymorphism loci; SNPs) markers. Peshastin Creek and the Entiat River served as no-hatchery-outplant controls. Genetic data were interrogated for the presence or absence of spatial and temporal trends in allele frequencies, genetic distances, and effective population size.

**Allele Frequencies**—Changes to the summer steelhead hatchery supplementation program had no detectable effect on genetic diversity of wild populations. On average, hatchery-origin adults had higher minor allele frequencies (MAF) than natural-origin adults, which may simply reflect the mixed ancestry of hatchery adults. Both hatchery and natural-origin adults had MAF similar to juveniles collected in spawning tributaries and in the Entiat River. There was no temporal trend in allele frequencies or observed heterozygosity in adult or juvenile collections and allele frequencies in control populations were no different than those still receiving hatchery outplants. This suggests that the hatchery program has had little effect on allele frequencies since broodstock sources changed in 1998 from mixed-ancestry broodstock collected in the Columbia River to using broodstock collected in the Wenatchee River.

**Genetic Distances**—As intended, interbreeding of Wenatchee River hatchery and natural-origin adults reduced the genetic differences between Wells Hatchery adults and Wenatchee River natural-origin adults observed in the first few years after changing the broodstock collection protocol. Although there were detectable genetic differences between hatchery and natural-origin adults, the magnitude of that difference declined over time. Hatchery adults were genetically different from natural-origin adults and juveniles based on pair-wise  $F_{ST}$  and principal components analysis, most likely because of the smaller effective population size ( $N_b$ ) in the hatchery population (see below). Pair-wise  $F_{ST}$  estimates and genetic distances between hatchery and natural-origin adults collected the same year declined over time suggesting that the interbreeding of hatchery and natural-origin adults in the hatchery (and presumably in the wild) is slowly homogenizing Wenatchee River summer steelhead. Analyses using brood year were inconclusive because of limitations in the data.

**Effective Population Size**—Although the effective population size of the Wenatchee River hatchery steelhead program was consistently small, it does not appear to have caused a reduction in the effective population size of wild populations. On average, estimates of  $N_b$  were much lower and varied less for hatchery adults than for natural-origin adults and juveniles. Estimates of  $N_b$  for hatchery adults declined from the earliest brood years to a stable new low value after broodstock practices were changed in 1998. There was no indication that this had any effect on  $N_b$  in natural-origin adults and juveniles;  $N_b$  estimates for natural-origin adults and juveniles were, on average, higher and varied considerably over the 1998-2010 period and showed no temporal trend.

It is important to note that no new information will be reported on genetics until the next five-year report (2018).

### Proportionate Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock (pNOB) and the proportion of hatchery-origin fish in the natural spawning escapement (pHOS). We calculated Proportionate Natural Influence (PNI) by iterating Ford's (2002) equations 5 and 6 to equilibrium, using a heritability of 0.3 and a selection strength of three standard deviations.<sup>7</sup> The larger the PNI value, the greater the strength of selection in the natural environment relative to that of the hatchery

---

<sup>7</sup> According to authorized annual take permits, PNI is calculated using the PNI approximate equation 11 (HSRG 2009; Appendix A). However, in this report, we used Ford's (2002) equations 5 and 6 with a heritability of 0.3 and a selection strength of three standard deviations to calculate PNI (C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI). This approach is more accurate than using the PNI approximate equation.

environment. For the natural environment to dominate selection, PNI should be greater than 0.50, and important integrated populations should have a PNI of at least 0.67 (HSRG/WDFW/NWIFC 2004). For the Wenatchee steelhead program, PNI is managed with the goal of achieving a five-year running average of  $PNI \geq 0.67$  basin-wide. In years when the natural-origin escapement is low (i.e., < 433 fish), the Wenatchee steelhead population will be managed to meet escapement goals rather than PNI.

For brood years 2001-2016, PNI values were less than 0.67 (Table 3.26), suggesting that the hatchery environment has a greater influence on adaptation of Wenatchee steelhead than does the natural environment.

**Table 3.26.** Proportionate Natural Influence (PNI) values for the Wenatchee steelhead supplementation program for brood years 2001-2016. NOS = number of natural-origin steelhead on the spawning grounds; HOS = number of hatchery-origin steelhead on the spawning grounds; NOB = number of natural-origin steelhead collected for broodstock; and HOB = number of hatchery-origin steelhead included in hatchery broodstock.

| Brood year     | Spawners <sup>a</sup> |            |             | Broodstock |           |             | PNI <sup>b</sup> | PNI (5-yr mean) |
|----------------|-----------------------|------------|-------------|------------|-----------|-------------|------------------|-----------------|

<sup>a</sup> The presence of eroded fins or missing adipose fins was used to distinguish hatchery fish from wild fish during video monitoring at Tumwater. The PNI estimates are appropriate for steelhead spawning upstream from Tumwater Dam but may not represent PNI for steelhead spawning downstream from Tumwater Dam. Because not all hatchery fish have eroded fins or missing adipose fins, it is likely we are underestimating WxW hatchery steelhead returns based on video monitoring.

<sup>b</sup> PNI was calculated previously using PNI approximate equation 11 (HSRG 2009; their Appendix A). All PNI values presented here were recalculated by iterating Ford's (2002) equations 5 and 6 to equilibrium using a heritability of 0.3 and a selection strength of three standard deviations. C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI.

### Post-Release Survival and Travel Time

We used PIT-tagged fish to estimate survival rates and travel time (arithmetic mean days) of hatchery steelhead from release sites (e.g., Chiwawa River, Nason Creek, and Wenatchee River) to McNary Dam, and smolt to adult ratios (SARs) from release to detection at Bonneville Dam (Table 3.27).<sup>8</sup> Over the 12 brood years for which PIT-tagged hatchery fish are available, survival rates from the release sites to McNary Dam ranged from 0.055 to 0.785 (note that survival rates of 0.000 were associated with very small sample sizes); SARs from release to detection at Bonneville Dam ranged from 0.000 to 0.038. Average travel time from the release sites to McNary Dam ranged from 13 to 100 days.

Some of the variation in survival rates and travel time was related to release location, type of release, and rearing scenario. For example, on average, steelhead released in the Chiwawa River appeared to have higher survival rates to McNary Dam than did steelhead released in the lower and upper Wenatchee River or Nason Creek. Within the Chiwawa River, steelhead identified as “movers” had the highest survival rates to McNary Dam, while those identified as “non-screened” had the lowest survival. For steelhead released into Nason Creek and the Wenatchee River, fish released from circulars had higher survival rates than those released from raceways. On average, steelhead released from Blackbird Pond had lower survival rates to McNary Dam than those released from circulars. Based on the available data, SARs varied little among the release locations or rearing scenarios.

Travel time from release to McNary Dam varied among release locations and rearing scenario. In general, steelhead released into the Chiwawa River and Nason Creek appeared to travel more quickly to McNary Dam than did steelhead released into the Wenatchee River. Of those released into the Chiwawa River, steelhead released voluntarily from raceways appeared to travel to McNary Dam more quickly than those forced released; although there are few replicates and differences in travel times are small. On average, there appeared to be little differences in travel times for steelhead reared in raceways or circulars that were released into Nason Creek.

**Table 3.27.** Total number of Wenatchee hatchery summer steelhead released with PIT tags, their survival and travel times (mean days) to McNary Dam, and smolt-to-adult (SAR) ratios for brood years 2005-2015. SARs were estimated to Bonneville Dam. Standard errors are shown in parentheses. NA = not available (i.e., for SARs, not all the adults from the release groups have returned to the Columbia River).

| Brood year | Release location <sup>a</sup> | Crosses <sup>b</sup> | Type of release | Rearing scenario <sup>c</sup> | Number of tagged fish released | Survival to McNary Dam | Travel time to McNary Dam (d) | SAR to Bonneville Dam |

<sup>8</sup> It is important to point out that because of fish size differences among rearing tanks or raceways, fish PIT tagged in one tank or raceway may not represent untagged fish rearing in other tanks or raceways.

<sup>a</sup> All = Chiwawa River, Nason Creek, and the Wenatchee River.

<sup>b</sup> HxH = hatchery by hatchery cross; WxW = wild by wild cross; Mixed = both HxH and WxW crosses; E = early; and L = late.

<sup>c</sup> Circ = circulars; RCY = raceway.

### Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). Natural-origin recruits are naturally produced (wild) fish that survive to contribute to harvest (directly or indirectly), to broodstock, and to spawning grounds. We do not account for fish that died in route to the spawning grounds (migration mortality) or died just before spawning (pre-spawn mortality) (see Appendix B in Hillman et al. 2012). For brood years 1998-2012, NRR for summer steelhead in the Wenatchee River basin averaged 0.66 (range, 0.13-3.10) if harvested fish were included in the estimate (Table 3.28).

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and were calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. These rates should be greater than the NRRs and greater than or equal to 6.9 (the calculated target value in Hillman et al. 2013). The target value of 6.9 includes harvest. In nearly all years, HRRs were greater than NRRs (Table 3.28). HRRs exceeded the estimated target value of 6.9 in 11 of the 15 years.

**Table 3.28.** Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR with harvest) for summer steelhead in the Wenatchee River basin, brood years 1998-2012.

| Brood year     | Broodstock Collected | Spawning Escapement | Harvest included |              |              |             |

### Smolt-to-Adult Survivals

Smolt-to-adult ratios (SARs) are calculated as the number of returning hatchery adults divided by the number of tagged hatchery smolts released. SARs are generally based on CWT returns. However, prior to brood year 2011, Wenatchee steelhead were not extensively tagged with CWTs. Therefore, elastomer-tagged fish were used to estimate SARs from release to capture at Priest Rapids Dam. With the return of brood year 2011, SARs will be based on PIT-tag detections at Bonneville Dam.

SARs (not adjusted for tag loss) for Wenatchee steelhead ranged from 0.0009 to 0.0315 (mean = 0.0093) for brood years 1996-2010 (Table 3.29). For brood years 2011 to present, SARs (to Bonneville Dam) averaged 0.0056 (Table 3.29).

**Table 3.29.** Smolt-to-adult ratios (SARs) for Wenatchee hatchery steelhead. Estimates for brood years 1996-2010 were based on elastomer tags recaptured at Priest Rapids Dam. SARs were not adjusted for tag loss after release. For brood years 2011 to present, SARs are based on PIT-tag detections to Bonneville Dam.

| Brood year | Number of tagged smolts released | SAR    |
|------------|----------------------------------|--------|
| 1996       | 348,693                          | 0.0034 |
| 1997       | 429,422                          | 0.0041 |

| Brood year        | Number of tagged smolts released | SAR           |
|-------------------|----------------------------------|---------------|
| 1998              | 172,078                          | 0.0009        |
| 1999              | 175,661                          | 0.0111        |
| 2000              | 184,639                          | 0.0017        |
| 2001              | 335,933                          | 0.0308        |
| 2002              | 302,060                          | 0.0063        |
| 2003              | 374,867                          | 0.0025        |
| 2004              | 294,114                          | 0.0038        |
| 2005              | 452,184                          | 0.0107        |
| 2006              | 258,697                          | 0.0100        |
| 2007              | 306,690                          | 0.0315        |
| 2008              | 327,133                          | 0.0090        |
| 2009              | 484,826                          | 0.0080        |
| 2010 <sup>a</sup> | 192,363                          | 0.0054        |
| <b>Average</b>    | <b>309,291</b>                   | <b>0.0093</b> |
| <b>Median</b>     | <b>306,690</b>                   | <b>0.0063</b> |
| 2011              | 30,019                           | 0.0057        |
| 2012              | 25,134                           | 0.0055        |
| <b>Average</b>    | <b>27,577</b>                    | <b>0.0056</b> |
| <b>Median</b>     | <b>27,577</b>                    | <b>0.0056</b> |

<sup>a</sup> Only 192,363 WxW progeny from brood year 2010 were elastomer tagged; 161,951 HxH steelhead were released.

## 3.7 ESA/HCP Compliance

### Broodstock Collection

Collection of brood year 2015 broodstock for Wenatchee summer steelhead at Dryden and Tumwater dams began on 1 July and ended on 15 October 2014 at Dryden Dam and 10 November 2014 at Tumwater Dam consistent with the collection period identified in the 2014 broodstock collection protocol. The broodstock collection achieved a total collection of 142 steelhead, including 76 natural-origin steelhead (of the 76 fish collected, 58 were spawned and 13 were released back to the river).

About 1,278 steelhead were handled and released (or surplus) at Tumwater and Dryden dams during brood year 2015 Wenatchee steelhead broodstock collection. Most were hatchery-origin fish handled at Tumwater Dam and ultimately surplus to meet the PHOS objective upstream from Tumwater Dam. Fish released at Dryden Dam were released because the weekly quota for hatchery or wild steelhead had been attained, but not for both hatchery and wild fish, or because they were non-target fish (adipose clipped), or they were unidentifiable hatchery-origin steelhead. All steelhead released were allowed to fully recover from the anesthesia and released immediately upstream from the trap sites.

In addition to steelhead encountered at Dryden Dam during steelhead broodstock collection, an estimated 48 spring Chinook salmon were captured and released unharmed immediately upstream

from the trap facility. Consistent with ESA Section 10 Permit 1395 impact minimization measures, all ESA species handled were subject of water-to-water transfers.

### Hatchery Rearing and Release

The 2015 brood Wenatchee steelhead reared throughout all life stages without significant mortality (defined as >10% population mortality associated with a single event). However, the 2015 brood had poor fertilization to eyed-egg survival (60.3%) combined with somewhat low eyed-egg to ponding survival resulting in an unfertilized-to-release survival of 68.5%, which was considerably less than the program target of 81% (see Section 3.2).

Juvenile rearing occurred at three separate facilities including Eastbank Fish Hatchery, Chelan Fish Hatchery, and the Chiwawa Acclimation Facility. Multiple facilities were used to take advantage of variable water temperatures to manipulate growth of juveniles from different parental crosses. Typically, wild steelhead spawn later than their hatchery cohort and are therefore reared at Chelan Fish Hatchery on warmer water to accelerate their growth so they achieve a size-at-release similar to HxH parental cross progeny reared on cooler water at Eastbank Fish Hatchery. All parental cross groups received final rearing and over-winter acclimation at the Chiwawa Acclimation Facility on Wenatchee River and Chiwawa River surface water before direct release (scatter planting) in the Wenatchee River basin.

The 2015 brood steelhead smolt release in the Wenatchee River basin totaled 195,344 smolts, representing about 79% of the program target of 247,300 smolts identified in the Rocky Reach and Rock Island Dam HCPs and within the maximum 110% allowed in ESA Section 10 Permit 1395. As specified in ESA Section 10 Permit 1395, all steelhead smolts released were externally marked or internally tagged and a representative number were PIT tagged (see Section 3.2).

### Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, 1395, 18118, 18120, and 18121, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There was no NPDES violations reported at PUD Hatchery facilities during the period 1 January 2016 through 31 December 2016. NPDES monitoring and reporting for Chelan PUD Hatchery Programs during 2016 are provided in Appendix F.

### Smolt and Emigrant Trapping

Per ESA Section 10 Permit No. 1395, the permit holders are authorized a direct take of up to 20% of the emigrating steelhead population and a lethal take not to exceed 2% of the fish captured (NMFS 2003). Based on the estimated wild steelhead population (smolt trap expansion) and hatchery juvenile steelhead population estimate (hatchery release data) for the Wenatchee River basin, the reported steelhead encounters during the 2016 emigration complied with take provisions in the Section 10 permit and are detailed in Table 3.30. Additionally, juvenile fish captured at the trap locations were handled consistent with provisions in ESA Section 10 Permit 1395 Section B.

**Table 3.30.** Estimated take of Upper Columbia River steelhead resulting from juvenile emigration monitoring in the Wenatchee River basin, 2016. NA = not available.

| Trap location                      | Population estimate |                       |      |     | Number trapped |          |        |        | Total  | Take allowed by Permit |

### Spawning Surveys

Steelhead spawning ground surveys were conducted in the Wenatchee River basin during 2016, as authorized by ESA Section 10 Permit No. 1395. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential effects to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

### Stock Assessment at Priest Rapids Dam

Upper Columbia River steelhead stock assessment sampling at Priest Rapids Dam (PRD) is authorized through ESA Section 10 Permit No. 1395 (NMFS 2003). Permit authorizations include interception and biological sampling of up to 15% of the Upper Columbia River steelhead passing PRD to determine upriver adult population size, estimate hatchery to wild ratios, determine age-class contribution, and evaluate the need for managing hatchery steelhead consistent with ESA recovery objectives, which include fully seeding spawning habitat with naturally produced Upper Columbia River steelhead supplemented with artificially propagated steelhead (NMFS 2003). The 2014-2015 run-cycle report (BY 2015) for stock assessment sampling at Priest Rapids Dam was compiled under provisions of ESA Section 10 Permit 1395. Data and reporting information are included in Appendix G.

## SECTION 4: WENATCHEE SOCKEYE SALMON

The goal of sockeye salmon supplementation in the Wenatchee Basin was to use artificial production to replace adult production lost because of mortality at Rock Island Dam, while not reducing the natural production or long-term fitness of sockeye in the basin. The Rock Island Fish Hatchery Complex began operation in 1989 under funding from Chelan PUD. The Complex operated originally through the Rock Island Settlement Agreement, but since 2004 has operated under the Anadromous Fish Agreement and Habitat Conservation Plans.

Adult sockeye were collected for broodstock from the run-at-large at Tumwater Dam. Beginning in 2011, because of passage delays at Tumwater Dam during trapping operations, sockeye broodstock were collected at Dryden Dam. The goal was to collect up to 260 natural-origin adult sockeye for the program. Broodstock collection occurred from about 7 July through 28 August with trapping occurring no more than 16 hours per day, three days a week at Tumwater Dam and up to seven days per week at the Dryden Dam left and right-bank facilities.

Adult sockeye were held and spawned at Eastbank Fish Hatchery. The fertilized eggs were also incubated at the hatchery. For brood years 1989 through 1998, unfed fry were transferred from the hatchery to Lake Wenatchee net pens. From 1998 to 2011, juvenile sockeye were reared at Eastbank Fish Hatchery until July when they were transferred to the net pens. The initial rearing at Eastbank was to increase growth rates. During most years up through 2005, juvenile sockeye were released from net pens at two different times, August and November. Since 2006, all juvenile sockeye were released in late October.

The production goal for the Wenatchee sockeye supplementation program was to release 200,000 subyearlings into Lake Wenatchee at 20 fish per pound. Targets for fork length and weight were 133 mm (CV = 9.0) and 22.7 g, respectively. Over 90% of these fish were marked with CWTs. In addition, from 2006-2011, about 15,000 juvenile sockeye were PIT tagged annually. Following an evaluation of the supplementation program in 2011, the Hatchery Committees decided to convert the Wenatchee sockeye hatchery program to summer steelhead in 2012. Monitoring occurs annually to track the status of the natural sockeye population.

### 4.1 Broodstock Sampling

As noted above, the Wenatchee sockeye program was terminated in 2012. Thus, no broodstock have been collected since 2011 and the release of juvenile sockeye into Lake Wenatchee in 2012 (2011 brood) was the last. Therefore, this section presents the history of the program and tracks the juveniles from the 2011 brood that were released as parr into Lake Wenatchee in 2012. Some of these fish began their smolt migrations in 2013.

#### Origin of Broodstock

Wenatchee sockeye broodstock have not been collected since 2011. Table 4.1 shows the history of the number of broodstock that were collected during the period 1989 to 2011.

**Table 4.1.** Numbers of wild and hatchery sockeye salmon collected for broodstock, numbers that died before spawning, and numbers of sockeye spawned, 1989-2011. Unknown origin fish (i.e., undetermined by scale analysis, no CWT or fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes sockeye that died of natural causes typically near the end of spawning and were not needed for the program, surplus sockeye killed at spawning, sockeye that died but were not recovered from the net pens, and sockeye that may have jumped out of the net pens.

| Brood year     | Wild sockeye     |                            |           |                |                 | Hatchery sockeye |                            |           |                |                 | Total number spawned |
|----------------|------------------|----------------------------|-----------|----------------|-----------------|------------------|----------------------------|-----------|----------------|-----------------|----------------------|
|                | Number collected | Prespawn loss <sup>a</sup> | Mortality | Number spawned | Number released | Number collected | Prespawn loss <sup>a</sup> | Mortality | Number spawned | Number released |                      |
| 1989           | 299              | 93                         | 47        | 115            | 44              | 0                | 0                          | 0         | 0              | 0               | 115                  |

<sup>a</sup> Pre-spawn loss represents the number of fish that died during the holding period before spawning. Mortality is the number of fish that were surplus following spawning.

### Age/Length Data

Ages of sockeye were determined from scales and otoliths collected from broodstock and are shown in Table 4.2.

**Table 4.2.** Percent of hatchery and wild sockeye salmon of different ages (total age) collected from broodstock, 1994-2011.

| Return year | Origin   | Total age |      |     |
|-------------|----------|-----------|------|-----|
|             |          | 4         | 5    | 6   |
| 1994        | Wild     | 57.3      | 41.7 | 1.0 |
|             | Hatchery | 40.0      | 60.0 | 0.0 |

### Sex Ratios

Sex ratios of wild and hatchery sockeye collected during the life of the sockeye hatchery program are presented in Table 4.4.

**Table 4.4.** Numbers of male and female wild and hatchery sockeye collected for broodstock, 1989-2011. Ratios of males to females are also provided.

| Return year | Number of wild sockeye |             |           | Number of hatchery sockeye |             |           | Total M/F ratio |
|-------------|------------------------|-------------|-----------|----------------------------|-------------|-----------|-----------------|
|             | Males (M)              | Females (F) | M/F       | Males (M)                  | Females (F) | M/F       |                 |
| 1989        | 162                    | 137         | 1.18:1.00 | 0                          | 0           | -         | 1.18:1.00       |
| 1990        | 177                    | 156         | 1.13:1.00 | 0                          | 0           | -         | 1.13:1.00       |

## Fecundity

Fecundities of sockeye collected during the life of the hatchery program are presented in Table 4.5.

**Table 4.5.** Mean fecundity of female sockeye salmon collected for broodstock, 1989-2011. Fecundities were determined from pooled egg lots and were not identified for individual females.

| Return year    | Mean fecundity |
|----------------|----------------|
| 1989           | 2,344          |
| 1990           | 2,225          |
| 1991           | 2,598          |
| 1992           | 2,341          |
| 1993           | 2,340          |

## 4.2 Hatchery Rearing

### Rearing History

#### *Number of eggs taken*

Numbers of eggs taken from sockeye broodstock during the life of the sockeye hatchery program are shown in Table 4.6.

**Table 4.6.** Numbers of eggs taken from sockeye broodstock, 1989-2011.

| Return year    | Number of eggs taken |
|----------------|----------------------|
| 1989           | 133,600              |
| 1990           | 326,267              |
| 1991           | 231,254              |
| 1992           | 381,561              |
| 1993           | 231,700              |
| 1994           | 338,562              |
| 1995           | 247,900              |
| 1996           | 314,390              |
| 1997           | 254,459              |
| 1998           | 163,278              |
| 1999           | 190,732              |
| 2000           | 227,234              |
| 2001           | 301,925              |
| 2002           | 356,982              |
| 2003           | 319,470              |
| 2004           | 225,499              |
| 2005           | 211,985              |
| 2006           | 292,136              |
| 2007           | 302,363              |
| 2008           | 316,476              |
| 2009           | 304,963              |
| 2010           | 278,171              |
| 2011           | 290,046              |
| <i>Average</i> | <i>271,389</i>       |
| <i>Median</i>  | <i>290,046</i>       |

#### *Number of acclimation days*

During the life of the program, Wenatchee sockeye were only acclimated on Lake Wenatchee water in net pens. Acclimation days are presented in Table 4.7.

**Table 4.7.** Water source and mean acclimation period for Wenatchee sockeye, brood years 1989-2011.

| Brood year | Release year | Transfer date | Release date | Number of Days | Water source   |
|------------|--------------|---------------|--------------|----------------|----------------|
| 1989       | 1990         | 5-Apr         | 24-Oct       | 202            | Lake Wenatchee |
| 1990       | 1991         | 10-Apr        | 19-Oct       | 192            | Lake Wenatchee |
| 1991       | 1992         | 1-Apr         | 20-Oct       | 202            | Lake Wenatchee |
| 1992       | 1993         | 5-Apr         | 7-Sep        | 155            | Lake Wenatchee |
|            |              | 5-Apr         | 26-Oct       | 204            | Lake Wenatchee |
| 1993       | 1994         | 5-Apr         | 1-Sep        | 149            | Lake Wenatchee |
|            |              | 5-Apr         | 17-Oct       | 195            | Lake Wenatchee |
| 1994       | 1995         | 4-Apr         | 15-Sep       | 164            | Lake Wenatchee |
|            |              | 4-Apr         | 23-Oct       | 202            | Lake Wenatchee |
| 1995       | 1996         | 4-Apr         | 25-Oct       | 204            | Lake Wenatchee |
| 1996       | 1997         | 4-Apr         | 22-Oct       | 201            | Lake Wenatchee |
| 1997       | 1998         | 1-Apr         | 9-Nov        | 222            | Lake Wenatchee |
| 1998       | 1999         | 1-Apr         | 29-Oct       | 211            | Lake Wenatchee |
| 1999       | 2000         | 25-Jul        | 28-Aug       | 34             | Lake Wenatchee |
|            |              | 26-Jul        | 1-Nov        | 98             | Lake Wenatchee |
| 2000       | 2001         | 2-Jul         | 27-Aug       | 56             | Lake Wenatchee |
|            |              | 3-Jul         | 27-Sep       | 86             | Lake Wenatchee |
| 2001       | 2002         | 15-Jul        | 28-Aug       | 44             | Lake Wenatchee |
|            |              | 16-Jul        | 22-Sep       | 68             | Lake Wenatchee |
| 2002       | 2003         | 30-Jun        | 25-Aug       | 56             | Lake Wenatchee |

| 2011       | 2012         | 9-10-Jul      | 29-Oct       | 112-113        | Lake Wenatchee |

## Release Information

### Numbers released

Numbers of juvenile sockeye released into Lake Wenatchee during the life of the program are shown in Table 4.8. Coded wire tag marking rates and numbers of PIT-tagged juvenile sockeye released are also shown in Table 4.8.

**Table 4.8.** Total number of sockeye parr released and numbers of released fish with CWTs and PIT tags for brood years 1989-2011. The release target for sockeye was 200,000 fish.

| Brood year        | Release year | CWT mark rate | Number of released fish with PIT tags | Number released |
|-------------------|--------------|---------------|---------------------------------------|-----------------|
| 1989              | 1990         | Not marked    | 0                                     | 108,400         |
| 1990              | 1991         | 0.9308        | 0                                     | 270,802         |

| <i>Average</i>    |              | <b>0.9379</b> | <b>11,994<sup>b</sup></b>             | <b>208,271</b>  |
| <i>Median</i>     |              | <b>0.9561</b> | <b>14,764<sup>b</sup></b>             | <b>197,195</b>  |

<sup>a</sup> These groups were only adipose fin clipped.

<sup>b</sup> Average and median are based on brood years 2004 to 2010.

### *Fish size and condition at release*

The size and condition of the juvenile sockeye released into Lake Wenatchee during the life of the program are presented in Table 4.9.

**Table 4.9.** Mean lengths (FL, mm), weight (g and fish/pound), and coefficient of variation (CV) of sockeye released, brood years 1989-2011. Size targets are provided in the last row of the table.

| Brood year | Release year | Fork length (mm) |      | Mean weight |            |
|------------|--------------|------------------|------|-------------|------------|
|            |              | Mean             | CV   | Grams (g)   | Fish/pound |
| 1989       | 1990         | 128              | -    | 18.2        | 25         |
| 1990       | 1991         | 131              | -    | 18.9        | 24         |

### Survival Estimates

Life-stage survival estimates for juvenile sockeye during the life of the hatchery program are shown in Table 4.10.

**Table 4.10.** Hatchery life-stage survival rates (%) for sockeye salmon, brood years 1989-2011. Survival standards or targets are provided in the last row of the table.

| Brood year     | Collection to spawning |             | Unfertilized egg-eyed | Eyed egg-ponding | 30 d after ponding | 100 d after ponding | Ponding to release | Transport to release | Unfertilized egg-release |
|----------------|------------------------|-------------|-----------------------|------------------|--------------------|---------------------|--------------------|----------------------|--------------------------|
|                | Female                 | Male        |                       |                  |                    |                     |                    |                      |                          |
| 1989           | 41.6                   | 100.0       | 88.1                  | 63.9             | 99.2               | 98.9                | 98.1               | 65.2                 | 83.0                     |
| 1990           | 96.2                   | 99.4        | 90.8                  | 96.3             | 99.9               | 99.2                | 98.4               | 98.4                 | 81.1                     |
| 1991           | 91.8                   | 94.1        | 79.2                  | 94.8             | 99.8               | 99.3                | 96.4               | 96.4                 | 72.4                     |
| 1992           | 91.1                   | 98.8        | 92.3                  | 98.0             | 99.9               | 99.8                | 98.6               | 98.8                 | 89.2                     |
| 1993           | 57.1                   | 99.2        | 89.2                  | 98.3             | 99.6               | 99.1                | 93.7               | 93.8                 | 82.2                     |
| 1994           | 89.8                   | 99.2        | 79.2                  | 96.0             | 99.5               | 98.6                | 98.3               | 98.2                 | 74.7                     |

### 4.3 Disease Monitoring

Because the sockeye hatchery program was terminated in 2012, there are no disease-monitoring results.

### 4.4 Natural Juvenile Productivity

Sockeye smolt abundance was estimated at a rotary screw trap located near the mouth of Lake Wenatchee during the period 1997 to 2011. Because the efficiency of the trap was difficult to assess, the operation was terminated in 2011. In 2012, the trap was relocated downstream near the mouth of the Chiwawa River and operated there for two years. Again, because few marked sockeye smolts were recaptured, the operation was terminated in 2013. Beginning in 2013, smolt abundance has been estimated at the Lower Wenatchee Trap.

#### Emigrant and Smolt Estimates

The Lower Wenatchee Trap operated between 29 January and 26 July 2016. During that time, the trap was inoperable for 23 days because of high and low river discharge, debris, elevated river temperature, large hatchery releases, and mechanical issues. During the sampling period, a total of 1,346 wild juvenile sockeye were captured at the Lower Wenatchee Trap. A significant relationship between trap efficiency and river discharge was created ( $R^2 = 0.52$ ,  $P < 0.043$ ). Using this model, the number of juvenile sockeye emigrants was estimated at 208,250 ( $\pm 29,447$ ; 95% CI) during the 2016 trapping season (Table 4.11). Because of high flows coupled with mechanical issues, the trap was not fully operational during peak sockeye emigration. For this reason, the population estimate is considered a minimum. Figure 4.1 shows the monthly captures of sockeye collected at the Lower Wenatchee Trap in 2016. All fish captured in the Lower Wenatchee trap are reported in Appendix B.

**Table 4.11.** Estimated numbers of wild and hatchery sockeye smolts that emigrated from Lake Wenatchee during run years 1997-2016; NS = no data. Estimates for the run years 1997-2011 were based on sampling at the Upper Wenatchee smolt trap; estimates beginning in 2013 were based on sampling at the Lower Wenatchee smolt trap.

| Run year | Numbers of sockeye smolts |                 |
|----------|---------------------------|-----------------|
|          | Wild smolts               | Hatchery smolts |
| 1997     | 55,359                    | 28,828          |
| 1998     | 1,447,259                 | 55,985          |
| 1999     | 1,944,966                 | 112,524         |

<sup>a</sup> Estimates refined based on PIT tag survival to McNary Dam.

<sup>b</sup> Summary statistics were calculated for years in which hatchery fish were being released (1997-2011).

**Figure 4.1.** Monthly captures of wild sockeye salmon smolts at the Lower Wenatchee Trap, 2016.

Age classes of wild sockeye smolts were determined from a length frequency analysis based on scales collected randomly each year since 1997 (Table 4.12). Each year, a small number of markedly smaller sockeye (<50 mm FL) are collected, and starting with run year 2013, an age-0 class was retroactively assigned based on catch records. For the available run years, most wild sockeye smolts migrated as age 1+ fish. Only in two years (1997 and 2005) did more smolts migrate as age 2+ fish. Relatively few smolts migrated at age 3+.

**Table 4.12.** Age structure and estimated number of wild sockeye smolts that emigrated from Lake Wenatchee, 1997-2016; ND = no data. Estimates for the run years 1997-2011 were based on sampling at the Upper Wenatchee smolt trap; estimates beginning in 2013 were based on sampling at the Lower Wenatchee smolt trap.

| Run year       | Proportion of wild smolts |              |              |              | Total wild emigrants |
|----------------|---------------------------|--------------|--------------|--------------|----------------------|

## Freshwater Productivity

Egg-smolt survival estimates for wild sockeye salmon are provided in Table 4.13. Estimates of egg deposition were calculated based on the spawner escapement at Tumwater Dam and the sex ratio and fecundity of the broodstock. For the 2012 brood year (a year where brood was not collected), a linear relationship with post-orbital to hypural length as the independent variable was used to calculate average fecundity of sockeye sampled at Tumwater Dam ( $r^2 = 0.40$ ,  $P < 0.01$ ). Smolts for brood years 1995-2009 were based on captures at the Upper Wenatchee Trap. No smolt

estimates are available for brood year 2010. Smolt estimates for brood years since 2012 are derived from captures made at the Lower Wenatchee Trap. Egg-smolt survival rates for brood years 1995-2014 have ranged from 0.012 to 0.212 (mean = 0.084).

**Table 4.13.** Estimated egg deposition (estimated as mean fecundity times estimated number of females), numbers of smolts, and survival rates for wild Wenatchee sockeye salmon, brood years 1995-2014; NA = not available.

| Brood year     | Number of females | Mean fecundity | Total eggs        | Numbers of wild smolts |                      |                |              |                  | Egg-smolt survival |

<sup>a</sup> There is no emigrant estimate for trapping during 2012.

<sup>b</sup> Emigrant estimates are derived from captures at the Lower Wenatchee Trap.

Juvenile survival rates for hatchery sockeye salmon are provided in Table 4.14. Release-smolt survival rates for brood years 1995-2009 have ranged from 0.000 to 1.000 (mean = 0.570). Egg-smolt survival rates for the same brood years ranged from 0.000 to 0.710 (mean = 0.294). On average, egg-smolt survival of hatchery sockeye is about three times greater than egg-smolt survival of wild sockeye.

**Table 4.14.** Juvenile survival rates for hatchery Wenatchee sockeye, brood years 1995-2009.

| Brood year | Number of eggs | Number of parr released | Date of release | Estimated number of smolts | Egg-smolt survival | Release-smolt survival |

<sup>a</sup> There is no emigrant estimate for the 2010 or 2011 brood years.

### PIT Tagging Activities

A total of 1,065 wild juvenile sockeye salmon were PIT tagged and released in 2016 at the Lower Wenatchee Trap. Numbers of wild sockeye salmon PIT-tagged and released as part of the Comparative Survival Study and PUD studies during the period 2006-2016 are shown in Table 4.15. See Appendix C for a complete list of all fish captured, tagged, lost, and released.

**Table 4.15.** Summary of the numbers of wild sockeye salmon that were tagged and released at the Upper and Lower Wenatchee Traps within the Wenatchee River basin, 2006-2016.

| Sampling Location    | Numbers of PIT-tagged sockeye salmon released |       |        |      |      |      |       |       |       |

## 4.5 Spawning Escapement

The sockeye salmon hatchery program ended after the 2011 brood year. As a result, monitoring activities that focused on evaluating the effects of the supplementation program on the natural population switched to monitoring the abundance and productivity of the natural population. Broadly, the proposed monitoring and evaluation activities cover juvenile and adult life-history stages and provide the data necessary to track or estimate viable salmonid population parameters (VSP); abundance, productivity, spatial structure, and diversity (McElhaney et al. 2000).

From 2009-2013, mark-recapture methods were used to estimate spawning escapement within the White River, while area-under-the-curve (AUC) methods were used to estimate spawning escapement within the Little Wenatchee River. Beginning in 2014, mark-recapture methods were used to estimate the spawning escapement of sockeye in the White River and Little Wenatchee watersheds (see Appendix H for more details).

### Mark-Recapture Estimates

Spawning escapement of sockeye salmon in 2016 was estimated using mark-recapture methods. This method relied on PIT tags to estimate sockeye spawning escapement (see Appendix H for more details).

Using mark-recapture methods, the estimated total escapement of sockeye in the Upper Wenatchee River basin in 2016 was 45,068 (Table 4.16). About 85% of the escapement entered the White River watershed (including the Napeequa River).

**Table 4.16.** Estimated escapement of adult sockeye into the Little Wenatchee and White River watersheds for return years 2009-2016. Escapement was based on recapture of PIT-tagged fish.

| Return year       | Tumwater Dam count | Recreational harvest | Little Wenatchee escapement | White River escapement | Total spawning escapement |
|-------------------|--------------------|----------------------|-----------------------------|------------------------|---------------------------|
| 2009              | 16,034             | 2,285                | 576                         | 13,876                 | 14,452                    |

| <i>Median</i>     | <i>43,628</i>      | <i>7,089</i>         | <i>2,569</i>                | <i>19,820</i>          | <i>22,204</i>             |

<sup>a</sup> Spawning escapements in 2011 and 2013 were calculated using AUC counts and a regression model.

The spawning escapement of 45,068 Wenatchee sockeye was greater than the overall average of 27,434 (Table 4.17).

**Table 4.17.** Spawning escapements for sockeye salmon in the Wenatchee River basin for return years 1989-2016; NA = not available and AUC = area under the curve.

| Return year    | Escapement estimation method | Spawning escapement |               |               |

## 4.6 Carcass Surveys

As described earlier, carcass surveys were not conducted in 2016. The information contained in this section represents carcass data collected before 2014.

### Number sampled

Table 4.18 shows the number of carcasses sampled within different survey streams during the period 1993-2013.

**Table 4.18.** Numbers of sockeye carcasses sampled within different streams/watersheds within the Wenatchee River basin, 1989-2013.

| Survey year    | Numbers of sockeye carcasses |              |           |              |
|----------------|------------------------------|--------------|-----------|--------------|
|                | Little Wenatchee             | White        | Napeequa  | Total        |

### Carcass Distribution and Origin

Based on the available data (1993-2013), the largest percentage of both wild and hatchery sockeye spawned in Reach 2 on the White River (Table 4.19 and Figure 4.2). However, a greater percentage of wild fish was found in Reach 2 than hatchery fish.

**Table 4.19.** Numbers of wild and hatchery sockeye carcasses sampled within different reaches in the Wenatchee River basin, 1993-2013. Reach codes are described in Table 2.9.

| Survey year | Origin   | Numbers of sockeye carcasses |    |             |       |     | Total |
|-------------|----------|------------------------------|----|-------------|-------|-----|-------|
|             |          | Little Wenatchee             |    | White River |       |     |       |
|             |          | L2                           | L3 | H1          | H2    | Q1  |       |

**Figure 4.2.** Distribution of wild and hatchery produced carcasses in different reaches in the Wenatchee River basin, pooled data from 1993-2013. Reach codes are described in Table 2.9; L = Little Wenatchee, H = White River, and Q = Napeequa River.

### 4.7 Life History Monitoring

Life history characteristics of Wenatchee sockeye were assessed by examining carcasses on spawning grounds and fish sampled at broodstock collection sites or during stock assessment, and by reviewing tagging data and fisheries statistics.

#### Migration Timing

There was little difference in migration timing of hatchery and wild sockeye past Tumwater Dam (Table 4.20a and b; Figure 4.3). On average, early in the run, hatchery and wild sockeye arrived at the dam at about the same time. Toward the end of the migration period, hatchery sockeye tended

to arrive at the dam slightly later than did wild sockeye. Most hatchery and wild sockeye migrated upstream past Tumwater Dam during July through early August. The peak migration time for both hatchery and wild sockeye was the last two weeks of July (Figure 4.3).

**Table 4.20a.** The Julian day and date that 10%, 50% (median), and 90% of the wild and hatchery sockeye salmon passed Tumwater Dam, 1998-2016. The average Julian day and date are also provided. Migration timing is based on video sampling at Tumwater. Data for 1998 through 2003 were based on videotapes and broodstock trapping and may not reflect the actual number of hatchery sockeye salmon. All sockeye were visually examined during trapping from 2004 to present.

| Survey year       | Origin   | Sockeye Migration Time (days) |        |               |        |               |        |        |        | Sample size |

<sup>a</sup> The origin of sockeye passing Tumwater Dam during 8 through 11 August 2012 was not assessed. The total number of sockeye passing Tumwater Dam in 2012 was 30,617 adults. Thus, about 9,023 adults of unknown origin passed Tumwater Dam in 2012.

**Table 4.20b.** The week that 10%, 50% (median), and 90% of the wild and hatchery sockeye salmon passed Tumwater Dam, 1998-2016. The average week is also provided. Migration timing is based on video sampling at Tumwater. Data for 1998 through 2003 were based on videotapes and broodstock trapping and may not reflect the actual number of hatchery sockeye salmon. All sockeye were visually examined during trapping from 2004 to present.

<sup>a</sup> The origin of sockeye passing Tumwater Dam during 8 through 11 August 2012 was not assessed. The total number of sockeye passing Tumwater Dam in 2012 was 30,617 adults. Thus, about 9,023 adults of unknown origin passed Tumwater Dam in 2012.

### Sockeye Migration Timing

**Figure 4.3.** Proportion of wild and hatchery sockeye observed (using video) passing Tumwater Dam each week during their migration period late-June through early-October; data were pooled over survey years 1998-2016.

### Age at Maturity

Although sample sizes are small, most hatchery sockeye returned as age-4 fish, while most wild sockeye returned as age-4 and 5 fish (Table 4.21; Figure 4.4). Only wild fish have returned at age-6.

**Table 4.21.** Proportions of wild and hatchery sockeye of different ages (total age) sampled in broodstock (1994-2011), on spawning grounds (1994-2012), and at Tumwater Dam (2013-2016).

| Survey year | Origin   | Total age |      |      |      |      |      | Sample size |

### Sockeye Age Structure

**Figure 4.4.** Proportions of wild and hatchery sockeye salmon of different total ages sampled at Tumwater Dam and on spawning grounds in the Wenatchee River basin for the combined years 1994-2016.

### Size at Maturity

Although sample sizes are small, wild and hatchery sockeye differed in mean length in 2016 (Table 4.22). However, the pooled data indicate that there is little difference in mean sizes of hatchery and wild sockeye salmon sampled in the Wenatchee River basin (Table 4.22). Analyses for the five-year reports will compare sizes of hatchery and wild fish of the same age groups and sex.

**Table 4.22.** Mean lengths (POH; cm) and variability statistics for wild and hatchery sockeye salmon sampled at Dryden Dam (broodstock) and on spawning grounds in the Wenatchee River basin, 1994-2016; SD = 1 standard deviation. From 2014 to present, data are collected from sockeye sampled at Tumwater Dam.

| Survey year | Origin   | Sample size | Sockeye length (POH; cm) |    |         |         |
|-------------|----------|-------------|--------------------------|----|---------|---------|
|             |          |             | Mean                     | SD | Minimum | Maximum |

### Contribution to Fisheries

The total number of hatchery and wild sockeye captured in different fisheries is provided in Tables 4.23 and 4.24. Harvest on hatchery-origin sockeye has been less than the harvest on wild sockeye.

**Table 4.23.** Estimated number and percent (in parentheses) of hatchery-origin Wenatchee sockeye captured in different fisheries, brood years 1989-2010.

| Brood year     | Ocean fisheries | Columbia River Fisheries |                        |                                   | Total      |

<sup>a</sup> Includes the Lake Wenatchee fishery.

## Straying

Stray rates were determined by examining CWTs recovered on spawning grounds within and outside the Wenatchee River basin. In addition, PIT tagging of hatchery sockeye, which began with brood year 2005, allows estimation of stray rates by brood return. Targets for strays based on return year (recovery year) outside the Wenatchee River basin should be less than 5%. The target for brood year strays should also be less than 5%.

Based on CWTs and brood year analysis, virtually no hatchery-origin Wenatchee sockeye strayed into non-target spawning areas or hatchery programs before brood year 2006 (Table 4.25). However, sockeye from brood years 2006 and 2007 strayed into the Entiat River and a few into the Methow River (non-target streams) and a non-target hatchery (Umpqua Trap) (Table 4.25).

Stray rates of Wenatchee sockeye from brood year 2006-2010 exceeded the target of 5%. The number of returning hatchery sockeye has decreased since brood year 2008.

**Table 4.25.** Number and percent of hatchery-origin Wenatchee sockeye that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and hatchery programs, by brood years 1990-2010. Hatchery-origin sockeye from brood years 1995-1998 were not tagged because of columnaris disease (NA = not available). Percent stays should be less than 5%.

| Brood year     | Homing         |             |                  |            | Straying           |             |                       |            |

\* Homing to the target hatchery includes Wenatchee hatchery sockeye that are captured and included as broodstock in the Wenatchee Hatchery program. These hatchery fish were collected at Tumwater Dam.

Based on PIT-tag analyses, on average, about 11% of the hatchery sockeye returns were last detected in streams outside the Wenatchee River basin (Table 4.26). The numbers in Table 4.26 should be considered rough estimates because they are not based on confirmed spawning (only last detections). Nevertheless, these data do indicate that some hatchery sockeye from the Wenatchee program have strayed into the Entiat and Methow rivers and possibly into the Okanogan system (based on sockeye detected at Wells Dam but not in the Methow River).

**Table 4.26.** Number and percent of hatchery-origin Wenatchee sockeye that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and hatchery programs for brood years 2005-2011. Estimates were based on last detections of PIT-tagged hatchery sockeye. Percent strays should be less than 5%.

## Genetics

Genetic studies were conducted in 2008 to determine the potential effects of the Wenatchee sockeye supplementation program on natural-origin sockeye in the upper Wenatchee River basin (Blankenship et al. 2008; the entire report is appended as Appendix I). Specifically, the objective of the study was to determine if the genetic composition of the Lake Wenatchee sockeye population had been altered by the supplementation program, which was based on the artificial propagation of a small subset of the Wenatchee population. Microsatellite DNA allele frequencies were used to differentiate between temporally replicated collections of natural and hatchery-origin sockeye in the Wenatchee River basin. A total of 13 collections of Wenatchee sockeye were analyzed; eight temporally replicated collections of natural-origin sockeye (N = 786) and five temporally replicated collections of hatchery-origin sockeye (N = 248). Paired natural-hatchery collections were available from return years 2000, 2001, 2004, 2006, and 2007. All collections were taken at Tumwater Dam and consisted of dried scales and fin clips.

Overall, the study showed that allele frequency distributions were consistent over time, regardless of origin, resulting in small, insignificant measures of genetic differentiation among collections. This indicates that there were no year-to-year differences in allele frequencies between natural and hatchery-origin sockeye. In addition, the analyses found no differences between pre- and post-supplementation collections. Thus, it was concluded that the allele frequencies of the broodstock collections equaled the allele frequency of the natural collections.

It is important to note that no new information will be reported on genetics until the next five-year report (2018).

## Proportionate Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock (pNOB) and the proportion of hatchery-origin fish in the natural spawning escapement (pHOS). We calculated Proportionate Natural Influence (PNI) by iterating Ford's (2002) equations 5 and 6 to equilibrium, using a heritability of 0.3 and a selection strength of three standard deviations. The larger the PNI value, the greater the strength of selection in the natural environment relative to that of the hatchery environment. For the natural environment to dominate selection, PNI should be greater than 0.50, and important integrated populations should have a PNI of at least 0.67 (HSRG/WDFW/NWIFC 2004).

The PNI values for the life of the program (brood years 1989-2011) are shown in Table 4.27. Throughout the program, PNI was consistently greater than 0.67. The hatchery program was terminated in 2012.

**Table 4.27.** Proportionate Natural Influence (PNI) values for the Wenatchee sockeye supplementation program for brood years 1989-2016. NOS = number of natural-origin sockeye counted at Tumwater Dam; HOS = number of hatchery-origin sockeye counted at Tumwater Dam; NOB = number of natural-origin sockeye collected for broodstock; and HOB = number of hatchery-origin sockeye included in hatchery broodstock. NP = no hatchery program.

| Brood year | Escapement <sup>a</sup> |       |      | Broodstock |     |      | PNI <sup>b</sup> |

<sup>a</sup> Proportions of natural-origin and hatchery-origin spawners were determined from reading video tape at Tumwater Dam, adjusted for fish harvested in the Lake Wenatchee recreational fishery.

<sup>b</sup> PNI was calculated previously using PNI approximate equation 11 (HSRG 2009; their Appendix A). All PNI values presented here were recalculated by iterating Ford's (2002) equations 5 and 6 to equilibrium using a heritability of 0.3 and a selection strength of three standard deviations. C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI.

### Post-Release Survival and Travel Time

We used PIT-tagged fish to estimate survival rates and travel time (arithmetic mean days) of hatchery sockeye salmon from Lake Wenatchee to McNary Dam, and smolt to adult ratios (SARs) from release to detection at Bonneville Dam (Table 4.28).<sup>9</sup> Over the seven brood years for which PIT-tagged hatchery fish were released, survival rates from Lake Wenatchee to McNary Dam ranged from 0.211 to 0.370; SARs from release to detection at Bonneville Dam ranged from 0.005 to 0.044. Average travel time from Lake Wenatchee to McNary Dam ranged from 176 to 202 days.

**Table 4.28.** Total number of hatchery sockeye parr released with PIT tags, their survival and travel times (mean days) to McNary Dam, and smolt-to-adult (SAR) ratios for brood years 2005-2011. Standard errors are shown in parentheses.

| Brood year | Number of sockeye released with PIT tags | Survival to McNary Dam | Travel time <sup>1</sup> to McNary Dam (d) | SAR to Bonneville Dam |
|------------|--|------------------------|--|-----------------------|
| 2005       | 14,859                                   | 0.334 (0.013)          | 176.4 (61.9)                               | 0.020 (0.001)         |
| 2006       | 14,764                                   | 0.370 (0.030)          | 202.0 (9.1)                                | 0.044 (0.002)         |

| 2008       | 14,858                                   | 0.307 (0.020)          | 192.9 (35.7)                               | 0.015 (0.001)         |
| 2009       | 14,486                                   | 0.211 (0.015)          | 194.2 (29.1)                               | 0.005 (0.001)         |
| 2010       | 5,039                                    | 0.302 (0.048)          | 191.7 (26.6)                               | 0.014 (0.002)         |
| 2011       | 5,074                                    | 0.318 (0.038)          | 196.7 (7.3)                                | 0.036 (0.003)         |

<sup>9</sup> It is important to point out that because of fish size differences among rearing tanks or raceways, fish PIT tagged in one tank or raceway may not represent untagged fish rearing in other tanks or raceways.

<sup>1</sup> Travel time is calculated from the date of release from the net pens in the fall, overwintering in Lake Wenatchee, to spring outmigration.

### Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population. Natural-origin recruits are naturally produced (wild) fish that survive to contribute to harvest (directly or indirectly), to broodstock, and to spawning grounds. We do not account for fish that died in route to the spawning grounds (migration mortality) or died just before spawning (pre-spawn mortality) (see Appendix B in Hillman et al. 2012). We calculated NORs with and without harvest. NORs without harvest include all returning fish that either returned to the basin or were collected as wild broodstock. NORs with harvest include all fish harvested and are based on a brood year harvest rates from the hatchery program. For brood years 1989-2010, NRR in the Wenatchee averaged 1.58 (range, 0.13-5.72) if harvested fish were not included in the estimate and 1.87 (range, 0.14-6.88) if harvested fish were included in the estimate (Table 4.29).

Hatchery replacement rates (HRR) were estimated as hatchery adult-to-adult returns. These rates should be greater than the NRRs and greater than or equal to 5.4 (the calculated target value in Hillman et al. 2013). The target value of 5.4 includes harvest. HRRs exceeded NRRs in 14 or 15 of the 23 years of data depending on if harvest was or was not included in the estimates (Table 4.29). Hatchery replacement rates for Wenatchee sockeye have equaled or exceeded the estimated target value of 5.4 in five of the 23 years (Table 4.29).

**Table 4.29.** Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR; with and without harvest) for sockeye salmon in the Wenatchee River basin, 1989-2010.

| Brood year | Broodstock Collected | Spawning Escapement | Harvest not included |        |       |      | Harvest included |        |       |      |
|------------|----------------------|---------------------|----------------------|--------|-------|------|------------------|--------|-------|------|
|            |                      |                     | HOR                  | NOR    | HRR   | NRR  | HOR              | NOR    | HRR   | NRR  |
| 1989       | 255                  | 21,802              | 2,757                | 23,616 | 10.81 | 1.08 | 3,680            | 30,672 | 14.43 | 1.41 |

### Juvenile-to-Adult Survivals

When possible, both parr-to-adult ratios (PAR) and smolt-to-adult ratios (SAR) were calculated for hatchery sockeye salmon. Ratios were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery parr released or the estimated number of smolts emigrating from Lake Wenatchee. Here, survival ratios were based on CWT returns, when available, or on the estimated number of hatchery adults recovered on the spawning grounds, in broodstock, and harvested. For the available brood years, PARs have ranged from 0.0001 to 0.0339 for hatchery sockeye salmon and SARs have ranged from 0.0002 to 0.0255 (Table 4.30).

**Table 4.30.** Parr-to-adult ratios (PAR) and smolt-to-adult ratios (SAR) for Wenatchee hatchery sockeye salmon, brood years 1990-2010; NA = not available.

| Brood year | Number of parr released | Number of smolts | Estimated adult recaptures | PAR    | SAR    |
|------------|-------------------------|------------------|----------------------------|--------|--------|
| 1989       | 108,400                 | NA               | 3,680                      | 0.0339 | NA     |

## 4.8 ESA/HCP Compliance

### Smolt and Emigrant Trapping

ESA-listed spring Chinook and steelhead were encountered during operation of the Lower Wenatchee trap. ESA takes are reported in the steelhead (Section 3.8) and spring Chinook (Section 5.8) sections and will not be repeated here.

### Spawning Surveys

Sockeye spawning ground surveys conducted in the Wenatchee River basin during 2016 were consistent with ESA Section 10 Permit No. 1347. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential effects to established redds, wading was restricted to the extent practical and extreme caution was used to avoid established redds when wading was required.

## SECTION 5: WENATCHEE (CHIWAWA) SPRING CHINOOK

The goal of Chiwawa spring Chinook salmon supplementation is to achieve “No Net Impact” to the productivity of spring Chinook caused by the operation of the Rock Island Hydroelectric Project. The Rock Island Fish Hatchery Complex began operation in 1989 under funding from Chelan PUD. The Complex operated originally through the Rock Island Settlement Agreement, but since 2004 has operated under the Rock Island and Rocky Reach Anadromous Fish Agreement and Habitat Conservation Plans.

Adult spring Chinook are collected for broodstock at the Chiwawa Weir and Tumwater Dam. From 2011 through 2013, all spring Chinook broodstock were collected at the Chiwawa Weir in order to reduce passage delays caused by trapping at Tumwater Dam. Before 2009, the goal was to collect up to 379 adult spring Chinook for the program with natural-origin fish making up not less than 33% of the broodstock. In 2011, the Hatchery Committees reevaluated the amount of hatchery compensation needed to achieve NNI. Based on that evaluation, the goal of the program was revised. The current goal (beginning with brood year 2013) is to collect 74 natural-origin spring Chinook. The number collected cannot exceed 33% of the natural-origin spring Chinook returns to Tumwater. Beginning in 2014, previously PIT-tagged hatchery-origin Chiwawa spring Chinook are collected at Tumwater Dam, while the Chiwawa Weir is used to collect natural-origin brood for the Chiwawa spring Chinook program. Broodstock collection occurs from May through July at Tumwater with trapping occurring up to 24 hours per day, seven days a week and at the Chiwawa Weir with trapping occurring from 15 June to 1 August (not to exceed 15 cumulative trapping days) on a 24-hour-up/24-hour-down schedule consistent with annual broodstock collection protocols.

Adult spring Chinook are spawned and reared at Eastbank Fish Hatchery. Juvenile spring Chinook are transferred from the hatchery to the Chiwawa Acclimation Facility in late September or early October. They are released volitionally from the Chiwawa Acclimation Facility during April the following year.

The production goal for the Chiwawa spring Chinook supplementation program up to brood year 2009 was to release 672,000 yearling smolts into the Chiwawa River at 12 fish per pound. Brood years 2010-2011, and 2012 were transition years to a reduced program of 298,000 smolts and 205,000 smolts, respectively. Beginning with the 2013 brood, the revised production goal is to release 144,026 smolts as part of a conservation program at 18 fish per pound. The Wenatchee spring Chinook safety-net program is now part of the Nason Creek spring Chinook program. Targets for fork length and weight are 155 mm (CV = 9.0) and 37.8 g, respectively. Over 90% of these fish are marked with CWTs. In addition, since 2006, juvenile spring Chinook have been PIT tagged annually.

With issuance of new ESA Section 10 permits in 2013, adult management (i.e., removal of excess hatchery-origin adults at dams, traps, and weirs, and in conservation fisheries) was implemented in 2014 to achieve PHOS and PNI goals for the Wenatchee spring Chinook programs.

Although this section of the report focuses on results from monitoring the Chiwawa spring Chinook program, information on spring Chinook collected throughout the Wenatchee River basin is also provided. Information specific to the Nason Creek spring Chinook conservation program is

presented in Section 6 and the White River Captive Broodstock Program is presented in Section 7.

## 5.1 Broodstock Sampling

This section focuses on results from sampling 2014-2016 Chiwawa spring Chinook broodstock, which were collected at the Chiwawa Weir and at Tumwater Dam, consistent with methods in the broodstock collections protocols (Tonseth 2014, 2015, and 2016). Some information for the 2016 return is not available at this time (e.g., age structure and final origin determination). This information will be provided in the 2017 annual report.

### Origin of Broodstock

Natural-origin adults made up between 31.3% and 100.0% of the Chiwawa spring Chinook broodstock for brood years 2014-2016 (Table 5.1). Natural and hatchery-origin adults were collected at Tumwater Dam and the Chiwawa Weir for return year 2016. Broodstock were trapped at Tumwater Dam from end of-May through mid-July 2016, and at the Chiwawa Weir from mid-June through late-July. Hatchery-origin broodstock were collected at Tumwater Dam in 2016 to meet the Nason Creek Safety Net broodstock requirements and to fill potential shortfalls of natural-origin broodstock requirements for the Chiwawa River Conservation program. Additional hatchery-origin broodstock were collected to ensure production obligations were achieved in the event that insufficient natural-origin collections could be made. A total of 21 hatchery-origin fish collected in 2016 were surplus at Eastbank Fish Hatchery.

**Table 5.1.** Numbers of wild and hatchery Chiwawa spring Chinook collected for broodstock, numbers that died before spawning, and numbers of Chinook spawned, 1989-2016. Unknown origin fish (i.e., undetermined by scale analysis, no CWT or fin clips, and no additional hatchery marks) were considered naturally produced.

| Brood year | Wild spring Chinook |                            |           |                |                 | Hatchery spring Chinook |                            |           |                |                 | Total number spawned |
|------------|---------------------|----------------------------|-----------|----------------|-----------------|-------------------------|----------------------------|-----------|----------------|-----------------|----------------------|

<sup>a</sup> Pre-spawn loss represents the number of fish that died during the holding period before spawning. Mortality is the number of fish that were surplus following spawning.

<sup>b</sup> The average and median represent the program before recalculation in 2011.

<sup>c</sup> The average and median represent the current program, which began in 2012. Origin determinations should be considered preliminary pending scale analyses.

<sup>d</sup> HOR Chiwawa spring Chinook were collected to meet both Chiwawa and Nason Creek obligations; broodstock and subsequent progeny were pooled together in the hatchery. About 12 Chiwawa HOR's were used to fulfill the Chiwawa Program; about 122 Chiwawa HOR's were used to fulfill the Nason Creek safety net obligation.

<sup>e</sup> For the Chiwawa program, 36 hatchery-origin returns were collected in case the program fell short on natural-origin returns. After eye-up, all of the hatchery-origin recruit eggs were culled because fecundity of natural-origin recruits was high enough to meet the WxW program.

### Age/Length Data

Ages were determined from scales and/or coded wire tags (CWT) collected from broodstock. For both the 2014 and 2015 returns, most adults, regardless of origin, were age-4 Chinook (Table 5.2). All age-5 Chinook were natural-origin fish; hatchery-origin Chinook were all age-4 fish. There were no age-3 natural or hatchery-origin fish collected for broodstock.

**Table 5.2.** Percent of hatchery and wild spring Chinook of different ages (total age) collected from broodstock, 1991-2015.

| Return year | Origin   | Total age  |     |      |      |
|-------------|----------|------------|-----|------|------|
|             |          | 2          | 3   | 4    | 5    |

<sup>a</sup> Comprised of age results for both Chiwawa and Nason Creek obligations.

There was little difference in mean lengths between hatchery and natural-origin broodstock of age-4 Chinook in 2014 and 2015; however, age-5 natural-origin Chinook in 2014 were larger than hatchery-origin broodstock (Table 5.3). All age-5 Chinook in 2015 were natural-origin fish.

**Table 5.3.** Mean fork length (cm) at age (total age) of hatchery and wild spring Chinook collected from broodstock, 1991-2015; N = sample size and SD = 1 standard deviation.

| Return year | Origin   | Spring Chinook fork length (cm) |   |    |       |    |    |       |     |    |       |    |    |

<sup>a</sup> Comprised of age results from HOR's used for both Chiwawa and Nason Creek obligations.

### Sex Ratios

Male spring Chinook in the 2014-2016 return years made up 49.2%, 53.5%, and 47.2%, respectively, of the adults collected. This resulted in overall male to female ratios of 0.97:1.00, 1.15:1.00, and 0.89:1.00, respectively (Table 5.4). For the 2016 return year, natural-origin and hatchery-origin fish both consisted of a slightly lower proportion of males than females (Table 5.4).

**Table 5.4.** Numbers of male and female wild and hatchery spring Chinook collected for broodstock, 1989-2016. Ratios of males to females are also provided.

| Return year       | Number of wild spring Chinook |             |                  | Number of hatchery spring Chinook |              |                  | Total M/F ratio  |

<sup>a</sup> Comprised of HOR's used for both Chiwawa and Nason Creek obligations.

## Fecundity

Mean fecundities for the 2014-2016 returns of spring Chinook ranged from 4,045-4,847 eggs per female (Table 5.5). These fecundities were generally more than the overall average of 4,655 eggs per female, but were close to the expected fecundity of 4,400 eggs per female assumed in the broodstock protocols. For the 2016 return year, natural-origin Chinook produced more eggs per female than did hatchery-origin fish. This could be attributed to differences in size and age of hatchery and natural-origin fish described above (Tables 5.2 and 5.3).

**Table 5.5.** Mean fecundity of wild, hatchery, and all female spring Chinook collected for broodstock, 1989-2016; NA = not available.

| Return year    | Mean fecundity |              |                    |

\* Individual fecundities were not tracked with females until 1997.

<sup>a</sup> Estimated as the mean of fecundities two years before and two years after 1992.

## 5.2 Hatchery Rearing

### Rearing History

#### *Number of eggs taken*

Based on the unfertilized egg-to-release survival standard of 81%, a total of 829,630 eggs were required to meet the program release goal of 672,000 smolts for brood years 1989-2010. For the 2011 and 2012 brood years, a total of 367,536 and 252,410 eggs were required to meet the release goals of 298,000 and 204,452 smolts, respectively. Since 2013, 169,442 eggs have been required to achieve a release goal of 144,026 smolts for the Chiwawa spring Chinook Program. Between 1989 and 2016, the egg take goal was reached only in 2001, 2015, and 2016<sup>10</sup> (Table 5.6). The green egg takes for 2014-2016 brood years were 99.7%, 109.0%, and 109.0% of program goals, respectively.

At the beginning of the Chiwawa spring Chinook program, the production level was set at 372,000 smolts. The primary reason for not meeting the egg take requirements included a lack of returning hatchery adults (because of program start up) and low wild fish abundance (along with no weir in the Chiwawa for first few years). Post ESA listing and issuance of Section 10(a)(1)(A) permit 1196 in 1999, continued low abundance (hatchery and natural origin), as well as the permit limitation requiring a minimum of 33% natural-origin fish in the broodstock further constrained meeting the requisite egg take goal for a 672,000 program. In 2010, it was expected that recalculation of the mitigation obligation beginning with the 2012 brood year was going to result in a significant reduction in the production level and the Hatchery Committees subsequently agreed to reduce the production target to 298,000 in advance of recalculation to increase the likelihood of meeting the overall production goal. In 2011, the Joint Fisheries Parties developed the Wenatchee Basin Spring Chinook Management Plan, which split the program into a conservation and safety-net component; the conservation program using natural origin fish to meet recovery objectives and the safety net using returning adults from the conservation program to satisfy the balance of the production requirement.

Per amended Section 10(a)(1)(A) permit 18121, natural-origin broodstock is currently collected for the Chiwawa spring Chinook Program using PIT-tagged wild fish (tagged as juveniles) intercepted at Tumwater Dam and at the Chiwawa Weir. Operational limitations (e.g., flows, days per season, and bull trout encounters) reduce the opportunity to meet the natural-origin broodstock requirement, particularly in years of low adult abundance. Subsequently, to ensure the mitigation obligation is met, a component of hatchery adult returns are trapped and retained from Tumwater Dam during broodstock collection for the Nason Creek Program, which uses a composited broodstock (for the conservation component) identified through genetic analysis. The genetic analysis is used to prioritize those adults assigned with the highest probability to either the Nason or Chiwawa spawning aggregates, and excludes those assigned to the White River spawning aggregate.

---

<sup>10</sup> In 2016, the natural-origin egg-take goal was not achieved, but the program egg-take goal was achieved.

**Table 5.6.** Numbers of eggs taken from spring Chinook broodstock, 1989-2016; NP = no program.

| <b>Return year</b>                   | <b>Number of eggs taken for the Chiwawa Program</b> |

\* Although the program egg-take goal was achieved, the natural-origin egg-take goal was not.

### Number of acclimation days

Early rearing of the 2014 brood Chiwawa spring Chinook was similar to previous years with fish being held on well water before being transferred to the Chiwawa Acclimation Facility for final acclimation. Beginning in 2006 (2005 brood acclimation), modifications were made to the Chiwawa Acclimation Facility intakes so that Wenatchee River water could be applied to the Chiwawa River intakes during severe cold periods to prevent the formation of frazzle ice. During acclimation of the 2014 brood, fish were acclimated for 190 to 198 days on Chiwawa River water (Table 5.7).

**Table 5.7.** Number of days spring Chinook broods were acclimated and water source, brood years 1989-2014; NA = not available.

| Brood year | Release year | Transfer date | Release date  | Number of days and water source |         |                  |

<sup>a</sup> Represents the number of days Wenatchee River water was applied to the Chiwawa River intake screen to prevent the formation of frazzle ice.

## Release Information

### Numbers released

The 2014 brood Chiwawa spring Chinook program achieved 100% of the 144,026 goal with about 144,360 smolts (126,330 WxW and 18,030 HxH) being released volitionally into the Chiwawa River in 2016 (Table 5.8). Water-intake issues with the Nason spring Chinook program resulted in the transfer of the safety-net program to the Chiwawa Acclimation Facility. Release numbers in Table 5.8 reflect the inclusion of Nason Spring Chinook.

**Table 5.8.** Numbers of spring Chinook smolts tagged and released from the hatchery, brood years 1989-2013. The release target for Chiwawa spring Chinook is 144,026 smolts. For brood years 2012 to present, conservation program fish are not adipose fin clipped (they receive CWT only).

| Brood year | Release year | Type of release | CWT mark rate | Number released that were PIT tagged | Number of smolts released | Total number of smolts released |  |

<sup>a</sup> This does not include the 226,456 eyed eggs that were planted in the Chiwawa River.

<sup>b</sup> This high ELISA group was only adipose fin clipped and directly planted into Big Meadow Creek in May.

<sup>c</sup> This does not include 18,480 eyed eggs that were culled because of high ELISA.

<sup>d</sup> Brood years 2013 to present WxW spring Chinook are not adipose fin clipped (they receive CWT only); HxH Chinook are adipose fin clipped and receive a CWT.

<sup>e</sup> The total number of smolts released includes the HxH Nason Creek program that was transferred to the Chiwawa Acclimation Facility on 2-3 March 2016 because of water-intake concerns at the Nason Creek Acclimation Facility.

<sup>f</sup> The HxH Nason Creek program that was released from the Chiwawa Acclimation Facility.

### Numbers tagged

The 2014 brood Chiwawa spring Chinook were 98% CWT (Table 5.8).

In 2016, a total of 10,207 WxW Chiwawa spring Chinook from the 2015 brood were PIT tagged at Eastbank Hatchery on 11-14 July 2016. These were tagged and released into raceway #11. Fish were not fed during tagging or for two days before and after tagging. Fish averaged 87 mm in length and 8.0 g at time of tagging. These fish were transferred to the Chiwawa Acclimation Facility in October 2016.

Table 5.9 summarizes the number of hatchery spring Chinook that have been PIT-tagged and released into the Chiwawa River.

**Table 5.9.** Summary of PIT-tagging activities for Chiwawa hatchery spring Chinook, brood years 2005-2014.

<sup>a</sup> This release consisted of 4,988 tagged Chinook that were released volitionally and 4,993 that were forced released.

### *Fish size and condition at release*

Spring Chinook from the 2014 brood were released as yearling smolts between 15 and 20 April 2016. Size at release (13 fpp) was larger than the target of 18 fpp established for the program. The CV for fork length was 55% over the target (Table 5.10).

**Table 5.10.** Mean lengths (FL, mm), weight (g and fish/pound), and coefficient of variation (CV) of spring Chinook smolts released from the hatchery, brood years 1989-2014. Size targets are provided in the last row of the table.

| Brood year | Release year | Fork length (mm) |     | Mean weight |            |
|------------|--------------|------------------|-----|-------------|------------|
|            |              | Mean             | CV  | Grams (g)   | Fish/pound |

<sup>a</sup> Forced-release group.

<sup>b</sup> Volitional-release group.

<sup>c</sup> This represents the combination of the WxW Chiwawa, HxH Chiwawa, and the HxH Nason Creek programs. The HxH Nason Creek program was transferred to the Chiwawa Acclimation Facility on 2-3 March 2016 because of water-intake concerns at the Nason Creek Acclimation Facility.

## Survival Estimates

Overall survival of the 2014 brood Chiwawa spring Chinook from green (unfertilized) egg to release was above the standard set for the program (Table 5.11). There was higher than expected survivals throughout most stages except unfertilized to eye-egg, contributing to increased program performance. Pre-spawn survival of adults was also above the standard set for the program.

**Table 5.11.** Hatchery life-stage survival rates (%) for spring Chinook, brood years 1989-2014. Survival standards or targets are provided in the last row of the table.

| Brood year | Collection to spawning |       | Unfertilized egg-eyed | Eyed egg-ponding | 30 d after ponding | 100 d after ponding | Ponding to release | Transport to release | Unfertilized egg-release |
|------------|------------------------|-------|-----------------------|------------------|--------------------|---------------------|--------------------|----------------------|--------------------------|
|            | Female                 | Male  |                       |                  |                    |                     |                    |                      |                          |

<sup>a</sup> Survival estimates do not include the 18,840 eyed eggs that were culled because of high ELISA levels.

<sup>b</sup> Survival estimates do not include the HxH Nason Creek program that was transferred to the Chiwawa Acclimation Facility because of water-intake concerns at the Nason Creek Acclimation Facility.

### 5.3 Disease Monitoring

Results of 2016 adult broodstock bacterial kidney disease (BKD) monitoring indicated that most females had ELISA values less than 0.199. About 81.1% of females had ELISA values less than 0.120, which would have required about 18.9% of the progeny to be reared at densities not to exceed 0.06 fish per pound (Table 5.12).

For the 2014 brood, a formalin drip was used shortly after transfer to the Chiwawa Acclimation Facility to prevent infection associated with stress caused by the transfer. No significant health issues were encountered for the remainder of juvenile rearing.

**Table 5.12.** Proportion of bacterial kidney disease (BKD) titer groups for the Chiwawa spring Chinook broodstock, brood years 1996-2016. Also included are the proportions to be reared at either 0.125 fish per pound or 0.060 fish per pound.

| Brood year <sup>a</sup> | Optical density values by titer group |                 |                      |                | Proportion at rearing densities (fish per pound, fpp) <sup>b</sup> |                      |
|-------------------------|---------------------------------------|-----------------|----------------------|----------------|--|----------------------|
|                         | Very Low (≤ 0.099)                    | Low (0.1-0.199) | Moderate (0.2-0.449) | High (≥ 0.450) | ≤ 0.125 fpp (<0.119)   | ≤ 0.060 fpp (>0.120) |

<sup>a</sup> Individual ELISA samples were not collected before the 1996 brood.

<sup>b</sup> ELISA values from broodstock BKD testing dictate what density the progeny of the broodstock are reared. Progeny of broodstock with high ELISA values are reared at lower density.

<sup>c</sup> Comprised of HOR's used for both Chiwawa and Nason Creek obligations.

## 5.4 Natural Juvenile Productivity

During 2016, juvenile spring Chinook were sampled at the Lower Wenatchee, Nason Creek, White River, and Chiwawa River traps and counted during snorkel surveys within the Chiwawa River basin. Results from sampling at the Nason Creek Trap are provided in Section 6 and from the White River Trap in Section 7.

## Parr Estimates

Based on snorkel surveys, a total of 140,172 ( $\pm 10\%$ ) subyearling and 282 ( $\pm 43\%$ ) yearling spring Chinook were estimated in the Chiwawa River basin in August 2016 (Table 5.13 and 5.14). During the survey period 1992-2016, numbers of subyearling and yearling Chinook have ranged from 5,815 to 149,563 and 5 to 967, respectively, in the Chiwawa River basin (Table 5.13 and 5.14; Figure 5.1). Numbers of all fish counted in the Chiwawa River basin are reported in Appendix A.

**Table 5.13.** Total numbers of subyearling spring Chinook estimated in different streams in the Chiwawa River basin during snorkel surveys in August 1992-2016; NS = not sampled.

| Sample Year    | Number of subyearling spring Chinook |              |                |              |               |                  |             |             |             |               |

**Figure 5.1.** Numbers of subyearling and yearling Chinook salmon within the Chiwawa River Basin in August 1992-2016; ND = no data.

Juvenile Chinook were distributed contagiously among reaches in the Chiwawa River. Their densities were highest in the upper portions of the basin, with the highest densities within tributaries. Juvenile Chinook were most abundant in multiple channels and least abundant in glides and riffles. Most Chinook associated closely with woody debris in multiple channels. These sites (multiple channels) made up 16% of the total area of the Chiwawa River basin, but they provided habitat for 56% of all subyearling Chinook in the basin in 2016. In contrast, riffles made up 54% of the total area, but provided habitat for only 8% of all juvenile Chinook in the Chiwawa River basin. Pools made up 24% of the total area and provided habitat for 35% of all juvenile Chinook in the basin. Virtually no Chinook used glides that lacked woody debris.

Mean densities of juvenile Chinook in two reaches of the Chiwawa River were generally less than those in corresponding reference areas on Nason Creek and the Little Wenatchee River (Figure 5.2). Within both the Chiwawa River and its reference areas, pools and multiple channels consistently had the highest densities of juvenile Chinook.

**Figure 5.2.** Comparison of the 23-year means of subyearling spring Chinook densities within state/habitat types in reaches 3 and 8 of the Chiwawa River and their matched reference areas on Nason Creek and the Little Wenatchee River. NC = natural channel; S = straight channel; EB = eroded banks; MC = multiple channel. There was no sampling in 2000 and no sampling within reference areas in 1992.

### Smolt and Emigrant Estimates

Numbers of spring Chinook smolts and emigrants were estimated at the Chiwawa and Lower Wenatchee traps in 2016.

### Chiwawa Trap

The Chiwawa Trap operated between 2 March and 21 November 2016. During that time, the trap was inoperable for 72 days because of high and low river flows, debris, major hatchery releases, and mechanical issues. The trap operated in a single position throughout the sampling season. Daily trap efficiencies were estimated for each age class of fish (e.g., subyearling and yearling). The daily number of fish captured was expanded by the estimated trap efficiency to estimate daily total emigration. Monthly captures of all fish and results of mark-recapture efficiency tests at the Chiwawa Trap are reported in Appendix B.

Wild yearling spring Chinook (2014 brood year) were primarily captured in March and April 2016 (Figure 5.3). A significant relationship between trap efficiency and river flow was found ( $R^2 = 0.875$ ;  $P < 0.028$ ) and the total number of wild yearling Chinook emigrating from the Chiwawa River was estimated at 37,170 ( $\pm 6,524$ ; 95% CI). Combining the total number of subyearling spring Chinook (77,510  $\pm 9,074$ ) that emigrated during the fall of 2015 with the total number of yearling Chinook (37,170  $\pm 6,524$ ) that emigrated during 2016, the total emigrant estimate for brood year 2014 was 114,680 ( $\pm 12,268$ ) (Table 5.15). No non-trapping estimate was calculated for brood year 2014 (see Appendix B).

**Figure 5.3.** Monthly captures of wild subyearling, wild yearling, and hatchery yearling spring Chinook at the Chiwawa Trap, 2016.

**Table 5.15.** Numbers of redds and juvenile spring Chinook at different life stages in the Chiwawa River basin for brood years 1991-2016; NS = not sampled.

| Brood year     | Number of redds | Egg deposition   | Number of parr      | Number of smolts produced within Chiwawa River basin <sup>a</sup> | Number of emigrants |

<sup>a</sup> The estimated number of smolts (yearlings) that are produced entirely within the Chiwawa River basin. Smolt estimates for brood years 1992-1996 were calculated with a mark-recapture model; brood years 1997-present were calculated with a flow model.

<sup>b</sup> Estimate only includes numbers of Chinook in the Chiwawa River. Tributaries were not sampled at that time.

Wild subyearling spring Chinook (2015 brood year) were captured between March and November 2016. Based on capture efficiencies, the total number of wild subyearling (fry and parr) Chinook from the Chiwawa River basin was 145,971 ( $\pm 48,393$ ). Removing fry from the estimate, a total of 80,543 ( $\pm 27,967$ ) subyearling parr emigrated from the Chiwawa River basin in 2016. Although subyearling parr migrated during all months of sampling, the majority (83%) migrated during March, June, July, August, and October (Figure 5.3).

Yearling spring Chinook sampled in 2016 averaged 91 mm in length, 8.3 g in weight, and had a mean condition of 1.06 (Table 5.16). These size estimates were similar to the overall mean of yearling spring Chinook sampled in previous years (overall means: 93 mm, 9.1 g, and condition of 1.08). Subyearling spring Chinook sampled in 2016 at the Chiwawa Trap averaged 71 mm in length, averaged 4.5 g, and had a mean condition of 1.10 (Table 5.16). In general, subyearlings were slightly smaller than previous years (overall means, 76 mm, 5.3 g, and condition of 1.09).

**Table 5.16.** Mean fork length (mm), weight (g), and condition factor of subyearling (excluding fry) and yearling spring Chinook collected in the Chiwawa Trap, 1996-2016. Numbers in parentheses indicate 1 standard deviation.

| Sample year | Life stage  | Sample size <sup>a</sup> | Mean size   |            |               |

<sup>a</sup> Sample size represents the number of fish that were measured for both length and weight.

### Lower Wenatchee Trap

The lower Wenatchee Trap operated in a new location beginning in 2013. Hence, historic flow-discharge relationships are invalid and new models to estimate trap efficiency are being developed for all species.

The Lower Wenatchee Trap operated between 29 January and 26 July 2016. During that time, the trap was inoperable for 23 days because of high and low river discharge, debris, elevated river temperature, large hatchery releases, and mechanical issues. During the sampling period, a total of 610 wild yearling Chinook, 27,407 wild subyearling Chinook (mostly summer Chinook), and 7,701 hatchery yearling Chinook were captured at the Lower Wenatchee Trap. Based on capture efficiencies and river discharge, a significant model was developed ( $R^2 = 0.620$ ,  $P < 0.02$ ). The flow efficiency model estimated the total number of wild yearling Chinook that emigrated past the Lower Wenatchee Trap at 36,752 ( $\pm 5,330$ ; 95% CI) (Table 5.17). Monthly captures of all fish collected at the Lower Wenatchee Trap are reported in Appendix B.

**Table 5.17.** Numbers of redds and wild spring Chinook smolts produced in the Wenatchee River basin for brood years 2000-2014; NS = not sampled. From 2000-2010 the trap operated at Monitor; from 2013 to present the trap operated near Cashmere.

| Brood year | Number of redds | Egg deposition | Number of smolts produced within Wenatchee River basin |
|------------|-----------------|----------------|--|
| 2000       | 350             | 1,758,050      | 76,643   |

| <b>Median</b>  | <b>872</b>      | <b>3,823,720</b> | <b>76,643</b>  |

Yearling spring Chinook sampled in 2016 at the Lower Wenatchee Trap averaged 94 mm in length, 9.0 g in weight, and had a mean condition of 1.06 (Table 5.18). These size estimates were similar to the overall mean of yearling spring Chinook sampled in previous years (overall means: 98 mm, 10.5 g, and condition of 1.10).

**Table 5.18.** Mean fork length (mm), weight (g), and condition factor of yearling spring Chinook collected in the Lower Wenatchee Trap, 2000-2016. From 2000-2010 the trap operated at Monitor; from 2013 to present the trap operated near Cashmere. Numbers in parentheses indicate 1 standard deviation.

| Sample year | Sample size <sup>a</sup> | Mean size   |            |               |
|-------------|--------------------------|-------------|------------|---------------|
|             |                          | Length (mm) | Weight (g) | Condition (K) |

<sup>a</sup> Sample size represents the number of fish that were measured for both length and weight.

### PIT Tagging Activities

As part of the Comparative Survival Study (CSS) and PUD studies, a total of 14,158 wild juvenile Chinook (10,888 subyearling and 3,270 yearlings) were PIT tagged and released in 2016 in the Wenatchee River basin (Table 5.19a). Most of these (71.2%) were tagged at the Chiwawa trap. See Appendix C for a complete list of all fish captured, tagged, lost, and released.

**Table 5.19a.** Numbers of wild Chinook that were captured, tagged, and released at different locations within the Wenatchee River basin, 2016. Numbers of fish that died or shed tags are also given.

| Sampling Location              | Chinook Salmon Life Stage | Number captured | Number of recaptures | Number tagged | Number died | Shed tags | Total tags released | Percent mortality |
|--------------------------------|---------------------------|-----------------|----------------------|---------------|-------------|-----------|---------------------|-------------------|

## Freshwater Productivity

Both productivity and survival estimates for different life stages of spring Chinook in the Chiwawa River basin are provided in Table 5.20. Estimates for brood year 2014 fall within the ranges estimated over the period of brood years 1991-2014. During that period, freshwater productivities ranged from 125-1,015 parr/redd, 39-673 smolts/redd, and 124-834 emigrants/redd. Survivals during the same period ranged from 2.7-19.1% for egg-parr, 0.9-14.5% for egg-smolt, and 2.9-18.0% for egg-emigrants. Overwinter survival rates for juvenile spring Chinook within the Chiwawa River basin have ranged from 15.7-100.0%.

**Table 5.20.** Productivity (fish/redd) and survival (%) estimates for different juvenile life stages of spring Chinook in the Chiwawa River basin for brood years 1991-2014; ND = no data. These estimates were derived from data in Table 5.15.

| Brood year | Parr/Redd | Smolts/Redd <sup>a</sup> | Emigrants/Redd | Egg-Parr (%) | Parr-Smolt <sup>b</sup> (%) | Egg-Smolt <sup>a</sup> (%) | Egg-Emigrant (%) |

<sup>a</sup> These estimates include Chiwawa smolts produced only within the Chiwawa River basin.

<sup>b</sup> These estimates represent overwinter survival within the Chiwawa River basin. It does not include Chiwawa smolts produced outside the Chiwawa River basin.

Seeding level (egg deposition) explained most of the variability in productivity and survival of juvenile spring Chinook in the Chiwawa River basin. That is, for estimates based on “within-Chiwawa-Basin” life stages (e.g., parr and smolts), survival and productivity decreased as seeding levels increased (Figure 5.4). This suggests that density dependence regulates juvenile productivity and survival within the Chiwawa River basin. This form of population regulation is less apparent with total emigrants. However, one would expect the number of emigrants to increase as seeding levels exceed the rearing capacity of the Chiwawa River basin.

### Juvenile Spring Chinook

**Figure 5.4.** Relationships between seeding levels (egg deposition) and juvenile life-stage survivals and productivities for Chiwawa spring Chinook, brood years 1991-2014. Smolts represent yearling Chinook produced within the Chiwawa River basin.

#### Population Carrying Capacity

Population carrying capacity ( $K$ ) is defined as the maximum equilibrium population size estimated with population models (e.g., logistic equation, Beverton-Holt model, hockey stick model, and the

Ricker model).<sup>11</sup> Maximum equilibrium population size is generated from density dependent mechanisms that reduce population growth rates as population size increases (negative density dependence). This is referred to as compensation. Population size fluctuates about the maximum equilibrium size because of variability in vital rates that are unrelated to density (density independent factors) and measurement error. In this section, we estimate parr and smolt carrying capacities using the smooth hockey stick stock-recruitment model (see Appendix C in Hillman et al. 2012 for a detailed description of methods). This model explains most of the information contained in the juvenile spring Chinook data (see Appendix A).

Based on the smooth hockey stick model, the population carrying capacity for spring Chinook parr in the Chiwawa River basin is 113,801 parr (95% CI: 94,343 – 139,922) (Figure 5.5). The capacity for spring Chinook smolts is 45,161 (95% CI: 34,226 – 55,445) (Figure 5.6). Here, smolts are defined as the number of yearling spring Chinook produced entirely within the Chiwawa River basin. These estimates reflect current conditions (most recent two decades) within the Chiwawa River basin. Land use activities such as logging, mining, roads, development, and recreation have altered the historical conditions of the watershed. Thus, the estimated population capacity estimates may not reflect historical capacities for spring Chinook parr and smolts in the Chiwawa River basin.

**Figure 5.5.** Relationship between spawners and number of parr produced in the Chiwawa River basin. Population carrying capacity ( $K$ ) was estimated using the smooth hockey stick model, which explained most of the information in the data.

<sup>11</sup> Population carrying capacity ( $K$ ) should not be confused with habitat carrying capacity ( $C$ ), which is defined as the maximum population of a given species that a particular environment can sustain.

**Figure 5.6.** Relationship between spawners and number of yearling smolts produced in the Chiwawa River basin. Population carrying capacity ( $K$ ) was estimated using the smooth hockey stick model, which explained most of the information in the data.

We tracked the precision of the smooth hockey stick parameters for Chiwawa spring Chinook smolts over time to see if precision improves with additional years of data, and the parameters and statistics stabilize over time. Examination of variation in the alpha ( $A$ ) and beta ( $B$ ) parameters of the smooth hockey stick model and their associated standard errors and confidence intervals indicates that the parameters appear to stabilize after 19 years of smolt and spawning escapement data (Table 5.21; Figure 5.7). This was also apparent in the estimates of population carrying capacity (Figure 5.8). That is, after 19 years of data, additional years of data had relatively little effect on the parameters of the smooth hockey stick model and its statistics. This observation will change if more extreme spawning escapements occur in the future or density independent factors overwhelm the influence of density dependent factors.

**Table 5.21.** Estimated parameters and statistics associated with fitting the smooth hockey stick model to spawning escapement and smolt data. Smolts represent numbers of smolts produced entirely within the Chiwawa River basin.  $A$  = alpha parameter;  $B$  = beta parameter; SE = standard error (estimated from 5,000 bootstrap samples); and  $r^2$  = coefficient of determination. Spawners represent the stock size needed to achieve population capacity.

| Years of data | Parameter |       |        |           | Population capacity | Intrinsic productivity | Spawners | $r^2$ |
|---------------|-----------|-------|--------|-----------|---------------------|------------------------|----------|-------|
|               | $A$       | SE    | $B$    | SE        |                     |                        |          |       |

**Figure 5.8.** Time series of population carrying capacity estimates derived from fitting the smooth hockey stick model to Chiwawa spring Chinook smolt and spawning escapement data.

## 5.5 Spawning Surveys

Surveys for spring Chinook redds were conducted during the last week of July through September 2016 in the Chiwawa River (including Rock, Chikamin, and Phelps creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and the White River (including the Napeequa River and Panther Creek).

Spawning escapement for spring Chinook was calculated as the total number of redds times the male-to-female ratio (i.e., fish per redd expansion factor) estimated from broodstock and fish sampled at adult trapping sites.<sup>12</sup> Beginning with return year 2015, WDFW used the Gaussian area-under-the-curve (AUC) method (Millar et al. 2012) to estimate the number of redds within survey reaches (see Appendix J). The number of redds within each reach were then divided by the mean net error (ratio of observed redds to true number of redds) to estimate the “true” number of redds within each reach. The Mean net error was modeled based on covariates such as surveyor experience, channel complexity (mean thalweg CV), and observed redd density (number of redds per km).

<sup>12</sup> Expansion factor =  $(1 + (\text{number of males}/\text{number of females}))$ .

## Redd Counts

A total of 554 spring Chinook redds were counted in the Wenatchee River basin in 2016 (Table 5.22). This is lower than the average of 674 redds counted during the period 1989-2015 in the Wenatchee River basin. Most spawning occurred in the Chiwawa River (56.3% or 312 redds) (Table 5.22; Figure 5.9). Nason Creek contained 15.3% (85 redds), Icicle Creek contained 13.0% (72 redds), White River contained 7.9% (44 redds), Little Wenatchee contained 4.0% (22 redds), the Upper Wenatchee River 3.1% (17 redds), and Peshastin Creek contained 0.4% (2 redds).

**Table 5.22.** Numbers of spring Chinook redds counted (not “true” estimates) within different streams or watersheds within the Wenatchee River basin, 1989-2016. WDFW began full implementation of adult management in 2014.

| Sample year | Number of spring Chinook redds |       |                  |       |                 |        |           | Total |
|-------------|--------------------------------|-------|------------------|-------|-----------------|--------|-----------|-------|
|             | Chiwawa                        | Nason | Little Wenatchee | White | Wenatchee River | Icicle | Peshastin |       |
| 1989        | 314                            | 98    | 45               | 64    | 94              | 24     | NS        | 639   |
| 1990        | 255                            | 103   | 30               | 22    | 36              | 50     | 4         | 500   |

\* Redd counts in Peshastin Creek in 2001 and 2002 were elevated because the U.S. Fish and Wildlife Service planted 487 and 350 spring Chinook adults, respectively, into the stream. These counts were not included in the total or average calculations.

### Spring Chinook Redds

**Figure 5.9.** Percent of the total number of spring Chinook redds counted in different streams/watersheds within the Wenatchee River basin during August through September 2016.

As noted above, since 2015, WDFW has estimated the “true” number of redds within survey areas in the Wenatchee River basin using the Gaussian area-under-the-curve method. Based on two years of data, the average difference between the observed (counted) and true estimate is about 105 redds (Table 5.23).

**Table 5.23.** Comparison of the observed number and estimated “true” number of spring Chinook redds within different streams/watersheds within the Wenatchee River basin, 2015-2016.

### Redd Distribution

Spring Chinook redds were not evenly distributed among reaches within survey streams in 2016 (Table 5.24). Most of the spawning in the Chiwawa River basin occurred in Reaches 1 through 6. About 66% of the spawning in the Chiwawa River basin occurred in the lower two reaches (RKM 0.0-36.97; from the mouth to Rock Creek). Relatively few fish spawned in Rock and Chikamin creeks. The spatial distribution of redds in Nason Creek was weighted towards Reach 3, having 45% of the Nason Creek redds. In the Little Wenatchee River, about 89% of all spawning occurred in Reach 3 (RKM 9.2-14.0; Lost Creek to Falls). On the White River, 81% of the spawning occurred in Reach 3 (RKM 20.3-23.3; Napeequa River to Grasshopper Meadows). In the Wenatchee River about 50% of the fish spawned downstream from the mouth of the Chiwawa River, 41% spawned upstream from the mouth, and about 9% spawned in Chiwaukum Creek. In Icicle Creek, about 85% of spawning occurred in Reach 2 (RKM 4.9-6.7; Hatchery to Sleeping Lady). All the spawning in Peshastin Creek occurred upstream from the confluence with Camas Creek (RKM 9.0).

**Table 5.24.** Numbers (both observed and estimated) and proportions of spring Chinook redds estimated within different streams/watersheds within the Wenatchee River basin during August through September 2016. NS = not surveyed. See Table 2.8 for description of survey reaches.

| Stream/watershed | Reach           | Observed number of redds | Estimated number of redds | Proportion of estimated redds within stream/watershed |

<sup>a</sup> Reach H1 of the White River was surveyed once during the peak of the season to verify that no spawning was occurring in the lower portion of the river.

### Spawn Timing

Spring Chinook began spawning during the last week of July in Nason Creek and the second week of August in the Chiwawa River. Spawning began the third week of August in the Little Wenatchee and White rivers, the fourth week of August in Icicle Creek, the fifth week of August in Peshastin Creek, and the first week of September in the Wenatchee River (Figure 5.10). Spawning peaked the last week of August in Icicle Creek and the Little Wenatchee River. The Chiwawa River and Nason Creek peaked during the first week of September. The White River peaked during the second week of September and the Wenatchee River peaked during the fourth week of September.

The 11 redds observed on the Wenatchee River during the fourth week of September may have been present the previous week when no survey occurred. Peshastin Creek had two redds, one occurring the last week of August and one during the second week of September. Chinook completed spawning by the end of September.

**Figure 5.10.** Proportion of spring Chinook redds counted during different weeks in different sampling streams within the Wenatchee River basin, August through September 2016.

### Spawning Escapement

Spawning escapement for spring Chinook was calculated as the observed number of redds times the male-to-female ratio (i.e., fish per redd expansion factor) estimated from broodstock and fish sampled at adult trapping sites.<sup>13</sup> The estimated fish per redd ratio for spring Chinook upstream from Tumwater in 2016 was 1.83 (based on sex ratios estimated at Tumwater Dam). The estimated fish per redd ratio for spring Chinook downstream from Tumwater (Icicle and Peshastin creeks) was 1.81 (derived from broodstock collected at the Leavenworth National Fish Hatchery). Multiplying these ratios by the number of redds counted in the Wenatchee River basin resulted in a total spawning escapement of 1,012 spring Chinook (Table 5.25). The Chiwawa River basin had the highest spawning escapement (574 Chinook), while Peshastin Creek had the lowest (4 Chinook).

<sup>13</sup> Expansion factor = (1 + (number of males/number of females)).

**Table 5.25.** Number of observed redds, fish per redd ratios, and total spawning escapement for spring Chinook in the Wenatchee River basin, 2016. Spawning escapement was estimated as the product of redds times fish per redd.

| Sampling area         | Total number of redds | Fish/redd | Total spawning escapement* |
|-----------------------|-----------------------|-----------|----------------------------|
| Chiwawa               | 312                   | 1.83      | 571                        |
| Nason                 | 85                    | 1.83      | 156                        |
| Upper Wenatchee River | 17                    | 1.83      | 31                         |
| Icicle                | 72                    | 1.81      | 130                        |
| Little Wenatchee      | 22                    | 1.83      | 40                         |
| White                 | 44                    | 1.83      | 81                         |
| Peshastin             | 2                     | 1.81      | 4                          |
| <b>Total</b>          | <b>554</b>            | <b>--</b> | <b>1,012</b>               |

\* Spawning escapement estimate is based on total number of observed redds by stream. If escapement is calculated at the reach scale, then the total escapement may vary from what is shown here because of rounding errors.

The estimated total spawning escapement of 1,012 spring Chinook in 2016 was less than the overall average of 1,367 spring Chinook (Table 5.26). The escapement in the Chiwawa River basin in 2016 was 3.7 times the escapement in Nason Creek, the second most abundant escapement in the Wenatchee River basin (Table 5.26).

**Table 5.26.** Spawning escapements for spring Chinook in the Wenatchee River basin for return years 1989-2016; NA = not available.

| Return year       | Upper basin spawning escapement |         |       |                  |       |                 | Lower basin spawning escapement |        |           | Total        |

<sup>a</sup> In 2004, the fish/redd expansion estimate of 3.56 was applied to the Chiwawa River only and 3.00 fish/redd was applied to the rest of the upper basin.

## 5.6 Carcass Surveys

Surveys for spring Chinook carcasses were conducted during August through September 2016 in the Chiwawa River (including Rock, Chikamin, and Phelps creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and White River (including the Napeequa River and Panther Creek).

### Number sampled

A total of 362 spring Chinook carcasses were sampled during August through September in the Wenatchee River basin (Table 5.27). Most were sampled in the Chiwawa River basin (58% or 211 carcasses) and Nason Creek (26% or 95 carcasses) (Figure 5.11). A total of 25 carcasses were sampled in Icicle Creek, 13 in the Wenatchee River, 13 in the White River, and 5 in the Little Wenatchee River.

**Table 5.27.** Numbers of spring Chinook carcasses sampled within different streams/watersheds within the Wenatchee River basin, 1996-2016.

\* The number of carcasses sampled in the Wenatchee River in 2016 include two recovered in reach (W6) just downstream from the mouth of Icicle Creek.

### Spring Chinook Carcasses

**Figure 5.11.** Percent of the total number of spring Chinook carcasses sampled in different streams/watersheds within the Wenatchee River basin during August through September 2016.

#### Carcass Distribution and Origin

Spring Chinook carcasses were not evenly distributed among reaches within survey streams in 2016 (Table 5.28). Most of the carcasses (71%) in the Chiwawa River basin occurred in Reaches

1 and 2 (downstream from Rock Creek). In Nason Creek, most carcasses (51%) were collected in Reach 3 and the fewest (8%) in Reach 4. Most carcasses in the Little Wenatchee River were sampled in Reach 3 (Lost Creek to Rainy Creek). On the White River, most (85%) occurred in Reach 3 (Napeequa River to Grasshopper Meadows). On the Wenatchee River, 62% of the carcasses were found upstream from the confluence of the Chiwawa River and 38% were found downstream from the confluence. Most of the carcasses in Icicle Creek (60%) were found in Reach 2 (Hatchery to Sleeping Lady). No carcasses were found in Peshastin Creek.

**Table 5.28.** Numbers and proportions of carcasses sampled within different streams/watersheds within the Wenatchee River basin during August through September 2016. See Table 2.8 for description of survey reaches.

| Stream/watershed | Reach                   | Number of carcasses | Proportion of carcasses within stream/watershed |
|------------------|-------------------------|---------------------|---|

<sup>a</sup> Reach Wen 6 is not a survey reach for spring Chinook surveys; however, in 2016 two carcasses were sampled during a spring Chinook survey on the Icicle River. The carcasses were located downstream of the confluence of the Icicle River and Wenatchee River.

Final origin was determined for 208 of the 211 carcasses sampled in the Chiwawa River basin in 2016. Of those 208, 30% were hatchery fish (Table 5.29). In the Chiwawa River basin, the spatial distribution of hatchery and wild fish was not equal (Table 5.29). A larger percentage of hatchery fish were found in the lower reaches (C1 and C2; i.e., Mouth to Rock Creek). This general trend was also apparent in the pooled data (Figure 5.12).

**Table 5.29.** Numbers of wild and hatchery spring Chinook carcasses sampled within different reaches in the Chiwawa River basin, 1993-2016. Numbers represent recovered carcasses that had definitive origins. See Table 2.8 for description of survey reaches.

| Survey year | Origin   | Survey Reach |     |     |     |     |     |     |          |      | Total     |

### Sampling Rate

Overall, 36% of the estimated total spawning escapement of spring Chinook in the Wenatchee River basin was sampled in 2016 (Table 5.30). Sampling rates among streams/watershed varied from 0 to 61%.

**Table 5.30.** Number of redds and carcasses, total spawning escapement, and sampling rates for spring Chinook salmon in the Wenatchee River basin, 2016.

| Sampling area    | Total number of observed redds | Total number of carcasses | Total spawning escapement | Sampling rate |
|------------------|--------------------------------|---------------------------|---------------------------|---------------|

## Length Data

Mean lengths (POH, cm) of male and female spring Chinook carcasses sampled during surveys in the Wenatchee River basin in 2016 are provided in Table 5.31. The average size of males and females sampled in the Wenatchee River basin was 63 cm.

**Table 5.31.** Mean lengths (postorbital-to-hypural length; cm) and standard deviations (in parentheses) of male and female spring Chinook carcasses sampled in different streams/watersheds in the Wenatchee River basin, 2016.

| Stream/watershed | Mean lengths (cm) |                 |
|------------------|-------------------|-----------------|
|                  | Male              | Female          |
| Chiwawa          | 64 (12.0)         | 65 (6.5)        |
| Nason            | 59 (10.1)         | 64 (6.2)        |

| Peshastin        | --                | --              |
| <b>Total</b>     | <b>62 (11.5)</b>  | <b>64 (6.3)</b> |

## 5.7 Life History Monitoring

Life history characteristics of spring Chinook were assessed by examining carcasses on spawning grounds and fish collected at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

### Migration Timing

In 2016, there was a small difference in migration timing of hatchery and wild spring Chinook past Tumwater Dam (Table 5.32a and b; Figure 5.13). Hatchery fish arrived at the dam later than did wild fish, but ended their migration earlier than did wild fish. This same pattern was also observed in the overall average. Most hatchery and wild spring Chinook migrated upstream past Tumwater Dam during June and July (Figure 5.13).

**Table 5.32a.** The Julian day and date that 10%, 50% (median), and 90% of the wild and hatchery spring Chinook salmon passed Tumwater Dam, 1998-2016. The average Julian day and date are also provided. Migration timing is based on video sampling at Tumwater. Data for 1998 through 2003 were based on videotapes and broodstock trapping and may not reflect the actual number of hatchery spring Chinook. All spring Chinook were visually examined during trapping from 2004 to present.

| Survey year | Origin   | Spring Chinook Migration Time (days) |        |               |        |               |        |        |        | Sample size |
|-------------|----------|--------------------------------------|--------|---------------|--------|---------------|--------|--------|--------|-------------|
|             |          | 10 Percentile                        |        | 50 Percentile |        | 90 Percentile |        | Mean   |        |             |

**Table 5.32b.** The week that 10%, 50% (median), and 90% of the wild and hatchery spring Chinook salmon passed Tumwater Dam, 1998-2016. The average week is also provided. Migration timing is based on video sampling at Tumwater. Data for 1998 through 2003 were based on videotapes and broodstock trapping and may not reflect the actual number of hatchery spring Chinook. All spring Chinook were visually examined during trapping from 2004 to present.

**Figure 5.13.** Proportion of wild and hatchery spring Chinook observed (using video) passing Tumwater Dam each week during their migration period May through September; data were pooled over survey years 1998-2016.

### Age at Maturity

Most of the wild and hatchery spring Chinook sampled during the period 1994-2016 in the Chiwawa River basin were age-4 fish (total age) (Table 5.33; Figure 5.14). On average, hatchery fish made up a higher percentage of age-3 Chinook than did wild fish. In contrast, a higher proportion of age-5 wild fish returned than did age-5 hatchery fish. Thus, wild fish tended to return at an older age than hatchery fish.

**Table 5.33.** Proportions of wild and hatchery spring Chinook of different ages (total age) sampled on spawning grounds in the Chiwawa River basin, 1994-2016.

| Sample year | Origin   | Total age |      |      |      |      | Sample size |
|-------------|----------|-----------|------|------|------|------|-------------|
|             |          | 2         | 3    | 4    | 5    | 6    |             |

### Spring Chinook Age Structure

**Figure 5.14.** Proportions of wild and hatchery spring Chinook of different total ages sampled at the Chiwawa Weir and on spawning grounds in the Chiwawa River basin for the combined years 1994-2016.

#### Size at Maturity

On average, hatchery and wild spring Chinook of a given age differed slightly in length (Table 5.34). Differences were usually no more than 4 cm between hatchery and wild fish of the same age.

**Table 5.34.** Mean lengths (POH in cm;  $\pm 1SD$ ) and sample sizes (in parentheses) of different ages (total age) of male and female spring Chinook of wild and hatchery-origin sampled in the Chiwawa River basin, 1994-2016. Return years 2004-2016 include carcasses and live fish PIT-tag detections. In addition, 2005 and 2006 include fish released at the weir.

| Return year | Total age | Mean length (cm) |                  |                  |                  |
|-------------|-----------|------------------|------------------|------------------|------------------|
|             |           | Male             |                  | Female           |                  |
|             |           | Wild             | Hatchery         | Wild             | Hatchery         |
| 1994        | 3         |                  |                  |                  | 43 $\pm$ 0 (1)   |

### Contribution to Fisheries

Nearly all the harvest on hatchery-origin Chiwawa spring Chinook occurs within the Columbia River basin. Ocean catch records (Pacific Fishery Management Council) indicate that very few Upper Columbia spring Chinook are taken in ocean fisheries. Most of the harvest on hatchery-origin Chiwawa spring Chinook occurs in the Lower Columbia River fisheries, which are managed by the states and tribes pursuant to management plans developed in *U.S. v Oregon*. The Lower Columbia River fisheries occur during what is referred to in *U.S. v Oregon* as the winter, spring, and summer seasons, which begin in February and ends 31 July of each year. The Tribal fishery occurs upstream from Bonneville Dam, but primarily in Zone 6, the area between Bonneville and McNary dams; the non-treaty commercial fisheries occur in Zones 1-5, which are downstream from Bonneville Dam. The non-treaty recreational (sport) fishery occurs in the lower mainstem.

The total number of hatchery-origin spring Chinook captured in different fisheries has been relatively low (Table 5.35). The largest harvest occurred on the 2008 brood year.

**Table 5.35.** Estimated number and percent (in parentheses) of hatchery-origin Chiwawa spring Chinook captured in different fisheries, brood years 1989-2011; NP = no hatchery program.

| Brood year | Ocean fisheries | Columbia River Fisheries |                        |                                   | Total |

<sup>a</sup> Includes the Wanapum fishery and the Icicle and Wenatchee fisheries when they occurred.

## Straying

Stray rates were determined by examining CWTs recovered on spawning grounds within and outside the Wenatchee River basin. Targets for strays based on return year (recovery year) within the Wenatchee River basin should be less than 10% and targets for strays outside the Wenatchee River basin should be less than 5%. The target for brood year stray rates should be less than 5%.

The percentage of the spawning escapement made up of hatchery-origin Chiwawa spring Chinook in non-target spawning areas within the Wenatchee River basin has been high in some years and exceeded the target of 10% (Table 5.36). Over the years of sampling, Chiwawa spring Chinook have strayed into all non-target spawning areas, but, on average, have contributed most to the Nason Creek and Upper Wenatchee spawning escapements.

**Table 5.36.** Number (No.) and percent (%) of the spawning escapement in other non-target spawning streams within the Wenatchee River basin that consisted of hatchery-origin Chiwawa spring Chinook, return years 1992-2015. For example, for return year 2001, 35.3% of the spring Chinook spawning escapement in Nason Creek consisted of hatchery-origin Chiwawa spring Chinook. Percent strays should be less than 10%.

| Return year    | Nason Creek |             | Icicle Creek |            | Peshastin Creek |            | Upper Wenatchee |             | White River |             | Little Wenatchee |             |

| <b>Median</b>  | <b>135</b>  | <b>33.3</b> | <b>4</b>     | <b>1.3</b> | <b>0</b>        | <b>0.0</b> | <b>33</b>       | <b>55.0</b> | <b>6</b>    | <b>4.8</b>  | <b>4</b>         | <b>3.9</b>  |

Hatchery-origin Chiwawa spring Chinook have strayed into the Methow and Entiat basins (Table 5.37). Based on return year analyses, rates of hatchery-origin Chiwawa spring Chinook straying into these populations have been low in most years; in 2015, Chiwawa spring Chinook made up 4.7% of the spawning escapement in the Entiat River and 0.5% in the Methow River. However, during return years 2002, 2006, 2008-2009, and 2011-2013, Chiwawa spring Chinook made up more than 5% of the spawning escapement in the Entiat River basin. In three years, Chiwawa spring Chinook hatchery fish made up more than 20% of the spawning escapement in the Entiat River basin; however, in return year 2014, no strays were detected in the Entiat or Methow River basins.

**Table 5.37.** Number and percent of spawning escapements within other non-target basins that consisted of hatchery-origin Chiwawa spring Chinook, return years 1992-2015. For example, for return year 2002, 9.2% of the spring Chinook spawning escapement in the Entiat River basin consisted of hatchery-origin Chiwawa spring Chinook. Percent strays should be less than 5%. NS = not sampled.

Based on brood year analyses, on average, about 30% of the hatchery returns have strayed into non-target spawning areas, exceeding the target of 5% (Table 5.38). Depending on brood year, percent strays into non-target spawning areas have ranged from 0-81%. In most years, few (<1%) have strayed into non-target hatchery programs.

**Table 5.38.** Number and percent of hatchery-origin Chiwawa spring Chinook that homed to target spawning areas and the target hatchery program, and number and percent that strayed to non-target spawning areas and non-target hatchery programs, by brood years 1989-2011. Percent strays should be less than 5%.

\* Homing to the target hatchery includes Chiwawa hatchery spring Chinook that are captured and included as broodstock in the Chiwawa Hatchery program. These hatchery fish are typically collected at the Chiwawa weir and Tumwater Dam.

Ford et al. (2015) used parentage analysis to estimate rates of straying and homing of spring Chinook within the Wenatchee River basin. They found that stray rates of hatchery spring Chinook based on parentage analysis were consistent with rates estimated using physical tag recoveries (the latter estimates are shown in the tables above). They also found that stray rates among the major spawning tributaries were higher than stray rates of tagged fish to areas outside of the Wenatchee River basin (e.g., Entiat and Methow basins), which is consistent with the results shown in the

tables above. Finally, the researchers noted that hatchery spring Chinook homed at a far lower rate than natural-origin fish and stray rates of natural-origin fish ranged from about 0-100%. Rates of straying of natural-origin spring Chinook were affected by spawning tributary and by parental origin (i.e., progeny of naturally spawning hatchery-produced fish strayed at higher rates than progeny whose parents were of natural origin).

## Genetics

Genetic studies were conducted in 2007 to determine the potential effects of the Chiwawa Supplementation Program on natural-origin spring Chinook in the upper Wenatchee River basin (Blankenship et al. 2007; the entire report is appended as Appendix K). A total of 32 population collections of adult spring Chinook were obtained from the Wenatchee River basin between 1989 and 2006. This included nine collections of natural-origin Chinook adults from the Chiwawa River (N = 501) and nine collections of Chiwawa hatchery-origin Chinook (N = 595) at the Chiwawa weir. Collections in 1993 and 1994 included hatchery-origin smolts. Additional samples were collected from the White River, Little Wenatchee River, and Nason Creek; six collections of natural-origin Chinook from the White River (N = 179), one collection from the Little Wenatchee (N = 19), and six collections from Nason Creek (N = 268). A single collection was obtained for Chinook spawning in the mainstem Wenatchee River and from the Leavenworth National Fish Hatchery. Finally, an out-of-basin collection from the Entiat River was included in the analysis. Scale, fin clips, or operculum punches were collected from each sample. Microsatellite DNA allele frequencies were used to statistically assign individual fish to specific demes (locations) within the Wenatchee population. In addition, genetic effects of the hatchery program were assessed by examining relationships between census and effective population sizes ( $N_e$ ) from samples collected before and after supplementation.

Overall, this work showed that although allele frequencies within and between natural and hatchery-origin spring Chinook were significantly different, there was no evidence (i.e., robust signal) that the difference was the result of the hatchery program. Rather, the differences were more likely the result of life history characteristics. However, there was an increasing trend toward homogenization of the allele frequencies of the natural and hatchery-origin fish that comprised the broodstock, even though there was consistent year-to-year variation in allele frequencies among hatchery and natural-origin fish. In addition, there were no robust signals indicating that hatchery-origin hatchery broodstock, hatchery-origin natural spawners, natural-origin hatchery broodstock, and natural-origin natural spawners were substantially different from each other. Finally, the  $N_e$  estimate of 387 was only slightly larger than the pre-hatchery  $N_e$  (based on demographic data from 1989-1992), which means that the Chiwawa hatchery program has not reduced the  $N_e$  of the Wenatchee spring Chinook population.

Significant differences in allele frequencies were observed within and among major spawning areas in the Upper Wenatchee River basin. However, these differences made up only a very small portion of the overall variation, indicating genetic similarity among the major spawning areas. There was no evidence that the Chiwawa program has changed the genetic structure (allele frequency) of spring Chinook in Nason Creek and the White River, despite the presence of hatchery-origin spawners in both systems.

It is important to note that no new information will be reported on genetics until the next five-year report (2018).

## Proportionate Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock (pNOB) and the proportion of hatchery-origin fish in the natural spawning escapement (pHOS). We calculated Proportionate Natural Influence (PNI) by iterating Ford's (2002) equations 5 and 6 to equilibrium, using a heritability of 0.3 and a selection strength of three standard deviations.<sup>14</sup> The larger the PNI value, the greater the strength of selection in the natural environment relative to that of the hatchery environment. For the natural environment to dominate selection, PNI should be greater than 0.50, and important integrated populations should have a PNI of at least 0.67 (HSRG/WDFW/NWIFC 2004).

For brood years 1989-1994, PNI values were greater than or equal to 0.67 (Table 5.39). Since brood year 1994, PNI has been less than 0.67, except for brood year 2016, which was 0.70.

**Table 5.39.** Proportionate Natural Influence (PNI) values for the Chiwawa spring Chinook supplementation program for brood years 1989-2016. NOS = number of natural-origin Chinook on the spawning grounds; HOS = number of hatchery-origin Chinook on the spawning grounds; NOB = number of natural-origin Chinook collected for broodstock; and HOB = number of hatchery-origin Chinook included in hatchery broodstock.

| Brood year | Spawners |      |      | Broodstock |     |      | PNI <sup>a</sup> |
|------------|----------|------|------|------------|-----|------|------------------|
|            | NOS      | HOS  | pHOS | NOB        | HOB | pNOB |                  |
| 1989       | 713      | 0    | 0.00 | 28         | 0   | 1.00 | 1.00             |

| 1999       | 87       | 7    | 0.07 | No Program |     |      |                  |
| 2000       | 233      | 113  | 0.33 | 9          | 21  | 0.30 | 0.50             |
| 2001       | 506      | 1219 | 0.71 | 113        | 259 | 0.30 | 0.32             |
| 2002       | 254      | 453  | 0.64 | 20         | 51  | 0.28 | 0.33             |
| 2003       | 168      | 102  | 0.38 | 41         | 53  | 0.44 | 0.55             |
| 2004       | 575      | 276  | 0.32 | 83         | 132 | 0.39 | 0.57             |
| 2005       | 139      | 460  | 0.77 | 91         | 181 | 0.33 | 0.32             |
| 2006       | 114      | 415  | 0.78 | 91         | 224 | 0.29 | 0.29             |

<sup>14</sup> According to authorized annual take permits, PNI is calculated using the PNI approximate equation 11 (HSRG 2009; Appendix A). However, in this report, we used Ford's (2002) equations 5 and 6 with a heritability of 0.3 and a selection strength of three standard deviations to calculate PNI (C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI). This approach is more accurate than using the PNI approximate equation.

| Brood year     | Spawners   |            |             | Broodstock |           |             | PNI <sup>a</sup> |

<sup>a</sup> PNI was calculated previously using PNI approximate equation 11 (HSRG 2009; their Appendix A). All PNI values presented here were recalculated by iterating Ford's (2002) equations 5 and 6 to equilibrium using a heritability of 0.3 and a selection strength of three standard deviations. C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI.

### Post-Release Survival and Travel Time

We used PIT-tagged fish to estimate survival rates and travel time (arithmetic mean days) of hatchery spring Chinook from the Chiwawa River release site to McNary Dam, and smolt to adult ratios (SARs) from release to detection at Bonneville Dam (Table 5.40).<sup>15</sup> Over the ten brood years for which PIT-tagged hatchery fish were released, survival rates from the Chiwawa River to McNary Dam ranged from 0.435 to 0.662; SARs from release to detection at Bonneville Dam ranged from 0.003 to 0.018. Average travel time from the Chiwawa River to McNary Dam ranged from 14 to 44 days. Although there is only one year in which a forced release was compared to a volitional release (brood year 2005), hatchery spring Chinook that were forced out of the Chiwawa Acclimation Facility had slightly higher survival rates and SARs, and a faster travel time to McNary Dam, than did the volitional release.

**Table 5.40.** Total number of Chiwawa hatchery spring Chinook released with PIT tags, their survival and travel times (mean days) to McNary Dam, and smolt-to-adult (SAR) ratios for brood years 2005-2014. Standard errors are shown in parentheses. NA = not available (i.e., not all the adults from the release groups have returned to the Columbia River).

| Brood year | Number of tagged fish released | Survival to McNary Dam | Travel time to McNary Dam (d) | SAR to Bonneville Dam |
|------------|--------------------------------|------------------------|-------------------------------|-----------------------|
| 2005       | 4,993 (forced)                 | 0.662 (0.027)          | 22.9 (6.6)                    | 0.008 (0.001)         |
| 2005       | 4,988 (volitional)             | 0.638 (0.027)          | 43.6 (6.9)                    | 0.003 (0.001)         |
| 2006       | 9,894                          | 0.619 (0.038)          | 30.6 (7.6)                    | 0.011 (0.001)         |
| 2007       | 10,031                         | 0.435 (0.019)          | 32.9 (7.7)                    | 0.007 (0.001)         |
| 2008       | 10,006                         | 0.631 (0.038)          | 39.9 (10.3)                   | 0.018 (0.001)         |

<sup>15</sup> It is important to point out that because of fish size differences among rearing tanks or raceways, fish PIT tagged in one tank or raceway may not represent untagged fish rearing in other tanks or raceways.

| Brood year | Number of tagged fish released | Survival to McNary Dam | Travel time to McNary Dam (d) | SAR to Bonneville Dam |
|------------|--------------------------------|------------------------|-------------------------------|-----------------------|
| 2009       | 9,412                          | 0.547 (0.044)          | 30.2 (6.7)                    | 0.006 (0.001)         |

| 2011       | 9,987                          | 0.458 (0.029)          | 14.2 (7.5)                    | 0.009 (0.001)         |
| 2012       | 5,061                          | 0.478 (0.043)          | 30.9 (6.5)                    | NA                    |
| 2013       | 10,021                         | 0.438 (0.041)          | 29.5 (5.9)                    | NA                    |
| 2014       | 10,179                         | 0.628 (0.029)          | 24.9 (6.2)                    | NA                    |

### Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). Natural-origin recruits are naturally produced (wild) fish that survive to contribute to harvest (directly or indirectly), to broodstock, and to spawning grounds. We do not account for fish that died in route to the spawning grounds (migration mortality) or died just before spawning (pre-spawn mortality) (see Appendix B in Hillman et al. 2012). We calculated NORs with and without harvest. NORs without harvest include all returning fish that either returned to the basin or were collected as wild broodstock. NORs with harvest include all fish harvested and are based on a brood year harvest rates from the hatchery program. For brood years 1989-2010, NRR for spring Chinook in the Chiwawa averaged 1.05 (range, 0.01-4.40) if harvested fish were not included in the estimate and 1.16 (range, 0.01-4.81) if harvested fish were included in the estimate (Table 5.41). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and were calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. These rates should be greater than the NRRs and greater than or equal to 6.7 (the calculated target value in Hillman et al. 2013). The target value of 6.7 includes harvest. In nearly all years, HRRs were greater than NRRs, regardless if harvest was or was not included (Table 5.41). HRRs exceeded the estimated target value of 6.7 in 9 of the 20 years.

**Table 5.41.** Broodstock collected, spawning escapements, natural and hatchery-origin recruits (NOR and HOR), and natural and hatchery replacement rates (NRR and HRR; with and without harvest) for spring Chinook in the Chiwawa River basin, brood years 1989-2010; NP = no hatchery program.

| Brood year | Broodstock Collected | Spawning Escapement | Harvest not included |     |      |      | Harvest included |     |      |      |
|------------|----------------------|---------------------|----------------------|-----|------|------|------------------|-----|------|------|
|            |                      |                     | HOR                  | NOR | HRR  | NRR  | HOR              | NOR | HRR  | NRR  |
| 1989       | 28                   | 713                 | 180                  | 194 | 6.43 | 0.27 | 204              | 282 | 7.29 | 0.40 |

### Smolt-to-Adult Survivals

Smolt-to-adult survival ratios (SARs) were calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery smolts released. Here, SARs were based on CWT returns. For the available brood years, SARs have ranged from 0.00036 to 0.01563 for hatchery spring Chinook (Table 5.42).

**Table 5.42.** Smolt-to-adult ratios (SARs) for Chiwawa hatchery spring Chinook, brood years 1989-2011.

| Brood year | Number of tagged smolts released <sup>a</sup> | Estimated adult captures <sup>b</sup> | SAR     |
|------------|---|---------------------------------------|---------|
| 1989       | 42,707  | 204                                   | 0.00478 |
| 1990       | 52,798  | 19                                    | 0.00036 |
| 1991       | 61,088  | 35                                    | 0.00057 |
| 1992       | 82,976  | 31                                    | 0.00037 |
| 1993       | 221,316                                       | 284                                   | 0.00128 |
| 1994       | 27,135  | 21                                    | 0.00077 |
| 1995       | No hatchery program                           |                                       |         |
| 1996       | 12,767  | 67                                    | 0.00525 |
| 1997       | 259,585                                       | 2,549                                 | 0.00982 |
| 1998       | 71,571  | 1,119                                 | 0.01563 |
| 1999       | No hatchery program                           |                                       |         |

| Brood year     | Number of tagged smolts released <sup>a</sup> | Estimated adult captures <sup>b</sup> | SAR            |
|----------------|---|---------------------------------------|----------------|
| 2000           | 46,726  | 375                                   | 0.00803        |

<sup>a</sup> Includes all tag codes and CWT released fish (CWT + Ad Clip fish and CWT-only fish).

<sup>b</sup> Includes estimated recoveries (spawning ground, hatcheries, harvest, etc.) and observed recoveries if estimated recoveries were unavailable.

## 5.8 ESA/HCP Compliance

### Broodstock Collection

The collection of 2014 Brood Chiwawa River spring Chinook broodstock was consistent with the 2014 Upper Columbia River salmon and steelhead broodstock objectives and site-based broodstock collection protocols. Specifically, broodstock collection targeted previously PIT-tagged natural-origin fish at Tumwater Dam and operation of the Chiwawa Weir. In-season adjustments were made to the natural-origin spring Chinook collected for broodstock as needed and were based on in-season escapement monitoring at Tumwater Dam and estimated Chiwawa run-escapement.

Trapping at Tumwater Dam began on 8 June 2014 and concluded on 14 July 2014. Operation of the Chiwawa Weir was limited to 15 days between 1 June and 15 August and was further constrained by flows and total available bull trout effects. Broodstock collection targeted natural-origin spring Chinook and hatchery-origin spring Chinook as needed to attain a 100% natural-origin broodstock and a maximum 33% extraction of the estimated natural-origin return to the Chiwawa River.

The 2014 brood collection retained a total of 61 natural-origin spring Chinook. All spring Chinook, steelhead, and bull trout that were captured were anesthetized with tricaine methanesulfonate (MS-222) and subject to water-to-water transfers during handling. All fish were allowed to fully recover before release.

The estimated broodstock extraction rate of natural-origin Chiwawa spring Chinook and overall extraction of spring Chinook upstream from Tumwater Dam comply with provisions of ESA Permit 18121.

### Hatchery Rearing and Release

The rearing and release of 2014 brood Chiwawa spring Chinook was completed without incident. No mortality events occurred that exceeded 10% of the population. Fish were acclimated on Chiwawa River water with regulated amounts of Wenatchee River water to prevent frazzle ice formation during the winter months (see Section 5.2).

The release of 2014 brood Chiwawa spring Chinook smolts totaled 144,360 fish, representing 100% of the program objective of 144,023 smolts and complied with the ESA Section 10 Permit 18121 program not to exceed the level of 158,425 smolts.

### Hatchery Effluent Monitoring

Per ESA Permits 1196 (expired), 1347 (expired), 1395 (expired), 18118, 18120, and 18121, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at the Chelan PUD Hatchery facilities during the period 1 January through 31 December 2016. NPDES monitoring and reporting for Chelan PUD Hatchery Programs during 2016 are provided in Appendix F.

### Smolt and Emigrant Trapping

Per ESA Section 10 Permit Nos. 18118, 18120, and 18121, the permit holders are authorized a direct take of up to 20% of the emigrating spring Chinook population during juvenile emigration monitoring and a lethal take not to exceed 2% of the fish captured (NMFS 2013). Based on the estimated wild spring Chinook population (smolt trap expansion) and hatchery juvenile spring Chinook population estimate (hatchery release data) for the Wenatchee River basin, the reported spring Chinook encounters during 2016 emigration monitoring complied with take provisions in the Section 10 permit. Spring Chinook encounter and mortality rates for each trap site (including PIT tag mortalities) are detailed in Table 5.43. Additionally, juvenile fish captured at the trap locations were handled consistent with provisions in ESA Section 10 Permits 18118, 18120, and 18121, Section B.

**Table 5.43.** Estimated take of Upper Columbia River spring Chinook resulting from juvenile emigration monitoring in the Wenatchee River basin, 2016.

<sup>a</sup> Smolt population estimate derived from juvenile emigration trap data.

<sup>b</sup> 2016 BY smolt release data for the Wenatchee River basin.

<sup>c</sup> Based on size, date of capture and location of capture, sub-yearling Chinook encountered at the Lower Wenatchee Trap are categorized as summer Chinook salmon.

<sup>d</sup> Combined trapping and PIT tagging mortality.

## Spawning Surveys

Spring Chinook spawning ground surveys were conducted in the Wenatchee River basin during 2016, as authorized by ESA Section 10 Permits 18118, 18120, and 18121. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential effects to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

## Spring Chinook Reproductive Success Study

ESA Section 10 Permits 18118, 18120, and 18121 specifically provide authorization to capture, anesthetize, biologically sample, PIT tag, and release adult spring Chinook at Tumwater Dam for reproductive success studies and general program monitoring. During 2010 through 2016, all spring Chinook passing Tumwater Dam were enumerated, anesthetized, biologically sampled, PIT tagged, and released (not including hatchery-origin Chinook retained for broodstock) as a component of the reproductive success study (BPA Project No. 2003-039-00). Please refer to Ford et al. (2010, 2011, 2012, 2013, 2014, 2015, and 2016) for complete details on the methods and results of the spring Chinook reproductive success study for the period 2010-2016.

## SECTION 6: NASON CREEK SPRING CHINOOK

The goals of the Nason Creek spring Chinook salmon supplementation program are to conserve, aid in the recovery, and prevent the extinction of naturally spawning spring Chinook in Nason Creek, and to meet the mitigation responsibilities of Grant County PUD. In 1997, a spring Chinook captive-broodstock program was initiated for the Nason Creek population to reduce the risk of extinction. Improvements in adult escapement in Nason Creek have reduced the near-term risk of extinction and therefore the captive-broodstock program was discontinued. An adult-based supplementation program began with the collection of broodstock in 2013. The first releases of the program occurred from the Nason Creek Acclimation Facility in the spring of 2015.

In 2013, natural-origin adult spring Chinook were collected for broodstock at Tumwater Dam and from Nason Creek using tangle and dip nets. In 2014, all natural-origin broodstock were collected from Nason Creek using tangle and dip nets. While these brood collection methods were successful at collecting adults from the Nason Creek spawning aggregate, they were unable to collect the necessary number of adults to meet mitigation production goals in 2013 and 2014. The PRCC Hatchery Subcommittee decided to implement the Nason Creek conservation program using a composite of Nason and Chiwawa natural-origin broodstock beginning with brood year 2015 in order to be able to consistently meet program goals. The decision was also made to collect all the brood at Tumwater Dam.

The production goal for the Nason Creek program requires collection of 126 adult spring Chinook (64 natural-origin fish and 66 hatchery-origin fish). However, the Section 10 permit requirements restrict the number of natural-origin adults collected and cannot exceed 33% of the natural-origin spring Chinook estimates to Tumwater Dam.

Adult spring Chinook broodstock are spawned and reared at Eastbank Fish Hatchery. Juvenile spring Chinook are transferred from the hatchery to the Nason Creek Acclimation Facility in late September or early October. Fish are reared in 30-foot dual-drain circular tanks throughout winter at the Nason Creek Acclimation Facility. Yearling Chinook were released voluntarily during April and May the following year up until 2015. Beginning in 2016, all fish are force released at night to improve survival.

The current production goal is to release 223,670 smolts (125,000 for conservation and 98,670 for safety net). Juveniles released from the Nason facility will be 100% marked with CWTs and a minimum of 5,000 fish will be PIT tagged annually.

The following information focuses on results from monitoring the Nason Creek spring Chinook program. Information on spring Chinook collected throughout the Wenatchee River basin is presented in Section 5.

### 6.1 Broodstock Sampling

This section focuses on results from sampling 2014-2016 Nason Creek spring Chinook broodstock, which were collected in Nason Creek in 2014 and at Tumwater Dam in 2015 and 2016.

### Origin of Broodstock

Natural-origin adults made up between 48% and 100% of the Nason Creek spring Chinook broodstock for return years 2014-2016 (Table 6.1). Beginning with brood year 2015, natural-origin adults were targeted for collection at Tumwater Dam during trapping operations. Natural-origin fish collected at Tumwater Dam were used for broodstock if genotyping confirmed they were natural-origin fish from the Wenatchee population and they were not White River fish. Fish that were genotyped to the White River were returned to the upper Wenatchee River basin to spawn naturally.

**Table 6.1.** Numbers of wild and hatchery Nason Creek spring Chinook collected for broodstock, numbers that died before spawning, and numbers of Chinook spawned, 2013-2016. Unknown origin fish (i.e., undetermined by scale analysis, no CWT or fin clips, and no additional hatchery marks) were considered naturally produced. Mortality includes fish that died of natural causes typically near the end of spawning and were not needed for the program or were surplus fish killed at spawning.

| Brood year                 | Wild spring Chinook |                            |           |                |                 | Hatchery spring Chinook |                            |           |                |                 | Total number spawned |
|----------------------------|---------------------|----------------------------|-----------|----------------|-----------------|-------------------------|----------------------------|-----------|----------------|-----------------|----------------------|
|                            | Number collected    | Prespawn loss <sup>a</sup> | Mortality | Number spawned | Number released | Number collected        | Prespawn loss <sup>a</sup> | Mortality | Number spawned | Number released |                      |
| 2013                       | 22                  | 0                          | 1         | 21             | 0               | 4                       | 0                          | 0         | 4              | 0               | 25                   |
| 2014 <sup>b</sup>          | 28                  | 2                          | 5         | 21             | 0               | 0                       | 0                          | 0         | 0              | 0               | 21                   |
| 2015                       | 78                  | 1                          | 6         | 59             | 12              | 63                      | 0                          | 0         | 63             | 0               | 122                  |
| 2016                       | 82                  | 0                          | 1         | 70             | 11              | 68                      | 1                          | 1         | 66             | 0               | 136                  |
| <i>Average<sup>c</sup></i> | <i>53</i>           | <i>1</i>                   | <i>3</i>  | <i>43</i>      | <i>6</i>        | <i>34</i>               | <i>0</i>                   | <i>0</i>  | <i>33</i>      | <i>0</i>        | <i>76</i>            |
| <i>Median<sup>c</sup></i>  | <i>53</i>           | <i>1</i>                   | <i>3</i>  | <i>40</i>      | <i>6</i>        | <i>34</i>               | <i>0</i>                   | <i>0</i>  | <i>34</i>      | <i>0</i>        | <i>74</i>            |

<sup>a</sup> Pre-spawn loss represents the number of fish that died during the holding period before spawning. Mortality is the number of fish that were surplus following spawning.

<sup>b</sup> Until sufficient Nason Creek Spring Chinook HOR's are collected to meet broodstock objectives, Chiwawa Spring Chinook HOR's are utilized to fulfill program goals (see table 5.1 and the 2014 Broodstock Protocols). About 12 Chiwawa HORs were used to fulfill the Chiwawa Program; about 122 Chiwawa HORs were used to fulfill the Nason Creek safety-net obligation.

<sup>c</sup> Origin determinations should be considered preliminary pending scale analyses.

### Age/Length Data

Ages were determined from scales and/or coded wire tags (CWT) collected from broodstock. For both the 2015 and 2016 returns, most adults, regardless of origin, were age-4 Chinook (Table 6.2). A larger percentage of the age-3 and 5 Chinook were natural-origin fish.

**Table 6.2.** Percent of hatchery and wild spring Chinook of different ages (total age) collected from broodstock, 2013-2016.

| Return year | Origin                | Total age |      |       |      |
|-------------|-----------------------|-----------|------|-------|------|
|             |                       | 2         | 3    | 4     | 5    |
| 2013        | Wild                  | 0.0       | 14.3 | 85.7  | 0.0  |
|             | Hatchery              | 0.0       | 0.0  | 100.0 | 0.0  |
| 2014        | Wild                  | 0.0       | 18.2 | 68.2  | 13.6 |
|             | Hatchery <sup>a</sup> | 0.0       | 0.0  | 98.5  | 1.5  |

<sup>a</sup> Data from Table 5.3.

## Sex Ratios

Male spring Chinook in the 2014-2016 return years made up 60%, 50%, and 49%, respectively, of the adults collected. This resulted in overall male to female ratios of 1.50:1.00, 1.01:1.00, and 0.95:1.00, respectively (Table 6.4).

**Table 6.4.** Numbers of male and female wild and hatchery spring Chinook collected for broodstock, 2013-2016. Ratios of males to females are also provided.

| Return year       | Number of wild spring Chinook |             |                  | Number of hatchery spring Chinook |             |                  | Total M/F ratio  |
|-------------------|-------------------------------|-------------|------------------|-----------------------------------|-------------|------------------|------------------|
|                   | Males (M)                     | Females (F) | M/F              | Males (M)                         | Females (F) | M/F              |                  |
| 2013              | 12                            | 10          | 1.20:1.00        | 1                                 | 3           | 0.33:1.00        | 1.00:1.00        |
| 2014 <sup>a</sup> | 18                            | 12          | 1.50:1.00        | 0                                 | 0           | -                | 1.50:1.00        |
| 2015              | 40                            | 38          | 1.05:1.00        | 31                                | 32          | 0.97:1.00        | 1.01:1.00        |
| 2016              | 40                            | 42          | 0.95:1.00        | 33                                | 35          | 0.94:1.00        | 0.95:1.00        |
| <b>Total</b>      | <b>110</b>                    | <b>102</b>  | <b>1.08:1.00</b> | <b>65</b>                         | <b>70</b>   | <b>0.93:1.00</b> | <b>1.02:1.00</b> |

<sup>a</sup> Data for HOR brood are in Table 5.4.

### Fecundity

The mean fecundities for the 2014-2016 returns of Nason Creek spring Chinook ranged from 3,787- 4,487 eggs per female (Table 6.5). Fecundities in the 2013 and 2015 natural-origin brood, and in the 2013, 2014, and 2016 hatchery-origin brood were less than the expected fecundity of 4,400 eggs per female assumed in the broodstock protocol.

**Table 6.5.** Mean fecundity of wild, hatchery, and all female spring Chinook collected for broodstock, 2013-2016.

| Return year       | Mean fecundity |              |              |
|-------------------|----------------|--------------|--------------|
|                   | Wild           | Hatchery     | Total        |
| 2013              | 4,047          | 4,069        | 4,052        |
| 2014 <sup>a</sup> | 4,484          | 3,834        | 3,787        |
| 2015              | 4,380          | 4,535        | 4,463        |
| 2016              | 4,688          | 4,274        | 4,487        |
| <i>Average</i>    | <i>4,400</i>   | <i>4,178</i> | <i>4,197</i> |

<sup>a</sup> Average fecundities are from Table 5.5.

## 6.2 Hatchery Rearing

### Rearing History

#### *Number of eggs taken*

Based on the unfertilized egg-to-release survival standard of 85%, a total of 263,141 eggs are required to meet the program release goal of 223,670 smolts (Table 6.6). The green egg take for the 2014-2016 brood years was 102%, 102%, and 119% of program goal, respectively.

**Table 6.6.** Numbers of eggs taken from spring Chinook broodstock, 2013-2016.

| Return year       | Number of eggs taken |
|-------------------|----------------------|
| 2013 <sup>a</sup> | 49,720               |
| 2014 <sup>b</sup> | 267,783              |
| 2015              | 268,247              |
| 2016              | 314,090              |
| <i>Average</i>    | <i>224,960</i>       |
| <i>Median</i>     | <i>268,015</i>       |

<sup>a</sup> Safety-net obligation met through the White River Program. Conservation egg take goal was 116,082.

<sup>b</sup> Includes surrogate Chiwawa HxH egg take calculated from tagging proportions.

#### *Number of acclimation days*

Fish from the 2014 brood were acclimated for 119-166 days on Nason Creek water and 12 days on well water with oxygen (Table 6.7).

**Table 6.7.** Number of days spring Chinook broods were acclimated on Nason Creek water and well water, brood years 2013-2014.

| Brood year        | Release year | Transfer date | Release date   | Number of acclimation days |
|-------------------|--------------|---------------|----------------|----------------------------|
| 2013              | 2015         | 13 Oct        | 13 Apr – 1 May | 182-200                    |
| 2014 <sup>a</sup> | 2016         | 21-23 Oct     | 15-20 Apr      | 119-122 Nason, 12 Well     |

<sup>a</sup> Because of water-intake concerns at the Nason Creek Acclimation Facility, the HxH Chinook were transferred to the Chiwawa Acclimation Facility on 2-3 March for final acclimation and release. The WxW fish were on Nason Creek water for 166 days. The HxH fish were on Nason Creek water for 119-122 days and on Chiwawa River water for 43-49 days. WxW and HxH fish were on well water and oxygen for 12 days while rearing at the Nason Creek Acclimation Facility.

## Release Information

### Numbers released

The 2014 brood Nason Creek spring Chinook program achieved 25.8% of the 125,000 target goal with about 32,215 WxW smolts forced into Nason Creek in 2016 (Table 6.8). The remainder of the smolt obligation was fulfilled with HxH progeny. The HxH Nason program was transferred to the Chiwawa Acclimation Facility on 2-3 March 2016 for final acclimation because of water-intake concerns at the Nason Creek Acclimation Facility (see Table 5.8). A total of 196,866 HxH smolts were released from the Chiwawa Acclimation Facility for the Nason spring Chinook program.

**Table 6.8.** Numbers of spring Chinook smolts tagged and released from the hatchery, brood years 2013-2014. The release target for Nason Creek spring Chinook is 125,000 smolts.

| Brood year        | Release year | Type of release | CWT mark rate | Number released that were PIT tagged | Number of smolts released | Total number of smolts released |
|-------------------|--------------|-----------------|---------------|--------------------------------------|---------------------------|---------------------------------|
| 2013              | 2015         | Volitional      | 0.9303        | 20,139                               | 43,082                    | 43,082                          |
| 2014 <sup>a</sup> | 2016         | Forced          | 0.9650        | 5,009                                | 32,215                    | 32,215                          |

<sup>a</sup> Only the WxW Nason program was released from the Nason Creek Acclimation Facility because of water-intake concerns. The HxH Nason program was transferred to the Chiwawa Acclimation Facility on 2-3 March 2016 (see Table 5.8).

### Numbers tagged

The 2014 brood Nason spring Chinook were 96% CWT and blank CWT adipose tagged (Table 6.8).

In 2017, a total of 10,104 Nason Creek spring Chinook from the 2015 brood were tagged at the Nason Creek Acclimation Facility on 6-9 March. Chinook in Ponds 1, 3, 5, and 7 were HxH fish, while Chinook in Ponds 2, 4, 6, and 8 were WxW fish. Fish were not fed during tagging or for two days before and after tagging. Fish averaged 110-115 mm in length and 17-19 g at time of tagging.

Table 6.9 summarizes the number of hatchery spring Chinook that have been PIT-tagged and released into Nason Creek.

**Table 6.9.** Summary of PIT-tagging activities for Nason Creek hatchery spring Chinook, brood years 2013-2014.

| Brood year | Release year | Number of fish tagged | Number of tagged fish that died | Number of tags shed | Number of tagged fish released |
|------------|--------------|-----------------------|---------------------------------|---------------------|--------------------------------|
| 2013       | 2015         | 20,234                | 94                              | 1                   | 20,139                         |
| 2014       | 2016         | 5,010                 | 1                               | 0                   | 5,009                          |

**Fish size and condition at release**

The WxW spring Chinook from the 2014 brood were released as yearling smolts from 15-20 April 2016. Size at release (21 fpp) was larger than the approximate target of 24 fpp established for the program. The CV for fork length was just short of the target (Table 6.10).

The HxH spring Chinook were transferred to the Chiwawa Acclimation Facility for final rearing on 2-3 March 2016 because of water-intake concerns at the Nason Creek Acclimation Facility. These fish were volitionally released as yearling smolts from 15-20 April 2016 into the Chiwawa River. Size at release (16 fpp) was larger than the approximate target of 18 fpp established for the Chiwawa program. The CV for fork length was just short of the target (see Table 5.10).

**Table 6.10.** Mean lengths (FL, mm), weight (g and fish/pound), and coefficient of variation (CV) of spring Chinook smolts released from the hatchery, brood years 2013-2014. Size targets are provided in the last row of the table.

| Brood year        | Release year | Fork length (mm) |            | Mean weight |            |
|-------------------|--------------|------------------|------------|-------------|------------|
|                   |              | Mean             | CV         | Grams (g)   | Fish/pound |
| 2013              | 2015         | 129              | 8.3        | 27.6        | 16         |

<sup>a</sup> This represents only the WxW Nason program released from the Nason Creek Acclimation Facility. The HxH program was transferred to the Chiwawa Acclimation Facility on 2-3 March 2016 for release because of water-intake concerns at the Nason Creek Acclimation Facility. Statistics on the 2014 brood HxH program pre-release sample at the Chiwawa Acclimation Facility were 134 mean length, 17.5 length CV, 28.6g mean wt., and 16 fpp.

**Survival Estimates**

Overall survival of Nason Creek spring Chinook from green (unfertilized) egg to release was above the standard set for the program (Table 6.11). There was higher than expected survivals throughout all stages contributing to increased program performance. Pre-spawn survival of adults was also above the standard set for the program.

**Table 6.11.** Hatchery life-stage survival rates (%) for spring Chinook, brood years 2013-2014. Survival standards or targets are provided in the last row of the table.

| Brood year        | Collection to spawning |              | Unfertilized egg-eyed | Eyed egg-ponding | 30 d after ponding | 100 d after ponding | Ponding to release | Transport to release | Unfertilized egg-release |
|-------------------|------------------------|--------------|-----------------------|------------------|--------------------|---------------------|--------------------|----------------------|--------------------------|
|                   | Female                 | Male         |                       |                  |                    |                     |                    |                      |                          |

<sup>a</sup> The survival estimates are a combination of the WxW and HxH Nason programs. The WxW program was reared at the Nason Creek Acclimation Facility until release. The HxH Chinook that were reared at the Nason Creek Acclimation Facility until transferred to the Chiwawa Acclimation Facility on 2-3 March 2016 because of water-intake concerns at the Nason Creek Acclimation Facility. The HxH fish were released from the Chiwawa Acclimation Facility on 15-20 April 2016.

### 6.3 Disease Monitoring

Results of 2016 adult broodstock bacterial kidney disease (BKD) monitoring indicated that most females (90%) had ELISA values less than 0.199. Ten percent of the females had ELISA values greater than 0.120, resulting in no limitations to rearing densities (Table 6.12).

For the 2014 brood, a formalin drip treatment was used shortly after transfer to the Nason Creek Acclimation Facility to prevent infection associated with stress caused by the transfer. No significant health issues were encountered for the remainder of juvenile rearing.

**Table 6.12.** Proportion of bacterial kidney disease (BKD) titer groups for the Nason Creek spring Chinook broodstock by origin, brood years 2013-2016. Also included are the proportions to be reared at either 0.125 fish per pound or 0.060 fish per pound.

| Brood year        | Optical density values by titer group |               |                 |               |                      |               |                |               | Proportion at rearing densities (fish per pound, fpp) <sup>b</sup> |               |                      |               |

<sup>a</sup> Determination of origin should be considered preliminary pending scale analyses.

<sup>b</sup> ELISA values from broodstock BKD testing dictate what density the progeny of the broodstock are reared. Progeny of broodstock with high ELISA values are reared at lower density.

### 6.4 Natural Juvenile Productivity

During 2016, juvenile spring Chinook were sampled at the Nason Creek trap.

### Smolt and Emigrant Estimates

Numbers of spring Chinook smolts and emigrants were estimated at the Nason Creek trap in 2016. A complete description of trapping operations on Nason Creek can be found in Appendix L.

#### Nason Creek Trap

The Nason Creek Trap operated between 1 March and 30 November 2016. During that time, the trap was inoperable for 62 days because of low stream discharge or flooding. Daily trap efficiencies were estimated from a flow-efficiency regression model. The daily number of fish captured was expanded by the estimated trap efficiency to estimate total emigration. If a viable flow-efficiency regression could not be developed, a pooled efficiency was used to expand daily catch. All pooled estimates will be recalculated as flow-efficiency models are developed.

Wild yearling spring Chinook (2014 brood year) were captured primarily from March through April 2016 (Figure 6.1). Because a viable yearling emigrant flow-efficiency regression model could not be established at the downstream trap location, a pooled estimate was employed as a temporary method of expansion. Based on this pooled efficiency, the total number of wild yearling Chinook from the Nason Creek basin was 930 ( $\pm 5,083$ ). Combining the number of subyearling spring Chinook (2,851) that emigrated during the fall of 2015 with the total number of yearling Chinook (930) that emigrated during 2016 resulted in an emigrant estimate of 3,781 ( $\pm 5,102$ ) spring Chinook (Table 6.13). Based on PIT-tag analysis, an additional 29 ( $\pm 37$ ) spring Chinook immigrated during the winter (1 December – 28 February) when the trap was inoperable. Thus, the total number of emigrants was 3,810 ( $\pm 5,126$ ) spring Chinook for the 2014 brood year.

**Figure 6.1.** Monthly captures of wild subyearling and wild and hatchery yearling spring Chinook at the Nason Creek Trap, 2016.

**Table 6.13.** Numbers of redds and juvenile spring Chinook at different life stages in the Nason Creek basin for brood years 2002-2015; ND = no data.

| Brood year     | Number of redds | Egg deposition <sup>a</sup> | Number of subyearling emigrants <sup>b</sup> | Number of smolts produced within Nason Creek basin | Number of emigrants <sup>c</sup> |

<sup>a</sup> Egg deposition is calculated as the number of redds times the fecundity of both wild and hatchery spring Chinook salmon (from Table 5.5).

<sup>b</sup> Subyearling emigrants does not include fry that left the watershed before 1 July.

<sup>c</sup> Brood years 2002-2012 do not include estimates of numbers of juvenile spring Chinook that emigrated during non-trapping periods (1 Dec to 28 Feb). Brood years 2013 to present include estimates of numbers of juvenile spring Chinook that emigrated during non-trapping periods.

Wild subyearling spring Chinook (2015 brood year) were captured between 10 March and 29 November 2016 (Figure 6.1). Based on capture efficiencies estimated from the flow model, the total number of wild subyearling Chinook emigrating from Nason Creek was 5,540 ( $\pm 997$ ).

Yearling spring Chinook sampled in 2016 averaged 96 mm in length, 9.0 g in weight, and had a mean condition of 1.01 (Table 6.14). Estimated length and weight for these fish were greater than the overall mean of yearling spring Chinook sampled in previous years (overall means, 93 mm and 8.5 g), while the estimated condition was less (overall mean, 1.05). Subyearling spring Chinook sampled in 2016 at the Nason Creek Trap averaged 85 mm in length, 6.9 g in weight, and had a mean condition of 1.07 (Table 6.14). These size estimates were greater than the overall mean of subyearling spring Chinook sampled in previous years (overall means, 77 mm, 5.1 g, and condition of 1.07).

**Table 6.14.** Mean fork length (mm), weight (g), and condition factor of subyearling and yearling spring Chinook collected in the Nason Creek Trap, 2004-2016. Numbers in parentheses indicate 1 standard deviation.

| Sample year    | Life stage         | Sample size <sup>a</sup> | Mean size     |                  |                    |
|----------------|--------------------|--------------------------|---------------|------------------|--------------------|
|                |                    |                          | Length (mm)   | Weight (g)       | Condition (K)      |
| 2004           | Subyearling        | 656                      | 82 (7)        | 5.9 (1.7)        | 1.04 (0.11)        |

<sup>a</sup> Sample size represents the number of fish that were measured for both length and weight.

### Freshwater Productivity

Both productivity and survival estimates for different life stages of spring Chinook in the Nason Creek watershed are provided in Table 6.15. Estimates for brood year 2014 were generally lower than estimates for brood years 2002-2013. During the period 2002-2014, freshwater productivities

ranged from 8-77 smolts/redd and 33-271 emigrants/redd. Survivals during the same period ranged from 0.2-1.3% for egg-smolt and 0.9-5.8% for egg-emigrants.

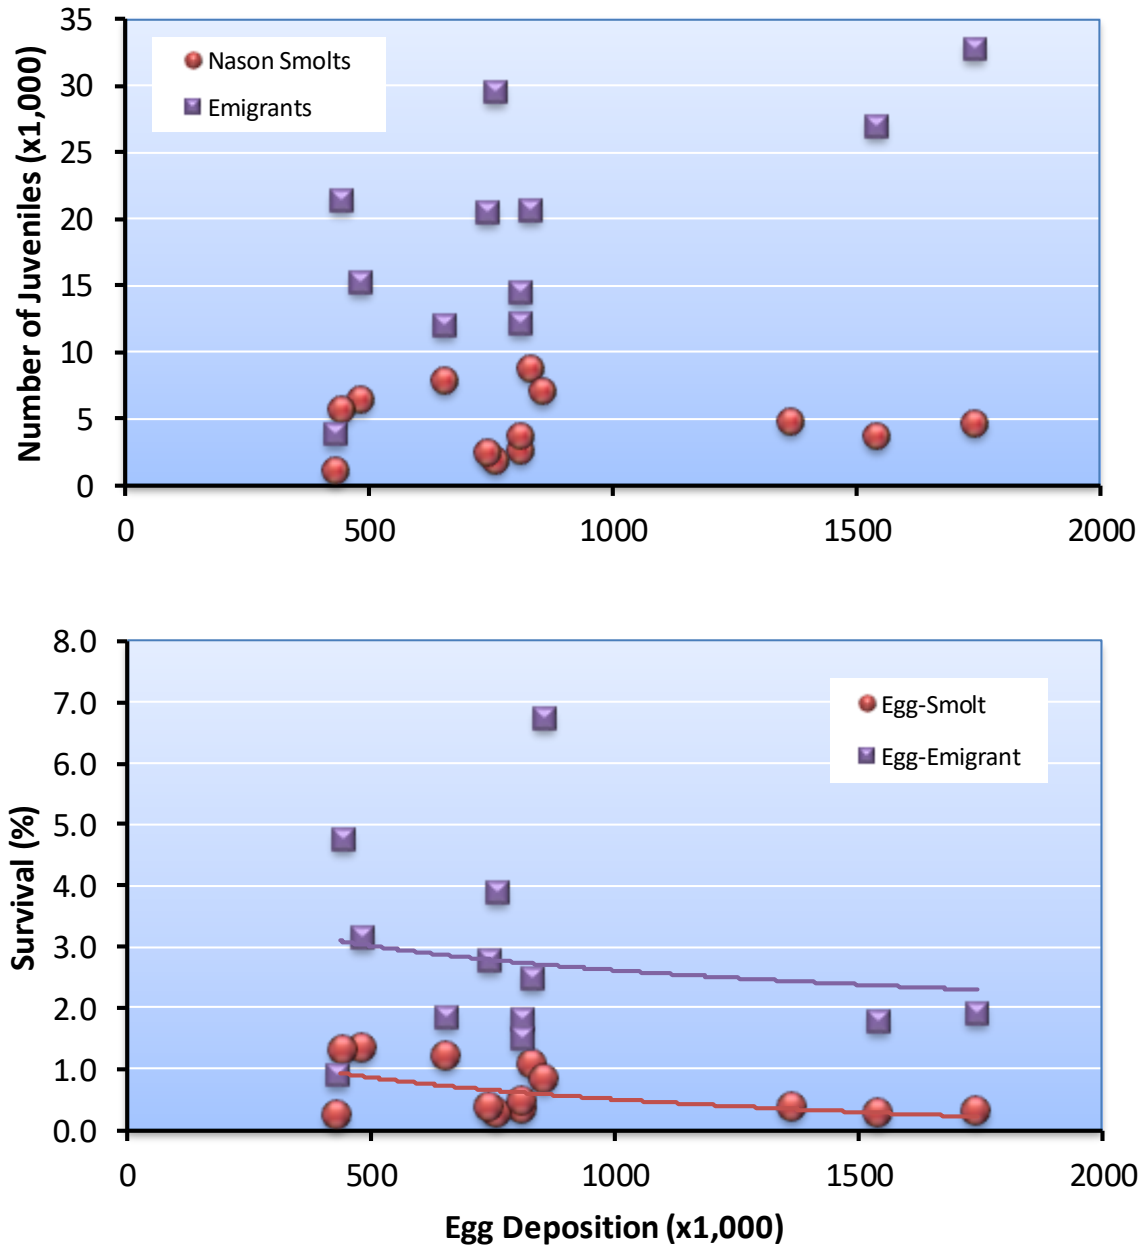

**Table 6.15.** Productivity (fish/redd) and survival (%) estimates for different juvenile life stages of spring Chinook in the Nason Creek watershed for brood years 2002-2014; ND = no data. These estimates were derived from data in Table 6.13.

| Brood year     | Smolts/Redd <sup>a</sup> | Emigrants/ Redd | Egg-Smolt <sup>a</sup> (%) | Egg-Emigrant (%) |
|----------------|--------------------------|-----------------|----------------------------|------------------|
| 2002           | 16                       | ND              | 0.3                        | ND               |
| 2003           | 77                       | 183             | 1.3                        | 3.1              |
| 2004           | 15                       | 85              | 0.3                        | 1.8              |
| 2005           | 45                       | 106             | 1.0                        | 2.5              |
| 2006           | 51                       | 79              | 1.2                        | 1.8              |
| 2007           | 56                       | 210             | 1.3                        | 4.7              |
| 2008           | 11                       | 80              | 0.2                        | 1.7              |
| 2009           | 10                       | 176             | 0.2                        | 3.9              |
| 2010           | 19                       | 64              | 0.4                        | 1.5              |
| 2011           | 14                       | 120             | 0.3                        | 2.7              |
| 2012           | 11                       | 79              | 0.3                        | 1.9              |
| 2013           | 33                       | 271             | 0.8                        | 6.7              |
| 2014           | 8                        | 33              | 0.2                        | 0.9              |
| <i>Average</i> | <i>28</i>                | <i>124</i>      | <i>0.6</i>                 | <i>2.8</i>       |
| <i>Median</i>  | <i>16</i>                | <i>96</i>       | <i>0.3</i>                 | <i>2.2</i>       |

<sup>a</sup> These estimates include Nason Creek smolts produced only within the Nason Creek basin.

Seeding level (egg deposition) explained most of the variability in productivity and survival of juvenile spring Chinook in the Nason Creek watershed. That is, for estimates based on smolts produced within the Nason Creek watershed, survival and productivity decreased as seeding levels increased (Figure 6.2). This suggests that density dependence regulates juvenile productivity and survival within the Nason Creek watershed.

## Juvenile Spring Chinook

**Figure 6.2.** Relationships between seeding levels (egg deposition) and juvenile life-stage survivals and productivities for Nason Creek spring Chinook, brood years 2002-2014. Nason Creek smolts are smolts produced only in the Nason Creek watershed.

### Population Carrying Capacity

Population carrying capacity ( $K$ ) is defined as the maximum equilibrium population size estimated with population models (e.g., logistic equation, Beverton-Holt model, hockey stick model, and the

Ricker model).<sup>16</sup> Maximum equilibrium population size is generated from density dependent mechanisms that reduce population growth rates as population size increases (negative density dependence). This is referred to as compensation. Population size fluctuates about the maximum equilibrium size because of variability in vital rates that are unrelated to density (density independent factors) and measurement error. In this section, we estimate smolt carrying capacities using the Ricker stock-recruitment model (see Appendix C in Hillman et al. 2012 for a detailed description of methods). The Ricker model was the only stock-recruitment model that could be fit to the juvenile spring Chinook data.

Based on the Ricker model, the population carrying capacity for spring Chinook smolts in the Nason Creek watershed is 4,412 smolts (95% CI: 0 – 7,833) (Figure 6.3). Here, smolts are defined as the number of yearling spring Chinook produced entirely within Nason Creek. These estimates reflect current environmental conditions (most recent 13 years) within the Nason Creek watershed. Land use activities such as logging, roads, railways, development, and recreation have altered the historical conditions of the watershed. Thus, the estimated population capacity estimates may not reflect historical capacities for spring Chinook smolts in Nason Creek.

**Figure 6.3.** Relationship between spawners and number of yearling smolts produced in the Nason Creek watershed. Population carrying capacity ( $K$ ) was estimated using the Ricker model.

<sup>16</sup> Population carrying capacity ( $K$ ) should not be confused with habitat carrying capacity ( $C$ ), which is defined as the maximum population of a given species that a particular environment can sustain.

We tracked the precision of the Ricker parameters for Nason Creek spring Chinook smolts over time to see if precision improves with additional years of data, and the parameters and statistics stabilize over time. Examination of variation in the alpha ( $A$ ) and beta ( $B$ ) parameters of the Ricker model and their associated standard errors and confidence intervals indicates that the parameters have not stabilized and they lack precision (Table 6.16; Figure 6.4). This was also apparent in the estimates of population carrying capacity (Figure 6.5).

**Table 6.16.** Estimated parameters and statistics associated with fitting the Ricker model to spawning escapement and smolt data. Smolts represent numbers of smolts produced entirely within the Nason Creek watershed.  $A$  = alpha parameter;  $B$  = beta parameter; SE = standard error (estimated from 5,000 bootstrap samples); and  $r^2$  = coefficient of determination. Spawners represent the stock size needed to achieve population capacity.

| Years of data | Parameter |         |        |        | Population capacity | Intrinsic productivity | Spawners | $r^2$ |
|---------------|-----------|---------|--------|--------|---------------------|------------------------|----------|-------|
|               | $A$       | SE      | $B$    | SE     |                     |                        |          |       |
| 5             | 90.60     | 87.13   | 0.0046 | 0.0015 | 7,293               | 91                     | 219      | 0.453 |

**Figure 6.4.** Time series of alpha and beta parameters and 95% confidence intervals for the Ricker model that was fit to Nason Creek spring Chinook smolt and spawning escapement data. Confidence intervals were estimated from 5,000 bootstrap samples.

**Figure 6.5.** Time series of population carrying capacity estimates derived from fitting the Ricker model to Nason Creek spring Chinook smolt and spawning escapement data.

## 6.5 Spawning Surveys

Surveys for spring Chinook redds were conducted during late July through September 2016 in the Chiwawa River (including Rock, Chikamin, and Phelps creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and White River (including the Napeequa River and Panther Creek). See Section 5.5 for complete coverage of spring Chinook redd surveys in the Wenatchee River basin. In the following section, we describe the number and distribution of redds within the Nason Creek basin.

### Redd Counts and Distribution

A total of 85 spring Chinook redds were counted in Nason Creek in 2016 (Table 6.17; see Table 5.20 for the complete time series of redd counts). This is lower than the average of 144 redds counted during the period 1989-2015 in Nason Creek. Redds were not distributed evenly among the four reaches in Nason Creek. Most redds (68%) were located in Reach 2 and Reach 3 (Table 6.17).

**Table 6.17.** Numbers (both counted and estimated) and proportions of spring Chinook redds counted within different reaches within Nason Creek during August through September 2016. See Table 2.8 for description of survey reaches.

| Stream/watershed | Reach        | Number of observed redds | Estimated number of redds* | Proportion of redds estimated within stream/watershed |
|------------------|--------------|--------------------------|----------------------------|---|
| Nason            | Nason 1 (N1) | 14                       | 14                         | 0.14  |
|                  | Nason 2 (N2) | 20                       | 23                         | 0.23  |
|                  | Nason 3 (N3) | 37                       | 45                         | 0.45  |
|                  | Nason 4 (N4) | 14                       | 18                         | 0.18  |
| <b>Total</b>     |              | <b>85</b>                | <b>100</b>                 | <b>1.00</b>   |

\* Estimated redds represent the “true” number of redds based on Gaussian area-under-the-curve method (see Appendix J).

### Spawn Timing

Spring Chinook began spawning during the last week of July in Nason Creek and peaked the first week of September (Figure 6.6). Spawning in Nason Creek ended the fourth week of September.

**Figure 6.6.** Proportion of spring Chinook redds counted during different weeks within Nason Creek, August through September 2016.

### Spawning Escapement

Spawning escapement for spring Chinook was calculated as the number of redds times the male-to-female ratio (i.e., fish per redd expansion factor) estimated from broodstock and fish sampled

at adult trapping sites.<sup>17</sup> The estimated fish per redd ratio for spring Chinook upstream from Tumwater in 2016 was 1.83 (based on sex ratios estimated at Tumwater Dam). Multiplying this ratio by the number of redds counted in Nason Creek resulted in a total spawning escapement of 156 spring Chinook. The estimated total spawning escapement of spring Chinook in 2016 was less than the overall average of 313 spring Chinook in Nason Creek (see Table 5.23).

## 6.6 Carcass Surveys

Surveys for spring Chinook carcasses were conducted during August through September 2016 in the Chiwawa River (including Rock, Chikamin, and Phelps creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and the White River (including the Napeequa River and Panther Creek). In 2016, 95 spring Chinook carcasses were sampled in Nason Creek. Most of these were sampled in Reach 3. The number of carcasses sampled in 2016 was less than the overall average of 148 carcasses sampled during the period 1996-2015. See Section 5.6 for a complete coverage of spring Chinook carcass surveys in the Wenatchee River basin.

In the Nason Creek watershed, the spatial distribution of hatchery and wild fish was not equal among survey reaches (Table 6.18). In 2016, more wild fish were collected during surveys than hatchery fish. On average, over the survey years, more wild fish were collected than hatchery fish in each of the reaches except Reach 1 where more hatchery fish have been collected (Figure 6.7). It should be noted that the hatchery fish spawning in Nason Creek are primarily strays from the Chiwawa spring Chinook Program. Nason Creek hatchery fish began returning to Nason Creek in 2016 as age-3 fish.

**Table 6.18.** Numbers of wild and hatchery spring Chinook carcasses sampled within different reaches in the Nason Creek watershed, 1999-2016. Numbers represent recovered carcasses that had definitive origins. See Table 2.8 for description of survey reaches.

| Survey year | Origin   | Survey Reach |     |     |     | Total |
|-------------|----------|--------------|-----|-----|-----|-------|
|             |          | N-1          | N-2 | N-3 | N-4 |       |

## Spring Chinook Carcass Distribution

**Figure 6.7.** Distribution of wild and hatchery produced carcasses in different reaches in the Nason Creek watershed, 1999-2016. Reach codes are described in Table 2.8.

### 6.7 Life History Monitoring

Life history characteristics of spring Chinook were assessed by examining carcasses on spawning grounds and fish collected at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

#### Migration Timing

See Section 5.7 for a description of migration timing of spring Chinook at Tumwater Dam.

#### Age at Maturity

Most of the wild and hatchery spring Chinook sampled during the period 1999-2016 in the Nason Creek watershed were age-4 fish (total age) (Table 6.19; Figure 6.8). Except for 2014 fish, hatchery fish made up a higher percentage of age-3 Chinook than did wild fish. As in other years, a higher proportion of age-5 wild fish returned than did age-5 hatchery fish. Thus, wild fish tended to return at an older age than hatchery fish.

**Table 6.19.** Numbers of wild and hatchery spring Chinook of different ages (total age) sampled on spawning grounds in the Nason Creek watershed, 1999-2016.

| Sample year | Origin   | Total age |   |    |   |   | Sample size |
|-------------|----------|-----------|---|----|---|---|-------------|
|             |          | 2         | 3 | 4  | 5 | 6 |             |

### Spring Chinook Age Structure

**Figure 6.8.** Proportions of wild and hatchery spring Chinook of different total ages sampled on spawning grounds in the Nason Creek watershed for the combined years 1999-2016.

#### Size at Maturity

On average, hatchery and wild spring Chinook of a given age differed little in length (Table 6.20). Differences were usually no more than 5 cm between hatchery and wild fish of the same age.

**Table 6.20.** Mean lengths (POH in cm; ±1SD) and sample sizes (in parentheses) of different ages (total age) of male and female spring Chinook of wild and hatchery-origin sampled in the Nason Creek watershed, 1999-2016.

| Return year | Total age | Mean length (cm) |            |            |             |
|-------------|-----------|------------------|------------|------------|-------------|
|             |           | Male             |            | Female     |             |
|             |           | Wild             | Hatchery   | Wild       | Hatchery    |

### Contribution to Fisheries

Because the Nason Creek program began in 2013, there will be no harvest information on Nason Creek hatchery spring Chinook until 2018, when brood year 2013 fish have returned.

### Straying

Stray rates will be determined by examining CWTs and PIT tags recovered on spawning grounds within and outside the Wenatchee River basin. Targets for strays based on return year (recovery year) within the Wenatchee River basin should be less than 10% and targets for strays outside the Wenatchee River basin should be less than 5%. The target for brood year stray rates should be less than 5%. Straying of Nason Creek spring Chinook will be estimated beginning in 2017 when the 2013 brood fish return.

### Genetics

Because the Nason Creek spring Chinook program began in 2013 with the collection of broodstock, there are no studies that examine the effects of the program on the genetics of natural-origin spring Chinook in the Wenatchee River basin. However, genetic studies were conducted to determine the potential effects of the Chiwawa Supplementation Program on natural-origin spring Chinook in the upper Wenatchee River basin (Blankenship et al. 2007; the entire report is appended as Appendix K). This work included the analysis of Nason Creek spring Chinook. Researchers collected microsatellite DNA allele frequencies from temporally replicated natural and hatchery-origin spring Chinook to statistically assign individual fish to specific demes (locations) within the Wenatchee population.

Significant differences in allele frequencies were observed within and among major spawning areas in the Upper Wenatchee River basin. However, these differences made up only a very small portion of the overall variation, indicating genetic similarity among the major spawning areas. There was no evidence that the Chiwawa program has changed the genetic structure (allele frequency) of spring Chinook in Nason Creek and the White River, despite the presence of hatchery-origin spawners in both systems.

### Proportionate Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock (pNOB) and the proportion of hatchery-origin fish in the natural spawning escapement (pHOS). We calculated Proportionate Natural Influence (PNI) by iterating Ford's (2002) equations 5 and 6 to equilibrium, using a heritability of 0.3 and a selection strength of three standard deviations.<sup>18</sup> The larger the PNI value, the greater the strength of selection in the natural environment relative to that of the hatchery environment. For the natural environment to dominate selection, PNI should be greater than 0.50, and important integrated populations should have a PNI of at least 0.67 (HSRG/WDFW/NWIFC 2004).

For brood years 1989-2012, when no brood stock was collected for the Nason Creek Program, the PNI values ranged from 0.28 to 1.00 (Table 6.21). During this period, PNI values varied over time because of Chiwawa spring Chinook straying into Nason Creek. For brood years 2013-2016, a period when brood stock was collected for the Nason Creek Program, PNI values for the Nason Creek Program ranged from 0.46 to 0.77 (Table 6.21).

**Table 6.21.** Proportionate Natural Influence (PNI) Index of hatchery spring Chinook spawning in Nason Creek, brood years 1989-2016. See notes below the table for description of each metric.

| Brood year | Spawners |                  |                  |                   |                     | Broodstock       |                  |      | PNI  |
|------------|----------|------------------|------------------|-------------------|---------------------|------------------|------------------|------|------|

<sup>18</sup> According to authorized annual take permits, PNI is calculated using the PNI approximate equation 11 (HSRG 2009; Appendix A). However, in this report, we used Ford's (2002) equations 5 and 6 with a heritability of 0.3 and a selection strength of three standard deviations to calculate PNI (C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI). This approach is more accurate than using the PNI approximate equation.

HOS<sub>N</sub> = hatchery-origin spawners in Nason Creek from the Nason Creek spring Chinook Supplementation Program.

pHOS<sub>N</sub> = proportion of hatchery-origin spawners from Nason Creek spring Chinook Supplementation Program.

HOS<sub>S</sub> = stray hatchery-origin spawners in Nason Creek.

pHOS<sub>S</sub> = proportion of stray hatchery-origin spawners.

NOB<sub>N</sub> = natural-origin broodstock spawned in the Nason Creek spring Chinook Supplementation Program.

HOB<sub>N</sub> = hatchery-origin broodstock spawned in the Nason Creek spring Chinook Supplementation Program.

pNOB = proportion of hatchery-origin broodstock. Because of the high incidence of strays to Nason Creek from the Chiwawa River spring Chinook program, pNOB values from the Chiwawa program were used to estimate PNI values during the period from 1989 to 2012 (*italicized*). The weighting for those years was 100% based on the Chiwawa program broodstock selection, because there have been no hatchery returns from the Nason Creek spring Chinook program (see Table 5.1 for Chiwawa broodstock selection).

PNI<sub>N</sub> = Proportionate Natural Influence for Nason Creek spring Chinook calculated using the gene-flow model for multiple programs.

\* Average and median for the period 1989-2012, a period when no brood stock were collected for the Nason Creek Program.

\*\* Average and median for the period 2013-present, a period when brood stock was collected for the Nason Creek Program.

## Post-Release Survival and Travel Time

We used PIT-tagged fish to estimate survival rates and travel time (arithmetic mean days) of hatchery spring Chinook from the Nason Creek release site to McNary Dam, and smolt to adult ratios (SARs) from release to detection at Bonneville Dam (Table 6.22).<sup>19</sup> Over the two brood years for which PIT-tagged hatchery fish were released, survival rates from Nason Creek to McNary Dam ranged from 0.346 to 0.572. Average travel time from Nason Creek to McNary Dam ranged from 21 to 38 days. SARs from release to detection at Bonneville Dam will be calculated in 2018 with the return of 2013 brood fish.

<sup>19</sup> It is important to point out that because of fish size differences among rearing tanks or raceways, fish PIT tagged in one tank or raceway may not represent untagged fish rearing in other tanks or raceways.

**Table 6.22.** Total number of Nason hatchery spring Chinook released with PIT tags, their survival and travel times (mean days) to McNary Dam, and smolt-to-adult (SAR) ratios for brood years 2013-2014. Standard errors are shown in parentheses. NA = not available (i.e., not all the adults from the release groups have returned to the Columbia River).

| Brood year | Number of tagged fish released | Survival to McNary Dam | Travel time to McNary Dam (d) | SAR to Bonneville Dam |
|------------|--------------------------------|------------------------|-------------------------------|-----------------------|
| 2013       | 20,139                         | 0.346 (0.030)          | 38.1 (5.9)                    | NA                    |
| 2014       | 5,007                          | 0.572 (0.038)          | 20.6 (5.3)                    | NA                    |

### Natural and Hatchery Replacement Rates

Natural replacement rates (NRR) were calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). Natural-origin recruits are naturally produced (wild) fish that survive to contribute to harvest (directly or indirectly), to broodstock, and to spawning grounds. We do not account for fish that died in route to the spawning grounds (migration mortality) or died just before spawning (pre-spawn mortality) (see Appendix B in Hillman et al. 2012). We calculated NORs with and without harvest. NORs without harvest include all returning fish that either returned to the basin or were collected as wild broodstock. NORs with harvest include all fish harvested and are based on brood-year harvest rates from the Chiwawa Hatchery program. For brood years 1989-2010, NRR for spring Chinook in Nason Creek averaged 0.84 (range, 0.05-5.48) if harvested fish were not included in the estimate and 0.92 (range, 0.05-5.86) if harvested fish were included in the estimate (Table 6.23). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and will be calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. These rates should be greater than the NRRs and greater than or equal to 6.7 (the calculated target value in Hillman et al. 2013). The target value of 6.7 includes harvest and was based on HRRs for Chiwawa spring Chinook salmon. HRRs will be calculated beginning in 2018 with the return of 2013 brood fish.

**Table 6.23.** Spawning escapements, natural-origin recruits (NOR), and natural replacement rates (NRR; with and without harvest) for spring Chinook in the Nason Creek watershed, brood years 1989-2010.

| Brood year | Spawning Escapement | Harvest not included |      | Harvest included |      |
|------------|---------------------|----------------------|------|------------------|------|
|            |                     | NOR                  | NRR  | NOR              | NRR  |
| 1989       | 222                 | 171                  | 0.77 | 249              | 1.12 |

### Smolt-to-Adult Survivals

Smolt-to-adult survival ratios (SARs) will be calculated as the number of hatchery adult recaptures divided by the number of tagged hatchery smolts released. SARs will be calculated beginning in 2018 with the return of all 2013 brood fish.

## 6.8 ESA/HCP Compliance

### Broodstock Collection

Collection of brood year 2014 broodstock for Nason Creek spring Chinook used a combination of natural-origin adults previously PIT tagged as juveniles and intercepted at Tumwater Dam, and tangle netting in Nason Creek to target up to 64 natural-origin broodstock. Additionally, 130 Chiwawa hatchery-origin adults were collected at Tumwater Dam to secure Grant PUD's Wenatchee spring Chinook production obligation. Total broodstock achieved for the 2014 brood Nason Creek spring Chinook program was 28 and 130 natural and hatchery-origin adults, respectively. A total of 177 bull trout were handled and/or observed during broodstock collection at Tumwater Dam. One bull trout was handled/observed during tangle netting in Nason Creek in 2014.

### Hatchery Rearing and Release

The 2014 brood Nason Creek spring Chinook reared throughout all life stages without significant mortality (defined as >10% population mortality associated with a single event). A total of 32,215 WxW and 196,866 HxH smolts were released (25.5% of 2014 conservation program goal and 102.4% of the aggregate Nason program goal). Survival from green-egg through release survival was 87.4%, well above the 81.0% target.

From November 2015 through February 2016, a total of five major freshets occurred in the Nason Creek basin resulting in significant damage and blockage of the Nason Acclimation Facility (NAF) intake structure. To minimize the potential for major fish loss, in March 2016 the HxH component (derived from returning Chiwawa hatchery adults) were transferred to the Chiwawa Acclimation facility for the remainder of their rearing and release. This allowed the limited amount of surface water available at the NAF to be prioritized for the small conservation program. No additional mortality occurred as a result of these actions.

### Hatchery Effluent Monitoring

Per ESA Permits 1196, 1347, 1395, 18118, 18120, and 18121, permit holders shall monitor and report hatchery effluents in compliance with applicable National Pollution Discharge Elimination Systems (NPDES) (EPA 1999) permit limitations. There were no NPDES violations reported at PUD Hatchery facilities during the period 1 January through 31 December 2015. NPDES monitoring and reporting for PUD Hatchery Programs during 2015 are provided in Appendix F.

### Smolt and Emigrant Trapping

Per ESA Section 10 Permit No. 1196, 18118, 18120, and 18121 the permit holders are authorized a direct take of 20% of the emigrating spring Chinook population during juvenile emigration monitoring and a lethal take not to exceed 2% of the fish captured (NMFS 2003). Based on the estimated wild spring Chinook population (smolt trap expansion) and hatchery juvenile spring Chinook population estimate (hatchery release data) for the Wenatchee River basin, the reported spring Chinook encounters during 2015 emigration monitoring complied with take provisions in the Section 10 permit. Spring Chinook encounter and mortality rates for each trap site (including PIT tag mortalities) are detailed in Table 6.24. Additionally, juvenile fish captured at the trap locations were handled consistent with provisions in ESA Section 10 Permit 1196, 18118, 18120, and 18121, Section B. Table 6.24 includes incidental and direct take associated with the Nason Creek smolt trap operated by the Yakama Nation under separate permits.

**Table 6.24.** Estimated take of Upper Columbia River spring Chinook resulting from juvenile emigration monitoring in the Wenatchee River basin, 2016.

<sup>a</sup> Smolt population estimate derived from juvenile emigration trap data.

<sup>b</sup> 2014 BY smolt release data for the Wenatchee River basin.

<sup>c</sup> Based on size, date of capture and location of capture, subyearling Chinook encountered at the Lower Wenatchee Trap are categorized as summer Chinook salmon.

<sup>d</sup> Combined trapping and PIT tagging mortality.

### Spawning Surveys

Spring Chinook spawning ground surveys were conducted in the Wenatchee River basin during 2016, as authorized by ESA Section 10 Permits 18118, 18120, and 18121. Because of the difficulty of quantifying the level of take associated with spawning ground surveys, the Permit does not specify a take level associated with these activities, even though it does authorize implementation of spawning ground surveys. Therefore, no take levels are reported. However, to minimize potential effects to established redds, wading was restricted to the extent practical, and extreme caution was used to avoid established redds when wading was required.

### Spring Chinook Reproductive Success Study

ESA Section 10 Permit 1196 (expired) and new Section 10 Permits 18118, 18120, and 18121 specifically provide authorization to capture, anesthetize, biologically sample, PIT tag, and release adult spring Chinook at Tumwater Dam for reproductive success studies and general program monitoring. During 2010 through 2016, all spring Chinook passing Tumwater Dam were enumerated, anesthetized, biologically sampled, PIT tagged, and released (not including hatchery-origin and natural-origin Chinook retained for broodstock) as a component of the reproductive success study (BPA Project No. 2003-039-00). Please refer to Ford et al. (2010, 2011, 2012, 2013, 2014, 2015, and 2016) for complete details on the methods and results of the spring Chinook reproductive success study for the period 2010-2016.

## SECTION 7: WHITE RIVER SPRING CHINOOK

The White River spring Chinook salmon captive brood program began in 1997 with goals to conserve, aid in the recovery, and prevent the extinction of naturally spawning spring Chinook in the White River, and to meet the mitigation responsibilities of Grant County PUD. Collection of eggs or juveniles from the White River (brood years 1997-2009) made up the first-generation (F<sub>1</sub>) component of the White River captive brood program. Initially, rearing occurred at AquaSeed in Rochester, Washington, but transitioned to the Little White Salmon National Fish Hatchery near Cook, Washington, in 2006. The F<sub>1</sub> component was reared to maturation and spawned within the hatchery. The resulting progeny (F<sub>2</sub>) were then reared in the hatchery until final acclimation and released in the upper Wenatchee Basin. The first large release of F<sub>2</sub> juveniles was in 2008. The last release of juveniles from the captive brood program occurred in 2015.

The production goal for the White River captive brood program following the 2013 hatchery recalculation was to release 74,556 yearling smolts into the upper Wenatchee River basin at 18-24 fish per pound. Fish lengths and weights for the recent broods were manipulated to evaluate different approaches for reducing precocious maturation. All fish were marked with CWTs. In addition, from 2008 through 2015, juvenile spring Chinook were PIT tagged annually.

Since its inception, the captive brood program underwent several adaptive changes designed to improve program success. These changes included: (1) use of a pedigree approach to reduce the use of stray fish in the broodstock, (2) transfer of fish from AquaSeed to the Little White Salmon National Fish Hatchery to improve fish quality, (3) injection of hormones into F<sub>1</sub> females to improve maturation of eggs, (4) manipulation of diet and ration for the F<sub>2</sub> fish to reduce precocious maturation of males, (5) use of temporary tanks and natural enclosures during acclimation to improve homing, and (6) trucking juvenile fish around Lake Wenatchee to improve survival.

The following information focuses on results from monitoring the White River spring Chinook program. More detailed information on the White River program can be found in Lauver et al. (2012). Information on spring Chinook collected throughout the Wenatchee River basin is presented in Section 5.

### 7.1 Captive Brood Collection

The captive brood program was designed to provide a rapid, short-term demographic boost to the White River spring Chinook spawning aggregate, which was at a high risk of local extinction (Lauver et al. 2012). This section describes the collection of broodstock for the White River program.

#### Brood Collection and Rearing

A primary objective of the White River program was to collect progeny of naturally spawning spring Chinook in the White River. The progeny (eggs or juveniles) make up the first-generation (F<sub>1</sub>) of the captive brood program. However, strays from the Chiwawa supplementation program made this a challenge. As a result, researchers attempted to identify the origin of spawners on redds in the White River and then focused egg and juvenile collection efforts on those redds that had the highest likelihood of being produced from White River parents. During most years, this limited the number of redds from which eggs or juveniles could be collected. Starting with brood

year 2006, a pedigree approach was adopted to improve the likelihood that eggs or juveniles used in the captive brood program were of White River origin.

During 1997 to 2009, first-generation broodstock for the captive brood program originated from about 10,353 natural-origin eggs and juveniles collected from 122 redds in the White River. Broodstock from brood year 1997 were trapped as parr with nets in the fall of 1998. Broodstock from brood year 2006 were trapped as fry with nets in the spring of 2007. It was assumed that the parr and fry near known redds were produced from those redds, and origin was confirmed with pedigree analyses. All other brood years were collected as eggs in the fall using redd pumping techniques. Broodstock collection levels were calculated based on the following assumptions and the known number of suitable redds each year (Tonseth and Maitland 2011):

1. 150,000 smolt target/0.70 (green egg to release survival) = 214,000 green eggs
2. 214,000 green eggs/1,500 eggs per female = 143 females/0.50 (sex ratio) = 286 fish
3. 286 fish/0.30 (eyed egg to maturity survival) = 953 eyed eggs
4. 953 eyed eggs/X redds = Y eyed-eggs per redd

Eyed eggs or juveniles collected in the White River were transported to Aquaseed (brood years 1997-2007) or to the Little White Salmon Hatchery (brood years 2008-2009) and reared to adults. Table 7.1 summarizes the collection of eyed eggs or juveniles for the captive brood program.

**Table 7.1.** Numbers of eyed eggs or juvenile brood stock collected for the White River captive brood program, brood years 1997-2009 (2009 was the last year for broodstock collection). Also shown are the number of redds that were sampled for eggs or juveniles and the hatchery in which the fish were reared (LWSFH = Little White Salmon Fish Hatchery); NS = no sample.

| Brood year     | Number of eyed eggs collected | Number of juvenile Chinook collected | Number of redds sampled | Rearing facility             |
|----------------|-------------------------------|--------------------------------------|-------------------------|------------------------------|
| 1997           | 0                             | 527 (parr)                           | 8                       | Aquaseed                     |

| <b>Average</b> | <b>927</b>                    | <b>1,007</b>                         | <b>12</b>               |                              |

<sup>1</sup> Fish were transferred on 30 June and 2 July 2008 and 20 January 2009.

<sup>2</sup> Fish were transferred on 21 October and 13 November 2008.

<sup>3</sup> Fish were transferred on 26 September and 21 October 2008.

## 7.2 Hatchery Spawning and Release

### Captive Brood Spawning

As noted above, eyed eggs or juveniles collected in the White River were transported to Aquaseed (for brood years 1997-2007) or to the Little White Salmon Hatchery (for brood years 2008-2009) and reared to adults (Lauver et al. 2012). After rearing broodstock to maturity in captivity, adult spring Chinook were spawned and their progeny were grown to smolt size, acclimated to White River water, and ultimately released into the White River, Lake Wenatchee, or trucked and released below Lake Wenatchee.

During spawning, eggs and sperm were collected and those gametes were crossed based on a 2x2 factorial spawning matrix. That is, each female was spawned with two males and each male was spawned with two females. Using pedigree analysis, spawning crosses were arranged to maximize genetic diversity. Because incomplete maturation of ova was an issue in the program, implementation of hormone treatments began in 2011 to facilitate maturation. In addition, following spawning, milt from excess males was collected for cryopreservation. Based on a pilot study, the cryopreserved milt was relatively ineffective at fertilizing eggs, so it was not used widely in the program. There are no plans to use the cryopreserved milt in the future. It is noteworthy that most of the males used in spawning were mini-jacks. Table 7.2 shows the ages of first-generation males and females spawned for the captive brood program.

**Table 7.2.** Total ages of first-generation (F<sub>1</sub>) male and female spring Chinook spawned for the White River captive brood program, spawning years 2001-2011; NA = not available.

| Spawning year | Sex    | Total age |     |     |    | Total |
|---------------|--------|-----------|-----|-----|----|-------|

\* Included some unknown number of second-generation females.

## Release Information

### *Numbers released*

Several different acclimation and release scenarios were conducted since 1997. Acclimation scenarios have involved naturalized features such as in-channel enclosures, stream-side tanks supplied with pass-through surface water, and net pens in Lake Wenatchee near the mouth of the White River. Release scenarios have included on-site releases from tanks, in-channel enclosures, and net pens in Lake Wenatchee. The low survival of fish released in the lake and White River prompted exploring the release of fish near the mouth of the lake and downstream from the lake. In 2010, acclimated fish were towed in net pens to the mouth of the lake and released there. In 2011, tank and net-pen acclimated fish were loaded into transport trucks and released into the Wenatchee River. In addition, subyearling and yearling Chinook with no acclimation have been released from transport trucks directly into Lake Wenatchee and the White River. A total of 944,591 second-generation (F<sub>2</sub>) juvenile spring Chinook have been released from the captive brood program. Table 7.3 summarizes the acclimation and release history of F<sub>2</sub> spring Chinook released into the upper Wenatchee River basin.

**Table 7.3.** Numbers of White River juvenile spring Chinook released and their acclimation histories for brood years 2002-2013.

\* Subyearling release.

### Numbers tagged

Brood years 2005 and 2007-2014 spring Chinook were tagged with a CWT in their peduncle. None of these fish were adipose fin clipped.<sup>20</sup> Subyearling fish from the 2006 brood year were tagged with half of a CWT in their snouts. Yearling fish from the 2006 brood year were tagged with CWTs in the peduncle. None of these fish were adipose fin clipped. In addition, beginning in 2008 (brood year 2006), 303,207 juvenile spring Chinook have been PIT tagged before release. Table 7.4 identifies the number of second-generation (F<sub>2</sub>) juvenile spring Chinook tagged with PIT tags.

**Table 7.4.** Numbers of second-generation (F<sub>2</sub>) White River spring Chinook smolts tagged and released in the upper Wenatchee River basin, brood years 2002-2013.

| Brood year | Acclimation site | Acclimation vessel | Release scenario | CWT mark rate | Number released that were PIT tagged | Number of smolts released |
|------------|------------------|--------------------|------------------|---------------|--------------------------------------|---------------------------|
| 2002       | WR RM 11.5       | Tanks              | White River      | 0.00          | 0                                    | 2,589                     |
| 2003       | WR RM 11.5       | Tanks              | White River      | 0.00          | 0                                    | 2,096                     |
| 2004       | WR RM 11.5       | Tanks              | White River      | 0.00          | 0                                    | 1,639                     |
| 2005       | Lake Wen         | Net Pens           | Lake Wen         | 1.00          | 0                                    | 69,032                    |

<sup>20</sup> Given that juvenile spring Chinook were tagged with CWTs in the peduncle and were not ad-clipped, it is possible that field crews missed hatchery-origin adults on the spawning grounds because they did not know they were supposed to sample fish with adipose fins. Thus, this bias in carcass sampling may bias derived metrics such as spawning distribution of hatchery and natural-origin fish, spawn timing of hatchery and natural-origin fish, age at maturity, size at maturity, contributions to fisheries, HOR, NOR, HRR, NRR, PNI, straying, and SARs.

### Post-Release Survival

We used PIT-tagged fish to estimate survival rates and travel time (arithmetic mean days) of released second-generation (F<sub>2</sub>) White River spring Chinook smolts to McNary Dam, and smolt to adult ratios (SARs) from release to detection at Bonneville Dam.<sup>21</sup> Based on the available data, post-release survival has been low for fish released into the White River and Lake Wenatchee (Table 7.6). In contrast, survival of fish released in the Wenatchee River tends to be higher than those released in the White River or in Lake Wenatchee. These results suggest that high mortality in Lake Wenatchee may explain why adult returns of program fish have been consistently poor; however, other factors such as high precocious maturation may also contribute to the estimated low survival (e.g., see Ford et al. 2015).

Average travel time from release to McNary Dam ranged from 21 to 82 days (Table 7.6). Spring Chinook released in the Wenatchee River typically traveled faster to McNary Dam than those released in the White River or in Lake Wenatchee. Because of uncertain release times for several groups, we were unable to estimate travel times for all release groups.

<sup>21</sup> It is important to point out that because of fish size differences among rearing net pens, tanks, or raceways, fish PIT tagged in one pen, tank, or raceway may not represent untagged fish rearing in other pens, tanks, or raceways.

**Table 7.6.** Survival and travel times (mean days) of second-generation (F<sub>2</sub>) White River spring Chinook smolts to McNary Dam and SARs to Bonneville Dam for different release scenarios, brood years 2006-2013. Values in parentheses represent the standard error of the estimate. NA = not available (i.e., not all the fish from the release groups have returned to the Columbia River).

| Brood year | Release scenario           | Number of Chinook released with PIT tags | Survival to McNary Dam | Travel time to McNary Dam (d) | SAR to Bonneville Dam |

## 7.3 Disease Monitoring

### First-Generation Health Maintenance

First-generation (F<sub>1</sub>) adults were fed an azithromycin-medicated feed in the spring to prevent bacterial kidney disease (BKD), which is a common affliction of spring Chinook salmon. As needed, fish received a dose of 20 mg/kg of body weight. The fish also received formalin treatments as needed throughout the year to prevent and treat fungus infections. This was especially important during the pre-spawning period when individual fish were maturing in preparation for spawning. Formalin treatments were conducted three times per week and consist of one hour of flow-through at a concentration of 167 parts per million (ppm).

### Second-Generation Health Maintenance

Following fertilization and initial incubation in September, second-generation (F<sub>2</sub>) eggs were shocked in October. Eggs were treated with a 1,667 ppm formalin solution in a 15-minute flow-through treatment three times a week to prevent fungus growth. Formalin treatments ended after hatching, and water flow was increased from three to five gallons per minute. Dead and deformed fry were removed before relocating the fry to nursery tanks in late January or early February. Fry were then relocated to raceways in July, where they remained until transfer to the White River for acclimation the following March. Coded-wire tagging was typically conducted in July, and PIT tagging occurred the following January or February, just before the fish were transferred to acclimation facilities on the White River in March.

### 7.4 Natural Juvenile Productivity

Juvenile productivity estimation began with the monitoring of emigration of spring Chinook in the White River in 2007 (Lauver et al. 2012). A five-foot diameter rotary screw trap is operated annually from about 1 March through November. The purpose of the program is to estimate the number and timing of subyearlings and yearling spring Chinook emigrating from the White River basin.

#### Smolt and Emigrant Estimates

In 2016, the White River Trap operated between 1 March and 30 November 2016. During that period, the trap was not intentionally disabled under any circumstance. Daily trap efficiencies were estimated by conducting mark-recapture trials. The daily number of fish captured was expanded by the estimated trap efficiency to estimate daily total emigration. If trap efficiencies could not be assessed because of low numbers of juvenile Chinook trapped, a composite model based on efficiency trials from previous years was used to calculate abundance. Daily captures of fish and results of mark-recapture efficiency tests at the White River trap are reported in Appendix M.

Wild yearling spring Chinook (2014 brood year) were captured primarily from March through April 2016 (Figure 7.1). Based on a composite regression model, the total number of wild yearling Chinook emigrating from the White River was 386 ( $\pm 701$ ). Combining the total number of subyearling spring Chinook (1,950  $\pm 400$ ) that emigrated during the fall of 2015 with the total number of yearling Chinook (386) that emigrated during 2016 resulted in a total emigrant estimate of 2,336 ( $\pm 847$ ) spring Chinook for the 2014 brood year (Table 7.7).

**Figure 7.1.** Monthly captures of wild subyearling (parr) and yearling spring Chinook at the White River Trap, 2016.

**Table 7.7.** Numbers of redds and juvenile spring Chinook at different life stages in the White River basin for brood years 2005-2015; ND = no data.

| Brood year                 | Number of redds | Egg deposition <sup>a</sup> | Number of subyearling emigrants <sup>b</sup> | Number of smolts produced within White River basin | Number of emigrants |

| <i>Median<sup>c</sup></i>  | <i>33</i>       | <i>142,362</i>              | <i>2,429</i>                                 | <i>3,211</i>                                       | <i>5,484</i>        |

<sup>a</sup> Egg deposition is calculated as the number of redds times the fecundity of both wild and hatchery spring Chinook salmon (from Table 5.5).

<sup>b</sup> Subyearling emigrants do not include fry that left the watershed before 1 July.

<sup>c</sup> Average and median are based on the entire time series of data, not just the period 2006 through 2012.

Wild subyearling spring Chinook (2015 brood year) were captured between 7 March and 30 November 2016, with peak catch during August (Figure 7.1). Based on a composite regression model, the total number of wild subyearling Chinook emigrating from the White River was 2,430 ( $\pm 723$ ).

Yearling spring Chinook sampled in 2016 averaged 106 mm in length, 12.4 g in weight, and had a mean condition of 1.05 (Table 7.8). The estimated length and weight were greater than the overall mean of yearling spring Chinook sampled in previous years (overall means, 100 mm and 11.3 g). The estimated condition for the 2014 brood was less than the overall mean (overall mean, 1.10). Subyearling spring Chinook parr sampled in 2016 at the White River Trap averaged 89 mm in length, averaged 8.3 g, and had a mean condition of 1.13 (Table 7.8). Estimated length and weight were less than the overall mean of subyearling spring Chinook sampled in previous years (overall means, 90 mm and 8.5 g), while the estimated condition was greater (overall mean, 1.10).

**Table 7.8.** Mean fork length (mm), weight (g), and condition factor of subyearling (parr) and yearling spring Chinook collected in the White River Trap, 2007-2016. Numbers in parentheses indicate 1 standard deviation.

| Sample year | Life stage  | Sample size <sup>a</sup> | Mean size   |            |               |

<sup>a</sup> Sample size represents the number of fish that were measured for both length and weight.

### Freshwater Productivity

Both productivity and survival estimates for different life stages of spring Chinook in the White River basin are provided in Table 7.9. Estimates for brood year 2014 generally fall below the range of productivity and survival estimates for brood years 2005-2013. During that period, freshwater productivities ranged from 15-170 smolts/redd and 85-347 emigrants/redd. Survivals during the same period ranged from 0.4-3.8% for egg-smolt and 2.0-7.5% for egg-emigrants.

**Table 7.9.** Productivity (fish/redd) and survival (%) estimates for different juvenile life stages of spring Chinook in the White River basin for brood years 2005-2014. These estimates were derived from data in Table 7.7. ND = no data.

| Brood year | Smolts/Redd <sup>a</sup> | Emigrants/ Redd | Egg-Smolt <sup>a</sup> (%) | Egg-Emigrant (%) |

<sup>a</sup> These estimates include White River smolts produced only within the White River basin.

Seeding level (egg deposition) explained part of the variability in productivity and survival of juvenile spring Chinook in the White River basin. That is, for estimates based on smolts produced within the White River basin, survival and productivity decreased as seeding levels increased (Figure 7.2). This suggests that density dependence in part regulates juvenile productivity and survival within the White River basin.

### Juvenile Spring Chinook

**Figure 7.2.** Relationships between seeding levels (egg deposition) and juvenile life-stage survivals and productivities for White River spring Chinook, brood years 2005-2014. White River smolts are smolts produced only within the White River basin.

#### Population Carrying Capacity

Population carrying capacity ( $K$ ) is defined as the maximum equilibrium population size estimated with population models (e.g., logistic equation, Beverton-Holt model, hockey stick model, and the

Ricker model).<sup>22</sup> Maximum equilibrium population size is generated from density dependent mechanisms that reduce population growth rates as population size increases (negative density dependence). This is referred to as compensation. Population size fluctuates about the maximum equilibrium size because of variability in vital rates that are unrelated to density (density independent factors) and measurement error. In this section, we estimate smolt carrying capacities using the Ricker stock-recruitment model (see Appendix C in Hillman et al. 2012 for a detailed description of methods). The Ricker model was the only stock-recruitment model that could be fit to the juvenile spring Chinook data.

Based on the Ricker model, the population carrying capacity for spring Chinook smolts in the White River basin is 4,659 smolts (95% CI: 0 – 7,075) (Figure 7.3). Here, smolts are defined as the number of yearling spring Chinook produced entirely within the White River basin. These estimates reflect current conditions (most recent decades) within the White River basin. Land use activities such as logging, roads, development, and recreation have altered the historical conditions of the watershed. Thus, the estimated population capacity estimates may not reflect historical capacities for spring Chinook smolts in the White River basin.

**Figure 7.3.** Relationship between spawners and number of smolts produced in the White River basin. Population carrying capacity ( $K$ ) was estimated using the Ricker model.

<sup>22</sup> Population carrying capacity ( $K$ ) should not be confused with habitat carrying capacity ( $C$ ), which is defined as the maximum population of a given species that a particular environment can sustain.

We tracked the precision of the Ricker parameters for White River spring Chinook smolts over time to see if precision improves with additional years of data, and the parameters and statistics stabilize over time. Examination of variation in the alpha ( $A$ ) and beta ( $B$ ) parameters of the Ricker model and their associated standard errors and confidence intervals indicates that the parameters have not stabilized and lack precision (Table 7.10; Figure 7.4). This was also apparent in the estimates of population carrying capacity (Figure 7.5).

**Table 7.10.** Estimated parameters and statistics associated with fitting the Ricker model to spawning escapement and smolt data. Smolts represent numbers of smolts produced entirely within the White River basin.  $A$  = alpha parameter;  $B$  = beta parameter; SE = standard error (estimated from 5,000 bootstrap samples); and  $r^2$  = coefficient of determination. Spawners represent the stock size needed to achieve population capacity.

| Years of data | Parameter |       |        |        | Population capacity | Intrinsic productivity | Spawners | $r^2$ |
|---------------|-----------|-------|--------|--------|---------------------|------------------------|----------|-------|
|               | $A$       | SE    | $B$    | SE     |                     |                        |          |       |
| 5             | 95.89     | 44.84 | 0.0090 | 0.0040 | 3,928               | 96                     | 111      | 0.001 |
| 6             | 100.65    | 37.65 | 0.0092 | 0.0034 | 4,007               | 101                    | 108      | 0.019 |
| 7             | 81.75     | 36.97 | 0.0084 | 0.0042 | 3,602               | 82                     | 120      | 0.001 |
| 8             | 80.32     | 32.78 | 0.0080 | 0.0036 | 3,675               | 80                     | 124      | 0.009 |
| 9             | 78.79     | 42.85 | 0.0080 | 0.0037 | 3,605               | 79                     | 124      | 0.014 |

**Figure 7.4.** Time series of alpha and beta parameters and 95% confidence intervals for the Ricker model that was fit to White River spring Chinook smolt and spawning escapement data. Confidence intervals were estimated from 5,000 bootstrap samples.

**Figure 7.5.** Time series of population carrying capacity estimates derived from fitting the Ricker model to White River spring Chinook smolt and spawning escapement data.

## 7.5 Spawning Surveys

Surveys for spring Chinook redds were conducted during August through September 2016 in the Chiwawa River (including Rock, Phelps, and Chikamin creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and White River (including the Napeequa River and Panther Creek). See Section 5.5 for a complete coverage of spring Chinook redd surveys in the Wenatchee River basin. In the following section, we describe the number and distribution of redds within the White River basin.

### Redd Counts and Distribution

A total of 44 spring Chinook redds were counted in the White River basin in 2016 (Table 7.11; see Table 5.20 for the complete time series of redd counts). This is higher than the average of 35 redds counted during the period 1989-2015 in the White River. Redds were not distributed evenly among the six survey areas in the White River basin. Most redds (81%) were located in Reach 3 (Napeequa River to Grasshopper Meadows) in the White River (Table 7.11).

**Table 7.11.** Numbers (both observed and estimated) and proportions of spring Chinook redds counted within different survey areas within the White River basin during August through September 2016. See Table 2.8 for description of survey reaches.

| Stream/watershed | Reach           | Number of observed redds | Estimated number of redds* | Proportion of estimated redds within stream/watershed |
|------------------|-----------------|--------------------------|----------------------------|---|
| White River      | White 1 (H1)    | 0                        | --                         | --  |
|                  | White 2 (H2)    | 4                        | 6                          | 0.11  |
|                  | White 3 (H3)    | 37                       | 43                         | 0.81  |
|                  | White 4 (H4)    | 2                        | 3                          | 0.06  |
|                  | Napeequa 1 (Q1) | 1                        | 1                          | 0.02  |
|                  | Panther 1 (T1)  | 0                        | 0                          | 0.00  |
| <b>Total</b>     |                 | <b>44</b>                | <b>53</b>                  | <b>1.00</b>   |

\* Estimated redds represent the “true” number of redds based on Guassian area-under-the-curve method (see Appendix J).

### Spawn Timing

Spring Chinook began spawning during the third week of August in the White River and peaked the second week of September (Figure 7.6). Spawning in the White River ended the third week of September.

**Figure 7.6.** Proportion of spring Chinook redds counted during different weeks within the White River basin, August through September 2016.

### Spawning Escapement

Spawning escapement for spring Chinook was calculated as the number of redds times the male-to-female ratio (i.e., fish per redd expansion factor) estimated from broodstock and fish sampled

at adult trapping sites.<sup>23</sup> The estimated fish per redd ratio for spring Chinook upstream from Tumwater in 2016 was 1.83 (based on sex ratios estimated at Tumwater Dam). Multiplying this ratio by the number of redds counted in the White River basin resulted in a total spawning escapement of 81 spring Chinook. The estimated total spawning escapement of spring Chinook in 2016 was greater than the overall average of 76 spring Chinook in the White River basin (see Table 5.23).

## 7.6 Carcass Surveys

Surveys for spring Chinook carcasses were conducted during August through September 2016 in the Chiwawa River (including Rock, Phelps, and Chikamin creeks), Nason Creek, Icicle Creek, Peshastin Creek (including Ingalls Creek), Upper Wenatchee River (including Chiwaukum Creek), Little Wenatchee River, and the White River (including the Napeequa River and Panther Creek). In 2016, 13 spring Chinook carcasses were sampled in the White River basin. Most of these were sampled in Reach 3. The total number of carcasses sampled in 2016 was less than the overall average of 20 carcasses sampled during the period 1996-2015. See Section 5.6 for a complete coverage of spring Chinook carcass surveys in the Wenatchee River basin.

In the White River basin, the spatial distribution of hatchery strays (primarily from the Chiwawa Spring Chinook program) and wild spring Chinook was not equal (Table 7.12). Only one carcass was recovered in Reach 2, which was of hatchery origin, while Reach 3 had primarily wild fish (91%). In 2016, most carcasses (85%) were observed in the reach between the Napeequa River and Grasshopper Meadows (Reach 3) (Table 7.12). Over the years, spring Chinook have spawned more often in this reach than in other reaches (Figure 7.7).

**Table 7.12.** Numbers of wild, hatchery strays, and captive brood spring Chinook carcasses sampled within different reaches in the White River basin, 2000-2016. Numbers represent recovered carcasses that had definitive origins. See Table 2.8 for description of survey reaches.

| Survey year | Origin          | Survey Reach |     |     |          |         | Total |
|-------------|-----------------|--------------|-----|-----|----------|---------|-------|
|             |                 | H-2          | H-3 | H-4 | Napeequa | Panther |       |
| 2000        | Wild            | 1            | 0   | 0   | 0        | 0       | 1     |

## Spring Chinook Carcass Distribution

**Figure 7.7.** Distribution of wild, hatchery strays, and captive brood produced carcasses in different reaches in the White River basin, 2000-2016. Reach codes are described in Table 2.8.

### 7.7 Life History Monitoring

Life history characteristics of spring Chinook were assessed by examining carcasses on spawning grounds and fish collected at broodstock collection sites, and by reviewing tagging data and fisheries statistics.

#### Migration Timing

See Section 5.7 for a description of migration timing of spring Chinook at Tumwater Dam.

#### Age at Maturity

Most of the wild and hatchery stray spring Chinook sampled during the period 2001-2016 in the White River basin were age-4 fish (total age) (Table 7.13; Figure 7.8). A higher proportion of age-5 wild fish returned than did age-5 hatchery strays. Thus, wild fish tended to return at an older age than hatchery strays. Currently, few captive brood carcasses have been identified on the spawning grounds; most were age-4 and one was age-5. There has been a conspicuous absence of age-3 fish recovered as carcasses. In all years except 2007, no age-3 carcasses have been recovered.

**Table 7.13.** Numbers of wild, hatchery strays, and captive brood spring Chinook of different ages (total age) sampled on spawning grounds in the White River basin, 2001-2016.

| Sample year | Origin          | Total age |   |    |   |   | Sample size |
|-------------|-----------------|-----------|---|----|---|---|-------------|
|             |                 | 2         | 3 | 4  | 5 | 6 |             |
| 2001        | Wild            | 0         | 0 | 47 | 0 | 0 | 47          |

### Spring Chinook Age Structure

**Figure 7.8.** Proportions of wild, hatchery strays, and captive brood spring Chinook of different total ages sampled on spawning grounds in the White River basin for the combined years 2000-2016.

For comparison, Table 7.14 and Figure 7.9 show the age structure of spring Chinook carcasses sampled in the Little Wenatchee River. Similar to the White River, most of the wild and hatchery stray spring Chinook sampled during the period 2001-2016 in the Little Wenatchee River basin were age-4 fish (total age). A higher proportion of age-5 wild fish returned than did age-5 hatchery strays. Thus, wild fish tended to return at an older age than hatchery strays. As in the White River, few age-3 fish have been recovered in the Little Wenatchee River.

**Table 7.14.** Numbers of wild and hatchery stray spring Chinook of different ages (total age) sampled on spawning grounds in the Little Wenatchee River basin, 2001-2016.

| Sample year    | Origin                 | Total age |          |          |          |          | Sample size |
|----------------|------------------------|-----------|----------|----------|----------|----------|-------------|
|                |                        | 2         | 3        | 4        | 5        | 6        |             |

### Spring Chinook Age Structure

**Figure 7.9.** Proportions of wild and hatchery stray spring Chinook of different total ages sampled on spawning grounds in the Little Wenatchee River basin for the combined years 2000-2016.

#### Size at Maturity

On average, hatchery strays and wild spring Chinook of a given age differed little in length (Table 7.15). Differences were small (1-2 cm) and no more than 9 cm between hatchery strays and wild fish of the same age. Few captive brood carcasses have been identified on the spawning grounds; most were females. Those fish were about the same size as wild and hatchery strays of the same age.

**Table 7.15.** Mean lengths (POH in cm; ±1SD) and sample sizes (in parentheses) of different ages (total age) of male and female spring Chinook of wild, hatchery strays, and captive brood origin sampled in the White River basin, 2001-2016.

| Return year | Total age | Mean length (cm) |                |               |            |                |               |
|-------------|-----------|------------------|----------------|---------------|------------|----------------|---------------|
|             |           | Male             |                |               | Female     |                |               |
|             |           | Wild             | Hatchery stray | Captive brood | Wild       | Hatchery stray | Captive brood |

### Contribution to Fisheries

No White River spring Chinook from the captive brood program tagged with CWTs or PIT tags have been recaptured (or reported) in ocean or Columbia River (tribal, commercial, or recreational) fisheries.

### Straying

Stray rates of White River spring Chinook from the captive brood program were determined by examining the locations where PIT-tagged Chinook demonstrating anadromy (based on detections at Bonneville Dam) were last detected. PIT tagging of White River spring Chinook began with release year 2008, which allows estimation of stray rates by brood return. Targets for strays based on return year (recovery year) within the Wenatchee River basin should be less than 10% and targets for strays outside the Wenatchee River basin should be less than 5%. The target for brood year stray rates should be less than 5%.

Based on PIT-tag analyses, on average, about 61% of the White River spring Chinook returns were last detected in streams outside the White River (Table 7.16). The numbers in Table 7.16 should be considered rough estimates because they are not based on confirmed spawning (only last detections) and they represent small sample sizes. In addition, last detections in adult fishways (i.e., Bonneville, Rock Island, and Tumwater dams) were not included, nor were detections in areas outside the distribution of known spring Chinook spawning (i.e., Lower and Middle Wenatchee River). All fish reported in Table 7.16 are at least age-3 fish (total age) and some of them may not have migrated all the way to the ocean but rather resided completely in freshwater downstream from Bonneville Dam.

**Table 7.16.** Number and percent of White River spring Chinook from the captive brood program that homed to target spawning areas on the White River and the target hatchery program (Little White Salmon Fish Hatchery), and number and percent that strayed to non-target spawning areas and hatchery programs for brood years 2006-2011. Only PIT-tagged fish demonstrating anadromy were included in the analysis. Estimates were based on last detections of PIT-tagged spring Chinook. Percent strays should be less than 5%.

\* Homing to the target hatchery includes White River hatchery spring Chinook that are captured and included as broodstock in the White River Hatchery program.

The percentage of the PIT-tagged White River spring Chinook from the captive brood program that were last detected in different watersheds within and outside the Wenatchee River basin are shown in Table 7.17. On average, a small percentage of the PIT-tagged White River spring Chinook homed to the White River. Relatively high percentages of them were last detected in the Little Wenatchee River, Upper Wenatchee River, Nason Creek, and the Chiwawa River.

Few returning adults have strayed into spawning areas outside the Wenatchee River basin. One was last detected in the Entiat River. No other returning adults were detected outside the Wenatchee River basin. On the other hand, several juveniles were last detected in rivers outside the Wenatchee River basin. Juveniles were last detected in the Deschutes, Walla Walla, Hood, and North Fork Teanaway rivers. Juveniles were also last detected at the Little White Salmon Fish Hatchery. There is no evidence that these fish entered the ocean and returned as adults.

**Table 7.17.** Number and percent (in parentheses) of PIT-tagged White River spring Chinook from the captive brood program that were last detected in different tributaries within the Wenatchee River basin, return years 2010-2016. Only PIT-tagged fish demonstrating anadromy were included in the analysis.

| Return year | Homing      | Straying      |                 |              |                  |             |                 |                 |              |

## Genetics

At this time, there are no studies that examine the effects of the White River captive brood program on the genetics of natural-origin spring Chinook in the Wenatchee River basin. However, genetic studies were conducted to determine the potential effects of the Chiwawa Supplementation Program on natural-origin spring Chinook in the upper Wenatchee River basin (Blankenship et al. 2007; the entire report is appended as Appendix K). This work included the analysis of White River spring Chinook. Researchers collected microsatellite DNA allele frequencies from temporally replicated natural and hatchery-origin spring Chinook to statistically assign individual fish to specific demes (locations) within the Wenatchee population.

Significant differences in allele frequencies were observed within and among major spawning areas in the Upper Wenatchee River basin. However, these differences made up only a very small portion of the overall variation, indicating genetic similarity among the major spawning areas. There was no evidence that the Chiwawa program has changed the genetic structure (allele frequency) of spring Chinook in the White River, despite the presence of hatchery-origin spawners in both systems.

## Proportionate Natural Influence

Another method for assessing the genetic risk of a supplementation program is to determine the influence of the hatchery and natural environments on the adaptation of the composite population. This is estimated by the proportion of natural-origin fish in the hatchery broodstock (pNOB) and the proportion of hatchery-origin fish in the natural spawning escapement (pHOS). We calculated Proportionate Natural Influence (PNI) by iterating Ford's (2002) equations 5 and 6 to equilibrium, using a heritability of 0.3 and a selection strength of three standard deviations.<sup>24</sup> The larger the PNI value, the greater the strength of selection in the natural environment relative to that of the hatchery environment. In order for the natural environment to dominate selection, PNI should be greater than 0.50, and important integrated populations should have a PNI of at least 0.67 (HSRG/WDFW/NWIFC 2004).

For brood years 1989-2000, PNI values ranged from 0.95 to 1.00 (Table 7.18). For brood years 2001-2013, PNI for the White River Program averaged 0.60 (range, 0.33-1.00) (Table 7.18).

<sup>24</sup> According to authorized annual take permits, PNI is calculated using the PNI approximate equation 11 (HSRG 2009; Appendix A). However, in this report, we used Ford's (2002) equations 5 and 6 with a heritability of 0.3 and a selection strength of three standard deviations to calculate PNI (C. Busack, NOAA Fisheries, 21 March 2016, provided the model for calculating PNI). This approach is more accurate than using the PNI approximate equation.

**Table 7.18.** Proportionate Natural Influence (PNI) values for hatchery spring Chinook spawning in the White River, brood years 1989-2013. See notes below the table for description of each metric.

| Brood year       | Spawners  |                  |                  |                   |                   | Broodstock       |                  |             | PNI         |
|------------------|-----------|------------------|------------------|-------------------|-------------------|------------------|------------------|-------------|-------------|
|                  | NOS       | HOS <sub>w</sub> | HOS <sub>s</sub> | pHOS <sub>w</sub> | pHOS <sub>s</sub> | NOB <sub>N</sub> | HOB <sub>N</sub> | pNOB        |             |

HOS<sub>w</sub> = hatchery-origin spawners in White River from the White River spring Chinook Supplementation Program.

pHOS<sub>w</sub> = proportion of hatchery-origin spawners from White River spring Chinook Supplementation Program.

HOS<sub>s</sub> = stray hatchery-origin spawners in the White River.

pHOS<sub>s</sub> = proportion of stray hatchery-origin spawners.

NOB<sub>w</sub> = natural origin broodstock spawned for the White River spring Chinook Supplementation Program.

HOB<sub>w</sub> = hatchery-origin broodstock spawned in the White River spring Chinook Supplementation Program.

pNOB = proportion of hatchery-origin broodstock. Because of the high incidence of strays to the White River from the Chiwawa River spring Chinook program, pNOB values from the Chiwawa program were used to estimate PNI values during the period from 1989 to 2000 (*italicized*). The weighting for those years was 100% based on the Chiwawa program broodstock selection, because there have been no hatchery returns from the White River spring Chinook program during this period (see Table 5.1 for Chiwawa broodstock selection).

PNI = Proportionate Natural Influence for White River spring Chinook calculated using the gene-flow model for multiple programs.

\* Average and median for the period 1989-2000.

\*\* Average and median for the period 2001-2013.

## Natural and Hatchery Replacement Rates

In general, natural replacement rates (NRR) are calculated as the ratio of natural-origin recruits (NOR) to the parent spawning population (spawning escapement). Natural-origin recruits are naturally produced (wild) fish that survive to contribute to harvest (directly or indirectly), to broodstock, and to spawning grounds. We do not account for fish that died in route to the spawning grounds (migration mortality) or died just before spawning (pre-spawn mortality) (see Appendix B in Hillman et al. 2012). We calculated NORs with and without harvest. NORs include all returning fish that either returned to the basin or were collected as wild broodstock. For brood years 1989-2010, NRR for spring Chinook in the White River basin averaged 1.03 (range, 0.00-4.91) if harvested fish were not included in the estimate and 1.25 (range, 0.00-5.91) if harvested fish were included in the estimate (Table 7.19). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.

Hatchery replacement rates (HRR) are the hatchery adult-to-adult returns and are calculated as the ratio of hatchery-origin recruits (HOR) to the parent broodstock collected. For brood years 2006-2010, hatchery replacement rates averaged 0.17 (range, 0.00-0.48) if harvest is not included and 0.62 (range, 0.00-1.99) if harvest is included (Table 7.19a). Only for brood year 2009 was HRR greater than the NRR. The HRR values are much higher when they are calculated using the number of adult equivalents taken from the natural environment to initiate the captive brood program (Table 7.19b).

**Table 7.19a.** Numbers of brood stock spawned, spawning escapements, hatchery-origin recruits (HOR), natural-origin recruits (NOR), hatchery replacement rates (HRR), and natural replacement rates (NRR) with and without harvest for spring Chinook in the White River basin, brood years 1989-2010.

| Brood year | Brood stock spawned | Spawning Escapement | Harvest not included |                  |                  |                  | Harvest included |                  |                  |                  |

<sup>1</sup> HOR and HRR values represented here are detections of PIT-tag hatchery fish detected at Tumwater Dam. These values have been expanded based on the untagged proportion of fish released from the White River spring Chinook Program and PIT-tag detection efficiency at Tumwater Dam.

<sup>2</sup> NOR and NRR values represented here are based on carcasses recovery in the White River adjusted by H:W ratios and age composition and expanded to the escapement in the White River.

<sup>3</sup> Harvest on hatchery-origin White River spring Chinook was estimated based on harvest rates observed for Chiwawa spring Chinook.

<sup>4</sup> Expanded NORs for harvest were based on harvest rates from Chiwawa River spring Chinook.

**Table 7.19b.** Hatchery-origin recruits (HOR) and hatchery replacement rates (HRR) based on adult equivalents for spring Chinook in the White River basin, brood years 2006-2009. HORs were estimated at Tumwater Dam.

| Brood year     | Adult equivalents | Harvest not included |           | Harvest included |            |

For comparison, we calculated NRR for spring Chinook within the Little Wenatchee River basin. Fish from both the White River and Little Wenatchee River must migrate through Lake Wenatchee. Therefore, a comparison between the two subpopulations is appropriate.

NRRs for spring Chinook in the Little Wenatchee River basin were generally less than those for spring Chinook in the White River basin. For brood years 1989-2010, NRR for spring Chinook in the Little Wenatchee River basin averaged 0.83 (range, 0.00-4.50) if harvested fish were not included in the estimate and 1.01 (range, 0.00-5.28) if harvested fish were included in the estimate (Table 7.20). NRRs for more recent brood years will be calculated as soon as all tag recoveries and sampling rates have been loaded into the database.

**Table 7.20.** Spawning escapements, natural-origin recruits (NOR), and natural replacement rates (NRR) with and without harvest for spring Chinook in the Little Wenatchee River basin, brood years 1989-2010.

| Brood year | Spawning Escapement | Harvest not included |      | Harvest included |      |
|------------|---------------------|----------------------|------|------------------|------|

### Smolt-to-Adult Survivals

Smolt-to-adult survival ratios (SARs) were calculated as the number of hatchery adults detected at Tumwater Dam divided by the number of tagged hatchery smolts released. SARs were based on PIT-tag detections. For the available brood years, SARs have ranged from 0.00000 to 0.00196 (Table 7.21).

**Table 7.21.** Smolt-to-adult ratios (SARs) for White River spring Chinook from the captive brood program, brood years 2006-2011. Detections at Tumwater Dam are adjusted for PIT-tag detection efficiency.

| Brood year | Number of smolts released | Number of PIT-tagged smolts released | PIT-tags                     |         |
|------------|---------------------------|--------------------------------------|------------------------------|---------|
|            |                           |                                      | Adjusted Tumwater Detections | SAR     |
| 2006       | 142,033                   | 29,881                               | 1                            | 0.00003 |
| 2007       | 131,843                   | 39,820                               | 0                            | 0.00000 |
| 2008       | 48,556                    | 38,650                               | 23                           | 0.00060 |
| 2009       | 112,596                   | 41,742                               | 42                           | 0.00101 |
| 2010       | 18,850                    | 12,283                               | 6                            | 0.00049 |

## 7.8 ESA/HCP Compliance

### Brood Collection

The last collection of eggs or fry for this program occurred in 2010 (brood year 2009). From 2011 to 2013, the White River Captive Brood Program operated without ESA permit coverage. The hatchery program ended with the last release of juveniles in 2015 (brood year 2013).

### Hatchery Rearing, Spawning, and Release

From 2011 to 2013, the White River Captive Brood Program has operated without ESA permit coverage. The hatchery program ended with the last release of juveniles in 2015 (brood year 2013). No release of juveniles occurred under Section 10(a)(1)(A) Permit 18120 in 2016.

### Hatchery Effluent Monitoring

No juveniles were reared or released as part of the White River captive brood program in 2016 due to sun-setting of the program with the 2013 brood. Therefore, no effluent monitoring was required or conducted in 2016.

### Smolt and Emigrant Trapping

Per ESA Section 10 Permit No. 1196 (expired), 18118, 18120, and 18121, the permit holders are authorized a direct take of 20% of the emigrating spring Chinook population during juvenile emigration monitoring and a lethal take not to exceed 2% of the fish captured (NMFS 2003). Based on the estimated wild spring Chinook population (smolt trap expansion) and hatchery juvenile spring Chinook population estimate (hatchery release data) for the Wenatchee River basin, the reported spring Chinook encounters during 2016 emigration monitoring complied with take provisions in the Section 10 permit. Spring Chinook encounter and mortality rates for each trap site (including PIT tag mortalities) are detailed in Table 7.22. Additionally, juvenile fish captured at the trap locations were handled consistent with provisions in ESA Section 10 Permit 1196 (expired), 18118, 18120, and 18121, Section B. Table 7.22 includes incidental or direct take associated with the White River smolt trap operated by the Yakama Nation under separate permits.

**Table 7.22.** Estimated take of Upper Columbia River spring Chinook resulting from juvenile emigration monitoring in the Wenatchee River basin, 2016.

| Trap location                      | Population estimate |                       |                           | Number trapped |          |              | Total  | Take allowed under Permit |
